Identification of ACE-inhibitory peptides from

Phaseolus vulgaris after *in vitro* gastro-intestinal digestion

1 Abstract

2	The objective of the present study was to identify the ACE-inhibitory peptides released from
3	thermally treated Phaseolus vulgaris (pinto) whole beans after in vitro gastro-intestinal digestion.
4	The degree of hydrolysis increased during digestion reaching a value of 50% at the end of the
5	pancreatic digestion. The < 3 kDa fraction of the post-pancreatic sample showed high ACE-
6	inhibitory activity (IC ₅₀ = $105.6 \pm 2.1 \mu g$ of peptides/mL). Peptides responsible for the ACE-
7	inhibitory activity were isolated by reverse phase HPLC. Three fractions, showing the highest
8	inhibitory activity were selected for MS/MS experiments. Eleven of the identified sequences have
9	previously been described as ACE-inhibitors. Most of the identified bioactive peptides had a
10	hydrophobic amino acid, (iso)leucine or phenylalanine, or proline at the C-terminal position, which
11	is crucial for their ACE-inhibitory activity. The sequence of some peptides allowed us to anticipate
12	the presence of ACE-inhibitory activity.

15 Introduction

16

17

related diseases. Inhibition of the angiotensin I-converting enzyme (ACE) is a key point in the 18 treatment of hypertension. ACE is a dipeptidyl carboxypeptidase that catalyses, in vivo, the 19 conversion of the plasmatic peptide angiotensin I into the potent vasoconstrictor angiotensin II. 20 Moreover, ACE can also degrade the antihypertensive vasodilator bradykinin. Inhibition of ACE 21 22 plays an important role in regulation of blood pressure and drugs that inhibit ACE are commonly prescribed for the treatment of hypertension or related cardiovascular diseases (Acharya et al., 23 2003). 24 Bioactive peptides derived from parent proteins, either from animal or plant sources, are thought to 25 be beneficial in the management of hypertension, because of their ability to inhibit the activity of 26 27 the enzyme ACE (Phelan, & Kerins, 2011; García et al., 2013). Many ACE-inhibitory peptides have been isolated from milk or its derivatives through processes of 28 29 enzymatic hydrolysis, fermentation and *in vitro* gastrointestinal digestion (Phelan, & Kerins, 2011). 30 In addition to milk proteins, biologically active and ACE-inhibitory peptides can be released from plant derived food proteins following enzymatic hydrolysis. Cereals and legumes are the main 31 target of these researches, both being rich sources of proteins with a complementary spectrum of 32 amino acids (García et al., 2013). ACE-inhibitory peptides have been identified after hydrolysis by 33 34 commercial enzymes (such as alcalase) of mungbean, chickpea, rice, soybean and corn gluten meal (Garcia et al., 2013). Another process commonly used to generate ACE-inhibitory peptides is the in 35 36 vitro sequential gastro-intestinal digestion. Regarding vegetables, this approach has been used to 37 release ACE-inhibitory peptides from spinach, buckwheat and sunflower (Garcia et al., 2013). 38 Common bean (*Phaseolus vulgaris*) is, together with soybean and peanuts, one of the most important food legumes in the world. It contain high levels of protein (20-30% on a dry basis), 39

High blood pressure or hypertension is a major independent risk factor for cardiovascular and

fiber, as well as valuable minerals and vitamins. The most important proteins found in common 40 41 bean are the storage protein phaseolin (40–50% of the total) and lectins (10–27% of the total). Various epidemiological and clinical studies, suggested an association between the consumption of 42 common bean and legumes and the incidence of chronic diseases (Luna-Vital et al., 2014 and 43 references herein). For instance, the NHANES I epidemiologic follow-up study indicated that the 44 consumption of more than 4 serving of legumes (beans and peas) per week was correlated to a 45 reduction in the cardiovascular and coronary heart disease as well as in the development of 46 hypertension in US men and women (Bazzano et al., 2001). 47 Recently, some studies demonstrated that hydrolysis of proteins isolated from several varieties of 48 Phaseolus vulgaris lead to the release of ACE-inhibitory compounds (Torruco-Uco et al., 2009; Rui 49 et al., 2012a; Rui et al., 2012b; Boschin et al., 2014; Mojica et al., 2015). These studies suggested 50 that ACE-inhibition by bean-derived peptides may be a mechanism of action explaining the 51 52 epidemiological evidences related to a lower incidence of hypertension and cardiovascular disease in humans. However, in only one study the peptides responsible for the ACE-inhibitory activity was 53 54 identified (Rui et al., 2013). 55 To expand this knowledge, the current study was undertaken to identify the peptides responsible for the ACE-inhibitory activity released from common bean after gastro-intestinal hydrolysis. 56

57 We used an *in vitro* digestion procedure mimicking the chemical and physical condition of the

58 gastro-intestinal tract to process thermal-treated pinto bean (*Phaseolus vulgaris*). The digested

59 fraction was characterized for the ACE-inhibitory activity and then further separated with HPLC.

60 Finally, the different fractions containing low molecular weight peptides were characterized for

61 their ACE-inhibitory activity. The fractions with the highest activity were then analyzed with

62 nanoLC-QTOF-MS with the aim to identify the bioactive peptides.

63	Methods
----	---------

64

65 Materials

Bile salts (mixture of sodium cholate and sodium deoxycholate), porcine α -amylase, pepsin from 66 porcine gastric mucosa, pancreatin from porcine pancreas (4xUSP), angiotensin converting enzyme 67 from rabbit lung, mucin II and III, bovine serum albumin, lysozyme and urea were supplied by 68 Sigma (Milan, Italy). Amicon Ultra-4 regenerated cellulose 3 kDa were supplied by Millipore 69 (Milan, Italy). Phaseolus vulgaris beans (pinto beans) were purchased from a local market (Reggio 70 Emilia). All electrophoretic, HPLC and MS/MS reagents were from Biorad (Hercules CA, U.S.A.). 71 72 All the other reagents were from Carlo Erba (Milan, Italy). The absorbance was read using a Jasco V-550 UV/Vis spectrophotometer (Orlando FL, U.S.A.). 73

74

75 Sample preparation

Pinto beans were prepared by cooking 200 g of beans in 1000 mL of boiling water for 2h. Cooked
pinto beans were brought to room temperature and then subjected to the *in vitro* digestion protocol.

78

79 In vitro gastro-intestinal digestion

80 For the *in vitro* digestion, the protocol, developed within the COST Action FA1005 and further

validated for milk and solid food (Kopf-Bolanz et al., 2012; Stuknite et al., 2014), was followed.

82 Simulated salivary (SSF), simulated gastric (SGF), and simulated intestinal (SIF) fluids were

83 prepared according to Kopf-Bolanz et al. (2012). Intestinal fluid was prepared by mixing pancreatic

- 84 (PF) and bile (BF) fluids.
- 85 *Phaseolus vulgaris* beans (15.75 g) were homogenized in a stomacher laboratory blender for 1 min
- to simulate mastication in the presence of 21 mL of SSF and further incubated for 5 min (oral
- phase). Porcine α -amylase was added to SSF (150 U/mL of SSF) immediately before the
- 88 incubation. Afterwards, 42 mL of SGF was added, the pH was adjusted to 2.0 with HCl and

min (gastric phase). The intestinal digestion was carried out by adding to the gastric digested beans
63 mL of SIF (42 mL of PF and 21 mL of BF), adjusting the pH to 7.0 and incubating the sample
for 120 min (pancreatic phase). Pancreatin was added to the PF immediately before the incubation.
All incubations were performed at 37°C on a rotating wheel (10 rpm).
Control digestions were carried out by replacing pinto beans with the same amount of water.

supplemented with porcine pepsin (315 U/mL of SGF). The samples was further incubated for 120

95 Aliquots of the digested samples were collected at the end of each phase, cooled in ice and

96 immediately frozen at -80 °C for further analysis.

97 The digestions were performed in triplicate.

98

89

99 Determination of the degree of hydrolysis (DH)

100 The determination of protein hydrolysis in the digested samples was carried out by measuring the

101 peptide concentration using the TNBS method with leucine as standard (Adler-Nissen, 1979).

102 The hydrolysis degree was calculated as reported in equation (1):

103 **DH**= $(h/h_{tot}) \cdot 100$ (1)

where \mathbf{h} is the hydrolysis equivalent, defined as the concentration in milliequivalents/g of protein of

105 α -amino groups formed at the different stages of the simulated digestion, and **h**_{tot} is the hydrolysis

106 equivalent at complete hydrolysis to amino acids. The total number of amino groups was

107 determined by hydrolyzing the total protein extract in 6 mol/L HCl at 110°C for 24 h. The **h**_{tot} value

108 was calculated resulting in 7.43 milliequivalents/g of protein.

109 The total protein extract from pinto beans whole seeds was prepared according to Carrasco-Castilla110 et al. (2012).

111

112 SDS-PAGE electrophoresis

113 Samples taken at different times of digestion were subjected to SDS-PAGE electrophoresis using

114 13% polyacrylamide separating gel according to Carrasco-Castilla et al. (2012). Samples were

diluted to similar end dilutions in Laemmli buffer (0.05 mol/L Tris, pH 6.8, containing 2% SDS, 0.1

mol/L DTT, and 0.025% Bromophenol Blue). Vials were heated in boiling water for 4min, and 10

 μ L of each sample (corresponding to 20 μ g of undigested pinto bean proteins) was applied to the

gel. As a molecular ladder, the Blue-StepTM Broad range marker (14–200 kDa) was used. Gels were stained with Coomassie Blue.

120

121 Measurements of ACE-inhibitory activity

122 Samples (4 mL) collected at the end of the pancreatic step of the *in vitro* digestion were subjected to

123 ultrafiltration with Amicon Ultra-4 nominal cut-off 3kDa, at 7500g for 120 min at 4°C. The filtrates

124 containing low molecular weight peptides was further analyzed for their ability to inhibit ACE

activity. Peptides were quantified in the sample by using the TNBS method as described in

126 paragraph 2.4. Results are expressed as mg of leucine equivalent/g of pinto bean.

127 ACE-inhibitory activity was measured by the spectrophotometric assay of Ronca-Testoni (1983)

using the tripeptide, 2-furanacryloyl-phenylalanylglycylglycine (FAPGG) as substrate.

129 For the control assay, 350 µL of FAPGG 1.6 mM dissolved in the reaction buffer (Tris-Cl 100

130 mmol/L pH 8.2 and containing 0.6 mol/L of NaCl) was mixed directly in cuvette with 330 µL of

131 reaction buffer. The solution was kept at 37° C for 5 min before the addition of 20 μ L of ACE

solution (so that the final activity of the enzyme in the assay was 50 mU/mL).

133 For the inhibition assay, variable amount of sample were added in place of the buffer.

134 The reaction was followed at 345 nm for 10 min.

Results are expressed as IC₅₀ that is defined as the concentration of peptides required to inhibit 50%
of the enzymatic activity.

137

138 HPLC analysis of peptides

139 HPLC separation of the low molecular weight fractions of digested pinto beans was performed with

a Jasco HPLC system equipped with a reversed phase column Hamilton HxSil C18 (Hamilton,

Reno, Nevada; 250mm x 4.6mm) as described in Hernández-Ledesma et al. (2007). The two
solvents were: solvent A mixture of water-trifluoroacetic acid (0.037%) and solvent B acetonitriletrifluoroacetic acid (0.027%). A linear gradient of solvent B in A ranging from 0% to 45% in 115
min with a flow rate of 0.5 mL/min was used to separate the peptides contained in the low
molecular fractions of digested milk. The PDA detector was set at 214 nm. Five major fractions
were collected and freeze-dried. These fractions were characterized for their ACE-inhibitory
activity (paragraph 2.6) and for the peptide concentration (paragraph 2.4).

148

149 Nanoflow LC-ESI-QTOF-MS/MS analysis

The fractions with the highest ACE-inhibitory activity were subjected to QTOF MS/MS analysis for 150 peptides identification. Nano LC/MS and tandem MS experiments were performed on a 1200 Series 151 Liquid Chromatographic two-dimensional system coupled with a 6520 Accurate-Mass Q-TOF 152 153 LC/MS via a Chip Cube Interface (Agilent Technologies). Chromatographic separation was performed on a ProtID-Chip-43(II) including a 4 mm 40 nL enrichment column and a 43 mm × 75 154 155 μm analytical column, both packed with a Zorbax 300SB 5 μm C18 phase (Agilent Technologies). The mobile phase consisted of (A) H₂O/acetonitrile/formic acid (96.9:3:0.1, v/v/v) and (B) 156 acetonitrile/H2O/formic acid (94.9:5:0.1, v/v/v). The sample (4 µL) was loaded on the Chip 157 enrichment column at a flow rate of 4 µL/min with a mobile phase consisting of 100% A using a 158 G1376A capillary pump. A flush volume of 2 µL and a flush-out factor of 2 were used. After valve 159 switching a gradient elution was performed with the enrichment and analytical column at 500 160 nL/min using a G2226A nano pump. The gradient started at 3% B for 0.5 min then linearly ramped 161 162 up to 28% B in 16.5 min. The mobile phase composition was raised up to 40% B in 3 min, then 95% B in 1 min and maintained for 4 min in order to wash both enrichment and analytical columns. 163 164 The mass spectrometer was tuned, calibrated and set with the same parameters as reported by Dei Più et al. (2014). For identification, MS/MS spectra were converted to .mgf and de novo peptide 165

sequencing was performed using Pepnovo software. The following parameters were considered:

167 enzyme, none; peptide mass tolerance, \pm 40 ppm; fragment mass tolerance, \pm 0.12 Da; variable 168 modification, oxidation (M) and phosphorylation (ST); maximal number of PTMs permitted in a 169 single peptide 3.

A search for the biological activity of peptides identified was carried out through the BIOPEP 170 171 database (http://www.uwm.edu.pl/biochemia/biopep/start_biopep.php). Confirmation of peptides sequence in proteins performed using Peptide Match 172 common bean was (http://research.bioinformatics.udel.edu/peptidematch/index.jsp). 173

174

175 Statistical analysis

176 All data are presented as mean \pm SD for three replicates for each prepared sample. Univariate

analysis of variance (ANOVA) with Tukey post-hoc test was applied using Graph Pad Prism 6.0

178 (GraphPad Software, San Diego, CA). The differences were considered significant with P < 0.05.

179 **Results**

180

181 Assessment of protein hydrolysis during simulated digestion

Cooked pinto beans (*Phaseolus vulgaris*) were submitted to a consecutive three-step *in vitro* gastrointestinal digestion protocol. Protein hydrolysis during the digestion was followed both by
measuring the amount of released free amino group (degree of hydrolysis) and by SDS
electrophoresis.

186 The degree of hydrolysis increased after peptic digestion although not significantly (**Figure 1**). The

pancreatic digestion produced a high and significant increase (P < 0.001) in protein hydrolysis

reaching a degree of hydrolysis value of 50%.

SDS-PAGE analysis of the total bean protein preparation and of the different steps of digestion is 189 shown in Figure 2. Several bands were present in the total bean protein preparation (Figure 2; lane 190 191 **2**). The most abundant bands were the phaseolins subunits α and β with a molecular weight (MW) of 47 and 44 kDa (Montoya et al., 2008). Bands between 16 and 32 kDa corresponded to proteins 192 193 belonging to the family of lectins. Other bands were visible such as that at 10 kDa which 194 corresponded to protease inhibitor, and bands at 15.2 and 33.8 kDa corresponding to α -amylase inhibitor and its β-subunits (Carrasco-Castilla et al., 2012). After the oral phase of the digestion 195 (Figure 2; lane 3) only the band corresponding to the subunit β of phaseolin was visible, together 196 with some bands at lower MW which corresponded to lectin family proteins. Gastric digestion 197 resulted in the disappearance of all the visible bands suggesting that the major proteins extracted 198 during the oral phase were degraded during this phase (Figure 2; lane 4). Similarly after pancreatic 199 200 digestion (Figure 2; lane 6) no bands corresponding to the bean proteins were found. The bands in lane 6 corresponded to the digestive pancreatic enzymes since they showed the same electrophoretic 201 202 profile as the control digestion carried out without beans (Figure 2; lane 7).

203

204 ACE-inhibitory activity

205	The ACE-inhibitory activity of the < 3 kDa permeates was calculated as IC ₅₀ . While the < 3 kDa
206	fraction of undigested sample showed no effect, the ACE-inhibitory activity at the end of the
207	gastro-intestinal was determined to be $105.6 \pm 2.1 \ \mu g$ of peptides/mL.
208	The permeate < 3 kDa fraction was loaded on the HPLC C18 column and peptides detected at 214
209	nm with a photodiode array detector. The chromatogram presented in Figure 3 showed most
210	peptides eluting between 6 and 25 min. As shown in Figure 3, five fractions (F1–F5) were
211	collected. All fractions exerted some ACE-inhibitory activity. Table 1 shows the ACE-inhibitory
212	activity, expressed as IC ₅₀ values, of the peptide fractions isolated by RP-HPLC. IC ₅₀ values ranged
213	from 5.4 to 18.1 μ g/mL. In fractions F1, F3 and F4 a higher ACE inhibitory activity was observed.
214	The lowest IC ₅₀ values of 5.4 ± 0.2 and $5.5 \pm 0.1 \ \mu g$ peptides/mL were found in fractions F4 and
215	F3, respectively, which were about twenty times lower than the IC_{50} value of the post-pancreatic <
216	3 kDa permeate.
217	The yield of the five collected fractions was estimated (Table 1). For fractions F2, F3, F4 and F5
218	the yield was similar, ranging from 12.4 and 14.8%. Fraction F2 showed the highest yield of
219	approximately 22% (Table 1). The sum of the peptide concentration in the five fractions resulted in
220	3.42 mg/mL, giving a total yield of 75.5%.
221	
222	NanoLC-ESI-QTOF-MS/MS identification of peptides in the HPLC collected fractions
223	
224	Fractions with the highest ACE-inhibitory activity were then analyzed with nanoflow LC-ESI-
225	QTOF mass spectrometry to identify the peptides present in these fractions.
226	Each peak was selected for peptide identification by MS/MS ion scan using de novo sequencing
227	software. Results from peptide identification were subjected to a manual evaluation, and the
228	validated peptide sequences explained most of the major peaks in the MS spectra. The list of
229	compounds identified in these fractions is shown in Tables 2-4 . In addition, the list of peptides
230	identified in the fraction F2 and F5 is shown as online supplementary material (Tables S1 and S2).

Fraction F1 (Table 2) contained 10 peptides, most of them being dipeptides (7 peptides; 70% of the 231 identified peptides in F1). The longest peptide identified in this fraction (EEEES) had five amino 232 acid residues and derived from the α and β subunits of phaseolin. Fraction F2 (**Table S1**) showed a 233 45% of dipeptides (4 out of 9) with the longest peptides having five amino acid residues. In fraction 234 F3 (Table 3), 13 peptides, having 2-5 amino acid residues, were identified. Five peptides (~ 38% of 235 the identified peptides in F3) were dipeptides. The range of peptide length in F4 (**Table 4**) was 236 between 2 and 7 amino acid residues. Eight peptides from 24 are dipeptides (~ 33% of the identified 237 peptides in F4) as well as eight peptides contained three amino acid residues. The longest peptide 238 found in this fraction was the eptapeptide SGSGDEV derived from the α and β subunits of 239 phaseolin. Fraction F5 (Table S2) contained the lowest percentage of dipeptides (18%). 240 In general, the length of peptides increased with increasing acetonitrile concentration. The average 241 number of amino acid residues per peptide (sum of total amino acid residues in the fraction/number 242 243 of peptide in the fraction) in the five fractions increased from 2.5 in F1 to 2.8 in F2, 3.1 in F3, 3.4 in F4 and 4.3 in F5. 244 245 As can be seen in Tables 2-4, each fraction contained at least two peptides with previously reported 246 ACE-inhibitory activity.

Finally, some free amino acids (not reported in the tables) were found in three of the characterized

248 fractions. In F1 we identified methionine (M), glutamine (Q) and valine (V) whereas in F3 the

249 identified amino acids were threonine (T) and tyrosine (Y) and in F4 leucine/isoleucine (Lx).

Discussion 250

251

254

To our knowledge, the present study is the first demonstration that ACE-inhibitory peptides can be 252 released during the gastro-intestinal digestion of whole pinto beans. 253

Previous researches (Mojica et al., 2015; Rui et al. 2012a and 2012b; Boschin et al., 2014) showed the potential of bean proteins to release ACE-inhibitory peptides during hydrolysis catalyzed by 255 bacterial or gastro-intestinal enzymes. However, these works focused on the bioactive properties of 256 peptides released from protein isolates from beans and not from whole beans. 257

The proteolysis process during in vitro gastrointestinal digestion can be strongly influenced by food 258 259 matrix, e.g. by reducing the proteolysis rate of proteins (Mandalari et al., 2011). However, in most studies performed so far, pure proteins, extracted from whole bean, have been subjected to 260 enzymatic digestion assays excluding a potential impact of a food matrix. Common bean is a 261 262 complex matrix containing not only proteins but also polysaccharides and polyphenols which can have a strong impact on gastrointestinal degradation of protein. For example, polysaccharides were 263 264 shown to hamper pepsin activity (Polovic et al., 2007) whereas phenolic compounds may have a positive or a negative effect on protein digestion depending on the protease and on the nature of the 265 phenolic compound (Tagliazucchi et al., 2005). Thus, to give a picture more closely to the in vivo 266 physiological condition of the bioactive peptides released during in vitro digestion, food matrix 267 should be considered. 268

The degree of hydrolysis, which represents the extent of the digestion, increased reaching a value of 269 50% at the end of the pancreatic digestion. This value is comparable to that obtained by Mojica et 270 al. (2015) after simulated digestion of precooked pinto beans protein extract. 271

Previous researchers have reported a lower degree of hydrolysis after digestion of bean protein 272

extracts. Rui et al. (2012a), obtained a degree of hydrolysis of 16% after simulated digestion of 273

pinto bean protein extracts non-thermally treated. They digested nine varieties of beans achieving a 274

degree of hydrolysis between 7 and 16%. Pepsin-pancreatin digestion of hard-to-cook bean 275

extracted proteins resulted in a degree of hydrolysis of 28% (Betancour-Ancona et al., 2014). In 276 277 general, bean protein digestibility in a simulated digestive system seems to be related to the thermal treatment. Cooking of beans resulted in a higher degree of hydrolysis respect to non-cooked beans. 278 279 Bean proteins, especially phaseolin, are considered highly resistant to enzymatic hydrolysis (Jivotovskaya et al., 1996). However, thermal processing may result in a loss of the tri-dimensional 280 structure of the proteins, causing unfolding of the molecules. Thermally denatured bean proteins are 281 more susceptible to enzymatic hydrolysis (Montoya et al., 2008; Rui et al., 2012b). Protein 282 unfolding results in an increased exposure of the cleavage sites, facilitating the access to these sites 283 of digestive enzymes that are able, with greater efficiency, to hydrolyze proteins. 284 285 The extent of the hydrolysis also depend on the type of protease used. Despite pepsin-pancreatin digestion, without thermal processing, results in low (< 30%) degree of hydrolysis (Rui et al., 286 287 2012a; Betancour-Ancona et al., 2014), treatment with alcalase, termolysine, flavourzyme or a 288 combination of these resulted in a high degree of hydrolysis (35-70%) (Torruco-Uco et al., 2009; Rui et al., 2012b; Valdez-Ortiz et al., 2012). 289 290 Protein digestibility and the extent of hydrolysis affected the *in vitro* ACE-inhibitory activity. 291 Generally speaking, a higher degree of enzymatic hydrolysis represents a higher ACE-inhibitory activity. Digested pinto beans released ACE-inhibitory peptides with a calculated IC₅₀ value in the 292 post-pancreatic < 3 kDa permeate of 105.59 µg of peptides/mL. This value is about two times 293 lower than the IC₅₀ found by Mojica et al. (2015) and Rui et al. (2014) after simulated digestion of 294 295 pre-cooked pinto beans and a protein extract from pinto beans, respectively. This difference can arise from the different digestion system used and/or from the ultrafiltration step. The digestion 296 297 system used in our study has been validated for liquid and solid foods (Kopf-Bolanz et al., 2012; Stuknite et al., 2014) and developed within the COST Action FA1005. 298

299 This *in vitro* digestion system closely mimics the digestive process in humans, especially for protein

digestion, resulting in the formation of free amino acids and small peptides (2-6 amino acids)

301 (Kopf-Bolanz et al., 2012). Data reported in **Tables 1-4** and **Tables S1** and **S2** are in agreement

with the results of the Kopf-Bolanz study. The five collected fractions explained the 76% of the 302 303 total peptides present in the digested bean sample. The identification of the peptides in these fractions showed that the length of the peptides was between 2 and 7 amino acid residues. We 304 305 identified in the five fractions a total of 67 peptides. About 39% of the peptides are dipeptides (26 dipeptides), whereas tripeptides represent the 28% of the total identified peptides. The average size 306 of the identified peptides was 3.3 residues per peptides. To this purpose, it has been suggested that 307 short peptides (2-12 amino acid residues) are more effective inhibitors of ACE activity than longer 308 309 peptides (Garcia et al., 2013).

310 Furthermore, ultrafiltration is a technique largely used to enrich the digested food in ACE-

inhibitory peptides. For example, Vermeirssen et al. (2005), found higher ACE-inhibitory activity
in the < 3 kDa fraction than in the > 3 kDa fraction and in un-fractionated digested pea and whey
samples.

314 Among the identified peptides, several had previously been established to display ACE-inhibitory activity. More specifically, two dipeptides in fraction F3 showed very low IC₅₀ values. The 315 316 dipeptides EY and AI, which were previously isolated from shark meat hydrolysate and soy sauce-317 like seasoning, demonstrated IC₅₀ values of 2.7 and 3.4 µmol/L, respectively (Wu et al., 2008; Nakahara et al., 2010). The presence of these two small peptides justifies the high ACE-inhibitory 318 activity found in this HPLC fraction. Fraction F4, instead, contains two tripeptides with high ACE-319 inhibitory activity. The tripeptide LAP (isolated from hydrolyzed chicken muscle) and its isomeric 320 321 form IAP (isolated from wheat gliadin hydrolyzates) are potent inhibitors of ACE activity with IC₅₀ values of 3.5 and 2.7 µmol/L, respectively (Fujita et al., 2000; Motoi & Kodama, 2003). LAP was 322 323 found to be effective when intravenously administered to spontaneously hypertensive rats (SHR) (Fujita et al. 2000). Also the tripeptide LVE, previously isolated from pearl oysters, showed low 324 IC_{50} value of 14.2 μ mol/L (Qian et al., 2007). Additional dipeptides with higher IC₅₀ values were 325 found in fraction F3 (GLx) and F4 (PL, GF, SF and AF) as reported in Tables 3 and 4. Fraction F1, 326

instead, contained dipeptides (LF, IF and EV) with previously demonstrated ACE-inhibitory 327 328 activity which showed IC₅₀ values ranged between 350-930 μ mol/L (see **Table 2**). According to previous reports on the structure-activity correlations between different peptide 329 inhibitors of ACE (Wu et al., 2006), some other peptides may have the potential to inhibit ACE 330 activity. In the case of the dipeptides, for both positions, amino acid residues with large bulk chain 331 as well as hydrophobic side chains such as aromatic amino acids (phenylalanine, tyrosine and 332 tryptophan) and branched aliphatic side amino acids (leucine, isoleucine and valine) are preferred 333 (Wu et al., 2006). Based on these considerations, three dipeptides in fraction F4 (VLx, ELx and DF) 334 and two dipeptides in fraction F3 (DLx and TLx) could be active against ACE activity. All these 335 336 peptides have a hydrophobic amino acid residue, L or F, at the C-terminal position, showing they display structural characteristics of ACE-inhibitory peptides. 337

To exert an antihypertensive effect after oral ingestion, ACE-inhibitory peptides have to be adsorbed at intestinal level and arrive at the cardiovascular system in an active form. Peptides identified in our study are very short (di- or tri-peptides) and resistant to gastro-intestinal digestion by pancreatic proteases such as trypsin, chymotrypsin, elastase and carboxypeptidases. All these proteolytic enzymes are present in our digestive system and are responsible for the production of these ACE-inhibitory peptides.

344 Exopeptidases in the brush-border membrane may limit the absorption of small peptides because of their proteolytic activity. However, recent works suggested that proline-rich peptides may resist the 345 action of brush-border peptidases and cross, intact, the intestinal barrier in Caco-2 cell system. For 346 example, the proline-rich β -casein-derived peptides NIPPLTQTPV exhibited a relative stability 347 towards brush-border membrane peptidases and is translocated intact into Caco-2 cells (Picariello et 348 al., 2013). In general, Picariello et al. (2013) found that the majority of the peptides resistant to 349 350 intestinal hydrolysis and able to cross the Caco-2 cells are proline-rich peptides. Two peptides found in fraction F4, LxAP and PLx, are proline-containing peptides and therefore 351

352 potentially resistant to further digestion by brush-border exopeptidase. Indeed, it is now accepted

that significant amounts of small peptides can escape total digestion to amino acids and enter thecirculation intact (Vermeirssen et al., 2004).

355

356 Conclusions

- 357 In this study, for the first time, we demonstrated that the gastro-intestinal digestion of thermally-
- 358 treated *Phaseolus vulgaris* whole bean (pinto bean) released ACE-inhibitory peptides. We
- 359 identified, after ultrafiltration and RP-HPLC purification followed by nanoflowLC-ESI-QTOF-
- 360 MS/MS, eleven peptides with previously established ACE-inhibitory activity. These peptides are di-
- 361 or tri-peptides having the potential to survive the action of brush-border peptidases and lower the
- 362 blood pressure of hypertensive patients.

Table 1. Angiotensin-I converting enzyme (ACE)-inhibitory activity (IC₅₀ values), peptides concentration and yield of the post-pancreatic < 3 kDa permeate and peptide fractions obtained through RP-HPLC purification of the post-pancreatic fraction.

	Peptides concentration (mg/mL)	Estimated yield ^a (%)	IC50 ^b (µg peptides/mL)
< 3 kDa permeate	4.53 ± 0.12	100	105.6 ± 2.1
HPLC F1	0.98 ± 0.05	21.7	6.4 ± 0.1
HPLC F2	0.67 ± 0.01	14.8	18.1 ± 1.0
HPLC F3	0.62 ± 0.02	13.7	5.5 ± 0.1
HPLC F4	0.56 ± 0.01	12.4	5.4 ± 0.2
HPLC F5	0.59 ± 0.02	13.0	15.1 ± 0.7

^a yield was calculated as follow: (peptides concentration in the fraction)*100/ (peptides concentration in the post-pancreatic < 3 kDa permeate).

^bIC₅₀ is defined as the concentration of peptides needed to inhibit of 50% ACE activity.
