PLENARY LECTURES

PL1.1
Chromosome conformation and long-distance gene regulation

N. Benabdallah[1], S. Bhatia[1], I. Williamson[1], **W. Bickmore[2];**
[1]MRC Human Genetics Unit, IGMM, University of Edinburgh, Edinburgh, United Kingdom, [2]Edinburgh, United Kingdom.

Long-range gene regulation first became apparent in mammalian genomes through Mendelian disease genetics associated with extreme phenotypes in human, and developmental genetics in the mouse. It is now appreciated that long-range enhancers - found as far away as 1 megabase from their target gene and located either in intergenic regions or in introns - are key in controlling the precise spatial and temporal expression of genes. Deletion, translocation or point mutations can abrogate the function of these elements in Rare Disease. However, the majority of human genetic variation associated with common and complex disease and quantitative traits also maps to intergenic regions that are likely the site of enhancers. Therefore, lessons learnt from studying enhancer dysfunction in rare disease will be important for an understanding of milder phenotypes.
It is hard to envisage how distant enhancers function if one only considers the genome as a linear DNA sequence. Rather, three-dimensional chromatin folding must play a fundamental role in enhancer-promoter communication. I will describe our work using different experimental approaches to investigate the three-dimensional folding of the mammalian genome at genetically defined long-range regulatory elements important in development.

PL1.2
Deciphering Developmental Disorders

M. Hurles;
Cambridge, United Kingdom.

No abstract received as per date of production. Check http://www.eshg.org/abstracts2015.0.html for possible updates.

PL1.3
Ribonucleotides embedded in genomic DNA

A. Jackson;
The University of Edinburgh, Edinburgh, United Kingdom.

Our identification of biallelic hypomorphic mutations in three RNase H2 genes in the neuroinflammatory disorder, Aicardi-Goutières syndrome led us to investigate enzyme complex they encode. We subsequently established this is an important genome surveillance enzyme that removes over 1,000,000 ribonucleotides embedded in the genomic DNA of every replicating mammalian cell. Such ribonucleotides represent the most common non-canonical nucleotides incorporated into the genome by replicative polymerases and are an important potential source of genome instability. Furthermore, we have now exploited embedded ribonucleotides as a tool to trace the respective contribution of DNA polymerases, developing the technique emRiboSeq, and use this to implicate replicative polymerases as a determinant of local nucleotide substitution rates at functionally important sites, shaping the mutational landscape of the genome.

PL2.1
De novo mutations in *PLXND1* and *REV3L* cause Möbius syndrome

Introduction: Möbius syndrome (MBS) is a rare congenital neurological disorder characterized by facial and abducens nerve paralysis. Additional congenital anomalies are frequently associated. The etiology of this syndrome has been intensely debated and both teratogenic factors and genetic causes have been suggested. However, despite numerous clinical and molecular investigations since the description of the first patients in 1880 it has remained elusive.
Material and Methods: We hypothesized that de novo mutations contribute to the MBS phenotype and therefore performed exome sequencing in eight isolated MBS patients. All identified de novo variants were subsequently sequenced in a cohort of 103 MBS patients. The role of two candidate genes in MBS was addressed by morphological analysis of the knockout mouse brain.
Results: We report de novo mutations in two different genes PLXND1 and REV3L. Analysis of the Plxnd1 and Rev3l-knockout mice detected neuropathological findings similar to those found in MBS. Strikingly, both mouse models exhibited a reduced number of motoneurons in the facial motor nucleus, caused by defective neural migration in the Plxnd1-mutant mice or disrupted cellular proliferation in Rev3l-heterozygous mice. Conclusions: Our study establishs for the first time a genetic cause for MBS. We show morphological alterations in Plxnd1 and Rev3l mutant mouse models similar to MBS patients clinical features. Although PLXND1 and REV3L are involved in different pathways a protein defect of any of them result in a decrease of the number of motoneurons in the facial motor nucleus.

PL2.2
Beyond the ACMG 56: Parental choices and initial results from a comprehensive WGS-based search for predictive secondary variants in children

M. S. Meyn[1,2], *N. Monfared[1], C. Marshall[1], D. Merico[1], D. J. Stavropoulos[1,2], R. Z. Hayeems[1,2], M. Szego[3,2], R. Jobling[1], M. Gardia[2,1], G. D. Bader[2], M. Brudno[1,2], R. D. Cohn[1,2], R. Zlotnik-Shaul[1,2], C. Shuman[1,2], P. N. Ray[1,2], S. Bowdin[1,2];*
[1]The Hospital for Sick Children, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]St. Joseph's Health Centre and St. Michael's Hospital, Toronto, ON, Canada.

To pilot the implementation of paediatric genomic medicine we developed the SickKids Genome Clinic, a multidisciplinary project supporting research into clinical whole genome sequencing (WGS). The Genome Clinic conducts diagnostic WGS for 150+ children/year who are undergoing genetic evaluations. With parents' permission, we search childrens' genomes for secondary medically-actionable variants (MAVs) in 2800+ disease genes listed in the NIH Clinical Genomic Database.
Of 321 families approached to date, 54% agreed to participate. 58% of participants chose to learn their child's secondary adult-onset MAVs. Among these parents, 68% decided to learn their own status for the same risk variants. Parents declining secondary variants were most concerned about psychological burdens and/or insurance discrimination.
Bioinformatics analysis of the first 80 patient genomes yielded 2382 candidate variants in 1117 genes that then underwent manual assessment (~30 variants/genome.) While ~15% were novel, the large majority of candidates were listed in HGMD or ClinVar. Most variants listed in HGMD as disease-causing failed manual assessment. E.g., >80% of variants found in the 56 ACMG genes and listed in HGMD as disease causing were rejected due to inadequate evidence of pathogenicity.
We identified 7 reportable variants in the 56 ACMG genes in our first 80 patients (~9%). By expanding our search to 2800+ genes we are finding secondary MAVs in >25% of children, ~40% of which lie in genes for adult onset disorders. We conclude that parental opinions vary widely regarding return of secondary variants, children may harbour more secondary MAVs than adults, and disease prevalence and imperfect variant interpretation constrain the number of reportable secondary MAVs.

PL2.3
Spotlight on the pathogenesis of Kabuki syndrome

Kabuki syndrome (KS) is a genetic disorder characterized by developmental delay and multiple congenital anomalies. KS is caused primarily by mutations in *KMT2D (MLL2)*, a methyltransferase that promotes active transcription and, more rarely, in *KDM6A*, a demethylase of the KMT2D complex. Although the functions of chromatin modifying proteins have been well studied, the physiological systems regulated by them are largely unknown. Using whole exome sequencing we found a mutation converted to homozygosity by uniparental isodisomy (UPD) in *RAP1A* in a patient with KS, and a *de novo* dominant mutation in the closely related gene *RAP1B* in a second patient. We show that suppression of each of *RAP1* (*RAP1A* and *RAP1B*), *KMT2D*, and *KDM6A* leads to defective convergent-extension (CE) movements and to context-dependent MAPK signaling dysfunction. We further show that *RAP1* interacts genetically with *KMT2D* and that *RAP1B* expression is downregulated in both *kmt2d* morphant zebrafish (zf) embryos and KMT2D deficient patient cells. Regarding the frequent skeletal abnormalities in KS, we demonstrate that depletion of KS genes affects the layout of the pharyngeal skeleton in zf by disturbed F-actin polymerization and cell-cell intercalation. Interestingly, the CE and skeletal defects could be rescued *in vivo* by a small molecule MAPK inhibitor. Taken together, this study (i) identifies *RAP1A* and *RAP1B* as two novel genes for KS, (ii) reveals the first evidence that defective MEK-ERK signaling is a common molecular driver for KS, (iii) suggests that KS is a member of the RASopathy spectrum, and (iv) provides a potential direction for treatment design.

Mammalian genomes are organized into megabase-scale topologically associated domains (TADs) that have been proposed to partition the genome into large regulatory units. Here we demonstrate that the disruption of TAD structure can cause rewiring of functional interactions between genes and distant-acting enhancers, resulting in pathogenic phenotypes in humans and mice. We show that distinct limb malformations in human patients are caused by deletions, inversions or duplications altering the structure of the extended WNT6/IHH/EPHA4/PAX3 locus. To examine these variants in detail, we adapted CRISPR genome editing to generate mice with corresponding large rearrangements. 4C-seq in mouse limb tissue and patient-derived fibroblasts showed that the structural changes result in ectopic interactions between promoters and non-coding DNA across adjacent TADs. On the disease alleles, a cluster of limb enhancers normally associated with Epha4 is misplaced relative to TAD boundaries, causing it to interact with and drive ectopic limb expression of Wnt6, Ihh or Pax3, respectively. Taken together, our results demonstrate the critical importance of TADs for the functional orchestration of the genome in vivo and support their utility in predicting the pathogenicity of human structural variants.

PL2.5

A germline homozygous loss-of-function mutation in the base excision repair gene NTHL1 causes adenomatous polyposis and colorectal cancer

R. D. A. Weren[1], *M. J. L. Ligtenberg[1], C. M. Kets[1], R. M. de Voer[1], E. T. P. Verwiel[1], L. Spruijt[1], W. A. G. van Zelst-Stams[1], M. C. Jongmans[1], C. Gilissen[1], J. Y. Hehir-Kwa[1], A. Hoogerbrugge[1];*

[1]Radboud university medical center, Nijmegen, Netherlands, [2]University of Washington, Seattle, WA, United States.

Introduction: Patients diagnosed with adenomatous polyposis, i.e., the constitutive development of multiple colorectal adenomatous polyps, are at an increased risk to develop colorectal cancer (CRC). Currently, two adenomatous polyposis-associated syndromes are known: familial adenomatous polyposis (FAP) and *MUTYH*-associated polyposis (MAP). Whereas monoallelic *APC* germline mutations underlie FAP, MAP is caused by biallelic germline mutations in the base excision repair (BER) gene *MUTYH*. No other causative genes have been identified and, therefore, a considerable fraction of adenomatous polyposis patients remains unexplained

Materials and Methods: Whole-exome sequencing was applied to germline DNA derived from 51 individuals (from 48 families) with multiple colonic adenomas. After candidate gene selection, co-segregation analyses were performed. The somatic mutation spectrum of carcinomas and adenomas was determined by sequencing of 409 cancer-related genes and by targeted deep-sequencing of the *APC* gene, respectively.

Results: We identified a homozygous germline nonsense mutation in the BER gene *NTHL1* in seven affected individuals from three unrelated families. All three families showed recessive inheritance of the adenomatous polyposis phenotype, which was consistently and exclusively encountered in homozygous carriers, indicating a high-penetrant predisposing effect. In controls, this germline mutation was only found in a heterozygous state (MAF 0.0036, n=2,329). Sequence analysis of carcinomas and adenomas from different affected homozygous carriers revealed a non-hypermutated profile enriched for C-to-T transitions, in line with a germline BER defect.

Conclusions: We show for the first time that a homozygous loss-of-function germline mutation in the *NTHL1* gene predisposes to a novel subtype of BER-associated adenomatous polyposis and CRC.

PL2.6

The genetic handicap principle: a severely deleterious mutation can be tolerated if the genome-wide mutation load is sufficiently low

K. Popadin[1], *S. Peischl[2], R. Sailani[3], A. Letourneau[1], F. Santoni[1], M. Garieri[1], S. Nikolaev[1], D. Meyer[4], L. Excoffier[2], S. Antonarakis[1];*

[1]Department of Genetic Medicine and Development, Geneva, Switzerland, [2]Institute of Ecology and Evolution, Bern, Switzerland, [3]Stanford School of Medicine, Stanford, CA, United States, [4]University of Sao Paulo, Sao Paolo, Brazil.

Every human genome harbors hundreds of slightly-deleterious mutations. Even though most of these mutations have each a small effect, their cumulative effect (mutation load) could substantially reduce the fitness of an individual. Here we investigate an interaction between a severely deleterious mutation and the mutation load, formulating the genetic handicap principle: an individual bearing a severely deleterious variant (genetic handicap) is viable only if the genome-wide mutation load is sufficiently low. We develop a population-genetic model, which predicts that live-born individuals carrying a handicap mutation (causing, for example, 50-90% probability of miscarriage) show a reduction (5-20%) in their number of slightly-deleterious mutations as compared to controls. To test this prediction, we used data on trisomy of chromosome 21 (T21), a frequent chromosomal abnormality in humans which is associated with high miscarriage rates. Three evidences support the view that live-born T21 individuals have lower mutation load than the euploid population: (i) there is a deficit of homozygotes for rare derived alleles in the T21 cohort (N=338); (ii) the T21 cohort shows on chromosome 21 a deficit of gain-of-expression and an excess of loss-of-expression regulatory variants that can partially compensate the effect of trisomy; (iii) inter-individual whole-transcriptome variation in fibroblasts of the live-born T21 individuals (N=8) is lower than it is in the control cohort (N=8), reflecting potential selection against T21 fetuses with non-optimal pattern of expression. We conclude that the negative fitness consequences of severe mutations such as trisomy can be partially compensated by a reduced mutation load.

PL3.5

Should clinical geneticists have their genome sequenced during their training? Of course not!

Gijs W. Santen;
Leiden, Netherlands

Even asking the question whether clinical geneticists should have their genome sequenced would seem odd to any medical doctor: indeed, do we ask of gastroenterologists to undergo a colonoscopy during their training? Do anesthesiologist undergo anesthesia? Do radiologists undergo total-body MRI's? However, there is an exception: psychoanalysts do have to undergo

a 3-year 'training analysis' during their training. One can imagine that optimal psychoanalysis does depend on having an in-depth knowledge of your own psychological complexions and reactions to those of others. So the real question is perhaps whether a clinical geneticist is more comparable to a surgeon or a psychoanalysist. Does it help counseling a patient when you have in-depth knowledge of your own genome and the process that got you this knowledge?

An argument in favor of asking geneticists to sequence their own genome would be that personal understanding of the process that patients go through will improve counseling skill. However, there are important differences between genome sequencing of patients and healthy individuals, such as ourselves. In patients, we know that genome sequencing can be an efficient method to determine the genetic cause of an illness, which has implications for the patients themselves and their family. Indeed, that is the whole point! Yes, there is a risk of incidental findings but for most patients the risk-benefit ratio is acceptable. This is a different prospect than to ask a healthy individual to have their genome sequenced: what is the benefit that can be expected? To illustrate this, I have asked my Dutch peers who would have their genome sequenced, and the response was overwhelmingly negative. I think this reflects that we realize that at this point in time not much can be learned from the genome that would have major implications on our health, in the absence of symptoms in ourselves and a positive family history.

There are also practical objections that could be raised. First of all: the law. In the Netherlands at least, offering screening is bound to very strict laws and therefore sequencing a healthy person's genome might well be considered illegal! Cost is another one, but with sharply decreasing genome prices this may not be the most important hurdle. However, the data would have to be interpreted as well, and psychosocial counseling should be available for the geneticists who undergo sequencing. And who would analyze the data? Can I ask my dear colleagues to look at my genome data but to withhold information on late-onset untreatable disorders? And what if they find unclassified variants in colon cancer genes? 'How are you doing?' coming from the person who analyzed your data will never sound the same again!

In conclusion, although I do not believe all geneticists should have their genome sequenced during their training, I do think it might be interesting to start a pilot to offer this to a few of us, monitor the consequences and the costs. But I am not sure I would volunteer…

S02.1
Whole genome sequencing in newborn screening? A Statement on the continued importance of targeted approaches in newborn screening programmes

H. C. Howard[1], *B. M. Knoppers*[2], *M. C. Cornel*[3], *E. Wright Clayton*[4], *K. Sénécal*[5], *P. Borry*[6], *European Society of Human Genetics, the P3G International Paediatric Platform, the Human Genome Organisation, the PHG Foundation;*
[1]*Centre for Research Ethics and Bioethics, Uppsala University, Uppsala, Sweden,* [2]*Department of Human Genetics, Centre of Genomics and PolicyMcGill University, Montreal, QC, Canada,* [3]*Department of Clinical Genetics and EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands,* [4]*Center for Biomedical Ethics and Society, Vanderbilt University, Nashville, TN, United States,* [5]*Department of Human Genetics, Centre of Genomics and Policy, McGill University, Montreal, QC, Canada,* [6]*Department of Public Health and Primary Care, University of Leuven, Leuven, Belgium.*

The advent and refinement of sequencing technologies has resulted in a decrease in both the cost and time needed to generate data on the entire sequence of the human genome. This has increased the accessibility of using whole-genome sequencing and whole-exome sequencing approaches for analysis in both the research and clinical contexts. The expectation is that more services based on these and other high-throughput technologies will become available to patients and the wider population. Some authors predict that sequencing will be performed once in a lifetime, namely, shortly after birth. The Public and Professional Policy Committee of the European Society of Human Genetics, the Human Genome Organisation Committee on Ethics, Law and Society, the PHG Foundation and the P3G International Paediatric Platform address herein the important issues and challenges surrounding the potential use of sequencing technologies in publicly funded newborn screening (NBS) programmes. This statement presents the relevant issues and culminates in a set of recommendations to help inform and guide scientists and clinicians, as well as policy makers regarding the necessary considerations for the use of genome-sequencing technologies and approaches in NBS programmes. The primary objective of NBS should be the targeted analysis and identification of gene variants conferring a high risk of preventable or treatable conditions, for which treatment has to start in the newborn period or in early childhood.

S02.3
Carrier testing in children and adolescents
S. A. Metcalfe;
Murdoch Childrens Research Institute and The University of Melbourne, Parkville Victoria, Australia.

There are a number of circumstances in which a child or adolescent may be identified, either unintentionally or intentionally, as a carrier for a recessive condition. These are: following newborn screening (NBS) when the test also reveals carrier results; as a secondary or incidental finding from investigations into an existing unrelated condition; cascade testing when another family member, especially a sibling, is identified with a genetic condition (or as a carrier through NBS); as a result of prenatal testing by carrier parents; population-based or ethnicity-targeted carrier screening of adolescents, most typically in high school. Since the purpose of carrier testing is to provide information for future reproductive planning, guidelines have traditionally recommended against carrier genetic testing of minors, yet testing in each of the above circumstances has occurred and, in some instances, for many years.

Arguments against carrier testing include: not being in the best interest of the child because it denies the child's future autonomy and removes their right to decide testing for themselves; the potential for psychological, emotional and social harms, such as stigma and discrimination; possibility for misunderstanding the meaning of carrier status; uncertainty whether testing at a young age would result in future reproductive behaviour. On the other hand, many parents have indicated they would want to know their child's carrier status and arguments in favour acknowledge that parents make health care decisions regularly for their child, and that the child's interest is inevitably intertwined with those of the parents and the family. Knowledge of a child's carrier status from newborn screening could be used by parents for their own future reproductive decisions. Learning carrier status as a young child allows them to adapt to the information and, as an older child, the information can increase reproductive options before they are sexually active. Proponents have also commented that there is a lack of evidence of harm to the child while others have called for more empirical research.

These arguments will be further elaborated and research will be highlighted that has examined the ethical and psychosocial aspects of carrier testing in children and adolescents in the various circumstances described above.

S03.1
Heritable germline epimutations in humans
B. Horsthemke;
Essen, Germany.

Phenotypic variation results from genetic variation, epigenetic variation, environmental variation and cultural variation. While it is well established that we inherit our genes, our environment and our culture from our parents, it is less clear whether we also inherit epigenetic information. There is good evidence for epigenetic programming of the fetus by the maternal environment (mainly maternal glucose and hormone levels), but the transmission of epigenetic information through germ cells is a matter of debate. Epigenetic inheritance has been observed in plants and lower animals, but in mammals it faces two barriers: 1. the early separation of the soma and germ line (Weismann barrier) and 2. the epigenetic reprogramming of the genome during germ cell development and during early embryogenesis. Studies on epigenetic inheritance are hampered by the problem to distinguish epigenetic variants that have been transmitted through the germ line from epigenetic variants that arise anew in each generation as a consequence of inherited genetic, environmental or cultural variants. In fact, several reports on heritable germline epimutations have failed to recognize the presence of an underlying genetic mutation. On the other hand, it has been shown in rare cases that epigenetic states can - by accident - survive reprogramming in the germline. In these cases heritable epigenetic variation is most probably random and not adaptive. Nevertheless, it can be subject of selection.

S03.2
Maternal obesity during pregnancy and offspring later life disease
R. Reynolds;
University of Edinburgh, Edinburgh, United Kingdom.

One in five women in the UK is obese (body mass index BMI>30kg/m2) at antenatal booking. Maternal obesity is associated with complications for the mother including increased risk of developing gestational diabetes, pre-eclampsia and need for caesarean section. For the offspring short term complications include risk of macrosomia and need for admission to the neonatal unit. It is now apparent that the effects of maternal obesity for the offspring extend beyond the neonatal period with increased risk of obesity in childhood, adolescence and adult life. In addition there are risks of metabolic disturbance in childhood and young adulthood including glucose intolerance, hypertension and dyslipidaemia. In a record-linkage study we demonstrated that maternal obesity is associated with increased risk of premature mortality and hospital admissions for cardiovascular events in her adult offspring. Animal models suggest the adverse effects of maternal obesity on offspring outcomes are 'programmed' in utero. To investigate underlying mechanisms we have been carrying out a case-control study of very severely obese pregnant women (BMI>40kg/m2) vs. normal weight controls. We characterise maternal weight, body composition, and metabolic profiles through pregnancy and study infant growth and development at birth and 3 and 6 months. Placenta and cord blood are collected at birth and we are comparing placental function and epigenetic modifications of candidate genes in the lean and obese women. Our findings suggest early interventions to improve weight and diet in obese pregnant women are urgently needed. We have tested one such intervention in a randomised controlled trial in obese pregnant women using the insulin sensitiser metformin vs placebo with the aim of improving birth outcome.

S04.1
Spliceosome biology: Understanding causes and consequences of splicing mutations
M. J. Frilander;
University of Helsinki, Institute of Biotechnology, Helsinki, Finland.

Removal of noncoding intron sequences from the primary transcripts by the spliceosome is an essential step in eukaryotic gene expression pathway. Spliceosome is a molecular machine composed of five small nuclear RNAs (snRNAs) and numerous integral protein components. Human cells contain two separate spliceosomes, called as U2- and U12-dependent spliceosomes. U2-type spliceosome excises 99.5% of all introns in humans, while the U12-dependent spliceosome concentrates of a highly conserved subset of introns (termed as U12-type introns) that are found from approximately 700-800 genes in humans.

In addition to the essential role in generating functional mRNA molecules, the pre-mRNA splicing reaction serves also an important regulatory function. In a process called alternative splicing multiple mRNA isoforms are formed from a single gene. Alternative splicing is regulated through a number of non-spliceosomal protein components that can bind to regulatory sequences present in exon and intron sequences. Together with RNA secondary structure and chromatin modifications this leads to formation multiple mRNA species from a single gene that increases protein diversity but also provide important regulatory functions through regulating the stability of mRNA molecules.

A large number of human diseases are caused by defects in the pre-mRNA splicing process. Most common are mutations in either the splices site sequences located at intron-exon boundaries, or in the regulatory elements (splicing enhancers or suppressors) located in the exons or introns. Such mutations result in defects in pre-mRNA splicing that affect single gene only. In contrast, mutations in the components of the pre-mRNA splicing machinery lead to complex pleiotropic effects and affect the pre-mRNA processing in large number genes.

In my presentation I will describe the basic mechanism of intron recognition and splicing process. I will use the human disease causing mutations in the U12-dependent spliceosome to illustrate the effects that splicing machinery mutations have on pre-mRNA processing.

S04.2
Spliceosome and development in human
J. Amiel;
Institut Imagine, Paris, France.

Somatic and germline mutations of the spliceosomal machinery have first been described in cancers and retinitis pigmentosa. More recently, mutations in several genes involved in spliceosomal function or linked aspects of mRNA processing have been identified in human disorders with specific craniofacial malformations. As these gene products take part in widespread

cellular events, the phenotypic restriction is surprising and not yet fully understood. The syndromes and the pathophysiological hypotheses will be reviewed.

S04.3
Spliceosome and cancer

P. A. Greif[1,2,3];
[1]Department of Internal Medicine 3, Ludwig-Maximilians-Universität (LMU), München, Germany, [2]German Cancer Consortium (DKTK), Heidelberg, Germany, [3]German Cancer Research Center (DKFZ), Heidelberg, Germany.

The spliceosome machinery is a multi-subunit protein complex, responsible for mRNA processing. Recently, somatic mutations of genes encoding spliceosome components, such as SF3B1, U2AF1 and SRSF2, were discovered in haematological malignancies including myelodysplastic syndrome (MDS) and chronic lymphocytic leukemia (CLL).
While genetic lesions of the spliceosome are initiating events in MDS, they occur during disease progression in CLL. In acute myeloid leukemia (AML) spliceosome mutations seem to be rare and associated mostly with AML secondary to MDS, however, in the rare subgroup of AML with trisomy 13 the frequency of spliceosome alterations is strikingly high, with 81% of the patients habouring SRSF2 mutations. Of note, the mutational hotspot in SRSF2 is not captured efficiently by standard exome enrichment protocols. Thus, the burden of SRSF2 mutations might be underestimated.
Spliceosome mutations may alter gene expression or function by aberrant splicing, which could result in imbalance between alternatively spliced protein isoforms, non-physiological transcripts or haploinsufficiency due to nonsense-mediated RNA decay.
The exact mechanism of spliceosome dysfunction and the consequences for critical downstream genes during the onset and progression of neoplasia remain unclear.
Pharmacological inhibition of the spliceosome is currently being tested in early stage clinical trials opening up potential therapeutic applications.

S05.1
Using XIST to Silence Trisomy 21: Implications for Cell and Chromosome Therapy

J. Jiang[1], *Y. Jing*[1], *G. Cost*[2], *J. Chiang*[1], *H. Kolpa*[1], *A. Cotton*[3], *D. M. Carone*[4], *B. R. Carone*[4], *M. Byron*[4], *P. D. Gregory*[2], *C. J. Brown*[5], *F. D. Urnov*[2], *L. L. Hall*[4], *J. B. Lawrence*[6];
[1]University of Massachusetts Medical School, Worcester, MA, United States, [2]Sangamo BioSciences, Richmond, CA, United States, [3]University of British Columbia, Vancouver, BC, Canada, [4]Department of Cell and Developmental Biology, University of Massachusetts Medical School, Worcester, MA, United States, [5]Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada, [6]1Department of Cell and Developmental Biology, University of Massachusetts Medical School, Worcester, MA, United States.

Down syndrome, also known as trisomy 21, is the leading genetic cause of intellectual disabilities, occurring in 1 out of 1000 live births. The millions of Down syndrome patients across the world also face multiple other health issues, including congenital cardiac defects, high incidence of Early-onset Alzheimer disease, and hematopoietic disorders. Given that Down syndrome is caused by an extra copy of chromosome 21 that involves over-dosage of 400 genes across a whole chromosome, it precludes any possibility of a genetic therapy. Our lab has long studied the natural dosage compensation mechanism for X chromosome inactivation. To "dosage compensate" X-linked genes between females and males, the X-linked *XIST* gene produces a large non-coding RNA that silences one of the two X chromosomes in female cells. The initial motivation of this study was to translate the natural mechanisms of X chromosome inactivation into chromosome therapy for Down syndrome. Using zinc finger nuclease technology, we have successfully inserted a large *XIST* transgene into Chromosome 21 in Down syndrome iPS cells, which results in chromosome-wide transcriptional silencing of the extra Chromosome 21. Remarkably, deficits in proliferation and neural growth are rapidly reversed upon silencing one chromosome 21. Successful trisomy silencing *in vitro* surmounts the major first step towards potential development of "*chromosome therapy*" for Down syndrome. The human iPSC-based trisomy correction system we established opens a unique opportunity to identify molecular networks driving different aspects of pathogenesis and study transplantation therapies for Down syndrome.

S05.2
Having developed an accurate noninvasive prenatal test for aneuploidies- What else can we work on?

K. C. A. Chan;
The Chinese University of Hong Kong, Hong Kong, China.

The discovery of the presence of fetal DNA in the plasma of pregnant women has revolutionized the landscape of prenatal testing. In particular, the noninvasive prenatal test for chromosomal aneuploidies through sequencing maternal plasma DNA has been rapidly adopted throughout the world over the last 5 years. It is estimated that over 1 million noninvasive prenatal tests for chromosomal aneuploidies have been performed. The principle of this test is based on the detection of the increased amount of DNA released from the extra copy of the aneuploid chromosome of the fetus. The chromosome dosage can be accurately determined by counting the number of sequenced plasma DNA molecules mapping to the individual chromosomes. The sensitivities and specificities of this approach are remarkable for detecting trisomies 13, 18 and 21 in large-scale studies. However, this approach is recommended as a screening test and further confirmation of positive results by testing of fetal tissues obtained invasive procedures is recommended. In this lecture, the following questions as well as potential solutions will be discussed:
1. Will this approach be accurate enough to serve as a diagnostic test instead of a screening test?
2. Is it possible to differentiate chromosome aneuploidies coming from the mother and from the fetus?

S05.3
Status and outcome of randomized trials for aneuploidy screening preimplantation embryos

J. Traeger-Synodinos;
Department of Medical Genetics, University of Athens, Choremeio Research Laboratory, St. Sophia's Children's Hospital, Athens, Greece.

The primary aim of aneuploidy screening preimplantation embryos is to optimize outcomes in couples undergoing infertility treatment. Since the first *in-vitro* fertilization (IVF) cycle performed in 1978, it is estimated that over 5 million babies have been born following IVF. However, only about one third of IVF cycles result in the birth of a baby. Selection of IVF embryos most likely to implant is traditionally based on embryo morphology, although this is relatively imprecise. Based on observations that aneuploidies in clinical miscarriages increase with advanced maternal age (AMA), that aneuploidies are found in preimplantation IVF embryos and that most aneuploidies are incompatible with life, a rationale was developed to improve IVF pregnancy rates through selecting chromosomally normal embryos for embryo transfer. This procedure, usually called Preimplantation Genetic Screening (PGS), was initially applied 20 years ago for AMA, using FISH to analyze select chromosomes in single blastomeres biopsied from 3-day embryos (PGS version 1, PGS-1). Indications for PGS were subsequently widened to couples undergoing IVF for repeated implantation failure, spontaneous abortions and severe male infertility. However, following 10 years of clinical application, evidence from randomized trials did not support a clear benefit of PGS-1 (FISH on blastomeres). Reasons likely include high rates of mosaicism in day-3 preimplantation embryos, the inability of FISH to analyse all chromosomes in a single cell and possibly a negative impact of blastomere biopsy itself. Subsequent PGS strategies use 24-chromosome array-CGH analysis on biopsied polar-bodies or trophectoderm biopsies from blastocyst-stage embryos (PGS-2). Good randomized control trials are challenging, involving stringent patient recruitment, satisfactory patient numbers, monitoring all procedures/protocols, time and expense. The few on-going or recently published randomized trials have not yet clarified the optimum strategy and specific benefits (if any) of aneuploidy screening preimplantation embryos. Results of recent randomized trials will be presented.

S07.1
The International Mouse Phenotyping Consortium: New insights into the genetic and molecular bases of disease
S. Brown, *International Mouse Phenotyping Consortium;*
MRC Harwell, Harwell, United Kingdom.

A major challenge facing mammalian genetics over the next decade is the systematic and comprehensive annotation of mammalian gene function. As part of the International Knockout Mouse Consortium, several programmes are ongoing to generate conditional mutants for all mouse genes. An even greater challenge will be the determination of phenotypic outcomes for each mutation and the identification of disease models. The International Mouse Phenotyping Consortium (IMPC, www.impc.org) will undertake the development of a comprehensive Catalogue of Mammalian Gene Function and proposes to build on the several pilot programmes that have explored the feasibility of large-scale mouse phenotyping, such as the EUMODIC programme. The IMPC incorporates 16 major mouse centres around the world that will undertake mouse production and phenotyping. The IMPC envisages two phases to its programme: Phase 1, 2011-2016, is already well underway and is carrying out the phenotyping of around 5000 mouse lines; and Phase 2 from 2016-2021 which will undertake the analysis of 15,000 mouse lines. IMPC centres operate a core, standardised, broad-based adult phenotyping pipeline encompassing the major biological and disease systems, including gross pathology and tissue collection as a mandatory requirement. Many centres have also begun to employ a standardised embryonic phenotyping pipeline to analyse the many homozygous lethals, incorporating an assessment of time of lethality and morphological defects. In addition, lacZ expression data is being collected for adult organs and E12.5 embryos. All data from each production and phenotyping centre is uploaded to a central Data Coordination Centre (DCC), and following QC and analysis is archived and disseminated to the wider biomedical sciences community along with appropriate annotation tools. In the first 3 years of the programme, over 7000 ES cell lines have been injected, close to 4000 mouse mutant lines generated and phenotype data from nearly 2000 mutants collected at the DCC. We will describe many new insights into the genetic and molecular bases of disease, report the generation of numerous novel disease models, and elaborate a fundamental appraisal of the pleiotropic landscape of mammalian gene function.

S07.2
Investigating genetic diseases with intellectual disability in the mouse
Y. Herault[1,2], *The GENCODYS Network;*
[1]*INSTITUT CLINIQUE DE LA SOURIS, ICS, PHENOMIN, Illkirch, France,* [2]*INSTITUT DE GENETIQUE, BIOLOGIE MOLECULAIRE ET CELLULAIRE, IGBMC, Illkirch, France.*

Intellectual disability (ID) involved impairment of mental abilities that impacts adaptive functioning in the conceptual, the social or the practical domain. ID can occur during the developmental period and is defined by an intellectual quotient below 70. Several genetic conditions, including Down syndrome, copy number variants, and more than 500 genes, have been now associated with ID. To better understand the physiopathology of the different causes of ID, we generated a large series of mouse mutants for ID genes involved in different functions such as synaptic transmission or nuclear regulation, during the GENCODYS program (www.gencodys.eu). Here we will report the characterization of several ID mouse models using standardized behavioural and cognitive paradigms. We also took advantage of the International Mouse phenotyping resource to get additional information on the phenotypes of the ID models. Based on the new series of models and further studies, several ID genes were found inducing key defects in the mouse confirming, even for some challenged candidates, their involvement in ID. In addition we went further investigating more complex genetic conditions, such as copy number variant, and we were able to identify genes and their impact on the behaviour and cognition. The data generated are challenging our current knowledge on the role of ID genes, suggesting common outcome for various genetic conditions. Such studies offer perspectives for a better understanding of the ID and how the cognition and behaviour is affected in human.

S08.1
Constitutional and somatic variations in telomerase reverse transcriptase and human cancer
R. Kumar;
Heidelberg, Germany.

Human telomerase reverse transcriptase (TERT) encodes a rate limiting catalytic subunit of telomerase. We earlier described a disease segregating causal mutation at the -57 bp from ATG start site of the TERT gene in a large melanoma family with early on-set and severe form of the disease. Screening of the TERT core promoter in tumors from unrelated melanoma patients showed mutually exclusive mutations at the -124 and -146 bp from the ATG site at a frequency higher than any other mutation in melanoma (Horn et al. Science, 2013, 339:959-61). The familial and somatic mutations create de novo CCGGAA/T binding motifs for E-twenty six/ternary complex factors (Ets/TCF) transcription factors with consequent increase in TERT expression. The TERT promoter mutations have now been shown to be widespread in many cancer types and have been regularly associated with an increased gene expression and adverse forms of the disease. In bladder cancer, we demonstrated an association of the TERT promoter mutations with a poor patient survival and an increased disease recurrence (Rachakonda et al. PNAS 2013, 110:17426-31). While in glioma, TERT promoter mutations also associated with poor progression free and poor overall survival; in melanoma those mutations associated with parameters connected with poor outcome (Heidenreich et al. Oncotarget 2015; Heidenreich et al. Nature Communications 2014; 5:3401). Germline TERT promoter mutations in carriers result in an increased leukocyte telomere length; however, tumors with somatic TERT promoter mutations have shorter telomeres than tumors without mutations (Hosen et al. International Journal of Cancer 2015). Those findings have resulted in major conceptual advancements and have shown that tumor specific changes in a non-coding region can initiate cancer through change in gene expression. The effects of the promoter mutations on TERT transcription and telomere length emphasize the importance of telomere biology in cancer genesis and outcome.

S08.3
Novel insights into the telomere syndromes
I. Dokal;
Blizard Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, Barts Health NHS Trust, London, United Kingdom.

Dyskeratosis Congenita (DC) is a heterogeneous multi-system syndrome exhibiting marked clinical and genetic heterogeneity. In its classical form it is characterised by mucocutaneous abnormalities (abnormal skin pigmentation, nail dystrophy, leucoplakia), bone marrow failure and a predisposition to malignancy. Bone marrow failure is the principal cause of mortality and patients display features of premature aging.
Studies over the last two decades have led to significant advances with 11 disease genes (*DKC1*, *TERC*, *TERT*, *NOP10*, *NHP2*, *TINF2*, *USB1*, *TCAB1*, *CTC1*, *RTEL1*, and *ACD*) having been characterized. Ten of these are important in telomere maintenance. DC is therefore principally a disease of defective telomere maintenance and patients usually have very short/ and or abnormal telomeres.
The genetic advances have also led to the unification of DC with a number of other disorders. This includes the severe multi-system disorders Hoyeraal-Hreidarsson and Revesz syndromes as well as a subset of patients with aplastic anaemia, myelodysplasia, leukaemia, liver disease and idiopathic pulmonary fibrosis. This wide spectrum of diseases ranging from classical DC to aplastic anaemia can be regarded as disorders of defective telomere maintenance - "the telomereopathies".

Some cases of DC still remain uncharacterized. Using whole exome sequencing we have identified novel biallelic mutations in the poly(A)-specific ribonuclease (*PARN*) gene, in families exhibiting severe DC. PARN is an exonuclease whose deadenylation activity in part controls mRNA stability and therefore regulation of a large number of genes. The mutations identified affect key domains within the protein and studies on patient cells show reduced deadenylation activity. This deficiency causes an early DNA damage response, cell cycle arrest and reduced cell viability upon UV treatment. Individuals with biallelic *PARN* mutations and cells that are depleted of PARN have reduced RNA levels for several key genes associated with telomere biology (*TERC*, *DKC1*, *RTEL1* and *TERF1*). They also possess critically short telomeres. Collectively, these results identify a role for PARN in telomere maintenance and demonstrate that it is a new disease-causing gene in a subset of cases with severe DC.

S09.1
The AML Genome(s)

T. J. Ley, *on behalf of the Genomics of Acute Myeloid Leukemia Program Project Grant, and The Genome Institute;*
Departments of Medicine and Genetics, Washington University School of Medicine, St. Luis, MO, United States.

Acute myeloid leukemia (AML) is characterized by clinical, morphologic, genetic, genomic, and epigenomic heterogeneity. AML genomes are the most minimally mutated adult human neoplasms sequenced to date, with an average of only 13 genic somatic mutations (of which only 5 are in recurrently mutated AML genes). The complexity of the mutational associations is so great that it has not yet been possible to create a new classification scheme for all *de novo* AML patients based on the presence or absence of mutations alone.
Virtually all AML cases are clonally heterogeneous at presentation; this heterogeneity is influenced by treatment, and usually evolves at relapse. Nearly all de novo AML genomes have a single founding clone, and one or more subclones that are derived from it, or from another subclone. Although the genetic rules governing resistance and relapse are not yet clear, mutations that activate signaling pathways (e.g. *FLT3*, *KIT*, and *RAS* mutations, among others) are most often late mutations that occur in subclones, where they may provide a signal for explosive outgrowth. These mutations are usually cleared by induction therapy, while initiating mutations (e.g. in *DNMT3A* or *TET2*) are not.
Since we do not yet know the mutations that are relevant for resistance and/or relapse, and since the clonal architecture of the tumor at presentation may influence response and relapse, clinical sequencing will require not only an ability to identify the genes that are mutated in each sample, but also to an ability to define clonal architecture, and how subclones respond to induction therapy. The failure to clear all mutations after induction therapy significantly increases the risk of relapse, and reduces overall survival. Additional studies focusing on the epigenomes of AML cells will be required to fully understand the pathways and mechanisms that underlie the pathogenesis of this disease.

S09.2
Reconstruction of clonal composition in cancer

V. Mustonen;
Sanger Institute, Cambridge, United Kingdom.

Cells from a tumour are often not isogenic. The fraction of cancerous cells rather consists of a collection of subclones, with private and shared mutations, related by their joint evolutionary history. Such heterogeneity poses a challenge to cancer therapies. There is substantial evidence that it can underpin the emergence of resistance and so adversely affects treatment outcomes. Therefore, the ability to track subclonal dynamics and changes in clonal composition can inform therapy.
The challenge is that it is still not possible to sequence individual cells routinely to capture the full information about their genotype. Instead, short-read sequencing of cell populations is typically used in cancer genomics. Therefore it is necessary to use computational methods to reconstruct the subclonal lineages from sequenced samples.
Here we describe our work on the subclone reconstruction problem with applications to chronic lymphocytic leukaemia, colorectal cancer and experimental evolution.

S10.1
Genomics and Hypertension

A. Dominiczak;
Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, United Kingdom.

Human primary or essential hypertension is a complex, polygenic trait with some 50% contribution from genes and environment. Richard Lifton and colleagues provided elegant dissection of several rare Mendelian forms of hypertension, exemplified by the glucocorticoid remediable aldosteronism and Liddle's syndrome. These discoveries illustrate that a single gene mutation can explain the entire pathogenesis of severe, early onset hypertension as well as dictating the best treatment.
The dissection of the much more common polygenic hypertension has proven much more difficult. Early studies used a single polymorphic marker such as the I/D polymorphism in the ACE gene and small numbers of cases and controls. Candidate gene studies have been largely non-informative and non-reproducible. These were followed by linkage studies, which used approximately 300 microsatellite markers distributed across the genome. These studies resulted in large peaks covering regions with 50-100 genes, with no easy way to quickly focus on a few genes of causal relevance. The real breakthrough came with the initiation of the genome wide association studies (GWAS) characterised by a much more thorough coverage of the genome with thousands single nucleotide polymorphisms (SNPs). Typically 500,000 - 2,5000,000 SNPs have been used for the big, collaborative GWAS for hypertension. These studies resulted in several "hits" or signals with a genome-wide significance and a high level of reproducibility between studies. These "hits" have been used successfully to calculate genetic risk scores for cardiovascular complications such as left ventricular hypertrophy, stroke and coronary artery disease. Intragenic signals, such as for example Uromodulin, are being used to examine new pathways for cardiovascular protection and possibly new targets for drug discovery.
The next steps in genomic medicine belong to a combination of the next generation sequencing (NGS) and its linkage with electronic health records, including preferably the real time clinical data, biochemistry, imaging, histology as well as longitudinal health outcomes. These modalities of stratified or precision medicine are ready for the prime time now.

S10.3
Genetic variation in APOC3, plasma triglycerides and risk of ischemic cardiovascular disease

A. Jørgensen[1], R. Frikke-Schmidt[1], B. G. Nordestgaard[2], **A. Tybjaerg-Hansen**[1];
[1]Dept. of Clinical Biochemistry, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [2]Dept. of Clinical Biochemistry, Herlev University Hospital, Herlev, Denmark.

Background: High plasma levels of nonfasting triglycerides are associated with increased risk of ischemic cardiovascular disease. Whether lifelong low levels of nonfasting triglycerides, due to mutations in the gene for apolipoprotein C3 (APOC3), associate with reduced risk of ischemic cardiovascular disease in the general population is unknown. This is important, because APOC3 is a potential drug target for reducing residual cardiovascular risk.
Methods: Using 75,725 individuals from two general-population studies, we first tested whether low levels of nonfasting triglycerides were associated with reduced risk of ischemic vascular disease and ischemic heart disease. Second, we tested whether loss-of-function mutations in APOC3, which were associated with reduced levels of nonfasting triglycerides, were also associated with reduced risk of ischemic vascular disease and ischemic heart disease. During follow-up, 10,797 individuals developed ischemic vascular disease, of whom 7,557 developed ischemic heart disease.

Results: Individuals with nonfasting triglyceride levels less than 1.00 mmol/L had significantly less cardiovascular disease than those with levels of 4.00 mmol/L or higher (hazard ratio [HR] 0.43; 95% confidence interval [CI], 0.35-0.54 for ischemic vascular disease and HR 0.40; 95% CI, 0.31-0.52 for ischemic heart disease). Heterozygosity for loss-of-function mutations in APOC3 was associated with mean reductions in plasma nonfasting triglycerides of 44% (P=2x10-54). The cumulative incidence of ischemic vascular disease and ischemic heart disease was reduced in heterozygotes (P=0.009 and 0.05, respectively), with corresponding risk reductions of, respectively, 41% (HR: 0.59; 95% CI, 0.41-0.86; P=0.007) and 36% (HR: 0.64; 95% CI, 0.41-0.99; P=0.04).
Conclusions: Loss-of-function mutations in APOC3 are associated with low levels of triglycerides, and with reduced risk of ischemic cardiovascular disease. This suggests that APOC3 is an excellent drug target for reducing residual cardiovascular risk.

S11.1
Retrotransposons and human disease

J. Garcia-Pérez, *S. Morell, E. Blanco-Jimenez, S. Amador-Cubero;*
GENYO, Granada, Spain.

Long Interspersed Element-1 (LINE-1 or L1) is a family of active non-LTR retrotransposons that comprise around a fifth of our genome. Despite this substantial representation, an average human genome only contains 80-100 actively mobile or retrotransposition-competent L1s (RC-L1s). The mobility of RC-L1s continues to impact germline and somatic genomes and can lead to human genetic disease. L1 retrotransposition normally occurs by a mechanism known as target site-primed reverse transcription (TPRT), which requires both the L1-encoded endonuclease and reverse transcriptase activities. However, it has been reported that L1 can mobilize through an endonuclease-independent pathway (ENi), in which the element inserts at sites of DNA disrepair. Notably, recent data from our lab has demonstrated that the mobilization of L1 is de-regulated in Fanconi Anemia (FA) patients, including the ENi pathway. FA is a rare disease characterized by infant mortality and genomic instability, suggesting that de-regulated LINE-1 retrotransposition may affect genomic fluidity in FA patients.

S11.3
A Novel Dicer1-miR328-Bace1 Signaling Axis Controls Ageing- and Obesity-Induced Brown Fat Dysfunction

M. Oliverio, J. C. Brüning, **J. W. Kornfeld**;
Max-Planck Institute for Metabolism Research, Cologne, Germany.

Activated brown adipose tissue (BAT) contributes to control of energy and glucose homeostasis in rodents and humans. Defining the cell-autonomous processes that underly BAT differentiation and activation may thus reveal novel therapeutic targets for obesity and type 2 diabetes mellitus intervention. Here we show that ageing- and obesity-associated demises in BAT function coincide with coordinate down-regulation of mature microRNAs in BAT in the presence of reduced expression of the microRNA processing enzyme Dicer1. To mimic this partial down-regulation of microRNA processing in obesity and ageing, we inactivated one allele of Dicer1 selectively in BAT of mice. BAT-selective heterozygosity of Dicer1 caused glucose intolerance in lean mice and aggravated diet-induced-obesity (DIO)-evoked deterioration of glucose homeostasis. Using combinatorial analyses of altered microRNA-expression in BAT during in vitro brown preadipocyte commitment and mouse models of premature ageing, longevity and DIO, we identified 23 microRNAs dysregulated among these conditions. Of these, we identified miR-328 as a novel regulator of BAT differentiation. miR-328 over-expression promotes BAT-differentiation and impairs muscle progenitor commitment, while reducing miR-328 expression blocks brown but not white adipocyte differentiation. We validated the ß-Secretase Bace1 as a target of miR-328, which is consequently over-expressed in BAT of obese and premature ageing mice. Reducing Bace1 expression enhances brown adipocyte, while impairing myogenic differentiation in vitro. In vivo small-molecule Bace1 inhibition in obese mice delayed DIO-induced weight gain, ameliorated obesity-associated deterioration of glucose metabolism and improved insulin sensitivity. Collectively, these experiments reveal reduced Dicer1-miR-328-Bace1 axis in presence of generalized impairment of microRNA processing in ageing and obesity as a novel determinant of ageing- and obesity associated decline in BAT function. This may define in vivo Bace1-inhibition as an innovative therapeutic approach to not only target age-related neurodegenerative diseases but at the same time improving age-related impairment of BAT-function and metabolism.

S12.1
Mitochondria in neurodegeneration

E. Schon;
New York, NY, United States.

S12.2
A localized autophagic filter prevents entry of mitochondria carrying pathogenic Opa1 mutations in retinal ganglion cell axons

L. Scorrano;
Dept. of Biology, University of Padova, Padua, Italy.

Optic Atrophy 1 (Opa1) is a multifunctional protein involved in mitochondrial fusion, apoptosis and metabolism, but how its mutations affect retinal ganglion cell (RGC) health and result in Autosomal Dominant Optic Atrophy (ADOA) remains unknown. Here we show that pathogenic Opa1 triggers a localized accumulation of autophagosomes that filters mitochondria out from RGC axons. Mitochondrial dysfunction caused by mutated Opa1 results in localized AMPK activation and downstream axonal hillock autophagosome accumulation. Pharmacological or genetic autophagy inhibition restores axonal mitochondrial entry and rescues RGCs from apoptosis caused by mutated Opa1. In vivo, genetic autophagy inhibition rescues visual loss caused by Opa1 ablation. Thus, localized mitochondria autophagy emerges as a mechanism of neuronal dysfunction.

S12.3
Gene therapy for mitochondrial neurogastrointestinal encephalomyopathy (MNGIE)

R. Martí;
Vall d'Hebron Research Institute, Barcelona, Spain.

MNGIE (mitochondrial neurogastrointestinal encephalomyopathy) is a mitochondrial disease caused by mutations in the nuclear gene *TYMP*, encoding thymidine phosphorylase (TP). In recent years, knowledge gained from basic research on the biochemical mechanisms involved in this disorder has allowed us to design plausible therapy approaches. In MNGIE patients, TP dysfunction leads to systemic overload of the nucleosides thymidine and deoxyuridine, which results in alteration of the homeostasis of mitochondrial deoxyribonucleoside triphosphate (dNTP) pool. This imbalance interferes the correct replication of mitochondrial DNA (mtDNA). As a consequence, mtDNA depletion, multiple deletions and somatic point mutations occur in several tissues in patients, ultimately leading to mitochondrial dysfunction. As the clinical phenotype of MNGIE is the result of the toxic accumulation of thymidine and deoxyuridine, therapy approaches have focused on clearing the systemic overload of these nucleosides. First attempts to use hemodialysis failed to reduce nucleoside overload because of the high rate of endogenous production of these compounds by human metabolism. By contrast, hematopoetic stem cell transplantation restored nucleoside homeostasis in patients with successful engraftment, and led to slow clinical improvement. However, the high morbidity and mortality rates associated to the procedure encouraged us to find alternatives, and the most obvious one, gene therapy, has given very promising results in a murine model of the disease. Two different vectors carrying the human *TYMP* gene (a lentiviral vector transduced to hematopoietic stem cells, and an adeno-associated virus vector with targeted expression in liver) have been tested in a murine model of the disease. In both cases, successful and long-term stable expression of the transgene was achieved, resulting in permanent reduction of nucleoside overload *in vivo*. These results demonstrate that gene therapy is a feasible option for MNGIE patients; therefore, clinical trials should be implemented to investigate the safety and efficacy of this option.

S13.1

Nonsense suppression strategies to treat ocular malformations

C. Y. Gregory-Evans[1], *X. Wang*[1], *K. M. Wasan*[2], *K. Gregory-Evans*[1];
[1]*University of British Columbia, Vancouver, BC, Canada,* [2]*University of Saskatchewan, Saskatoon, SK, Canada.*

The extensive genetic and allelic heterogeneity observed with congenital eye diseases is a major barrier to the development of therapeutics. Leber congenital amaurosis is a typical example where more than 400 mutations have been identified in at least 19 different genes. Conversely, more than 600 mutations in a single gene (PAX6) cause aniridia. Developing treatments for each affected gene remains a significant challenge and would have to overcome the ethical and technical barriers associated with the delivery of a preventative prenatal treatment. To overcome these issues we have taken advantage of the observation that approximately 12% of all disease-causing mutations are nonsense mutations leading to premature stop codons. Our approach has therefore focussed on pharmacological strategies that specifically target nonsense mutations and are gene-independent. In our recent work we used systemic prenatal and postnatal nonsense suppression to correct the underlying genetic defects in choroideremia, ocular coloboma, aniridia, retinitis pigmentosa and most recently Leber congenital amaurosis. During these studies we developed a topical eye drop formulation (called START therapy) containing the nonsense suppression drug Ataluren that we tested in a mouse model of aniridia. Topical delivery not only reversed the malformation defects it also restored the electrical and behavioral responses of the retina. Further studies on the efficacy of this postnatal treatment have shown that the eye responds to changes in Pax6 dosage over a specific time window. These studies suggest that the eye retains significant developmental plasticity into the post-natal period and therefore postnatal therapeutic strategies delivered early in life could now be considered as potentially practical for some congenital eye abnormalities. Not only would topical drug delivery avoid the issue of systemic toxicity, but would likely lead to high compliance in young children. Furthermore, this approach would be relevant to new mutations that spontaneously occur without family history.

S13.2

Therapeutic targeting of the mTOR pathway

J. R. Sampson;
Institute of Medical Genetics, Cardiff University, Cardiff, United Kingdom.

Signalling through the mammalian (or mechanistic) target of rapamycin (mTOR) complex 1 (mTORC1) is hyperactivated in many sporadic cancers and in a family of inherited conditions such as tuberous sclerosis, PMSE syndrome and the DEPDC5-associated epilepsies that are characterised by variable combinations of hamartomas and other tumours, epilepsy and neurodevelopmental disorders. Rapamycin and its derivatives (the "rapalogs") inhibit mTORC1 and are being explored as therapies in these diverse clinical settings. Successful clinical trials have led to regulatory approvals in Europe and North America of Everolimus for the treatment of some sporadic cancers and tuberous sclerosis-associated renal and brain tumours. Promising results from phase II trials have led to current phase III trials in epilepsy and phase II trials are assessing efficacy and safety of rapamycin and rapalogs in relation to neurocognitive and neurodevelopmental deficits. Pre-clinical research and early phase trials are also exploring opportunities for targeting the signalling networks upstream and downstream of mTORC1 in sporadic cancers and tuberous sclerosis. In this talk I will review progress to date in translation to the clinic and discuss new therapeutic strategies that are in development.
J Sampson is Chief Investigator of the TRON trial which is funded significantly by Novartis Pharmaceuticals and has received modest lecture fees/Honoraria from Novartis Pharmaceuticals

S13.3

Efficient AAV gene therapy in cardiac and neurological murine models for Friedreich ataxia

H. Puccio;
Institut de Génétique et de Biologie Moléculaire (IGBMC), Illkirch-Strasbourg, France.

Friedreich's ataxia (FRDA), the most common autosomal recessive ataxia, is characterized by a sensory and spinocerebellar ataxia, hypertrophic cardiomyopathy and increase incidence of diabetes. FRDA is caused by reduced levels of frataxin (FXN), an essential mitochondrial protein involved in the biosynthesis of iron-sulfur (Fe-S) clusters. Impaired mitochondrial oxidative phosphorylation, bioenergetics imbalance, deficit of Fe-S cluster enzymes and mitochondrial iron overload occur in individuals with FRDA. To date there are not effective treatment for FRDA, and cardiac failure is the most common cuase of mortality in FRDA. We recently showed that adeno-associated virus (AAV) rh10 vector expressing human FXN injected intravenously not only prevented the onset of the cardiac disease in a faithful FRDA cardiac mouse model, but also, when administered at the time of heart failure, reversed rapidly and completely cardiac disease at the functional, cellular and molecular level in all treated animals. Our results also demonstrated the capacity of defective cardiomyocytes with severe energy failure and ultrastructure disorganization to be rapidly corrected and remodeled by gene therapy. These results established the primary proof-of-concept for developing gene therapy of FRDA cardiomyopathy. We are currently performing dose-response study in the mice to estimate the percentage of cardiomyocytes that need to be corrected to have a therapeutic effect. In addition, we have recently generated a novel mouse model that recapitulates faithfully the sensory ataxia associated to FRDA. These mouse models will be essential to dissect the pathophysiological pathway associated to the disease but also to test therapeutic approaches, including gene therapy.

S14.1

Chromatin organization and long-range control of gene expression

B. Ren;
University of California, San Diego, La Jolla, CA, United States.

Cell-type specific gene regulation is under the purview of enhancers. Great strides have been made recently to characterize and identify enhancers both genetically and epigenetically for multiple cell types and species, but efforts have just begun to functionally characterize these long-range control elements. Mapping interactions between enhancers and promoters, and understanding how the 3D landscape of the genome constrains such interactions is fundamental to our understanding of enhancer function. I will present recent findings related to 3D genome organization in mammalian cells, with a particular focus on how chromatin organization contributes to enhancer-mediated transcriptional regulation. I will describe higher-order organizational features that are observed at the level of both the whole chromosome and individual loci. I will highlight changes in genome organization that occur during the course of differentiation, and discuss the functional relationship between chromatin architecture and gene regulation. Taken together, mounting evidence now shows that the genome organization plays an essential role in orchestrating the lineage-specific gene expression programs through modulating long- range interactions between enhancers and target genes.

S14.2

Biological consequences of regulatory variation and disease

E. Dermitzakis;
University of Geneva, Geneva, Switzerland.

Molecular phenotypes inform us about genetic and environmental effects on cellular and tissue state. The elucidation of the genetic basis of gene expression and other cellular phenotypes is highly informative for the impact of genetic variants in the cell and the subsequent consequences in the organism. In this talk I will discuss recent advances in key areas of the analysis of the genomics of gene expression and cellular phenotypes in human populations and multiple tissues and how this assists in the interpretation of regulatory networks and human disease variants. I will also discuss how the recent advances in next generation sequencing and functional genomics are informing us about the impact of regulatory variation in cancer. Finally, I will present some perspectives on how these developments are bringing us closer to the promise of personalized medicine.

S14.3

Mutations in regulatory domains in human disease

S. Lyonnet[1], *C. T. Gordon*[2], *S. Benko*[2], *A. Pelet*[2], *J. Amiel*[2];
[1]*Paris, France,* [2]*Imagine Institute, INSERM 1163, University Paris Descartes Hôpital Necker-Enfants Malades, Paris, France.*

One of the key discoveries of vertebrate genome sequencing projects was the unexpected amount of DNA that remained evolutionarily conserved under selective pressure (or even non conserved despite likely functional; see EnCode project). Two-thirds of it does not correspond to coding sequences (exons and UTRs), which have been named conserved non-coding sequences (CNCs) and represent a vast amount of DNA (> 3% of the human genome). Interestingly, enrichment for CNCs has been demonstrated within gene deserts nearest to physically isolated genes known or suspected to be important developmental regulators. It has thus been suggested that, in these cases, CNCs may represent regulatory elements (enhancers or suppressors) necessary for the correct spatiotemporal expression of these genes needed

for embryonic development, and acting as modular, sometimes combinatorial, tissue-specific enhancers of gene transcription.
In that context, we will discuss a number of findings, following the seminal discovery of long-distance genomic alterations altering the expression of the SHH (Sonic Hedgehog) gene. Recent examples involve mutation of non-coding RNA genes (such as the deletions observed at the mir17-92 cluster in Feingold syndrome), but also regulatory DNA alterations that we will discuss as:
- Enhancer variants located within or close to a gene, such as a genomic variant in a highly conserved sequence located in a non-coding region of the RET gene, altering the binding of a transcription factor expressed in neural crest cell precursors to the enteric nervous system, which predispose to Hirschsprung disease.
- Long-distance disruption of CNCs, whatever their function, such as those observed on both side of the SOX9 gene coding sequences in either Pierre Robin sequence (PRS), a common orofacial cleft anomaly with mandibular hypoplasia, or isolated disorders of sex determination (DSDs). In these cases, the disruption of distant tissue-specific regulatory elements, required for the normal development of either the mandibula or the gonads, perturbs embryonic expression of SOX9 and could account for the PRS or DSD phenotypes respectively, as these evolutionarily constrained regions may be disrupted in a modular fashion.
Collectively, these observations suggest that the domains to study for genomic alterations, resulting in tissue-specific misregulation of a developmental gene and a subsequent malformation, should be much broader than traditionally investigated.

S15.1
How much of *de novo* is meiotic?

P. Stankiewicz[1,2];
[1]*Dept. of Molecular & Human Genetics, Baylor College of Medicine, Houston, TX, United States,* [2]*Institute of Mother and Child, Warsaw, Poland.*

Owing to the size and inherent instability of the human genome, more than one mutation is estimated to arise per mitotic division, resulting in somatic mosaicism. During the ~10^{16} mitotic cell divisions required to generate an adult, mosaic mutations can go unnoticed, underlie genetic disease or contribute to normal human variation, and may be transmitted to the next generation as constitutional variants. Early somatic mosaic mutations in the precursor somatic cells that will eventually constitute the germline can cause unexpected intergenerational recurrences of genetic and genomic disorders with multiple affected children born to unaffected parents, contrary to Mendelian expectations. Using the sensitivity of individual-specific breakpoint PCR, we prospectively screened 100 families with children affected by genomic disorders due to rare deletion CNVs determined to be *de novo* by clinical analysis of parental DNA. We found that an under-recognized and significant fraction of apparently *de novo* CNVs are not meiotic in origin, but rather arise during early post-zygotic mitoses and this can be identified either in the affected patients or their healthy parents. Our probabilistic model of gametogenesis to consider parental mosaicism as a source of transmitted mutations predicts that despite the fact that maternally transmitted mutations are the minority of alleles, a greater proportion of somatically mosaic transmitting mothers are at increased risk of recurrence. I will review the influence of the developmental timing of mutations, the mechanisms by which mutations arise, methods for detecting mosaic variants, and the risk of mosaic mutations being passed on to the next generation.

S15.2
Selfish mosaicism: impact of somatic mutations occurring in the paternal germline

A. Goriely;
Oxford, United Kingdom.

As mutations are at the origin of all genetic variations, understanding the factors that influence the apparent rate at which de novo mutations occur is crucial to the study of genome diversity, evolution and diseases. Although it is well established that point mutations initially arise as random miscopying events, preferentially from the paternal germline, we have described a new mechanism which predicts that certain pathogenic mutations may hijack the way sperm production is controlled to their own advantage. In doing so, these 'selfish' mutations become progressively enriched in the testis as men age and are therefore associated with an increased risk of transmission to the next generation.
The concept of selfish spermatogonial selection was originally proposed to account for the unusual presentation of a group of rare Mendelian diseases, which we collectively called 'paternal age-effect disorders'. It relies on principles similar to oncogenesis to explain why some paternally-derived mutations, such as those causing Apert (FGFR2) and Costello (HRAS) syndromes or achondroplasia (FGFR3), occur spontaneously at levels up to 1000-fold higher than the genomic background rate. The evidence - gathered originally through direct quantification of these ultra-rare pathogenic mutations in human sperm - suggests that selfish mutations, although occurring rarely, confer a selective advantage to mutant spermatogonial stem cells, leading to their clonal expansion and progressive enrichment in sperm over time.
Our understanding of this process so far suggests that molecularly selfish selection relies on the activation of the growth factor receptor-RAS signalling pathway, which is a key regulator of stem cell homeostasis in the testis. As RAS is required in many different cellular contexts, we will discuss to which extend dysregulation of this pathway is likely to be relevant to the pathology of common disorders, including cancer predisposition and neurodevelopmental disorders, such as schizophrenia and autism - for which paternal age-effects have been described epidemiologically.

S16.2
Ancient pathogen genomics of re-emerging infectious diseases

J. Krause[1,2];
[1]*Max Planck Institute, Jena, Germany,* [2]*Department of Archeological Sciences, University of Tübingen, Tübingen, Germany.*

Genome wide data from ancient microbes may help to understand mechanisms of pathogen evolution and adaptation for emerging and re-emerging infectious disease causing agents. Using high throughput DNA sequencing in combination with targeted DNA enrichment protocols we have reconstructed medieval bacterial genomes of *Yersinia pestis*, *Mycobacterium leprae* and *Mycobacterium tuberculosis* from ancient skeletal remains. Phylogenetic analysis indicate that the ancient *Y.pestis* strain from the Black Death pandemic is ancestral to most extant strains and falls very close to the ancestral node of human infectious *Y. pestis* bacteria. Temporal estimates suggest that the Black Death of 1346 - 1351 was the main historical event responsible for the introduction and worldwide dissemination of currently circulating *Y. pestis* strains pathogenic to humans, and further indicates that contemporary *Y. pestis* epidemics have their origins in the medieval era. In contrast the medieval *M. leprae* strains fall within the current genetic diversity and are found on at least two main branches in the phylogenetic tree of leprosy bacteria. The reconstructed *M.tuberculosis* genomes from 1000 year old Peruvian genomes, however, cluster together with *M.tuberculosis* strains found in modern mammalian species, suggesting a zoonotic origin for tuberculosis in the pre-columbian New World, likely introduced into human populations by contact to sea mammals. Dating analysis reveal a most recent common ancestor of *Y.pestis, M.leprae* and all *M.tuberculosis* strains within the last 6000 years, suggesting that all three human pathogens may have a recent Neolithic origin.

S16.3
Evaluating human genetic (and epigenetic) adaption to pathogen pressures

L. Quintana-Murci;
Pasteur Institute, CNRS, Paris, France.

Different environmental, demographic and selective forces, together with cultural and social characteristics of human lifestyle, shape the patterns of variability of the human genome at the population level. In particular, infectious diseases have been a major cause of human mortality, so natural selection is expected to act strongly on host defence genes. This is particularly expected for innate immunity genes, as they represent the first line of host defence against pathogens. I will present different cases of how some

of these genes and the pathways they trigger have been targeted by natural selection, in its different forms and intensities, helping to delineate genes that are important for host defence, with respect to those exhibiting higher immunological redundancy. I will also discuss how population-specific genetic variation can profoundly impact immune-related molecular phenotypes, such mRNA and miRNA expression upon infection (response eQTLs), and how these studies increase our understanding of immunological mechanisms under genetic control that have been crucial for our past and present survival against infection. Finally, I will discuss how the differences in lifestyle and habitat of human populations, together with their distinct patterns of genetic diversity, affect the epigenetic landscape of the human genome. Specifically, our studies of populations of African rainforest hunter-gatherers and sedentary farmers show that methylation variation associated with recent changes in habitat mostly involves immune functions, whereas that associated with historical lifestyle primarily affects developmental processes. Furthermore, methylation variation - particularly that correlated with historical lifestyle - shows strong associations with nearby genetic variants that, moreover, are enriched in signals of natural selection. Our work increases our understanding of whether and how populations are able to respond/adapt to environmental changes, including those related to pathogen pressures, and provides a resource for assessing the role of (epi) genetic mechanisms in human adaptation over different time scales.

EDUCATIONAL SESSIONS

ES1.1
Applications of CRISPR-Cas9 for Genome Engineering

L. Cong;
Broad Institute, Cambridge, MA, United States.

ES1.2
CRISPR-Cas9: biological roles, mechanisms, evolution and applications

E. Charpentier[1,2,3];
[1]Helmholtz Centre for Infection Research, Department of Regulation in Infection Biology, Braunschweig, Germany, [2]The Laboratory for Molecular Infection Medicine Sweden (MIMS), Umeå Centre for Microbial Research (UCMR), Umea, Sweden, [3]Hannover Medical School, Hannover, Germany.

The RNA-programmable CRISPR-Cas9 system has recently emerged as a transformative technology in biological sciences, allowing rapid and efficient targeted genome editing, chromosomal marking and gene regulation in a large variety of cells and organisms. In this system, the endonuclease Cas9 or catalytically inactive Cas9 variants are programmed with single guide RNAs (sgRNAs) to target site-specifically any DNA sequence of interest given the presence of a short sequence (Protospacer Adjacent Motif, PAM) juxtaposed to the complementary region between the sgRNA and target DNA. The system is efficient, versatile and easily programmable.
Originally, CRISPR-Cas is an RNA-mediated adaptive immune system that protects bacteria and archaea from invading mobile genetic elements (phages, plasmids). Short crRNA (CRISPR RNA) molecules containing unique genome-targeting spacers commonly guide Cas protein(s) to invading cognate nucleic acids to affect their maintenance. CRISPR-Cas has been classified into three main types and further subtypes. CRISPR-Cas9 originates from the type II CRISPR-Cas system that has evolved unique molecular mechanisms for maturation of crRNAs and targeting of invading DNA, which my laboratory has identified in the human pathogen *Streptococcus pyogenes*. During the step of crRNA biogenesis, a unique CRISPR-associated RNA, tracrRNA, base pairs with the repeats of precursor-crRNA to form anti-repeat-repeat dual-RNAs that are cleaved by RNase III in the presence of Cas9 (formerly Csn1), generating mature tracrRNA and intermediate forms of crRNAs. Following a second maturation event, the mature dual-tracrRNA-crRNAs guide the endonuclease Cas9 to cleave cognate target DNA and thereby affect the maintenance of invading genomes. We have shown that the endonuclease Cas9 can be programmed with sgRNAs mimicking the natural dual-tracrRNA-crRNAs to target site-specifically any DNA sequence of interest. I will discuss the biological roles of CRISPR-Cas9, the mechanisms involved, the evolution of type II CRISPR-Cas components in bacteria and the applications of CRISPR-Cas9 as a novel genome engineering technology.

ES2.1
Leveraging molecular networks to reveal pathways underlying complex diseases

D. Marbach[1,2];
[1]University of Lausanne, Lausanne, Switzerland, [2]Swiss Institute of Bioinformatics, Lausanne, Switzerland.

Genome-wide association studies (GWASs) have successfully identified thousands of genetic loci associated with a broad range of complex traits and diseases. However, translating these associations into a functional understanding of disease processes remains a difficult problem. One approach to address this challenge are network-based association strategies, which interpret genetic variants within the molecular circuits that sense and propagate them. The premise is that, for a given trait or disease, causal variants tend to perturb genes that cluster in relevant pathways or network modules. Based on this premise, methods identify dysregulated pathways and/or prioritize candidate genes using network connectivity.
In this educational session, I will: (1) review basic concepts as well as the latest developments in pathway and network-based GWAS analysis, (2) discuss different types of networks that are used by these methods and how they can be constructed, and (3) give a brief summary of our recent work. We inferred a unique compendium of ~400 cell type and tissue-specific enhancer-gene regulatory networks and demonstrated their value for integration with GWAS data across a broad range of traits and diseases. Our results suggest that cell type-specific regulatory circuits are key to understand the fine-scale mechanism of genes underlying complex diseases. Web resources: http://dream.broadinstitute.org, http://regulatorycircuits.org.

ES3.1
Inherited and acquired kidney cancers: opportunities for targeted therapeutic approaches
M. F. Di Renzo[1,2];
[1]Department of Oncology, University of Torino Medical School, Candiolo, Italy, [2]Candiolo Cancer Institute, Candiolo (Torino), Italy.

Hereditary renal cell carcinoma (RCC) may account for 5% to 8% of kidney cancers. This approximation may be significantly underestimated. However, the presentation will be focused on those inherited syndromes with kidney cancers, which have been associated to germline mutations in possibly "actionable" genes. Several hereditary RCC syndromes have been characterized, including von Hippel-Lindau (VHL), hereditary papillary renal cell carcinoma (HPRC), Birt-Hogg-Dube´ (BHD), hereditary leiomyomatosis and RCC (HLRCC), succinate dehydrogenase kidney cancer (SDH-RCC), tuberous sclerosis complex (TSC) and Cowden syndrome and have been shown to be associated with germline mutations in VHL, MET, FLCN, FH, SDHB/C/D, TSC1/2 or PTEN respectively. Although these syndromes have similarities, they vary in histology, aggressiveness, penetrance, and associated clinical manifestations. Understanding the genetic basis of cancer of the kidney, and in particular of the inherited forms, has significant implications for diagnosis and management of this disease and has provided the foundation for the development of targeted therapeutics. VHL is the gene for clear cell kidney cancer. The VHL protein forms a complex that targets the hypoxia-inducible factors (HIFs) for degradation. Knowledge of this pathway resulted in the development of therapeutic approaches now approved for treatment of this disease. Clinical trials are ongoing with agents targeting the tyrosine kinase MET in type I papillary RCC. BHD is thought to be involved in energy and/or nutrient sensing through the AMPK and mTOR signaling pathways. A hereditary form of type 2 papillary renal carcinoma is caused by inactivation of a Krebs cycle enzyme (FH or SDH) due to mutation. Also in these cases HIF might have a pathogenic role, but also other metabolic and signaling alterations might be targeted for therapy.

ES3.2
From inherited breast/ovarian cancer to PARP inhibitors and beyond
W. Foulkes;
Dept Human Genetics, McGill University, Montreal, QC, Canada.

It is now 20 years since the BRCA1 and BRCA2 genes were localized and identified. We know a tremendous amount about how these genes work, and great strides have been made in applying this knowledge clinically, most notably in the development of novel therapeutic approaches to cancers arising in mutation carriers. In addition, detailed, large-scale epidemiological studies have resulted in accurate estimations of cancer risks, and modifier genes are likely to be useful in the future to help stratify mutation carriers into clinically-useful risk categories. Despite these advances, 85% of the familial risk, and 60% of strongly heritable breast cancer remains unexplained, and similarly, a significant fraction of the genetic causes of ovarian cancer remains unexplained.
In this presentation, I will discuss newer breast and/or ovarian cancer susceptibility genes such as PALB2, ATM, CHEK2 and newly identified candidate genes such as RECQL, and others. First, I will discuss the genes, their key functions and their contribution to breast/ovarian cancer risk. Then I will introduce gene panel testing for breast/ovarian cancer, and consider the candidacy of these genes in the setting of testing unaffected women in the medical genetics clinic. Following on from this, I will debate the pros and cons of population-based testing for BRCA1, BRCA2 and other related genes. Finally, I will review data that relates to the use of germ-line genetic information about breast/ovarian cancer genes in making therapeutic decisions.

ES4.1
Patient perspective's to rare diseases
Y. Le Cam;
Paris, France.

No abstract received as per date of production. Check http://www.eshg.org/abstracts2015.0.html for possible updates.

ES4.2
European rare disease policies- what does it really mean for planning services?
K. Bushby;
Newcastle University John Walton Centre for Muscular Dystrophy Research, Newcastle upon Tyne, United Kingdom.

Rare diseases are chronically debilitating conditions, mostly inherited, that affect less than 5 in 10000 people. It is estimated that in the EU 5,000-8,000 rare diseases affect 27-36 million people (6-8% of the population).
The EU objectives in the field of rare diseases have been defined in order to assemble all the elements necessary for a global strategy to tackle rare diseases efficiently. The foremost aim is to improve patients' chances of obtaining the most appropriate and timely diagnosis, information and care on the assumption that this aim can be achieved more effectively through collaborative, European action than by the Member States individually.
Most EU policies do not differ significantly from what most Member States already have in place and these policies should not incur an extra burden for the Member States, particularly those with greater economic challenges and less-developed health systems.
In a nutshell, EU rare disease policies are aiming to make rare diseases more visible through the promotion of an appropriate coding system that will allow the correct and prompt identification of patients. Other key aspects include the development and implementation of National Plans to ensure equal access to prevention, diagnosis, treatment and rehabilitation for people with rare diseases. In general, the European rare diseases policies ensure that common guidelines are developed and shared everywhere in Europe for areas such as research, centres of expertise, development of orphan drugs etc.
The concept of European reference networks (ERNs) for rare diseases is one of the latest instruments provided by the EC to tackle rare diseases requiring specialised care. They should serve as research and knowledge networks, treating patients from other Member States and ensuring the availability of subsequent treatment facilities where necessary. This concept will certainly support the implementation of the "Cross-Border Healthcare Directive" and the equity of care for patients according to the state of the art; however, it will also be the measure that will likely inflict greater financial cost on Member States. To establish effective ERNs will require not only technical but also financial resources coupled with an EU-wide spirit of cooperation.

ES5.1
GeneConsult, Phenomizer, Face2gene with short presentations how they work and test cases to compare the tools

Clinical Face Phenotype Space: Using standard facial imaging to aid diagnosis of genetic syndromes
M. Alvi[1], Q. Ferry[1], J. Steinberg[1], C. Webber[1], D. R. FitzPatrick[2], C. P. Ponting[1], A. Zisserman[1], **C. Nellaker**[1];
[1]University of Oxford, Oxford, United Kingdom, [2]MRC Human Genetics Unit, Edinburgh, United Kingdom.

Clinical dysmorphology is a key discipline within clinical genetics and requires an enormous breadth of experience to correctly classify and diagnose ultra-rare diseases. There has been a significant amount of research into developing objective quantification methods to leverage clinician expertise. I will give a brief introduction to imaging based computational phenotyping research, touching on the morphometrics, anthropometry, 3D imaging modalities, and syndrome classification.
Recent developments in computer vision research have begun to enable analyses based on ordinary photographs to be performed for the purpose of computational phenotyping. I will present Clinical Face Phenotype Space (CFPS), an algorithm to automatically detect faces in photographs, annotate locations of key anatomical parts and extract machine readable feature descriptions of the facial gestalt. The approach uses machine learning to create a multidimensional space shaped to account for spurious variations such as lighting, pose, occlusions, and image quality. The CFPS locates patients in the context of known syndromes, and thus can help generating disease hypotheses. This holds promise as an impartial means of narrowing the search space to suspected rare diseases, and could augment the prioritisation of testing in clinical investigations. Moreover, CFPS allows the clustering of patients by phenotype even when no known syndrome diagnosis exists, thereby aiding disease identification.

Finally, I will describe new approaches to learn the CFPS models and the increased accuracies of facial phenotype representations, and how models of phenotype variation can aid inferring causative genetic variants from clinical sequencing.

My vision on genomic medicine

A. Wojcicki;
Mountain View, CA, United States.

Consumer genetic testing and big data is a powerful combination proven to have a significant impact on research. Large pools of genetic information - like that being collected in the UK, China and United States - can help find treatments for disease and fuel scientific discoveries. But it begins with people and their engagement. A people-powered research model is critical to advancing research.

ES7.1
Imprinting and long noncoding RNAs in health and disease

M. S. Bartolomei;
University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States.

Imprinted genes are expressed from a single parental allele and are the main reason why mammals require both a maternal and paternal contribution for normal development. Defects in imprinted gene expression or loss of a single allele of an imprinted gene are responsible for a number of human syndromes, including Prader-Willi Syndrome, Angelman Syndrome, Beckwith-Wiedemann Syndrome and Silver-Russell Syndrome. There are fewer than 200 imprinted genes that have been described thus far in mice. The imprinted expression and regulation of these genes is largely conserved between rodents and humans, which allows mechanistic studies of this most unusual form of gene expression using both animal models and human tissues and cell models. Most imprinted genes reside in clusters that are located throughout the mammalian genome. The clusters typically contain an imprinting control region (ICR), which harbors allele-specific DNA methylation and governs the imprinting of the entire domain. Deletion or inappropriate epigenetic modifications of the ICR causes deregulation of the entire cluster in cis. Although most imprinted clusters use long non-coding RNAs to regulate imprinted gene expression, a few are regulated by CTCF and allele-specific insulator function. One such cluster harbors the H19 and Igf2 imprinted genes, and is controlled by an ICR that contains multiple CTCF binding sites. Gain of maternal methylation and loss of paternal hypermethylation of the H19/IGF2 ICR are associated with the human growth disorders Beckwith-Wiedemann Syndrome and Silver-Russell Syndrome, respectively. Using gene targeting and genome editing, we have generated ES cells, iPS cell lines and mice to study the mechanisms of imprinting for these imprinted loci and to model the epigenetic mutations in human syndromes. We have also developed SNP-FISH to study the dynamics of allele-specific gene expression at the single cell level in cell lines and tissues exhibiting loss of imprinting.

ES7.2
Diagnosing imprinting-related disorders

K. I. Temple;
University of Southampton, Faculty of Medicine, Southampton, United Kingdom.

Genomic imprinting is a good example of epigenetic regulation of gene expression. Imprinted genes are characterised by expression from only one allele (of the pair) in a consistent parent of origin manner; often only in certain developmental windows and in some tissues of the body. The pattern is set by targeted methylation within the male or female germ line that resists the post fertilisation waves of demethylation of the zygote. Imprinted genes play an important role in fetal growth and development. Their carefully regulated expression is important for normal cellular metabolism and human behaviour.
Imprinting Disorders.
A genetic or epigenetic mutation that impacts imprinting expression can result in one of eight clinically recognisable disorders:-
1. Silver Russell syndrome
chrm 7, 11p15 (Growth restriction, asymmetry)
2. Transient Neonatal Diabetes Mellitus (TNDM)
6q24 (Transient neonatal diabetes, intrauterine growth retardation, diabetes)
3. Beckwith-Wiedemann syndrome (BWS)
11p15 (Overgrowth, omphalocoele, hypoglycaemia, tumour risk)
4. Wang-Kagami-Ogata syndrome (WKOS)
14q32 (mild overgrowth, mental retardation)
5. Temple syndrome (TS)
14q32 (Growth retardation, early puberty, obesity)
6. Angelman syndrome (AS)
15q11q13 (Mental retardation, ataxia)
7. Prader-Willi Syndrome (PWS)
15q11q13 (Growth retardation, mental retardation, obesity)
8. Pseudohypoparathyroidism Ib (PHP1b)
20q13.2 (Overgrowth, parathyroid hormone resistance)
The major overlapping features in most of these conditions (except Angelman) are disordered fetal growth, either excessive or restricted growth, neurodevelopmental delay and disordered metabolism. Diagnosis can be difficiult as many of the features are non-specific.
Most patients with IDs either have uniparental disomy (inheritance of both chromosome homologues from one parent with no contribution from the other), copy number variation involving imprinted loci, imprinted gene mutation or an epigenetic mutation.
To be discussed:
-examples of each phenotype together with the clinical challenges for diagnosis
-genetic counselling and risks to sibs and offspring dependent on the underlying epigenetic or genetic mutation

ES8.1
Wishes for the end of life in Huntington's Disease

S. Booij[1], *A. Tibben*[2], *R. A. C. Roos*[2], *D. P. Engberts*[2];
[1]*CWZ, Nijmegen, Netherlands,* [2]*CWZ, Leiden, Netherlands.*

Introduction: In the Netherlands euthanasia or physician assisted suicide (PAS) is legal since 2002 under strict conditions. Euthanasia or PAS is exempt from prosecution when the euthanasia or PAS is performed by a physician after a direct request from a patient or based on an advance directive. Furthermore the physician must be convinced that the patient suffers unbearable and without prospect or relief.
Huntington's Disease (HD) is an autosomal dominant progressive neurodegenerative disease, characterized by chorea and hypokinesia, psychiatric symptoms and progressive cognitive decline leading to dementia. In The Netherlands approximately 1,700 patients have HD and another 6,000-8,000 persons are at risk. Primary cause of death is pneumonia, second cause is suicide. Each year approximately 7 requests for euthanasia from a HD patient are granted. We have observed an increase in conversations about wishes for the end of life between physicians and patients, but this was never investigated.
Objective: to investigate presence and content of wishes for the end of life amongst HD patients, and the relationship with demographic or disease specific characteristics.
Methods: First, 14 patients in different stages of the disease and 15 physicians were interviewed. Based on the qualitative research a custom made questionnaire was developed and sent to 242 Dutch patients registered in the Leiden HD Registry Database. Information on demographic variables and clinical characteristics such as TFC, MMSE, UHDRS-M was collected.
Results: The interviews showed that most patients had strong ideas about things they do not want for the end of their life because of their experiences with family members. Knowledge about how to effectuate the wishes (for example the role of the physician or family and the value of the advance directive) was in some of them inadequate or lacking. In general, conversations about wishes for the end of life were not initiated by physicians. Physicians reported problems how to deal with an advance directive especially in light of cognitive decline, psychiatric symptoms and signs and 'response shift'.
The questionnaire was returned by 134 patients (55.4%) of whom 101 (75%) reported to have some kind of thoughts for the end of life. These thoughts concerned care (11%) and ; thoughts about euthanasia or PAS (64%). The presence of thoughts about the end of life was related to being familiar with HD but not to any other socio-demographic or clinical variable.
Conclusion: Thoughts about and wishes for the end of life are widely present amongst patients with HD and known gene carriers and these thoughts or wishes concern euthanasia or PAS in a majority of the respondents. Kno-

wing if end-of-life wishes are indeed increasingly present and knowing the content of these wishes could be helpful for physicians. It
could help treatment and guidance of HD patients, especially in light of the absence of any effective treatment. Based on this study it seems impossible to determine which patients will have thoughts or wishes for the end of life and which patients do not. Therefore these questions should be addressed in every patient with HD.

ES8.2
End of life decision making in neonates

A. A. E. Verhagen;
University Medical Center Groningen, Dept of Paediatrics, Groningen, Netherlands.

In the developed world, gone are the days were infants simply died. Now, almost every death is preceded by some exposure to medical care, where diagnoses and prognoses are rendered and decisions are made. The same is true of infants who survive life-threatening illness: they have often been through a long gauntlet of medical interventions. As a result, keeping track of all the care and decisions that preceded the current moment in time is essential to understand how the population of infants being observed came into existence, and to what we can validly infer from comparisons of groups of infants. And as our ability to intervene in the lives and deaths of these patients increases, and the decisions of what to do or not do hinge not only on data but also diverse human values, the importance of understanding and monitoring how infants die increases in equal measure. In this presentation, the most common decisions about life-sustaining interventions in sick newborn are being discussed. Special attention is given to recent developments in practices such as neonatal euthanasia (in some countries) and withdrawal of artificial fluid and nutrition that have may rendered boundaries between withholding and withdrawing life-saving treatments more complex.

C01.1
Implementation of a non-invasive prenatal testing (NIPT) for aneuploidy service in an NHS diagnostic laboratory

L. S. Chitty[1,2], *F. J. McKay[2], S. Mason[2], C. Boustred[2], K. Lo[1], L. Jenkins[2], R. Daley[3,2], M. Hill[2], C. Lewis[1], S. Drury[2], J. Fisher[4], T. Verhoef[5], S. Morris[5];*
[1]UCL Institute of Child Health, London UK, London, United Kingdom, [2]North East Thames Regional Genetics Service, Great Ormond Street NHS Foundation Trust, London, United Kingdom, [3]UCLH, London, United Kingdom, [4]Antenatal Results and Choices, London, United Kingdom, [5]Department of Applied Health Research, University College London, London, United Kingdom.

Non-invasive prenatal testing (NIPT) for aneuploidies is widely available through commercial providers, but implementation into public sector maternity care requires detailed evaluation because of the likely changes in care pathway, educational requirements and potential economic impact.
Here we report the results of a study where a massively parallel sequencing approach to aneuploidy was developed in our NHS Regional Genetics Laboratory, along with health professional and patient educational materials before introducing it into the DSS pathway in eight UK maternity units. Before the study we estimated that if NIPT cost ~£250 per case introduction as a contingent test at a cutoff of 1:1000 would increase the DS detection, whilst decreasing invasive testing with slight overall increase in cost of the DSS and diagnostic pathway.
Women with a DSS risk ≥1:1000 were offered NIPT for trisomies 21, 18, and 13. The study, in a population of ~40,000 women, resulted in over 2500 undergoing NIPT with results reported within 10 days, demonstrated the feasibility of introducing NIPT into the DSS pathway in the NHS. Women were very positive about NIPT, invasive testing rates fell significantly and the detection of aneuploidy increased subsequent to the detection of aneuploid cases in the intermediate (1:150-1:1000) risk group. The higher than expected uptake of testing, some for information only, indicates that for introduction of NIPT to be cost neutral, a lower risk cut off will be required. These data are informing a report to the UK National Screening Committee who are responsible for the UK DSS policy.

C01.2
TRIDENT: or monitored NIPT implementation in the Netherlands

In many countries, Non Invasive Prenatal testing (NIPT) has been introduced commercially, without governmental guidance. In the Netherlands the Population Screening Act regulates the introduction of screening programs for untreatable diseases such as Down syndrome. The Dutch NIPT consortium, consisting of all relevant stakeholders, obtained a license for 2 years for a nationwide NIPT implementation study called TRIDENT (Trial by Dutch laboratories for Evaluation
of Non-Invasive Prenatal Testing). The study started on April 1st 2014. Inclusion criteria are an increased risk (>1:200) for trisomy (T) 21, 18 or 13 based on the first trimester combined test, or because of medical history. After nine months of study, 2439 pregnant women have been tested and 2425 (99,4%) reports issued. We found 70 cases of T21 (2,9%), 8 cases of T18 (0,3%) and 10 cases of T13 (0,4%). Follow-up was completed for 78 cases of which 72 were confirmed, 6 were false positives, presumably due to confined placental mosaicism. Median turnaround time was 13 working days. Data on pregnancy outcomes are currently being collected. An amendment to TRIDENT to offer NIPT to all pregnant women as a first tier test is momentarily pending.
The Netherlands are the first country where NIPT is incorporated into a go-

vernmentally supported and health care funded prenatal Down syndrome screening program. The incorporation of the test in a university hospital laboratory and clinical service guarantees appropriate counselling and allows for proper follow up including thorough exploration of biological causes of false positive and false negative findings including detailed placental examination.

C01.3
Non-invasive prenatal diagnosis; expansion from de novo to autosomal recessive disorders using congenital adrenal hyperplasia as an example

S. Drury[1,2], *K. Lo*[3], *C. Boustred*[1], *F. McKay*[1], *S. Mason*[1], *P. Twiss*[1], *S. Edwards*[1,4], *M. Hill*[1,4], *C. Lewis*[1,2], *R. Daley*[1,4], *L. Jenkins*[1], *L. Chitty*[1,2,4];
[1]*NE Thames Regional Genetics, Great Ormond Street Hospital, London, United Kingdom,* [2]*Genetics & Genomic Medicine, UCL Institute of Child Health, London, United Kingdom,* [3]*UCL Genetics Institute, London, United Kingdom,* [4]*University College London Hospitals NHS Foundation Trust, London, United Kingdom.*

Introduction
Our public sector accredited laboratory offers non-invasive prenatal diagnosis (NIPD) but currently this is restricted to paternal exclusion and de novo mutations. Here we review our experience of NIPD and introduce congenital adrenal hyperplasia (CAH) as a model for NIPD of autosomal recessive (AR) disease.
Materials and methods
An audit of cases was carried out from our internal database for 2014.
Agilent Sureselect Custom enrichment assay, targeted at heterozygous SNPs around CYP21A2 was designed. CffDNA was prepared using Kappa Hyper Prep Kit. Libraries were sequenced on the Illumina MiSeq and variants called using BWA and Varscan. Parental and proband samples were used to construct parental haplotype. Fetal inheritance was determined using the constructed haplotypes.
Results
In 2014 203/337 (60%) molecular prenatal tests in our laboratory were non-invasive. NIPD for fetal sex determination accounted for 73%, 14% were for achondroplasia, 13% thanatophoric dysplasia and around 0.5% for other monogenic disorders. Of those giving a definitive diagnosis in a monogenic condition 63/197 (32%) were NIPD.
CAH analysis of two families to date has correctly identified fetally inherited alleles, consistent with either corresponding CVS sample or follow-up data from the pregnancy.
Conclusions
Non-invasive referrals exceed invasive in our prenatal service. NIPD in our laboratory is considered diagnostic and confirmatory invasive testing is not recommended. We are validating non-invasive assays for other recessive conditions including cystic fibrosis, sickle cell and beta-thalassemia.
Supported by International Fund Congenital Adrenal Hyperplasia and European Society for Paediatric Oncology, NIHR and GOSH-UCL BRC and GOSHCC

C01.4
Non-invasive prenatal diagnosis (NIPD) of Duchenne and Becker muscular dystrophies (DMD/BMD) by relative haplotype dosage

M. Parks, *S. Court, S. Cleary, S. Clokie, J. Hewitt, D. Williams, T. Cole, F. MacDonald, M. Griffiths, S. K. Allen;*
Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom.

As part of the NIPSIGEN project (Non-Invasive Prenatal diagnosis for Single Gene disorders), we are developing and validating a clinical test for NIPD of DMD/BMD in at-risk pregnancies. Through highly targeted enrichment (200 Kb across a 2.4 Mb region on ChrX) and massively parallel sequencing (Illumina MiSeq) of cffDNA followed by relative haplotype dosage (RHDO) analysis, we were able to determine fetal inheritance of the dystrophin gene in six male pregnancies: four healthy pregnant donors and two pregnant DMD carriers all undergoing invasive prenatal testing. Fetal genomic DNA from CVS of healthy donors was used to identify the haplotype of interest on ChrX. For the DMD pregnancies, the affected haplotype was identified from genomic DNA from an affected sibling. Using RHDO analysis, the allelic imbalance in 300-400 heterozygous SNPs was used to determine over /under-representation of the reference haplotype in statistically independent haplotype blocks. For all healthy pregnancies, over-representation of the expected fetal haplotype was observed for all haplotype blocks. Both DMD pregnancies were correctly diagnosed and a recombination event was detected. The fetal portion of cfDNA inputted into the RHDO analysis was calculated using the same allelic imbalance. This new assay for NIPD of DMD/BMD has shown great promise in the initial stages of validation with high sensitivity and specificity on samples tested so far. It is highly affordable (2-3 patients per sequencing run) and capable of detecting recombination events within the DMD gene by splitting the RHDO analysis into multiple statistically independent haplotype blocks across the targeted region.
Funded by: Health Innovation Challenge Fund (HICF) (DoH, Welcome Trust).

C01.5
Incidental findings of genome wide non-invasive fetal aneuploidy detection (NIPT): presymptomatic identification of maternal cancers

N. Brison[1], *K. Van Den Bogaert*[1], *P. Brady*[1], *L. Dehaspe*[1], *I. Wlodarska*[1], *F. Amant*[2], *P. Vandenberghe*[1], *T. de Ravel*[1], *H. Peeters*[1], *H. Van Esch*[1], *K. Devriendt*[1], *E. Legius*[1], *J. R. Vermeesch*[1];
[1]*Center for Human Genetics, UZ Leuven, Leuven, Belgium,* [2]*Department of Obstetrics and Gynaecology, UZ Leuven, Leuven, Belgium.*

Non-invasive prenatal testing (NIPT) for fetal aneuploidy detection is increasingly being offered in the clinical setting following studies demonstrating high sensitivities and specificities for trisomies 21, 18 and 13 detection. However, a baseline false positive and false negative rate remains. We introduced an analysis pipeline which addresses some of the technical and biologically-derived causes of error. Importantly, it differentiates high z-scores due to fetal trisomies from those due to local maternal CNVs causing false positives. Following routine clinical analysis of over 5000 prospective pregnancies, several other genomic imbalances were found in addition to detection of the common autosomal aneuploidies. These findings include (i) other (segmental) aneuploidies (0,3% of cases), 4 of which could be confirmed to be fetal (1 mosaic trisomy 16 and 1 mosaic trisomy 15 which contained a uniparental disomy cell line, 2 partial trisomies 18 and 1 terminal 5p deletion) and (ii) maternal imbalances. Importantly, three aberrant genome representation profiles were observed that could not be attributed to the maternal nor the fetal genomic constitution. Whole body diffusion-weighted magnetic resonance imaging and subsequent pathologic and genetic investigation uncovered the presence of respectively an ovarian carcinoma, a follicular lymphoma and a nodular sclerosis classical Hodgkin lymphoma. The copy number variations in those tumors were concordant with the NIPT plasma profile. NIPT thus enables the accurate presymptomatic detection of maternal tumors. These incidental findings are an unsuspected added benefit of NIPT.

C01.6
Non-invasive prenatal testing for aneuploidy and beyond: challenges of responsible innovation in prenatal screening - an ESHG/ASHG position statement

W. Dondorp[1], *G. de Wert*[1], *C. G. Van El*[2], *M. C. Cornel*[2];
[1]*Maastricht University, dept of Health Ethics & Society, and Research Schools CAPHRI & GROW, Maastricht, Netherlands,* [2]*VU University Medical Center, section community genetics and EMGO Institute for Health and Care Research, Amsterdam, Netherlands.*

Several professional societies have issued position statements on noninvasive testing (NIPT) in prenatal screening for common autosomal aneuploidies. Ethical aspects have not been a main focus of those statements. This ESHG/ASHG document fills this lacuna. Emerging scenarios for introducing NIPT into prenatal screening should not just be regarded as a matter of screening technology and health economics; the question is also how the trade-offs involved enable or impede meaningful reproductive choices and how they affect the balance of benefits and burdens for pregnant women and their partners. With improving screening technologies and decreasing costs of sequencing and analysis, it will become technically possible to expand the scope of prenatal screening beyond common autosomal aneuploidies. This should be limited to serious congenital and childhood disorders, and only following sound validation studies and a comprehensive evaluation of all relevant aspects. In countries where prenatal screening for fetal abnormalities is offered as a public health programme, governments and public health authorities should adopt a more active role to ensure the responsible innovation of prenatal screening on the basis of ethical principles. This requires guarantees of the quality of the screening process as a whole (including non-laboratory aspects such as information and counseling), education of professionals, systematic evaluation in the light of the aim of the practice, accountability to all stakeholders and promotion of equity of access. This document is the result of a unique collaboration between the ESHG Public and Professional Policy Committee, and the ASHG Social Issues Committee. The final version was approved by the Boards of both Societies in December 2014.

C02.1

Single cell analysis "simplification" dramatically increases complexity: considerations in technique, quality control, analysis, and possibilities for translation to the clinic

L. D. White, *J. D. Landua, L. Simon, M. T. Bernardi, D. Xavier, C. A. Shaw, M. T. Lewis; Baylor College of Medicine, Houston, TX, United States.*

Introduction: New technology platforms intended for single cell analysis (SCA) are bringing us to a new frontier in science and studies that were only dreamt are very possibly within reach of researchers studying everything from population dynamics, cell signaling, to cancer/metastases mutation detection, and eventual move of SCA into diagnostics/personalized medicine. We report on the challenges involved in developing SCA for RNA NGS: workflow, experimental design, techniques, quality control, analysis, and interpretation.
Materials and Methods: Utilizing Fluidigm's C1™ system, we captured 4 cell populations. cDNA was QCd with capillary electrophoresis. 96 single cells were prepped for Illumina sequencing using a modified Nextera XT kit. Samples were sequenced on the HiSeq2500 Rapid (PE 100 base reads).
Results: Integrated workflow between flow sorting and C1 capture required planning and a close relationship with the flow facility. Although cDNA, library preparation, and the sequencing run QC measurements passed, we had 14% failure (13/96 libraries). Data analysis (approximately 3 million reads/cell) demonstrates that accumulation of unique RNA species across multiple single cells yields coverage estimates for genomic expression, but that cell types can be differentiated.
Conclusions: SCA has great potential, however, variance in expression of individual genes requires detailed consideration, and cluster analysis of single cells from multiple compartments should take mean-variance relationships of individual genes into account. Analysis and experimental design require a mind shift from the averaging method to which we have been chained and there remains an inordinate amount of work to be done before single cell clinical diagnostics is possible.

C02.2

Large-scale genotyping of polymorphic inversions in the human genome

S. Villatoro[1], *R. Zaurin*[1], *M. Gayà-Vidal*[1], *C. Giner-Delgado*[1,2], *D. Vicente-Salvador*[1], *D. Izquierdo*[1], *M. Oliva*[1], *L. Pantano*[1], *M. Puig*[1], *M. Cáceres*[1,3];
[1]*Institut de Biotecnologia i de Biomedicina, Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain,* [2]*Departament de Genètica i de Microbiologia, Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain,* [3]*Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.*

Inversions are known to be associated to phenotypic and functional differences between individuals. Unfortunately, their study has lagged behind due to the technical difficulties of their analysis, especially when they are flanked by highly identical inverted repeats (IRs). Here, we present a new method called inverse MLPA (iMLPA, patent pending) to genotype simultaneously multiple inversions mediated by IRs in hundreds of individuals, which is based on a combination of inverse PCR and probe hybridization. In particular, current developed assays are able to genotype more than 30 inversions using only 25 ng of DNA per inversion, although it should be easy to include additional inversions as they are identified. To test the performance of the technique, we have genotyped 24 of these inversions in 550 individuals of seven diverse human populations from the 1000 Genomes Project with 98.5% genotyping success rate. In addition, by comparing with the results obtained by PCR for a subset of the samples, we have shown that iMLPA is highly accurate and most errors accumulate in specific inversions affected by restriction-site polymorphisms. Finally, we have established the population distribution and evolutionary history of the inversions, their functional effects on genes, and we have observed that most inversions with IRs are recurrent and are not linked to SNPs. Therefore, having a high-throughput technique to genotype these inversions is crucial to shed light on their association with complex phenotypes and disease susceptibilities, and could contribute to unravel the hidden heritability of the human genome.
Support: European Research Council (ERC) Starting Grant (INVFEST).

C02.3

Large-scale single-molecule sequencing of tandem repeats on the human X chromosome

A. Zablotskaya[1,2], *G. Peeters*[1,2], *W. I. M. Meert*[2,3], *K. J. Verstrepen*[4], *G. Froyen*[5,2,6], *J. R. Vermeesch*[1,2];
[1]*Laboratory for Cytogenetics and Genome Research, Department of Human Genetics, KU Leuven, Leuven, Belgium,* [2]*Center for Human Genetics, University Hospitals Leuven, KU Leuven, Leuven, Belgium,* [3]*Genomics Core, University Hospitals Leuven, Leuven, Belgium,* [4]*VIB lab for Systems Biology & CMPG Lab for Genetics and Genomics, KU Leuven, Leuven, Belgium,* [5]*Human Genome Laboratory, Department of Human Genetics, KU Leuven, Leuven, Belgium,* [6]*Jessa Hospital, Laboratory for Molecular Diagnostics, Clinical Biology, Hasselt, Belgium.*

Tandem repeats are short DNA sequences that are repeated head-to-tail with a propensity to be variable. They constitute a significant proportion of the human genome, also occurring within coding and regulatory regions. Variation in these repeats can alter the function and/or expression of genes allowing organisms to swiftly adapt to novel environments. Importantly, some repeat expansions have also been linked to certain diseases. Unfortunately, due to the nature of short read sequencing technologies, tandem repeats are not analyzed during whole genome or exome sequencing studies. We developed a novel capture assay for large-scale genotyping of tandem repeats (Duitama J., Zablotskaya A. et al., Nucl. Acids Research, 2014) and extended the assay for the identification of X linked disease-related repeats using long read (averaging 12 kb) PacBio RS II technology. For 837 (83% of all) potentially functional repeats, unique capture baits were designed, as well as for 1000 intronic and intergenic repeats. Of these, a full tandem repeat length sequence was obtained for 84-89% of the targets in male DNA samples. We are currently implementing this assay to screen for potentially causal variation underlying X-linked disorders that are not explained following array and exome sequencing.
Grant references: Fonds voor Wetenschappelijk Onderzoek (FWO)-Vlaanderen [G.0795.11 to K.J.V., J.R.V., G.F.]; Marguérite-Marie Delacroix [GV/B-155 to A.Z., G.F].

C02.4

The value of long-read single molecule sequencing in diagnostics

S. Y. Anvar[1], *H. Buermans*[1], *R. Vossen*[1], *M. Liem*[1], **M. Losekoot**[2], *T. van der Straaten*[3], *H. van der Klift*[1,2], *J. Wijnen*[1,2], *J. Swen*[3], *D. Peters*[1], *J. T. den Dunnen*[1,2];
[1]*Human Genetics, Leiden University Medical Center, Leiden, Netherlands,* [2]*Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,* [3]*Clinical Pharmacology and Toxicology, Leiden University Medical Center, Leiden, Netherlands.*

Sanger sequencing is THE standard to scan disease-genes for deleterious variants. Although next generation sequencing is gradually taken over it will not resolve all issues. A major limitation of both methods is their short read length (~1,000 nucleotides), making it impossible to study certain rearrangements and/or resolve regions with repetitive sequences. We have applied long-read single molecule sequencing (Pacific Biosciences) to overcome this limitation and tackle some of the remaining diagnostic problems.
For targeted sequencing we apply a two-step procedure: target amplification with gene-specific M13-tailed primers followed by barcoding using reusable M13-tailed barcode primers. Barcoded samples are then pooled and processed for smart-bell sequencing. Sequencing runs yield ~60,000 sequences with ~15kb read lengths.
Using this approach we have targeted several loci of interest. The CYP2D6 gene is amplified and sequenced as a 6.6kb fragment. Although homologous sequences may co-amplify (e.g. the CYP2D7 gene) the full length sequences simply their discrimination and recognition of both CYP2D6 alleles. The latter is important to accurately predict the drug dose to use. In PKD1 long-reads allow us to start in unique 3' sequences and read far into highly repetitive 5' sequences. In PMS2 they help to discriminate the active gene from several PMS2 pseudogenes. When genomic structure complicates amplification or compromises analysis, we use RNA to synthesize full-length cDNA and perform long-read sequencing. Finally, we use long-read single molecule sequencing to resolve individual alleles from repeat expansion disorders and to analyse complex disease-associated repeat structures (D4Z4 in FSHD). We conclude PacBio-sequencing is a powerful diagnostic tool facilitating analysis of complex genomic loci.

C02.5

Comparison of exome and genome sequencing technologies for the complete capture of protein coding regions

S. H. Lelieveld[1], *M. Spielmann*[2,3], *S. Mundlos*[2,3], *J. A. Veltman*[1,4], *C. Gilissen*[1];
[1]*Department of Human Genetics, Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Institute for Medical Genetics and Human Genetics, Charité Universitätsmedizin Berlin, Berlin, Germany,* [3]*Max Planck Institute for Molecular Genetics, Berlin, Germany,* [4]*Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands.*

For next-generation sequencing technologies sufficient base-pair coverage is the foremost requirement for the reliable detection of genomic variants. We investigated whether whole genome sequencing (WGS) platforms offer superior coverage of coding regions compared to whole exome sequencing (WES) platforms, and compared single-base coverage for a large set of different exome and genome samples (24 Agilent V4 (at 78x and 160x coverage), 12 Agilent V5 (100x), 12 NimbleGen V3 (95x), 24 Complete Genomics (44x and 87x), 11 Illumina HiSeq (28x), 12 Illumina X-Ten (40x)).

We find that WES platforms have improved considerably in the last years, but at comparable sequencing depth, WGS outperforms WES in terms of covered coding regions. At higher sequencing depth (95x-160x) WES successfully captures 95% of the coding regions with a minimal coverage of 20x, compared to 98% for WGS at 87 fold coverage. A comparison to published gene panel studies shows that these perform similar to WES and WGS in terms of coverage. Three different assessments of sequence coverage bias showed consistent biases for WES but not for WGS. We found no clear differences for the technologies concerning their ability to achieve complete coverage of 2,759 clinically relevant genes.
We show that WES performs comparable to WGS in terms of covered bases if sequenced at 2-3 times higher coverage. This does, however, go at the cost of substantially more sequencing biases in WES approaches, which may impact applications such as the identification of copy-number variants and somatic variation. Our findings will guide laboratories to make an informed decision on which sequencing platform and coverage to choose.

C02.6
A significant proportion of de novo point mutations arise post-zygotically

R. Acuna-Hidalgo[1], T. Bo[2], M. Kwint[1], M. van de Vorst[1], M. Pinelli[3], J. A. Veltman[1], H. Alexander[1], L. E. L. M. Vissers[1], **C. Gilissen**[1];

De novo mutations are recognized both as an important source of human genetic variation and as a prominent cause of sporadic disease. Mutations identified as de novo are generally assumed to have occurred during gametogenesis and, consequently, be present as germline events in an individual. However, Sanger sequencing does not provide the sensitivity to reliably distinguish somatic from germline mutations. Therefore, the proportion of de novo mutations occurring somatically rather than in the germline remains unknown. To determine the contribution of post-zygotic events to de novo mutations, we analysed a set of de novo mutations in 50 parent-offspring trios using three sequencing techniques. We found that 8 out of 107 presumed germline de novo mutations (7.5%) were in fact present as mosaic mutations in the blood of the offspring and were therefore likely to have occurred post-zygotically. Furthermore, genome-wide analysis of de novo variants led to the identification of 5 de novo mutations in the offspring which were also detectable in the blood of one of the parents. This implies parental mosaicism as the origin of these de novo mutations in 5 out of 50 trios. Remarkably, none of the parental low-level mosaicisms detected by Whole Genome Sequencing and validated by amplicon-based deep sequencing, were identified by Sanger sequencing. Our results show that a significant proportion of de novo mutations presumed to be germline in fact occurred either post-zygotically in the offspring or were inherited from low level mosaicism in one of the parents.

C03.1
De novo and familial *DDX3X* mutations are associated with X-linked intellectual disability and a diverse phenotypic spectrum

Next generation sequencing studies have led to the identification of a large number of novel autosomal intellectual disability (ID) genes. However, the interpretation of disease causality of genetic variants on the X chromosome has remained behind and up to now has been mostly dependent on segregation analysis in families. We identified *de novo* frameshift, missense, nonsense and splice site mutations in *DDX3X* in 15 females within cohorts of sporadic ID patients. These females showed mild to severe ID and various other features including cortical dysplasia, hypotonia, movement disorders, behaviour problems and epilepsy. In seeming contrast with these observations, we additionally identified three families with variants in *DDX3X* suggestive for a X-linked recessive inheritance pattern, in which males had mild to severe ID while carrier females were unaffected. Intriguingly, *in silico* prediction and protein modelling programs could not discriminate between the *de novo* variants in affected females and the variants associated with X-linked recessive inheritance. The gene *DDX3X* encodes a multifunctional RNA helicase and is particularly intolerant to genomic variation. To further explore the pathogenic mechanisms that might underlie the differences in disease transmission and phenotypic outcomes, we have employed a combination of in vitro and in vivo assays grounded on the known roles of DDX3X on the regulation of β-catenin signaling. Preliminary studies indicate a dosage-dependent effect of DDX3X on Wnt signaling that is altered by the introduction of the majority of the missense changes found in our cohort.

For the first time, inherited dysregulation of protein serine/threonine dephosphorylation is found to cause genetic disease. De novo missense mutations in two different subunits of protein phosphatase 2A (PP2A) were identified in 15 individuals with mild to severe ID, long-lasting hypotonia, epileptic susceptibility, frontal bossing, mild hypertelorism and downslanting palpebral fissures.
The PP2A holoenzymes comprise catalytic (C), scaffolding (A) and regulatory (B) subunits that determine subcellular anchoring, substrate specificity and physiological function. Nine patients had mutations (E198K, E200K, P201R or W207R) that brought a basic charge into a highly conserved acidic loop of the PPP2R5D-encoded regulatory B56δ subunit, including six individuals who had the same de novo E198K mutation. Five others had de novo mutations (P179L, R182W and R258H, all also cancer-associated) in the PPP2R1A-encoded scaffolding Aα subunit. Large ventricles causing macrocephaly and suspicion of hydrocephalus were features in some cases, and all Aα cases had partial or complete corpus callosum agenesis.
Functional studies showed that the mutant A and B subunits were stable and uncoupled from the C subunit: Mutant B56δ had deficient A and C subunit binding, while mutant Aα had deficient binding of C, but not of B56δ. This suggested that mutant B56δ or mutant Aα-B56δ complexes could hinder C subunit access to B56δ-anchored PP2A substrates. Such a dominant-negative effect was supported by our finding of hyperphosphorylation of B56δ-regulated substrates upon mutant subunit overexpression. This was also in line with clinical observation indicating a correlation between the degrees of ID and biochemical disturbance.

C03.3
Mutations in genes encoding components of protein phosphatase 2A (PP2A) cause human overgrowth and intellectual disability

C. Loveday[1], *K. Tatton-Brown[1], M. Clarke[1], I. Westwood[2], A. Renwick[1], E. Ruark[1], E. Ramsay[1], R. van Montfort[2], N. Rahman[1,3];*

Overgrowth syndromes comprise a group of heterogeneous disorders characterised by excessive growth parameters, often in association with intellectual disability. To identify new causes of human overgrowth, we have been

undertaking trio-based exome sequencing studies in overgrowth patients and their unaffected parents. Prioritisation of functionally relevant genes with multiple unique de novo mutations revealed four mutations in three related genes encoding components of the protein phosphatase 2A (PP2A), a key cellular serine-threonine phosphatase. All four mutations clustered within a highly conserved functional domain of 27 nucleotides shared by all three genes. Analysis of exome sequencing data from a follow-up cohort of overgrowth probands identified a further mutation in the cluster region, bringing the total number of patients with PP2A-related mutations to five. Mutation carriers shared some similar phenotypic features including increased height, increased head circumference and intellectual disability. We mapped the mutations onto the crystal structure of the PP2A holoenzyme complex to predict their molecular and functional consequences. These studies suggest that the mutations may affect substrate binding, thus perturbing the ability of PP2A to dephosphorylate certain protein substrates. PP2A is a major negative regulator of V-akt Murine Thyoma Viral Oncogene Homolog (AKT). Thus, our data further expands the list of genes encoding components of the PI3K/AKT signalling cascade that are disrupted in human overgrowth conditions.

Mutations in chromatin remodelling and histone modification genes are increasingly recognized as a major cause of intellectual disability (ID) and other frequently overlapping neurodevelopmental disorders such as autism. BCL11A has recently been shown to be a stable subunit of the BAF SWI/SNF complex in mammals. This evolutionary conserved complex is involved in transcriptional regulation through ATP-dependent modification of chromatin structure.

The Deciphering Developmental Disorders Study (DDD) has identified de novo mutations in *BCL11A* (previously linked to autism spectrum disorder) as a cause of non-syndromic intellectual disability. We present the clinical features of these patients, as well as model organism studies that support the role of *Bcl11a* in neurodevelopmental phenotypes.

In mouse embryonic development, *Bcl11a* is expressed in the forebrain and derivatives of the first and second pharyngeal arches. It maintains high expression in the central nervous system and craniofacial mesenchyme throughout postnatal stages. The study of the haploinsufficient mouse model of *Bcl11a* shows abnormal brain development, with overall decreased brain size, particularly in regions of the limbic system. Behavioural phenotyping has identified impaired social behaviour in the haploinsufficient mice compared to littermate controls.

Previously known for its role in lymphoid malignancies, *BCL11A* now joins the increasing number of genes involved in neurodevelopment through a putative role in chromatin remodelling.

C03.5

De novo loss-of-function mutations in WAC in the 10p12p11 critical region cause intellectual disability

M. R. F. Reijnders[1], *D. Lugtenberg*[1], *M. Fenckova*[1], *E. K. Bijlsma*[2], *B. W. M. van Bon*[1], *A. T. Vulto- van Silfhout*[1], *D. G. M. Bosch*[1], *E. E. Eichler*[3,4], *H. C. [1]*Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,* [3]*Department Genome Sciences, University of Washington, Seattle, WA, United States,* [4]*Howard Hughes Medical Institute, Seattle, WA, United States,* [5]*Division of Genetic Medicine, Department of Pediatrics, University of Washington, Seattle, WA, United States.*

Background – Trio-based exome sequencing in 100 patients with intellectual disability (ID) previously identified a *de novo* mutation in *WAC*, encoding a protein regulating transcription-coupled histone H2B ubiquitination. The *WAC* gene is located on chromosome 10p11.23 and has previously been implicated in a microdeletion syndrome also containing *BAMBI*. Here, we used different strategies to identify additional patients with mutations in *WAC* to establish the role of *WAC* in ID.

Methods - We collected *de novo* mutations affecting *WAC* through routine diagnostic procedures including genomic microarray analysis and/or exome sequencing, and supplemented these with mutations reported in (inter) national databases. Moreover, we performed targeted resequencing of *WAC* in 2,326 patients with unexplained ID. For patients with mutations, we performed a detailed phenotypic comparison to the previously described phenotype for 10p12p11 microdeletion syndrome.

Results – We identified four additional *de novo* loss-of-function mutations in *WAC*, including three point mutations and one partial deletion. Clinical re-evaluation of our total cohort of five patients revealed phenotypic overlap for mild ID, hypotonia, behavioral problems and distinct overlapping facial dysmorphism, including a square shape of the face, deep set eyes, Kabuki-like long palpebral fissures, broad mouth and broad chin. Notably, these clinical features are comparable to the main features observed in 10p12p11 microdeletion syndrome.

Conclusions –We defined a clinically recognizable ID syndrome, caused by *de novo* loss-of-function mutations in *WAC*, characterized by ID, hypotonia and distinctive facial features. In addition, our data suggest that haploinsufficiency of *WAC* contributes to the phenotypic appearance of patients with the 10p12p11 microdeletion syndrome.

Studies of genetic causes of intellectual disability and identification of monogenic causes of obesity in humans have made immense contributions towards the understanding of the brain and control of body mass. Here we describe a novel disorder of global developmental delay, intellectual disability and susceptibility to obesity caused by 6q16 deletions encompassing POU3F2 (Brn2 or N-Oct3 or OCT7) in nine patients from five families. The developmental delay and intellectual disability varied from mild to severe in our cohort. The body mass index (BMI) of all, but one patient, was above the 99th centile and in the obese category. BMI of one girl in our study was on the 91st centile putting her in overweight category.

POU3F2 upregulates proneuronal genes, is required for production, migration and positioning of neocortical neurons, is an essential factor needed to generate induced neuronal cells in vitro and is required for hypothalamic development and function. Using zebrafish as model organism we show that pou3f2 lies downstream of sim1 in the leptin>melanocortin>Sim1 pathway and controls oxytocin expression in the hypothalamic neuroendocrine preoptic area. Our zebrafish work, previous work on mouse models and the human phenotypes demonstrate that the molecular pathway linking the genes in the central molecular pathway that regulates body mass is conserved across multiple species. This is further supported by our analysis of expression pattern of POU3F2 and related genes in human brain. This work helps to delineate the neuro-endocrine pathway for energy balance/food intake and its role in monogenic obesity.

Smoking is a major preventable environmental risk factor related to human health. Smoking killed about 100 million people during the 20th century and is projected to kill one billion people during this century, assuming that the current frequency of smoking is retained. Lung cancer is the prime cause of cancer-associated death in relation to smoking. However, it is less well appreciated that smoking also causes tumors outside the respiratory tract, which are predominant in men, and cumulatively roughly as common as lung cancer. Moreover, it is known that males have a higher incidence and mortality from most sex-unspecific cancers, disregarding smoking status, and this fact is largely unexplained by known risk factors. We have shown that a male specific risk factor, acquired mosaic loss of chromosome Y (LOY) in non-cancerous blood cells, is associated with an increased risk of non-hematological tumors among aging males (Forsberg et al. 2014 Nature Genetics, PMID: 24777449). We have also recently shown that smoking is associated with LOY in blood cells in three independent cohorts (TwinGene: OR=4.3, 95% CI =2.8-6.7; ULSAM: OR=2.4, 95% CI=1.6-3.6; and PIVUS: OR=3.5, 95% CI=1.4-8.4) encompassing in total 6014 men. Our data also support a transient and dose-dependent mutagenic effect from smoking on LOY-status (Dumanski et al. 2015 Science, PMID: 25477213). Thus, smoking may induce LOY, linking the most common acquired human mutation with a severe preventable risk factor. Our results could explain the observed sex differences and why smoking seems a greater risk factor for cancer in men than women.

C04.2
SNP-SNP interaction analysis of NF-kB signaling pathway on breast cancer survival

M. Jamshidi[1], *R. Fagerholm[1], S. Khan[1], K. Aittomäki[2], D. E. Easton[3,4], P. Hall[5], C. Blomqvist[6], M. K. Schmidt[7], H. Nevanlinna[1], B. C.A.C (Breast Cancer Association Consortium)[8];*

[1]Department of Obstetrics and Gynecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, [2]Department of Clinical Genetics, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, [3]Centre for Cancer Genetic Epidemiology, Department of Oncology, University of Cambridge, Cambridge, United Kingdom, [4]Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom, [5]Center for Primary Health Care Research, University of Lund, Malmö, Sweden, [6]Department of Oncology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland, [7]Netherlands Cancer Institute, Antoni van Leeuwenhoek hospital, Amsterdam, Netherlands, [8]Breast Cancer Association Consortium, BCAC, United Kingdom.

Aberrant regulation of the NF-κB pathway has been shown in breast cancer, however, the impact of the genetic variation in the pathway on patient prognosis has been little studied. Possibly, for a complex disease such as breast cancer a single SNP is not independently critical in the biological function underlying the initiation or progression of the disease but multiple loci might jointly exert a greater impact. We used an extensive data set of the Breast Cancer Association Consortium (BCAC) with 30,431 cases to investigate the NF-κB activating pathway for association between 917 germline SNPs in 75 genes and breast cancer survival. Assessing two-way SNP-SNP interaction survival analyses, we found two pairs of genetic variations with interactive effect on breast cancer survival, i.e. rs5996080 and rs7973914 (HRinteraction 6.98, 95% CI 3.3-14.4, P=1.42E-07), and rs17243893 and rs57890595 (HRinteraction 0.51, 95% CI 0.3-0.6, P=2.19E-05). Based on in-silico functional analyses, we hypothesize that the rs5996080 and rs7973914 may affect the BAFFR and TNFR1/TNFR3 receptors and breast cancer survival possibly by disturbing both the canonical and the non-canonical NF-κB pathways or their dynamics, whereas rs17243893 and rs57890595 interaction on patient survival may be mediated through TRAF2 and TRAIL-R4 interplay. These results warrant further validation and functional analyses. BCAC is funded by Cancer Research UK [C1287/A10118, C1287/A12014] and by the European Community´s Seventh Framework Programme under grant agreement number 223175 (grant number HEALTH-F2-2009-223175) (COGS).

C04.3
Towards understanding the genomic architecture of cancer genomes

E. T. Lam[1], *A. R. Hastie[1], M. B. Imielinski[2], C. Zhang[2], J. Wala[2], Z. Dzakula[1], H. Cao[1];*

[1]BioNano Genomics, San Diego, CA, United States, [2]Broad Institute of Harvard and MIT, Cambridge, MA, United States.

Understanding the genetic architecture of cancer requires genomic and integrative approaches. Cancers feature genomic alterations ranging from single-base changes to large-scale structural variation (SV) involving gains and losses, and rearrangements. Having a complete catalogue of mutations in cancer is crucial for identifying key drivers and providing accurate diagnosis, prognosis, and targeted therapy. Whole-genome sequencing has become more routine and affordable since the introduction of next-generation sequencing (NGS) technologies. However, NGS platforms have limited power to decipher large, complex structural variants frequently observed in cancer. Genome mapping represents a complementary technology that provides critical structural information. It involves high throughput analysis of single molecules spanning hundreds of kilobases in nanochannels. Long-range information is preserved and direct interrogation of complex structural variants made possible.

Here, we present our analysis of well-studied and highly rearranged cancer genomes such as the near-tetraploid HCC1143 cell line. We constructed completely de novo genome map assemblies with N50 lengths of more than 1 Mb. We derived multi-sample normalized copy number profiles of matched tumor-control pairs based on genome mapping data. We observed that tumor samples had highly variable copy number profiles, corresponding to focal and chromosome-scale changes. We also present a pipeline to integrate NGS and genome mapping data to validate and refine translocation calls. Genome mapping data helped bridge and phase neighboring translocation events. Finally, we present a computational approach to identify translocations by clustering single molecules with abnormal alignment to the reference and by performing local assemblies of these molecules. Overall, integrating NGS and genome mapping data provides a comprehensive view of a cancer genome.

Cerebral gliomas of World Health Organization (WHO) grade II and III represent a major challenge in terms of histological classification and clinical management. Here, we characterize genomic and transcriptional profiles in a prospective patient cohort of the German Glioma Network. We performed microarray-based genome- and transcriptome-wide profiling of 137 primary glioma samples, including 61 WHO grade II and 76 WHO grade III tumors. Integrative bioinformatic analyses were employed to define molecular subgroups, which were then related to histology, molecular biomarkers, including *IDH1/2* mutation, 1p/19q co-deletion, *TERT* promoter mutation, and patient outcome. Genomic profiling identified five distinct glioma groups. Expression profiling revealed evidence for eight transcriptionally different tumor groups. Correlation of molecular stratification with clinical outcome defined three major prognostic groups with characteristic genomic aberrations. The best prognosis was found in patients with *IDH1/2* mutant and 1p/19q co-deleted tumors. Patients with *IDH1/2* wild-type gliomas and glioblastoma-like genomic alterations, including gain on 7q, loss on 10q, *TERT* promoter mutation and oncogene amplification, displayed the worst outcome. Intermediate survival was seen in patients with *IDH1/2* mutant but 1p/19q intact, mostly astrocytic gliomas, and in patients with *IDH1/2* wild-type gliomas lacking the +7q/-10q genotype and TERT promoter mu-

tation. This molecular subgrouping stratified patients into prognostically distinct groups better than histological classification. Addition of gene expression data to this genomic classifier did not further improve prognostic stratification. In summary, molecular profiling of cerebral gliomas distinguishes biologically distinct tumor groups and provides prognostically relevant information beyond histological classification and *IDH1/2* mutation status.

C04.5

Vaccination with monocyte-derived dendritic cells in Lynch syndrome patients: vigorous T cell responses to neoantigen frameshift-derived peptides.

N. Hoogerbrugge, *H. Westdorp, G. Schreibelt, K. Bol, M. Welzen, J. Krieken, T. Bisseling, M. Ligtenberg, W. Gerritsen, C. Figdor, I. Vries;*
Radboud University Medical Center, Nijmegen, Netherlands.

BACKGROUND: Mismatch repair (MMR) deficiency in tumor DNA causes shifts in the translational reading frame resulting in the production of altered peptides. Frame-shift peptides (FSP), such as Caspase-5 and TGF-bRII, are considered 'foreign' by the immune system. Dendritic cells are (DC) the professional antigen-presenting cells of the immune system and decisive in inducing immunity. This is the rationale for vaccination with monocyte-derived DC (moDC) loaded with FSPs to stimulate T-cells to combat Lynch syndrome-associated tumors.
PATIENTS AND METHODS: Lynch syndrome CRC patients (n=3) and healthy mutation carriers (n=20) were vaccinated with DC loaded with CEA and FSP MHC class I binding peptides. After each vaccination round (up to 3), antigen-specific CD8+ T cells were assessed in blood and challenged skin. Injection of minute amounts of the DC vaccine resulted in infiltration of immune cells into the skin. Specificity of these lymphocytes was assessed by flow cytometry with tetrameric MHC complexes binding to T cells that recognize the indicated peptides.
RESULTS: In most patients, after moDC vaccinations, both FSP- and CEA-specific CD8+ T-cells were present. Additionally CD8+ T-cells specific for Caspase-5 and CEA were detectable. The functionality of skin infiltrating T-cells was demonstrated by their production of IFN-g upon stimulation with target cells loaded with CEA or one of the FSPs.
CONCLUSIONS: DC vaccination against CEA and FSP-antigens appears feasible and immune responses towards Lynch syndrome tumor-specific peptides are induced. Our data emphasize DC vaccination can enhance the host's antitumor immunity and underline consideration for cancer prevention in Lynch syndrome.

Reversible transitions between epithelial and mesenchymal cellular states (EMT/MET) are considered dynamic processes relevant during cancer progression and metastatic spreading. Whereas EMT facilitates the initial steps of tumour cell detachment, promoting migration and invasion, MET is thought to be required for later on colonization at distant sites. However, MET is generally perceived as a process mirroring EMT, devoided of its own signature. We hypothesize that MET entails its own set of novel and/or differentially active molecular circuitries, generating cells with features distinct from the original epithelial state.
Using an in vitro TGFβ1-induced EMT/MET model, we demonstrate that MET is able to generate a heterogeneous population of cells (Reverted-Epithelial or RE cells) with a biological signature not necessarily mirroring that of EMT. These RE-cells displayed novel functional properties, such as increased self-renewal potential and in vivo tumourigenesis ability. Moreover, whole-transcriptome analysis revealed de novo activation of several pathways, such as Toll-like receptor signalling, further confirmed in RE-cells-derived tumours. Considering the increasing evidences towards tumours as a heterogeneous entities, our model is a valuable tool for the discovery of novel pathways of relevance for tumour progression.

Thoracic aortic aneurysm and dissection (TAAD) is an autosomal-dominant disorder with major life-threatening complications. Thedisease displays great genetic heterogeneity with some forms allelic to Marfan and Loeys-Dietz syndrome, and an important numberof cases still remain unexplained at the molecular level. Through whole-exome sequencing of affected members in a large TAAD-affectedfamily, we identified the c.472C>T (p.Arg158*) nonsense mutation in MFAP5 encoding the extracellular matrix component MAGP-2.This protein interacts with elastin fibers and the microfibrillar network. Mutation screening of 403 additional probands identifiedan additional missense mutation of MFAP5 (c.62G>T [p.Trp21Leu]) segregating with the disease in a second family. Functional analysesperformed on both affected individual's cells and in vitro models showed that these two mutations caused pure or partial haploinsufficiency.Thus, alteration of MAGP-2, a component of microfibrils and elastic fibers, appears as an initiating mechanism ofinherited TAAD.

Thoracic aortic aneurysms (TAA) are a common condition associated with high mortality due to aortic dissection or rupture. Investigations of the pathogenic mechanisms involved in syndromic types of TAA such as Marfan (MFS) and Loeys-Dietz syndromes (LDS), have revealed an important contribution of disturbed TGFβ signaling. Genes with mutations leading to TAA syndromes include FBN1, TGFBR1/2, SMAD3, TGFB2 and SKI.
To discover novel genes causing syndromic aortic aneurysms, we combined genome wide linkage analysis, whole exome sequencing and candidate gene Sanger sequencing in a total of 470 index cases with thoracic aortic aneurysms. Extensive clinical, cardiologic and imaging examinations were performed.

Presently, we report on 43 patients in 11 families with syndromic presentations of aortic aneurysms caused by mutations in the TGFB3 gene. We demonstrate for the first time that TGFB3 mutations are associated with significant cardiovascular involvement, including thoracic/abdominal aortic dissection and mitral valve disease. Other systemic features overlap clinically with LDS, MFS and Shprintzen-Goldberg syndrome, including cleft palate, bifid uvula, skeletal overgrowth, cervical spine instability and club foot deformity. In line with previous observations in aortic wall tissues of patients with mutations in effectors of TGFβ signaling (TGFBR1/2, SMAD3 and TGFB2), we confirm a paradoxical upregulation of both canonical and non-canonical TGFβ signaling in association with upregulation of expression of TGFβ ligands.
Our findings emphasize the broad clinical variability associated with TGFB3 mutations and highlight the importance of early recognition of the disease due to high cardiovascular risk.

C05.3

Exome-chip meta-analysis identifies novel associations of coding variants with cardiac conduction in 62,251 adults of European descent from the Cohorts for Heart and Aging Research in Genomic Epidemiology (CHARGE) Consortium.

Y. Jamshidi[1], *B. P. Prins[1], C. Liu[2], J. van Setten[3], L. Hall[4], F. Radmanesh[5], CHARGE Consortium Exome-Chip EKG Working Group;*

Introduction: Electrocardiogram measured QRS interval reflects ventricular depolarization and conduction time. Prolonged QRS is associated with increased risk of sudden cardiac death and heart failure. In previous work, we have identified common variants in loci associated with QRS interval duration comprising non-coding regions of the genome. We hypothesized that genes influencing this trait may harbour both common and rare variants in protein-coding regions.
Methods: The Illumina HumanExome Beadchip (Ex-Chip) is an array focused on rare and low frequency putative functional coding variation. We conducted an Ex-Chip meta-analysis for QRS interval duration in 62,251 participants from 17 studies collaborating in the CHARGE Ex-Chip EKG Consortium. Ex-Chip significance threshold was set at 2.37x10-7 (α=0.05/211,270 polymorphic markers passing QC) for single variant association analysis and 3.06x10-6 (α=0.05/16,326 genes with more than 1 polymorphic marker passing QC) for gene-collapsed variant analyses (SKAT).
Results: In addition to confirming previously associated loci, we identified 10 new loci associated with QRS duration, and provide suggestive evidence for very rare coding variants in previously unknown QRS loci in ADAMTS6, ARID1B, FHOD3 and KRT15 (P<1x10-5, MAF ~0.0021-0.000016).
Using SKAT we identified four novel genes harbouring uncommon and rare variants associated with QRS duration (PSKAT<3.06x10-6).
Conclusion: This is the largest genetic association study for QRS duration performed thus far. Replication studies are ongoing to validate the novel loci. Our study provides greater understanding of the genetic contribution to cardiac conduction and may ultimately lead to new approaches to diagnose, treat, and prevent SCD in humans.

C05.4

A genome-wide association study of nonsyndromic mitral valve prolapse and functional studies of risk loci provide insight into underlying biological mechanisms

N. Bouatia-Naji[1], *C. Dina[2], N. Tucker[3], R. A. Norris[4], D. Milan[3], S. Slaugenhaupt[5], R. A. Levine[6], J. Schott[2], A. A. Hagège[7], X. Jeunemaitre[8];*

Background. Nonsyndromic mitral valve prolapse (MVP) is a common (2-4%) degenerative valvulopathy, a risk factor for cardiac failure and the most frequent indication for surgical repair of mitral regurgitation. We performed a genome-wide association study to identify risk loci, which may uncover novel pathogenic mechanisms.
Methods. We tested 4.8 million common genotyped/imputed variants in 1412 MVP cases and 2439 controls. Replication for 23 loci was performed in 4 case control studies (Ncases=1442, NControls=6779). Candidate genes were investigated for protein expression by immunohistochemistry on valves in embryonic and adult mice and morpholino knockdown (KD) assessed cardiac function in zebrafish.
Results. Six susceptibility loci were identified after replication (P<5×10-8). Association was observed in LMCD1 (OR=1.32, P =1.3×10-11), a repressor of GATA6 previously implicated in cardiac hypertrophy. KD of Lmcd1 in zebrafish induced significant atrioventricular (AV) valve defect with regurgitation. Another signal on Chr2q35 (OR=1.25, P=3.1× 10-11) mapped upstream to TNS1, which encodes a focal adhesion and actin interacting protein. We found that tensin1 is expressed during valve morphogenesis in mice and maintained in the adult valvular interstitial cells. Nine months Tns1-/- mice exhibited enlarged posterior mitral leaflets compared to wild type. In addition, zebrafish KD of Tns1 induced AV regurgitation.
Conclusions. In this multidisciplinary study we discovered 6 loci with moderate effect sizes (OR range: 1.22-1.33) and identified new actors in valve development and biology. We provide genetic and functional evidence implicating LMCD1 and TNS1 in valve development and function for the first time. This study reveals new pathways that can potentially be modified to improve the natural history of MVP.

C05.5

Recessive mutations in matrix metallopeptidase 21 (MMP21) cause heterotaxy in humans

A. Guimier[1], *G. Gabriel[2], F. Bajolle[3], M. Tsang[2], M. Schwartz[2], A. Noll[4], L. Smith[4], H. Yagi[2], C. Saunders[4], C. Baker[5], M. Oufadem[1], N. Miller[4], K. Peterson[5], I. Thiffault[4], N. Klena[2], C. Bole-Feysot[1], P. Nitschke[1], S. Lyonnet[1], L. de Pontual[1], S. Murray[5], D. Bonnet[3], S. Kingsmore[4], J. Amiel[1], P. Bouvagnet[6], C. Lo[2], C. Gordon[1];*
[1]Institut Imagine, Paris, France, [2]Department of developmental biology, University of Pittsburgh, Pittsburgh, PA, United States, [3]Unité Médico-Chirurgicale de Cardiologie Congénitale et Pédiatrique, Centre de référence Malformations Cardiaques Congénitales Complexes - M3C, Hôpital Necker Enfants Malades, APHP, Paris, France, [4]Center for paediatric genomic medicine, Children's Mercy Hospitals, Kansas City, MO, United States, [5]The Jackson Laboratory, Bar Harbor, ME, United States, [6]Laboratoire cardiogénétique - Malformations cardiaques congénitales, CHU de Lyon, Bron, France.

Human heterotaxy syndrome results from a failure to establish normal left-right asymmetry early in embryonic development and comprises visceral malformations among which congenital heart defects (CHDs) are the major cause of morbidity and mortality. Mutations in several genes controlling early left–right patterning have been implicated in heterotaxy but account for a minority of cases.
We performed whole exome or genome sequencing in 2 families with recurrence of complex CHDs associated with laterality defects of abdominal organs. We identified compound heterozygous mutations (stop and missense or frameshift and exonic deletion) in matrix metallopeptidase 21 (*MMP21*) in both families. MMP family members are involved in extra-cellular matrix turnover. Interestingly, mice homozygous for ENU-induced missense mutations in *Mmp21* exhibit CHDs and heterotaxy. Also, we performed knockdown of *mmp21* in zebrafish using an antisense morpholino, which resulted in abnormal cardiac looping, a consequence of disrupted left-right patterning. We then performed next generation sequencing of *MMP21* in a cohort of 168 index cases with CHDs and heterotaxy. From this cohort we identified 9 families with one or more affected siblings exhibiting variations in *MMP21* on both alleles, including a homozygous missense affecting the start codon in one family and a homozygous frameshift in another. The frequency of *MMP21*-associated heterotaxy in this cohort is therefore potentially as high as 6%, pending the validation of all missense mutations in functional assays in zebrafish. Our results indicate that *MMP21* is a novel gene implicated in heterotaxy and CHDs and suggest that the regulation of the extra-cellular matrix is key for the establishment of laterality.

C05.6

Somatic/mosaic mutations are an important cause of sporadic vascular anomalies.

M. Vikkula, *A. Mendola, J. Soblet, M. Schlögel, M. Amyere, P. Brouillard, N. Limaye, L. M. Boon;*
de Duve Institute, Brussels, Belgium.

Vascular anomalies are localized defects of the lymphatic or vascular system. They are most commonly cutaneous, but can affect any body part. They are divided according to vessel type into arterial, capillary, venous, lymphatic and combined malformations.

Based on familial inheritance of some malformations, we have identified underlying germline changes, including in TIE2 (mucocutaneous venous malformations; VMCM), in glomulin (glomuvenous malformations; GVM), and RASA1 (capillary malformation-arteriovenous malformation; CM-AVM). These patients are characterized by small multifocal lesions, which may increase in number with time. We explained this by Knudson's double-hit theory and demonstrated somatic second-hits (intragenic or chromosomal anomalies, including acquired uniparental isodisomy) in all three entities.
The frequency of somatic 2nd-hits made us study sporadic patients for somatic changes. We screened resected tissues from >100 venous (VM), >70 lymphatic (LM) and >30 capillary (CM) malformations for mutations in candidate genes, either by RT-PCR or Ion Torrent PGM, for high sensitivity. We frequently pinpointed somatic activating mutations: in +/-50% of VMs in TIE2, 80% of LMs in PIK3CA, 50% of CMs in GNAQ, and in some syndromic forms, like CLOVES syndrome, in PIK3CA. Interestingly, sporadic patients with multifocal VMs were mosaic in blood with a somatic second-hit in tissues, whereas in Blue Rubber Bleb Nevus syndrome, somatic cis-mutations in distant lesions were shared, without blood mosaicism.
We conclude that somatic mutations are a common pathophysiologic cause of sporadic vascular anomalies. Wider mosaicism is evident in sporadic patients with multifocal lesions. Yet, migration of mutant "progenitor cells" underlies multifocality in others. Similar scenario may hold true for various other disorders.

C06.1
Neurogenetic disease diagnostics by targeted capture and next generation sequencing

N. G. Laing[1,2], *K. Yau*[1], *R. Allcock*[1], *R. Ong*[1], *K. Mina*[1,2], *G. Ravenscroft*[1], *M. Cabrera*[1], *R. Gooding*[2], *C. Wise*[2], *P. Sivadorai*[2], *D. Trajanoski*[2], *V. Atkinson*[1], *S. Wagner*[1], *K. J. Nowak*[1], *R. M. Duff*[1], *P. J. Lamont*[1], *M. R. Davis*[2];
[1]*University of Western Australia, Nedlands, Australia,* [2]*Pathwest, QEII Medical Centre, Nedlands, Australia.*

Introduction: Two problems for molecular diagnosis of neurogenetic disorders are high levels of genetic heterogeneity and involvement of large genes, e.g. titin.
Materials and Methods: To offset these problems we developed a TargetSeq (Life Technologies) capture panel containing 277 genes in which mutations detectable by next generation sequencing (NGS) cause neurogenetic diseases. The diseases range from foetal akinesia, through muscular dystrophies and peripheral neuropathies, to motor neuron disease. The targeted genes were captured from pooled bar-coded patient DNA samples. Up to 24 patient samples were sequenced at a time using Ion Proton™ (Life Technologies) sequencing. Variant analysis was by either custom Annovar or Cartagenia (Cartagenia, Inc.) based pipelines.
Results: Testing the panel identified 88% of the known small-scale mutations in 28 positive controls. Known mutations deliberately chosen in regions not sequenced well by NGS were not detected. Using FishingCNV, we identified 90% of CNV controls, including 100% of CMT1A/HNPP duplication/deletion controls. Although one single exon CNV was detected, not all small CNVs were detected. We have screened approaching 600 molecularly undiagnosed probands, whose clinical diagnosis matched the diseases screened by the panel. We identified mutations in 68 genes, 40 of which were not previously analysed at all by the diagnostic laboratory due to Sanger sequencing costs. The overall success rate (Class 5 and 4 variants) was 34%, varying from 20% in distal arthrogryposis and SMA/MND, to 57% in channelopathies.
Conclusions: It is remarkable that analyzing only 277 genes provides the molecular diagnosis for 34% of the spectrum of neurogenetic patients.

C06.2
The SMCHD1 mutation spectrum in Facioscapulohumeral muscular dystrophy

M. L. van den Boogaard[1], *R. J. L. F. Lemmers*[1], *P. J. van der Vliet*[1], *J. Balog*[1], *B. Bakker*[1], *S. J. Tapscott*[2], *S. Sacconi*[3], *R. Tawil*[4], *S. M. van der Maarel*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Fred Hutchinson Cancer Research Center, Seattle, WA, United States,* [3]*University Hospital of Nice, Nice, France,* [4]*University of Rochester Medical Center, Rochester, NY, United States.*

Facioscapulohumeral muscular dystrophy (FSHD) predominantly affects the muscles in the face, trunk and upper extremities. FSHD is associated with partial chromatin relaxation of the D4Z4 macrosatellite repeat array localized on chromosome 4 and transcriptional derepression of the D4Z4-encoded *DUX4* gene in skeletal muscle. In the most common form, FSHD1, this D4Z4 chromatin relaxation is caused by a D4Z4 repeat array contraction to 1-10 units (normal range 10-100 units). In the rare form of FSHD, FSHD2, D4Z4 chromatin relaxation occurs without repeat contraction, and is most often caused by loss of function mutations in the structural maintenance of chromosomes hinge domain containing 1 (*SMCHD1*) gene. SMCHD1 is involved in the maintenance of D4Z4 methylation and a repressed chromatin structure.
An *SMCHD1* mutation screen in a large cohort of FSHD2 individuals revealed a mutation spectrum that ranges from large deletions causing *SMCHD1* hemizygosity, to missense, nonsense and splice site mutations. In addition to the autosomal dominant inheritance seen in most FSHD2 families, we also identified a family with semidominant inheritance. Furthermore, *SMCHD1* mutations can also modify disease severity in FSHD1.
This mutation spectrum shows that epigenetic sensitivity to disease presentation depends on the nature of *SMCHD1* mutation in combination with *D4Z4* array size with *SMCHD1* open reading frame preserving mutations being more deleterious for the maintenance of repressive D4Z4 chromatin state, than open reading frame disrupting mutations. Collectively, our study positions SMCHD1 central in the FSHD2 and FSHD1 disease mechanisms and warrants further studies into SMCHD1 as therapeutic target.

C06.3
Plastin 3, a human protective modifier is highly upregulated in iPSC-derived motoneurons in asymptomatic individuals and rescues spinal muscular atrophy in mice

M. Peters[1], *L. Heesen*[1,2], *S. Hosseini Barkooie*[1], *M. Peitz*[2,3], *A. Kaczmarek*[1], *E. Janzen*[1], *O. Brüstle*[2,3], **B. Wirth**[1];
[1]*Institute of Human Genetics, Institute of Genetics and Center for Molecular Medicine Cologne, Cologne, Germany,* [2]*Institute of Reconstructive Neurobiology, LIFE & BRAIN Center, University of Bonn and Hertie Foundation, Bonn, Germany,* [3]*DZNE, German Center for Neurodegenerative Diseases, Bonn, Germany.*

Spinal muscular atrophy (SMA) is a devastating motoneuron disorder caused by functional loss of SMN1. Previously, we identified Plastin 3 (PLS3) as a strong candidate protective modifier using transcriptome differential expression analysis in SMA discordant families.
PLS3 was highly upregulated in lymphoblastoid cell lines of asymptomatic but not SMA siblings at both, RNA and protein level. Instead fibroblast cell lines from both SMA and asymptomatic siblings showed similar PLS3 expression, suggesting a tissue-specific regulation. To investigate whether PLS3 is upregulated in motorneurons, the primary affected cells in SMA, we generated induced pluripotent stem cells (iPSCs) from fibroblasts of three asymptomatic and three SMA III-affected siblings. After full characterization of pluripotency, small molecule neural precursor cells (smNPCs) were generated from iPSCs. Next, motoneurons were differentiated from smNPCs and characterized for any possible changes including survival, gem counts, protein and RNA expression of SMN and PLS3. Most strikingly, PLS3 was highly upregulated only in motoneurons from asymptomatic siblings pinpointing a tissue-specific regulation.
To finally address the PLS3 rescuing effect in SMA disorder, we generated PLS3 overexpressing mice, which were crossed into a severe SMA mouse model. By applying low amounts of exon 7 inclusion SMN antisense oligonucleotides (ASOs), we improved the multi-organ dysfunction in these severe SMA mice and increased their survival from 14 to 28 days. Most importantly, crossing the PLS3 transgene homozygously into these mice led to a robust increase of survival (>60% survived >180 days). These combined data provide strong evidence for PLS3 as protecting modifier in humans and SMA mouse model.

C06.4
Analysis of the Gdap1 knockout mice reveals calcium homeostasis and mitochondrial dynamics defects in the Charcot-Marie-Tooth disease pathogenesis

A. Civera-Tregón[1,2], *P. Juárez*[1,2], *M. Barneo-Muñoz*[1], *S. Fernández-Lizarbe*[1,2], *D. Pla-Martin*[2], *J. Zenker*[3], *C. Cuevas-Martín*[4,5,6], *M. Sánchez-Aragó*[4,5,6], *J. Forteza-Vila*[1,7], *J. M. Cuezva*[4,5,6], *R. Chrast*[3], *F. Palau*[1,2];

Definition of pathogenic mechanisms and druggable molecular targets in Mendelian diseases requires investigating the pathophysiological consequences of gene mutations in both cellular and animal disease models.
Mutations in *GDAP1*, which encodes a protein located in the mitochondrial outer membrane, cause axonal recessive (AR-CMT2), axonal dominant

(CMT2K) and demyelinating recessive (CMT4A) forms of Charcot-Marie-Tooth (CMT) neuropathy. Loss of function recessive mutations in *GDAP1* are associated with decreased mitochondrial fission activity, while dominant mutations result in impairment of mitochondrial fusion with increased production of reactive oxygen species and susceptibility to apoptotic stimuli.
Knockout *Gdap1* mice show abnormal motor behaviour at early stage. Electrophysiological and biochemical studies confirmed the axonal nature of the neuropathy whereas histopathological studies showed progressive loss of motor neurons (MNs) in the anterior horn of the spinal cord and defects in neuromuscular junctions. Cultured embryonic MNs neurons showed large and defective mitochondria, changes in the endoplasmic reticulum (ER) cisternae and increased autophagy vesicles. We observed defects in cytoskeletal α-tubulin acetylation and in the axonal mitochondria transport. MNs showed reduced Ca^{2+} inflow through store-operated Ca^{2+} entry (SOCE) upon mobilization of ER-Ca^{2+}, in association with an abnormal distribution of the mitochondrial network when treated with the ER stress inducer thapsigargin.
The phenotypic and functional study of the *Gdap1* KO mice revealed the presence of an axonal neuropathy. We propose that lack of GDAP1 induces changes in the mitochondrial network biology and mitochondria-endoplasmic reticulum interaction leading to abnormalities in calcium homeostasis, which may represent part of the *GDAP1*-related CMT pathophysiology.

C06.5
Junctophilin-1 expression levels could modify the effects of GDAP1 mutations in Charcot-Marie-Tooth disease

E. Calpena[1,2], *V. Lopez*[1,2], *V. Lupo*[1,2], *T. Sevilla*[3,2], *F. Palau*[1,2], *I. Galindo*[1,2], *C. Espinós*[1,2];
[1]*Centro de Investigación Príncipe Felipe (CIPF), Valencia, Spain,* [2]*CIBER de Enfermedades Raras (CIBERER), Valencia, Spain,* [3]*Hospital U. i P. La Fe, Valencia, Spain.*

Charcot-Marie-Tooth (CMT) disease is a hereditary sensory and motor neuropathy with more than 60 genes associated. CMT type 2K (CMT2K) is caused by mutations in the GDAP1 gene and is characterized by incomplete penetrance and intrafamilial clinical variability. We have recently described the junctophilin1 (JPH1) as a genetic modifier of GDAP1. We characterized the combination of the JPH1 p.R213P and the GDAP1 p.R120W mutation in one patient with a more severe clinical picture. Through cellular studies we established that the combination of these two mutations significant increases the basal cytosolic Ca2+ and reduces SOCE activity, and therefore, JPH1 contribute to the phenotypical consequences of GDAP1 mutations.
Junctophilin genes are characterized by having a long 3'UTR (from 1861 nt of JP in Drosophila melanogaster to 2347 nt of JPH1 in humans) and that is conserved in the case of JPH1. We searched for variants in the 3'UTR of JPH1 in CMT2K families with the GDAP1 p.R120W mutation. We have identified the ENST00000342232.4:c.*1962G>A (rs57375187) variant in two brothers with an unusual early onset and severe clinical picture. We have demonstrated that the c.*1962G>A increase the transcript levels by a luciferase assay. Moreover, with the aim to gain insight into the disease mechanisms, we have used a Drosophila models in order to investigate how altered junctophilin expression levels could modify the effects of the Gdap1 related neural degeneration. Moreover, the Drosophila model has allowed us to discover new pathways related to junctophilin.

Two siblings of non-consanguineous Ethiopian Jewish ancestry presented with congenital axial hypotonia, weakness of the abducens nerve, psychomotor developmental delay with brain ventriculomegaly and variable thinning of corpus callosum, cardiac septal defects and undescended testes. Homozygosity mapping identified a single disease-associated locus of 3.5Mb on chromosome 3. Studies of a Bedouin consanguineous kindred with 4 individuals affected with a similar recessive phenotype identified a single disease-associated 18Mb homozygosity locus containing the entire 3.5Mb locus of the Ethiopian family. Whole exome sequencing demonstrated one homozygous mutation in CCDC174 (c.1404A>G, p.[*468Trpext*6]) within a shared identical haplotype of 0.6Mb, common to both Bedouin and Ethiopian affected individuals, suggesting an ancient common founder effect. The mutation segregated as expected in both kindreds and was not found in 400 Bedouin and 100 Jewish Ethiopian controls. Knockdown of the CCDC174 ortholog in Xenopus laevis embryos resulted in poor neural fold closure at the neurula stage with later embryonic lethality. Knockdown embryos exhibited a sharp reduction in expression of n-tubulin, a marker for differentiating primary neurons, and of hindbrain markers krox20 and hoxb. The Xenopus phenotype could be rescued by the human normal, yet not the mutant CCDC174 transcripts. CCDC174 is ubiquitously expressed and was previously shown to interact with EIF4a3 which is crucial for RYR1 formation in frogs. In accordance, while maintaining normal mRNA level, RYR1 proteins in skeletal muscle of our patients were not detectable by immunohistochemistry. Also, in-vitro model showed co-localization of CCDC174 and EIF4a3 in the nucleus while overexpression of mutant but not wild-type CCDC174 caused rapid cell death.

C07.1
Does paternal imprinting of FOXF1 on 16q24.1 explain maternal UPD(16) phenotype?

A. V. Dharmadhikari[1,2], *B. Carofino*[1], *J. J. Sun*[3], *P. Szafranski*[1], *R. Ray*[3], *M. J. Justice*[4], *M. E. Dickinson*[5], *P. Stankiewicz*[1];
[1]*Dept of Molecular & Human Genetics, Baylor College of Medicine, Houston, TX, United States,* [2]*Program in Translational Biology & Molecular Medicine, Baylor College of Medicine, Houston, TX, United States,* [3]*Department of Neuroscience, Baylor College of Medicine, Houston, TX, United States,* [4]*The Hospital for Sick Children, Toronto, ON, Canada,* [5]*Department of Molecular Physiology & Biophysics, Baylor College of Medicine, Houston, TX, United States.*

Trisomy 16 in humans, typically resulting from maternal meiosis I nondisjunction, is the most common prenatal trisomy and lethal unless rescued early embryonically. In one-third of such cases, children with maternal UPD(16) manifest IUGR (attributed to trisomic placenta) and multiple congenital malformations, including heart defects, pulmonary hypoplasia, tracheosophageal fistula, gut malrotation, absent gall bladder, renal agenesis, hydronephrosis, imperforate anus, and single umbilical artery. In contrast, relatively normal phenotype was reported in few patients with paternal UPD(16), and imprinted gene(s) on chromosome 16 were suggested as causative for maternal UPD(16) phenotype. All the above clinical features, except IUGR, are observed in the vast majority of children with a neonatally lethal lung developmental disorder Alveolar Capillary Dysplasia with Misalignment of Pulmonary Veins (ACDMPV). ACDMPV is caused by heterozygous point mutations or genomic deletions involving *FOXF1* on 16q24.1, previously shown to be paternally imprinted, incompletely and in a tissue-specific manner. Most recently, genomic duplications involving *FOXF1* were associated with pyloric stenosis, mesenterium commune, and aplasia of the appendix [PMID: 25472632]. We knocked-in a Cre-inducible *Foxf1* allele at the *ROSA26* locus and activated it with *Tie2-cre* to specifically overexpress *Foxf1* in endothelial and hematopoietic cells. Using timed-matings, microCT, and plethysmography analyses, we found that these mice exhibit hypoplastic lungs, abnormal breathing, gastrointestinal abnormalities, edema, skin hemorrhages, and die perinatally. We propose that *Foxf1* overexpression in mice corroborates the clinical observations seen in patients with maternal UPD(16) and conclude that paternal imprinting of *FOXF1* may be responsible for the key phenotypic features of maternal UPD(16).

C07.2
Next-gen cytogenetics in prenatal diagnosis: lessons learned with balanced de novo rearrangements

C. C. Morton[1], *Z. Ordulu*[1], *T. Kammin*[1], *C. Hanscom*[2], *V. Pillalamarri*[2], *J. L. Andujar*[1], *B. B. Currall*[1], *J. F. Gusella*[2], *M. E. Talkowski*[2];
[1]*Brigham and Women's Hospital, Boston, MA, United States,* [2]*Massachusetts General Hospital, Boston, MA, United States.*

Specific identification of disrupted and dysregulated genomic regions is critical in precision diagnosis and in management of some individuals with constitutional and acquired rearrangements, especially considering the accelerated increase in annotation of the human genome. Rapidly defining structural chromosome abnormalities that underlie these genomic regions at the nucleotide level in a genome-wide fashion has become feasible

in recent years with ongoing improvements in sequencing technologies, and is revolutionizing the discipline of cytogenetics. The capability of mapping breakpoints precisely is the foundation of the Developmental Genome Anatomy Project (DGAP, www.dgap.harvard.edu), in which more than 150 subjects with apparently balanced chromosome rearrangements have been sequenced revealing a wide variety of genes in human development. In this exciting era of "Next-Gen Cytogenetics," in which traditional cytogenetic techniques and next-gen sequencing are used synergistically, integration of genomic sequencing into the prenatal diagnostic setting is possible within an actionable time frame. To date, we have participated in the evaluation of 10 prenatal cases of *de novo* balanced translocations and inversions for next-gen cytogenetic analysis, and nine cases are completed. With the exception of a complex case involving multiple chromosome rearrangements, all were interpreted by aCGH analyses to be without clinically significant gains or losses of DNA. Use of convergent genomic evidence and quantitative assessment of transcripts in the breakpoint regions are employed in interpretation of potential pathogenicity. In overview, each case has contributed uniquely to our experience in the evolution of this approach to a new standard of care in prenatal diagnosis.

Targeted prenatal screening as a successful and fast approach in cases with increased nuchal translucency and/or abnormal ultrasound

P. Joset[1], *A. Baumer*[1], *M. Papic*[1], *S. Papuc*[2], *M. Zweier*[1], *S. Azzarello-Burri*[1], *D. Niedrist*[1], *L. Gogoll*[1], *B. Oneda*[1], *K. Steindl*[1], *A. Rauch*[1];

[1]*Institute of Medical Genetics, University of Zurich, Schlieren-Zurich, Switzerland,* [2]*Institute of Medical Genetics, University of Zurich, Schwerzenbach-Zurich, Switzerland.*

Since we have successfully established Next Generation Panel Sequencing of more than 4800 known Mendelian disease genes in postnatal cases resulting in an overall diagnostic yield of more than 45% we investigated the diagnostic yield of targeted Next Generation Sequencing on prenatal cases. Routine PTPN11 sequencing on 53 cases with increased nuchal translucency revealed in 4 (7.5%) pathogenic mutations. Sequencing of the "Mendeliome" in so far 17 cases negative for PTPN11 and setting of specific in silico filters for Noonan genes revealed one novel pathogenic mutation in KRAS (c.149C>T/= (p.Thr50Ile/=) in a case with increased nuchal translucency and multiple heart anomalies, giving a diagnostic yield of about 6% in PTPN11-negative cases. Moreover, an average yield of less than one rare (MAF < 2%) non-synonymous call per case allows a fast and straightforward analysis. An average coverage of 200x and a 20x coverage in almost 96% of the targeted region assures also high sensitivity.

Additional analysis on further prenatal cases with intrauterine growth retardation (2), hydrops fetalis (1), brain malformations (1), fetal bronchial aplasia (1), or uniparental disomy 13 (1) unraveled one new possible disease causing candidate gene in a case with complex brain malformations. Furthermore, screening on 12 aborted samples achieved a diagnosis in 3 (25%) cases, i. e. autosomal recessive pathogenic mutations in the genes FRAS1, MKS1 and CC2D2A.

We conclude that the fast workflow and the high sensitivity makes the approach ideal for targeted screening on prenatal and aborted cases.

Introduction: Next-generation sequencing (NGS) enables screening for a wide range of conditions that a family history will never pick up. Here, we report the clinical results of a NGS-based preconception carrier genetic test (CGT) for mendelian conditions.

Materials and Methods: Massive sequencing of 548 autosomal recessive (AR) and X-linked genes involved in severe childhood phenotypes reinforced with 5 non-NGS complementary tests, performed in ART patients. In case of gamete donation, paired results (donor/patient) were blindly matched using a proprietary software.

Results: We performed a total of 2,559 CGT analysis: 1,158 tests for gamete donors; 1,127 tests for patients using donation, and 274 CGT for 137 couples undergoing ART with their own gametes. Positive results for at least one pathogenic or likely pathogenic variants were present in 92.5% samples (2,368). The average carrier burden per sample was 2.94 mutations and 14.39 variants of unknown significance. Female donors were discarded in case of pathogenic variant was found in an X-linked gene. In our series 1.5% resulted positive (8 premutated in FMR1 gene and 5 for other X-linked conditions). Twelve couples using their own gametes (8.7%) were positive for pathogenic mutations, 8 for AR genes and 4 X-linked genes. These couples received genetic counseling and PGD or gamete change was recommended.

Conclusions: We have developed a carrier genetic test that constitutes a powerful clinical tool to avoid more than 600 diseases in the offspring in infertile couples undergoing ART.

C07.5

Non-manifesting AHI1 truncations indicate localized loss-of-function tolerance in a severe Mendelian disease gene

Determination of variant pathogenicity represents a major challenge in the era of high-throughput sequencing. Erroneous categorization may result if variants affect genes which are in fact dispensable. We demonstrate that this also applies to rare, apparently unambiguous truncating mutations of an established disease gene. By whole-exome-sequencing (WES) in a consanguineous family with congenital non-syndromic deafness, we unexpectedly identified a homozygous nonsense variant, p.Arg1066*, in *AHI1*, a gene associated with Joubert syndrome (JBTS), a severe recessive ciliopathy. None of four homozygotes expressed any signs of JBTS, and one of them had normal hearing, which also ruled out p.Arg1066* as the cause of deafness. Homozygosity mapping and WES in the only other reported JBTS family with a homozygous C-terminal truncation (p.Trp1088Leufs*16) confirmed *AHI1* as disease gene, but based on a more N-terminal missense mutation impairing WD40-repeat formation. Morpholinos against N-terminal zebrafish *Ahi1*, orthologous to where human mutations cluster, produced a ciliopathy, but targeting near human p.Arg1066 and p.Trp1088 did not. Most *AHI1* mutations in JBTS patients result in truncated protein lacking WD40-repeats and the SH3 domain; disease was hitherto attributed to loss of these protein-interaction modules. Our findings indicate that normal development does not require the C-terminal SH3 domain. This has far-reaching implications, considering that variants like p.Glu984* identified by preconception screening ("Kingsmore panel") do not necessarily indicate JBTS carriership. Genomes of individuals with consanguineous background are enriched for homozygous variants that may unmask dispensable regions of disease genes, and unrecognized false positives in diagnostic large-scale sequencing and preconception carrier screening.

How to design expanded carrier screening panels? Results of an interview study with European geneticists

D. Chokoshvili[1,2], *S. Janssens*[2], *D. Vears*[3], *A. De Paepe*[2], *P. Borry*[1];

[1]*University of Leuven, Leuven, Belgium,* [2]*University of Ghent, Ghent, Belgium,* [3]*University of Melbourne, Melbourne, Australia.*

Preconception carrier screening for recessive disorders makes it possible to identify couples who, although unaffected by the disorder themselves, are at risk of having an affected child. Historically, carrier screening has been performed for a set of common pathogenic mutations associated with a limited number of disorders. However, recent advances in genetic technology have enabled a more comprehensive coverage of both disorders and pathogenic variants at little additional cost. With the development of expanded carrier screening (ECS) panels that screen for variants associated with hundreds of recessive disorders, it has become increasingly important to devise suitable criteria for the inclusion of disorders and specific pathogenic mutations on

screening panels.
We conducted in-depth interviews with 16 geneticists from 8 EEA countries to investigate their views on the composition of ECS panels. Most participants favored limiting carrier screening to disorders that, due to their severe nature, would clearly justify altering reproductive plans by at-risk couples. Notably, when discussing severity of the disease, some geneticists considered the impact of the disease on the family as a whole, suggesting screening should also be performed for severe conditions with effective yet burdensome therapeutic interventions. There was disagreement on the inclusion of adult-onset and X-linked disorders, with some geneticists favoring screening under certain conditions, while others supported active exclusion of such disorders. Regarding the selection of specific pathogenic mutations, all 16 participants were strongly in favor of limiting screening to the best-studied variants with clearly established genotype-phenotype associations.

Introduction: Obesity is a serious risk factor for cardiovascular and metabolic disease. Considering the steady increase in obesity prevalence and that GWAS variants explain <5% of body mass index variance, gene-environment interactions may contribute to obesity. We hypothesized that expression profiles in adipose tissue may reflect the molecular consequences of environmental changes underlying obesity. Accordingly, in an obese cellular environment, context-specific expression quantitative trait loci (cseQTL) variants might regulate gene expression distinctly from non-obese conditions.
Materials and Methods: We performed eQTL mapping (FDR<1%) using 7,932,277 SNPs with adipose RNA-sequence data on 17,210 expressed genes in 582 men from the Finnish METSIM cohort. We considered the eQTLs only observed in the obese group, but not in the non-obese or overall groups as obese eQTLs (OB), and vice versa for non-obese (NOB). We tested the OB and NOB eQTL genes for replication in an independent METSIM cohort (n=771) using microarray data (FDR<5%).
Results: We discovered 2,450 OB eQTL genes regulated by 28,267 cis (+/-1Mb) variants; and 1,455 NOB eQTL genes regulated by 10,814 variants, respectively. Of these 55% of the OB and 41% of the NOB genes were consistent across RNA-seq and microarrays in independent cohorts. When searching for potential drivers of context-specificity, we observed that estrogen signaling genes were enriched among OB versus NOB eQTL genes (P=0.001), including HSD17B12, which converts estrone into the most active estrogen, estradiol.
Conclusion: OB eQTL genes exhibit genetic-dependent transcriptional regulation mediated by obesity and involve genes in the estrogen pathway as regulators of male obesity.

C08.2
Genetic variants affect expression of nearly all genes, but only in a specific context

D. V. Zhernakova, *The BIOS consortium;*
Department of Genetics, University of Groningen, University Medical Centre Groningen, Groningen, Netherlands.

The expression of nearly all genes is subject to genetic regulation. This is a first conclusion from the largest population-based RNA-sequencing project executed so far, including 4,000 total blood mRNA samples from five Dutch biobanks. The large sample size, unprecedented resolution of this study and the comparison with other large population-based studies revealed that SNPs affecting expression (eQTLs) act in a context-dependent manner. Whereas microarray-identified blood eQTLs (Westra et al., Nature Genetics, 2013) replicated well in our study (87%, including 6.8% with opposite allelic direction), eQTLs identified by RNA-seq in lymphocyte cell lines (LCL) (Lappalainen et al., Nature, 2013) replicated less well (78%, including 12% with opposite allelic direction). This wasn't due to differences in data processing as we analyzed all RNA-sequencing data with a common pipeline, but was partly due to differences in cell types. We inferred cell-type-specific eQTLs, and observed that lymphocyte-specific eQTLs replicated well in LCL, but neutrophil-specific eQTLs didn't. We also observed that higher order effects (e.g. differences in proliferation, differentiation or metabolism) can induce, abrogate or inverse eQTLs. We observed several examples where genetic risk factors affect gene expression only in a specific context. We conclude that the effect of SNPs on gene expression depends on the cell and the cellular state. Since eQTL data is not available for every tissue, cell or cellular state (and their specific combinations), predictions of the effect of genetic variation on gene expression should be carefully interpreted.
The BIOS project is funded by the BBMRI-NL, a research infrastructure financed by the Netherlands Organization for Scientific Research (NWO project 184.021.007).

C08.3
Pedigree-Associated Genetics and Recent Environment Make Important Contributions to Metabolic Syndrome Traits.

C. Xia[1], *C. Amador[1], J. Huffman[1], H. Trochet[1], A. Campbell[1], G. Scotland[2], D. Porteous[1], N. Hastie[1], C. Hayward[1], V. Vitart[1], P. Navarro[1], C. S. Haley[1,3];*
[1]MRC IGMM, Edinburgh, United Kingdom, [2]A collaboration between the University Medical School and NHS in Aberdeen, Dundee, Edinburgh and Glasgow, Edinburgh, United Kingdom, [3]The Roslin Institute and R(D)SVS, Edinburgh, United Kingdom.

Genome-wide association studies (GWAS) have successfully identified thousands of loci for a range of human complex traits and diseases but explain only a limited proportion of trait variation. Mixed linear model analyses capture a greater proportion of phenotypic variance than GWAS single-SNP analyses and provide insight into the genetic and environmental architecture of traits. Using this approach we analysed 18 traits related to metabolic syndrome in a Scottish cohort of ~14,000 individuals genotyped for ~550,000 common autosomal SNPs. Trait variation was partitioned into genetic effects associated with SNPs, genetic effects associated with pedigree, shared family environment, shared couple environment and shared full-sibling environment. On average across traits SNP-associated and pedigree-associated genetic effects each explained around half the genetic variance with recently-shared environment of couples accounting for ~10% of the phenotypic variance on average, all of the three being important sources of variation in metabolic syndrome traits. On the other hand, the environment shared largely in the past by members of a nuclear family or by full-siblings, had a limited impact on trait variation. Our findings point to appropriate models to use in future studies as pedigree-associated genetic effects and couple environmental effects have seldom been taken into account in genotype-based analyses. In samples of unrelated individuals pedigree-associated effects cannot be captured, explaining at least part of the missing heritability, but even in such studies it may be necessary to account for unrelated couples included in the sample to appropriately model the variation and hence make accurate predictions and inferences.

C08.4
Genome-wide study for metabolic phenotypes identifies 62 loci and elucidates the metabolic context of LPA in coronary heart disease

Metabolic phenotypes are highly heritable and have great potential in providing insight into genetic variation influencing both metabolism and complex diseases. We present the largest evaluation of genetic variance in human

metabolism so far. We combined 123 metabolic phenotypes from blood samples of 24,925 individuals from fourteen European cohorts and associated 62 loci with blood metabolite concentrations. 8 of the loci were new. For 15 loci the lead SNP was low frequency, for 8 a coding variant and 22 involved transcription factor binding sites. We showed that two loci, known for Mendelian amino acid metabolism disease with severe neurological manifestations, also harbor low-frequency variants affecting the same circulating amino acid in healthy population samples. Moreover, we show new evidence that the biosynthesis of lipoprotein(a) (Lp(a)), a known coronary heart disease (CHD) biomarker, is associated with very-low-density lipoprotein metabolism and other lipoprotein particles. Causality of metabolite associations was shown with a genetic risk score ($GRS_{Lp(a)}$) for Lp(a), which composed of 18 SNPs independently associated with circulating Lp(a) levels at genome-wide significance in a discovery cohort. $GRS_{Lp(a)}$ SNPs were confirmed in a replication cohort, where $GRS_{Lp(a)}$ explained 45% of Lp(a) variance. Linking $GRS_{Lp(a)}$ to electronic health records of over 17 000 population-based persons showed that the risk score was associated with CHD outcomes but not with any other disease-category. (ICD10:I20-I25 category, P=6.4×10^{-10}, N_{events}=1251, OR=1.28 per one unit increment in $GRS_{Lp(a)}$)). We present a new hypothesis for the biosynthesis of Lp(a) and our results together with previous findings reinforce the observation that *LPA*-targeting treatment has great potential for CHD risk reduction in humans.

C08.5

Systematic identification of downstream trans-effects for 1,300 known disease associated SNPs

M. Bonder[1], *R. Luijk*[2], *BBMRI-NL BIOS Consortium;*
[1]*University Medical Center Groningen, Groningen, Netherlands,* [2]*Leiden University Medical Center, Leiden, Netherlands.*

Genetic risk factors identified in genome-wide association studies are mostly non-coding, making it difficult to understand their functional consequences. So far, large-scale trans-eQTL analyses have identified such downstream functional consequences for only 233 SNPs (Westra et al, NG 2013). To increase this, we used methylation-QTL mapping in peripheral blood of 4,000 population based samples from the Dutch BBMRI-NL BIOS consortium. We observed that 1,300 different GWAS SNPs affect methylation of over 10.000 unique CpGs sites in trans (FDR <0.05), representing a six-fold increase in the number of disease-associated SNPs for which downstream functional effects can be detected.

To address the question in what particular biological processes these specific CpGs are involved, we also generated RNA sequencing data for 2,000 of the samples, permitting us to empirically relate CpG methylation to gene expression effects (eQTMs) for over 18,500 CpG sites (FDR <0.05). By using different genomic annotations we could accurately predict (AUC = 0.8) whether these methylation-gene expression relationships were positive (35%) or negative (65%).

By finally integrating the trans-meQTLs and eQTMs and adapting pathway enrichment method DEPICT, we obtained insights in the downstream functional effects of many genetic risk factors: rs3774959 (mapping close to NFKB1 and associated with ulcerative colitis) significantly affects methylation levels of 355 different CpG sites, of which many map within genes of the NF-kappaB cascade.

These results indicate that large-scale meQTL mapping permits discovery of previously unknown downstream molecular effects for many genetic risk factors, and these effects on trans-methylation levels have a clear biological basis.

BIOS (Biobank-based Integrative Omics Study) is a BBMRI-NL Rainbow project.

C08.6

Integrated analysis of human and bacterial genomes in relation to BMI and blood lipid metabolites.

A. Zhernakova[1,2], *M. Bonder*[1], *M. Cenit*[1], *E. Tigchelaar*[1,2], *J. Dekens*[1,2], *J. Marczynska*[1,3], *F. Imhann*[1], *R. Weersma*[1], *T. Poon*[4], *R. Xavier*[4,5], *D. Gevers*[4], *L. Franke*[1], *M. Hofker*[1], *C. Wijmenga*[1], *J. Fu*[1];
[1]*University medical centre Groningen, Groningen, Netherlands,* [2]*Top Institute Food and Nutrition, Wageningen, Netherlands,* [3]*Jagiellonian University, Krakow, Poland,* [4]*Broad Institute of MIT and Harvard, Cambridge, MA, United States,* [5]*Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States.*

Increased body mass index (BMI) and blood lipid levels are risk factors for many metabolic diseases. We aimed to investigate the combined effect of gut microbiome and host genetics on human lipid metabolites. We measured LDL, HDL, triglycerides (TG) and total cholesterol (TC) in 893 individuals from a Dutch population cohort LifeLines-DEEP. The microbiome composition was accessed by 16S rRNA gene sequencing. The genotypes of 157 SNPs previously associated to lipid levels were available for all subjects. We developed the 2-part analysis model to account for both binary and qualitative features of microbiome. The variation of lipids explained by host genetics risk and microbiome were estimated using 80% random samples as discovery and 20% as validation set.

After adjusting for age and gender we identified 66 bacterial operational taxonomic units (OTUs) to be associated with BMI, 114 with TG, and 34 with HDL at false discovery rate (FDR)<0.05. No significant associations were detected for LDL or TC at FDR<0.05. Microbiome composition could explain up to 6.0% of the variation in TG level, 4.0% in HDL and 4.5% in BMI, but only 1.5% in LDL level and 0.7% in TC level. We did not observe strong interaction between genetics and microbiome in the respect to human lipid levels. Mendelian randomization analysis suggested that the microbiome is an independent, causal determinant of BMI and lipid levels. Overall, age, gender, genetics and gut microbiome could collectively explain 9.6% variation in BMI, 17.1% variation in TG and 25.9% variation in HDL cholesterol. These results provide rational for developing microbiome-targeting therapy.

C09.1

High yield of causative mutations by whole exome sequencing in selected individuals with childhood cancer

M. Jongmans[1], *E. Waanders*[1], *M. Ligtenberg*[1], *E. Kamping*[1], *P. Hoogerbrugge*[2], *M. Oldenrode-Berends*[3], *D. Koolen*[1], *G. van Santen*[4], *M. van Belzen*[4], *D. Mordaunt*[5], *A. Kattamis*[6], *E. de Bont*[3], *R. Kuiper*[1], *N. Hoogerbrugge*[1];

Childhood cancer predisposition shows extensive genetic heterogeneity with currently over 100 conditions described, and likely many to be identified. Recognition of genetic predisposition in a child with cancer may lead to better treatment choices and surveillance options. We applied whole exome sequencing on germline DNA of children, and their parents, with cancer and at least one of these features: intellectual disability, congenital anomalies, adult type of cancer, a family history for childhood cancer or multiple primary malignancies. All cases remained undiagnosed after consultation by a clinical geneticist and often multiple genetic tests. Analysis of the first 15 patients resulted in a high yield of causative mutations. Three patients carried mutations in the well-known cancer genes *TP53* and *DICER1* (n=2). In three children, exome sequencing revealed syndromes that possibly contributed to their malignancy (*EP300* based Rubinstein Taybi syndrome in a girl with acute myeloid leukemia; *ARID1A* based Coffin Siris syndrome and *ACTB* based Baraitser Winter syndrome in boys with acute lymphatic leukemia (ALL)). In addition, we identified novel candidate genes like a NOTCH1 pathway activating mutation in *MAML2* (p.P319T) and a mutation in *TYK2* (p.P760L) , both in children with two primary ALL occurrences. The latter finding is particularly interesting since we previously found p.G761V in *TYK2* in a patient with recurrent T-ALL. Both mutations were shown to activate STAT signaling, an important pathway in ALL. Our study shows the value of exome sequencing in childhood cancer predisposition, both to facilitate the diagnosis of known syndromes as well as to trace novel cancer susceptibility genes.

C09.2

Integration of somatic and germline exome data to evaluate pathogenicity of rare variants in cancer predisposition genes

S. Yost[1], *M. Clarke*[1], *E. Ruark*[1], *N. Rahman*[1,2];
[1]*Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom,* [2]*Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom.*

Genes in which germline mutations confer substantial increased risks of cancer are called cancer predisposition genes (CPG). To date characterisation of cancers arising in CPG mutation carriers has been limited as has utilisation of tumor data from CPG mutations carriers to facilitate clinical interpretation of their germline data. To explore this we have downloaded and reanalysed data from 7,632 germline exomes from the 28 cancer types in The Cancer Genome Atlas (TCGA) using the OpEx exome analytical pipeline which has high sensitivity and specificity for indel detection. In the first instance we have focussed on the BRCA1 and BRCA2 germline data. We identified 155 pathogenic BRCA mutations (PMs) in 7,632 samples and 856 rare nonsynonymous (missense) variants (RNVs), which would typically be reported as variants of uncertain significance (VUS). Tumor data of multiple types strongly suggest that the great majority of the RNVs are not pathogenic. For example, the PMs are highly clustered in patients with breast or ovarian cancer whereas the RNVs are equally distributed amongst 28 cancer types. Also the alternate allele frequency of the 155 PMs was significantly

higher in their matched tumor samples, but a similar pattern does not appear to be present for the RNVs (analyses still in process - data will be presented). These data indicate that integration of tumor and germline genetic information may have considerable utility in the interpretation of variants of uncertain significance. This work was funded by the RM/ICR NIHR BRC.

C09.3

Expanding the mutation spectrum and phenotype of Polymerase Proofreading-Associated Polyposis (PPAP): novel and previously reported POLE variants

M. Genuardi[1], *M. Calicchia[1], M. Ciavarella[1], B. Riboli[2], P. Cavalli[2], M. Castori[3], P. Grammatico[3], E. Lucci-Cordisco[1];*
[1]Institute of Medical Genetics, Catholic University, Rome, Italy, [2]Medical Genetics Unit, Azienda Istituti Ospitalieri, Cremona, Italy, [3]Medical Genetics Unit, San Camillo-Forlanini Hospital, Rome, Italy.

Constitutional mutations of the POLE and POLD1 genes, coding for DNA polymerase ε e δ subunits, respectively, have been recently identified in patients with multiple colonic adenomas (MCA) and colorectal cancer (CRC). So far, only few families with this autosomal dominant inherited cancer predisposition, named PPAP, have been reported and the phenotype and prevalence of the condition are not well defined. We therefore investigated a total of 62 patients with MCA (> 10), early onset CRC (EA-CRC) and/or familial CRC for mutations in the POLE and POLD1 exonuclease proofreading domains (aa 278-471 e 304-517, respectively), by direct sequencing of genomic DNA, to verify their frequency and associated clinical characteristics. Patients were APC, MUTYH and MMR mutation-negative. In-silico analyses were performed using Polyphen2, SIFT, Mutation Taster, ClustalOmega, Phyre2, and Chimera 1.6.2.
Five POLE variants were identified in 4/62 patients: p.L424V (which has already been reported as germline mutation) in a family with an autosomal dominant phenotype of Turcot syndrome (multiple polyps associated with gliomas) and cutaneous manifestations (multiple pilomatricomas); p.D392G and p.K425R in a patient with two metachronous CRC and familial CRC; p.S459C in a patient with 3 colorectal adenomas and a positive family history of EA-CRC; p.P436S in a proband with EA-CRC and MCA. Bioinformatic analyses are concordant in predicting a pathogenetic effect for p.K425R, p.S459C and p.P436S, while interpretations of p.D392G are discordant.
Our results contribute to a better definition of the phenotype and mutation spectrum of PPAP caused by POLE defects.

C09.4

Germline mutations in patients with hereditary breast and ovarian cancer establish ERCC2 as a cancer susceptibility gene.

A. Rump[1], *A. Benet-Pages[2], S. Schubert[3], R. Janavicius[4], K. Hackmann[1], E. Betcheva-Krajcir[1], L. Mackenroth[1], J. Lehmann[3], A. Nissen[2], J. Altmueller[5], H. Thiele[5], N. Di Donato[1], B. Klink[1], J. Kuhlmann[6], A. Tzschach[1], K. Kast[6], P. Wimberger[6], E. Holinski-Feder[2], A. Meindl[7], S. Emmert[3], E. Schrock[1];*
[1]Institute for Clinical Genetics, TU Dresden, Germany, Dresden, Germany, [2]MGZ - Medical Genetics Center, Munich, Germany, [3]Clinic for Dermatology Venerology and Allergology, Goettingen, Germany, [4]Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania, [5]Cologne Center for Genomics, Cologne, Germany, [6]Department of Gynecology and Obstetrics, Dresden, Germany, [7]Clinic for Gynecology and Obstetrics, TU Munich, Munich, Germany.

Background: Breast and ovarian cancer (BC/OC) predisposition is associated with a number of high- and low-penetrance susceptibility genes. Despite comprehensive testing there is still a large portion of high risk cases without mutation in any of the known susceptibility loci. Therefore novel candidate genes need to be screened. Here we report on the results of testing 94 genes in 717 patients from Germany and Lithuania.
Method: Inclusion criteria for the patients in this study were defined by the German Consortium for Breast and Ovarian Cancer. NGS was performed with 150 bp paired end sequencing (Illumina TruSight cancer panel).
Results: In 19.7 % of the patients, BRCA1/2 mutations have been found. Additional 17.9 % of the patients had null-mutations and unclassified missense variants in the BC/OC susceptibility genes ATM, CDH1, CHEK2, NBN, PALB2, RAD51C/D and TP53. Analysis of the non-BC/OC genes on the TruSight-panel identified 4 protein truncating mutations in the „excision repair gene" ERCC2. Additionally we found 20 rare, unclassified missense variations in ERCC2. These variants have a cumulative allele frequency of 2.9% in our BC/OC cohort, which is 14.5-fold overrepresented compared to the "exome aggregation consortium" cohort. Initial functional assays show that at least some of the protein variants (e.g. NM_000400.3:p.Val536Met) have lost their DNA repair ability.
Conclusion: Overrepresentation of deleterious mutations in our cohort defines ERCC2 clearly as a susceptibility gene for BC/OC predisposition. As part of ongoing research, affected individuals with excluded mutations in the known BC/OC predisposition genes should be tested for mutations in ERCC2.

C09.5

Tumour risks and genotype-phenotype-proteotype analysis in ~800 patients with germline mutations in the succinate dehydrogenase subunit genes SDHB, SDHC and SDHD

K. A. Andrews[1,2], *D. B. Ascher[3], D. E. V. Pires[3], L. Vialard[4], N. Bradshaw[5], L. Izatt[6], A. Kumar[7], F. Lalloo[8], R. Irving[9], J. Cook[10], T. Cole[4], D. Goudie[11], M. McConachie[11], R. Lindsay[12], C. Perry[12], J. Adlard[13], V. Murday[5], S. Stewart[4], E. Woodward[4], E. R. Maher[2,1,4];*
[1]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [2]Department of Medical Genetics, University of Cambridge and NIHR Cambridge Biomedical Research Centre, Cambridge, United Kingdom, [3]Department of Biochemistry, University of Cambridge, Cambridge, United Kingdom, [4]West Midlands Regional Genetics service, Birmingham Women's Hospital, Birmingham, United Kingdom, [5]West of Scotland Regional Genetics Service, Ferguson Smith Centre for Clinical Genetics, Glasgow, United Kingdom, [6]Regional Genetics Service Guy's Hospital, London, United Kingdom, [7]Department of Clinical Genetics, North East Thames Regional Genetics Unit, Great Ormond Street Hospital, London, United Kingdom, [8]Department of Genetic Medicine, Manchester Academic Health Science Centre, St. Mary's Hospital, University of Manchester, Mancheser, United Kingdom, [9]Department of ENT Surgery, University Hospital Birmingham Foundation Trust, Birmingham, United Kingdom, [10]Sheffield Clinical Genetics Service, Sheffield Children's Hospital, Sheffield, United Kingdom, [11]Ninewells Hospital and Medical School, Dundee, United Kingdom, [12]Institute of Cardiovascular & Medical Sciences, University of Glasgow, Glasgow, United Kingdom, [13]Yorkshire Regional Genetics Service, Leeds, United Kingdom.

Germline mutations in the succinate dehydrogenase subunit genes SDHB, SDHC and SDHD are the most frequent causes of inherited phaeochromocytomas and paragangliomas. Since these genes were identified over a decade ago, genetic testing for mutations in them has become a standard clinical tool for many patients with these, and other, tumour types. However, the lack of information regarding penetrance and phenotypic variability associated with SDHB/C/D mutations hinders optimum clinical management of individuals who are found to have a germline mutation. In order to address these issues we undertook a retrospective survey of 800 individuals (including 401 previously reported) with identified mutations in SDHB/C/D. Analysis of age-related tumour risks according to relevant gene and mutation type (for SDHB and SDHD) provided novel estimates of penetrance and genotype-phenotype correlations. In silico structural prediction analyses were performed to evaluate the functional effects of SDHB and SDHD mutations. Increased knowledge of the molecular basis of phenotypic variability commonly observed in individuals with germline SDHB/C/D mutations will facilitate the development of personalised management protocols based on gene and mutation-specific tumour risks.
We describe the distinct phenotypes of SDHB Ile127Ser and SDHD Pro81-Leu carriers, which can be explained using structural prediction studies and may indicate a need to move towards mutation-specific management plans for these patients.

C09.6

Germline SMAD9 Mutation Destabilizes PTEN: Exome Sequencing Reveals a Novel Susceptibility Gene For Hamartomatous Polyposis and Gastrointestinal Ganglioneuromas

J. Ngeow[1,2], *W. Yu[2], L. Yehia[2], C. Eng[2];*
[1]Cancer Genetics Service, National Cancer Centre Singapore, Singapore, Singapore, [2]Genomic Medicine Institute, Cleveland, OH, United States.

Hamartomatous polyposis syndromes (HPS) represent a small but appreciable number of the gastrointestinal inherited cancer predisposition syndromes associated with a substantial risk for developing colonic and extracolonic malignancies. We present a unique case of familial juvenile polyposis syndrome associated with gastrointestinal ganglioneuromas of unknown etiology. The patient underwent genetic testing for the known HPS genes (BMPR1A, SMAD4, ENG, PTEN, STK11) but no mutation was detected. Exome sequencing identified a novel germline mutation in SMAD9 resulting in reduced PTEN expression. We subsequently screened 40 JPS patients and 40 CS patients with HPS for SMAD9 mutations but did not detect any with SMAD9 mutations. Our patient, in addition to HPS, had significant ganglioneuromatosis which is rare but is overrepresented in CS patients with germline PTEN mutations. Our functional experiments show that our patient's SMAD9 mutation results in gain-of-function in SMAD8 leading to reduced PTEN mRNA and protein stability, together, yielding a phenotype (ganglioneuromatous polyps) seen more commonly in patients with germline PTEN mutations. Our study suggests that this may be indirectly regulated by miR21expression. We recommend that all patients with a clinical presentation of hamartomatous polyposis especially those with gastrointestinal ganglioneuromas be referred for genetics evaluation.

C10.1
Whole genome sequencing reveals the mutation characteristics in Autism Spectrum Disorder

Autism spectrum disorder (ASD) is genetically heterogeneous, with evidence for hundreds of susceptibility loci. Previous microarray and exome-sequencing studies have examined portions of the genome in simplex families (parents and one ASD-affected child) having presumed sporadic forms of the disorder. We used whole-genome sequencing (WGS) of 85 quartet families (parents and two ASD-affected siblings), consisting of 170 individuals with ASD, to generate a comprehensive data resource encompassing all classes of genetic variation (including noncoding variants) and accompanying phenotypes, in apparently familial forms of ASD. By examining de novo and rare inherited single-nucleotide and structural variations in genes previously reported to be associated with ASD or other neurodevelopmental disorders, we found that more than two-thirds of the affected siblings carried different ASD-relevant mutations. These siblings with discordant mutations tended to demonstrate more clinical variability than those who shared a risk variant. Our study emphasizes that substantial genetic heterogeneity exists in ASD, necessitating the use of WGS to delineate all genic and non-genic susceptibility variants in research and in clinical diagnostics. We have now sequenced 200 additional ASD families using WGS. We will present our complete data analysis as well as additional progress from this study.

C10.2
Identification of a common set of microRNAs deregulated in Autism Spectrum disorders

L. Nguyen[1], M. Lepleux[2], M. Makhlouf[3], C. Martin[2], J. Fregeac[1], A. Phillipe[1], F. Ferron[4], B. Gepner[4], C. Rougeulle[3], Y. Humeau[2], **L. Colleaux**[1];
[1]INSERM UMR 1163, Paris Descartes – Sorbonne Paris Cité University, Imagine Institute, Necker-Enfants Malades Hospital, Paris, France, [2]Institut Interdisciplinaire de NeuroSciences, UMR 5297 CNRS - Université de Bourdeaux, Bordeaux, France, [3]UMR 7216, Université Paris Diderot, Paris, France, [4]Faculté de Médecine Nord, Aix Marseille Université, NICN, CNRS UMR 7259, Marseille, France.

Autism spectrum disorder (ASD) is a neurodevelopmental disease caused by an interaction between genetic vulnerability and environmental factors. MicroRNAs (miRNAs) have emerged as key post-transcriptional regulators and are involved in multiple aspects of brain development and connectivity. Here, using olfactory mucosal stem cells biopsied from living patients, we identified a signature of four miRNAs (miR-146a, miR-221, miR-654-5p and miR-656) commonly deregulated in ASD. This signature is conserved in primary skin fibroblasts and allows discriminating between ASD and intellectual disability samples. Putative target genes of the differentially expressed miRNAs were enriched for pathways previously associated to ASD and altered levels of neuronal transcripts targeted by miR-146a, miR-221 and miR-656 were observed in patients' cells. In the mouse brain, miR-146a displays strong neuronal expression in regions important for high cognitive functions, and we demonstrate that overexpressing miR-146a leads to alteration of neuronal dendritic arborisation. These findings have strong diagnostic implications and emphasize the role of miRNA expression deregulation in the etiology of ASD, opening new opportunities for therapeutic approaches.

C10.3
Rare variants in GABAA receptor genes in Rolandic epilepsy and related syndromes

E. M. Reinthaler[1], *B. Dejanovic[2], D. Lal[3,4,5], M. Semtner[6], Y. Merkler[2], A. Reinhold[6], D. A. Pittrich[1], C. Hotzy[1], J. Altmüller[5,7], A. Kawalia[5], M. R. Toliat[5], EuroEPINOMICS Consortium, GABA receptor study group, P. Nürnberg[5,4], H. Lerche[8], M. Nothnagel[5], H. Thiele[5], T. Sander[5], J. C. Meier[6,9], G. Schwarz[2,4,10], B. A. Neubauer[3], F. Zimprich[1];*
[1]Department of Neurology, Medical University of Vienna, Vienna, Austria, [2]Institute of Biochemistry, Department of Chemistry, University of Cologne, Cologne, Germany, [3]Department of Neuropediatrics, University Medical Center Giessen and Marburg, Giessen, Germany, [4]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany, [5]Cologne Center for Genomics, University of Cologne, Cologne, Germany, [6]RNA Editing and Hyperexcitability Disorders Helmholtz Group, Max Delbrück Center for Molecular Medicine, Berlin, Germany, [7]Institute of Human Genetics, University of Cologne, Cologne, Germany, [8]Department of Neurology and Epileptology, Hertie Institute of Clinical Brain Research, University of Tübingen, Tübingen, Germany, [9]TU Braunschweig, Zoological Institute, Division of Cell Biology & Cell Physiology, Braunschweig, Germany, [10]Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany.

Purpose: Mutations in $GABA_A$ receptor ($GABA_A$-R) subunit genes have been described in a range of epilepsy syndromes. Here, we tested whether mutations in 18 genes encoding for $GABA_A$ receptor subunit genes contribute to the etiology of Rolandic epilepsy (RE) or its atypical variants (ARE).
Methods: We performed exome sequencing in 204 European patients with RE/ARE and compared the frequency of $GABA_A$R genes variants with 728 platform matched controls. We functionally assessed nonsynonymous *GABRG2* variants for protein stability, trafficking, postsynaptic clustering and receptor function.
Results: Out of 18 screened $GABA_A$-R genes, we found a significant enrichment of rare variants in the *GABRG2* gene in RE/ARE patients (5/204, 2.45%) when compared to controls (1/723, 0.14%) (OR = 18.07, 95% CI = 2.01 – 855.07, p = 0.0024, p_{corr} = 0.043). We detected a splice variant (c.549-3T>G) in two unrelated patients as well as three nonsynonymous *GABRG2* variations (p.G257R, p.R323Q, p.I389V). Functional analysis of the nonsynonymous variants showed reduced surface expression of p.G257R and decreased GABA-evoked currents for p.R323Q. The p.G257R mutation resulted in reduced palmitoylation, a posttranslational modification crucial for trafficking of proteins to the cell membrane. Enzymatically enhanced palmitoylation levels restored the surface expression of the p.G257R variant γ2-subunit.
Conclusion: The presented statistical association and functional evidence suggest that mutations in the *GABRG2* gene increase risk of RE/ARE. Restoring the impaired membrane trafficking of some *GABRG2* mutations by augmenting palmitoylation levels offers a therapeutic perspective to reverse the pathogenic effect of such mutants.

Epileptic encephalopathies are a phenotypically and genetically heterogeneous group of severe epilepsies accompanied by intellectual disability and other neurodevelopmental features. Using next generation sequencing, we identified four different *de novo* mutations in *KCNA2*, encoding the potassium channel $K_V1.2$, in six isolated patients with epileptic encephalopathy (one mutation recurred three times independently). Four individuals presented with febrile and multiple afebrile, often focal seizure types, multifocal epileptiform discharges strongly activated by sleep, mild-moderate intellectual disability, delayed speech development and sometimes ataxia. Functional studies of the two mutations associated with this phenotype revealed an almost complete loss-of-function with a dominant-negative effect. Two further individuals presented with a different and more severe epileptic encephalopathy phenotype. They carried mutations inducing a drastic gain-of-function effect leading to permanently open channels. These results establish *KCNA2* as a novel gene involved in human neurodevelopmental disorders by two different mechanisms, predicting either hyperexcitability or electrical silencing of $K_V1.2$-expressing neurons.

C10.5
Cysteine Correction of NOTCH3: exon skipping as a potential therapeutic strategy for CADASIL

J. W. Rutten[1], *H. G. Dauwerse*[1], *D. J. M. Peters*[1], *A. Goldfarb*[1], *R. R. Klever*[1], *H. Venselaar*[2], *S. Verbeek*[1], *A. M. J. M. van den Maagdenberg*[1], *G. B. van Ommen*[1], *A. M. Aarstma- Rus*[1], *S. A. J. Lesnik Oberstein*[1];
[1]*Leiden university medical center, Leiden, Netherlands,* [2]*Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

CADASIL is a disabling hereditary vascular dementia and stroke syndrome, occurring worldwide in ~1:50.000 individuals, for which no treatment is available. The disease is caused by stereotyped mutations in NOTCH3, which alter the number of cysteines in one of the epidermal growth factor-like repeat (EGFr) domains of the NOTCH3 protein. This causes toxic NOTCH3 aggregation and accumulation in the (cerebro)vasculature, leading to vascular smooth muscle cell degeneration and a reduced cerebral blood flow. We hypothesized that re-establishing the correct number of 6 cysteines within EGFr may prevent or reduce toxic NOTCH3 aggregation. To accomplish this NOTCH3 'cysteine correction', we use antisense-mediated exon skipping. Based on extensive in silico protein predictions, at least 12 NOTCH3 exons are eligible for this approach, targeting the majority of CADASIL causing mutations. We now have established that this targeted NOTCH3 exon skipping is feasible both in a CADASIL patient derived cell model and in human NOTCH3 transgenic mice. Using 'skip' cDNA constructs, we show that the modified NOTCH3 proteins are expressed at the cell surface and bind to their canonical ligand Jagged1. This indicates that this selected exon exclusion does not abrogate normal NOTCH3 processing and function. The human NOTCH3 transgenic mice which we generated for in vivo studies show progressive cerebrovascular NOTCH3 accumulation, and are therefore a good model to test potential therapies aimed at preventing or reducing NOTCH3 accumulation. Ongoing studies focus on optimizing in vivo exon skipping, to determine the effect of cysteine correction on vascular NOTCH3 accumulation and ultimately the CADASIL phenotype.

C10.6
De novo deleterious genetic variations target a biological network centered on Aβ peptide in early-onset Alzheimer disease

A. Rovelet-Lecrux[1], *C. Charbonnier*[1], *D. Wallon*[1], **G. Nicolas**[1], *M. N. J. Seaman*[2], *C. Pottier*[1], *S. Y. Breusegem*[2], *P. Prakash Mathur*[3], *P. Jenardhanan*[3], *K. We hypothesized that de novo variants (DNV) might participate in the genetic determinism of sporadic early-onset Alzheimer disease (EOAD, onset before 65 years). We investigated first by array-CGH and then by whole exome sequencing 14 sporadic EOAD trios. Two patients carried a de novo copy number variation and 7, among the remaining 12, had at least one non-synonymous DNV. Five of these 9 DNV (an APP duplication, a BACE2 intronic deletion, and three nucleotide variants affecting PSEN1, VPS35 and MARK4) targeted a biological network centered on the Amyloid beta (Aβ) peptide. Using appropriate statistical analyses, we showed that this a priori-defined genetic network was significantly enriched in amino acid-altering DNV, compared to the rest of the exome. In addition, we provided evidence of the functional impact of 4/5 DNV targeting this network: the causality of the APP de novo duplication (which is the first reported one) was obvious; the novel PSEN1 variant resulted in exon 9 skipping in patient's RNA, leading to a pathogenic missense at exons 8-10 junction; the VPS35 missense variant led to partial loss of retromer function, which may impact neuronal APP trafficking and Aβ secretion; and the MARK4 multiple nucleotide variant resulted into increased Tau phosphorylation which may trigger enhanced Aβ-induced toxicity. Despite the difficulty to recruit AD trios due to age structures of the pedigrees and the genetic heterogeneity of the disease, this strategy allowed us to highlight the role of de novo pathogenic events, the putative involvement of three new genes in AD genetics and the key role of Aβ network alteration in AD.

C11.1
Mutations in a novel dynein-2 light chain, TCTEX1D2, cause Jeune Asphyxiating Thoracic Dystrophy (JATD) with incomplete penetrance

Background: JATD is a very rare, autosomal recessively inherited ciliary chondrodysplasia mainly characterised by short ribs resulting and narrow thorax causing a life threatening respiratory phenotype, sporadic polydactyly and variable extraskeletal findings such as renal, hepatic and retinal disease. Known disease causing genes currently explain approximately 80% of the cases. We have recently identified mutations in components of the cytoplasmic dynein-2 complex, including the heavy chain and 2 novel intermediate chains, but not any light chains.
Objectives, methods and results: To define the underlying genetic and molecular basis, we have genetically explored a cohort of over 300 individuals using diverse DNA sequencing techniques including whole exome sequencing, identifying 3 families with loss of function ("null") mutations in *TCTEX1D2*, a new cytoplasmic dynein-2 (IFT-dynein) light chain. We observed an unusual inheritance pattern suggesting incomplete penetrance and in patient cells and *Chlamydomonas*, impairment of retrograde IFT seems milder than in models for other dynein-2 defects and in human, fish and *Chlamydomonas and* loss of *TCTEX1D2* conferred no apparent changes in gross ciliary structure. Our proteomics analysis in *Chlamydomonas* and human proteomic analysis confirmed that TCTEX1D2/Tctex2b represents a component of an intermediate chain/light chain sub-complex within IFT dynein and that in *Chlamydomonas*, the retrograde IFT defect observed is caused by instability of the entire IFT dynein complex.
Conclusion: Together, our results suggest *TCTEX1D2* is an integral component of the IFT-dynein complex in human, zebrafish and that loss of function mutations cause JATD, however its loss may be compensated for under certain conditions.

C11.2
Mutations in DVL1 cause an osteosclerotic form of Robinow Syndrome

S. Robertson[1], *K. Bunn*[1], *P. Daniel*[1], *H. Rosken*[1], *A. O'Neill*[1], *S. Cameron-Christie*[1], *D. Markie*[1], *H. Brunner*[2], *H. Kunst*[2], *A. Lai*[3];
[1]*Dunedin School of Medicine, Dunedin, New Zealand,* [2]*Radboud University Medical Center, Nijmegen, Netherlands,* [3]*KK Women's and Children's Hospital, Singapore, Singapore.*

Robinow Syndrome (RS) is a phenotypically and genetically heterogeneous condition that can be caused by mutations in genes encoding components of the non-canonical WNT signaling pathway. In contrast, germline mutations that act to increase canonical WNT signaling lead to distinctive osteosclerotic phenotypes. Here we identify de novo frameshift mutations in DVL1, a mediator of both canonical and non-canonical WNT signaling, as the cause of a subtype of RS with osteosclerosis (RS-OS) in three unrelated individuals. The mutations all delete the DVL1 C-terminus and replace it, in each instance, with a novel, highly basic sequence. We show the presence of mutant transcript in fibroblasts from one individual with RS-OS, and demonstrate unimpaired protein stability with transfected GFP-tagged constructs bearing a frameshift mutation. In vitro TOPFlash assays, in apparent contradiction to the osteosclerotic phenotype, revealed that the mutant allele is less active than the wild type in the canonical WNT signaling pathway. However, when the mutant and wild type alleles are co-expressed, there is a 2-fold increase in canonical WNT activity over that of the wild type construct alone. This work establishes that DVL1 mutations cause a specific subtype of RS, RS-OS, and that the osteosclerosis may be the result of an interaction between the wild type and mutant alleles leading to elevated canonical WNT signaling.

C11.3
Mutations in ZAK cause autosomal recessive split foot malformation in humans and complex hindlimb defects in mice

N. TAYEBI, *N. Kakar, M. Spielmann, C. Leettola, S. Kühl, G. Nürnberg,, N. Sowada, J. Altmüller, D. Lupianez, R. Flöttmann,, M. Radenz, H. van Bokhoven, C. Schwartz, H. Thiele, P. Nürnberg, M. Kühl, J. Bowie, C. Kubisch, S. Ahmad, S. Mundlos, G. Borck; Max planck institute, berlin, Germany.*

Split hand foot malformation (SHFM) is a clinically heterogeneous defect of the central rays of hands and feet.

By using a combination of homozygosity mapping and exome sequencing in a consanguineous Pakistani family, we have identified a c.1103T>G / p.Phe368Cys mutation in ZAK (also known as MLTK) on chromosome 2q31.1 as the cause of a unique autosomal recessive split foot-hearing loss syndrome with highly variable expressivity. Screening of genetically unresolved SHFM cases identified an unrelated Tunisian individual with a homozygous intragenic ZAK deletion. Our biochemical studies using a super negative GFP gel assay show that the SAM domain of ZAK is monomeric. In situ hybridisation in mouse embryos revealed strong Zak expression in the heart as well as in the developing forelimb and hindlimb between embryonic days (E) 9.5 and 11.5. Consistent with a role for Zak/Mltk in cartilage and bone development morpholino oligonucleotide-mediated knockdown resulted in abnormal cartilage development in Xenopus laevis embryos. Finally, CRISPR-Cas mediated complete inactivation of Zak in mice caused lethality at E 9.5 due to severe cardiac malformation. The targeted deletion of the SAM domain in mice however was associated with a complex hindlimb malformation with some animals showing severe clefting of the whole hindlimb including the femur, tibia, fibula and the feet. Furthermore expression analysis of mutant hindlimbs at E 10.5 and 11.5 showed a 60% decrease of Tp63 expression compared to wild type hindlimbs, suggesting a functional link between Zak and p63.

C11.4
Spondyloenchondrodysplasia: The expanding phenotype of TRAP deficiency

T. A. Briggs[1], *G. I. Rice*[1], *Y. J. Crow*[1,2];
[1]*Manchester Centre for Genomic Medicine, Institute of Human Development, Faculty of Medical and Human Sciences, Manchester Academic Health Sciences Centre, University of Manchester, Manchester, United Kingdom,* [2]*INSERM UMR 1163, Laboratory of Neurogenetics and Neuroinflammation, Paris Descartes – Sorbonne Paris Cite University, Institut Imagine, Hopital Necker, Paris, France.*

Spondyloenchondrodysplasia is a rare immuno-osseous dysplasia caused by biallelic mutations in *ACP5.* Clinical, molecular and serological data from a total of 22 patients from 17 families will be described, providing an update regarding the skeletal, neurological and immune phenotype in this condition, in which the spectrum of disease continues to widen with increased identification of affected individuals. Of particular note we propose that the OMIM differentiation between Spondyloenchondrodysplasia and Spondyloenchondrodysplasia with immune dysregulation is not required, as we have shown with molecular testing that they represent a continuum of the same disorder. We observed a diverse immune phenotype, frequently including autoimmune thrombocytopenia and systemic lupus erythematosus, and noted a possible increased susceptibility to infection. In the majority of patients tested we detected upregulated expression of type I interferon-stimulated genes, in keeping with the autoimmune phenotype observed and the likely immune regulatory function of the deficient protein: tartrate resistant acid phosphatase. Interestingly, however we identified two mutation positive patients without an upregulation of interferon-stimulated genes, including one patient with significant autoimmune disease, which was controlled by immunosuppressive therapy. This patient may demonstrate a useful therapy for the immune manifestations of Spondyloenchondrodysplasia.

C11.5
Brachyolmia with amelogenesis imperfecta can be caused by a defect in the TGFbeta signaling pathway

Brachyolmia refers to a heterogeneous group of skeletal dysplasias with a disproportionate short stature with short trunk. Radiographically the disorder is characterized by a predominant involvement of the axial skeleton with variable degrees of vertebral flattening (platyspondyly). Amelogenesis imperfecta (AI) is a defect in enamel formation/mineralization presenting as an isolated anomaly or occuring in association with other anomalies. In 1996, Verloes et al. described an autosomal recessive form of brachyolmia associated with AI (OMIM 601216). Bertola et al. (2009) subsequently published two other families with the combination of vertebral anomalies and enamel defects. Here we report on four additional families with the same phenotype. Three of the eight affected individuals had significant short stature. All patients had variable degrees of platyspondyly, very thin or almost absent enamel in both primary and permanent dentitions. A combined strategy of homozygosity mapping and whole exome sequencing resulted in the identification of recessive hypomorphic mutations in a gene involved in the TGFbeta signaling pathway. We further investigated the gene expression during mouse and tooth development. At E18.5 labeling was restricted to ameloblasts synthesizing enamel matrix proteins, and to odontoblasts. Investigating an available knockout mouse model showed that the mutant mice displayed thin to absent enamel in both incisors and molars, as well as disorganised ameloblasts layer and matrix hereby recapitulating the amelogenesis imperfecta phenotype in our patients. Our study confirms the role of the TFGbeta signaling pathway in both osteogenesis and amelogenesis.

C11.6
Pentosan Polysulfate: New Mechanistic Insights and Treatment of the Mucopolysaccharidoses

C. M. Simonaro[1], *S. Tomatsu*[2], *M. Frohbergh*[1], *M. Haskins*[3], *A. Solyom*[4], *E. Schuchman*[1];
[1]*Icahn School of Medicine at Mount Sinai, New York, NY, United States,* [2]*Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE, United States,* [3]*School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA, United States,* [4]*University Medical Center, Mainz, Germany.*

Pentosan polysulfate (PPS) is manufactured in both oral and injectable forms, and has been used clinically for over 40 years. Due to the i) anti-inflammatory properties of PPS, ii) positive effects in arthritic animals and patients, and iii) extensive safety history, we investigated the use of PPS in the mucopolysaccharidoses (MPS). Comparative studies of oral (daily) and injectable (weekly subcutaneous, s.c.) PPS were carried out in MPS VI rats (Schuchman et al., 2013; Frohbergh et al., 2014). Both studies led to reduced inflammatory markers, improved dentition and skull lengths, reduced tracheal deformities, and markedly improved mobility. Unexpectedly, a significant reduction of urine and tissue glycosaminoglycans (GAGs), was most evident after s.c. administration. Findings were confirmed by analysis of total GAGs and by mass spectrometry. The mechanism(s) leading to PPS-mediated GAG reduction in MPS are currently being investigated. Further preclinical studies were carried out in MPS I dogs, with oral (daily) and s.c. (every other week) PPS for >1 year. Significant reductions of inflammatory markers, tissue and urine GAGs were most evident with s.c. administration. Both treatment groups also exhibited reduced carotid and aortic inflammation with the absence of plaque formation, a common pathology in the vasculature of MPS I dogs and patients. Based on these findings, two clinical studies evaluating s.c. PPS have been initiated, in adult MPS I (Germany) and MPS II (Japan) patients. We conclude that PPS may be beneficial for MPS, either as an adjunct therapy or as a stand alone treatment that reduces inflammation and GAG storage.

C12.1
A novel disorder reveals Clathrin Heavy Chain-22 is essential for human pain and touch development

M. S. Nahorski[1], *L. Al-Gazali*[2], *J. Hertecant*[3], *D. J. Owen*[1], *G. Borner*[4], *Y. Chen*[1], *C. Benn*[5], *O. Carvalho*[1], *S. S. Shaikh*[1], *A. Phelan*[5], *M. Robinson*[1], *S. Royle*[6], *G. C. Woods*[1];

A congenital inability to feel pain is very rare but the identification of causative genes has yielded significant insights into pain pathways and also novel

targets for pain treatment. We report a novel recessive disorder characterised by congenital insensitivity to pain, inability to feel touch, and cognitive delay. Affected individuals harboured a homozygous missense mutation in CLTCL1 encoding the CHC22 clathrin heavy chain. The mutation p.E330K renders CHC22 non-functional in mediating endocytosis at the cell membrane. We found that CLTCL1 is significantly upregulated in the developing human brain, displaying an expression pattern suggestive of an early neurodevelopmental role. Guided by the disease phenotype, we investigated the role of CHC22 in two human neural crest differentiation systems; human iPSC derived nociceptors and TRKB dependant SH-SY5Y cells. In both there was a significant down-regulation of CHC22 upon the onset of neural differentiation. Furthermore, knockdown of CHC22 induced neurite outgrowth in neural precursor cells, which was rescued by stable overexpression of siRNA resistant CHC22 but not by mutant CHC22. Similarly, overexpression of wild-type, but not mutant, CHC22 blocked neurite outgrowth in cells treated with Retinoic Acid. Using a novel, quantitative proteomics approach we have identified the protein complement of clathrin coated vesicles in neuronal cells, and present insights into the neural-specific trafficking defects resulting from loss of functional CHC22. These results reveal an essential and non-redundant role for CHC22 in neural crest development and in the genesis of pain and touch sensing neurons.

C12.2

Exome sequencing of ataxia-blindness patients identifies atypical Brown-Vialetto-Van Laere syndrome-2 (BVVLS2) presentation and identifies PEX6 as the SCAR3 (MIM#271250) gene

C. Guissart[1,2], *E. Acar*[3], *H. Topaloglu*[3], *B. Leheup*[4], *S. Ferdinandusse*[5], *M. Koenig*[1,2];
[1]*Laboratoire de Génétique Moléculaire, Centre Hospitalier Universitaire (CHU) Montpellier, Montpellier, France,* [2]*Université de Montpellier, Montpellier, France,* [3]*Department of Pediatrics, Hacettepe University, Ankara, Turkey,* [4]*Service de Médecine Infantile et Génétique Clinique, CHU de Nancy, Vandoeuvre, France,* [5]*Laboratory of Genetic Metabolic Diseases, Academic Medical Center, Amsterdam, Netherlands.*

We reported in 2000 the linkage of spinocerebellar ataxia with blindness and deafness (SCAR3) to chromosome 6p23-p21 from the study of a single multigenerational consanguineous family (Bomont et al.). We have now performed exome sequencing of this family and found in all patients the homozygous p.Gly306Arg missense mutation in SLC52A2, previously reported in patients with BVVLS2, but located on chromosome 8qter. High recombination rate in the telomeric region and use of widely spaced microsatellite markers explains why correct linkage was initially missed. Exome sequencing of a second family with two children affected with progressive ataxia, bilateral optic atrophy and mild mental retardation revealed the novel homozygous p.Pro134Leu missense mutation in SLC52A2, confirming that treatable (by riboflavin supplementation) BVVLS2 should be considered for differential diagnosis of syndromic autosomal recessive ataxia. Exome sequencing of a third family with two children affected with progressive ataxia and retinitis pigmentosa and with linkage to 6p23-p21 revealed the p.Ala912Val mutation in PEX6. Retrospective analysis of peroxisomal markers showed just above normal serum phytanic acid levels but fibroblasts from a subsequent skin biopsy revealed absent peroxisomal catalase immunostaining, peroxisomal ghosts with abnormal structure and markedly increased C26/C22 ratio, confirming the pathogenicity of the p.Ala912Val mutation. Therefore, despite initial false linkage, the SCAR3 locus is confirmed and corresponds to PEX6 mutation. Identification of these hypomorphic missense mutations lends further support to the concept that numerous recessive ataxias are caused by partial loss of function mutations in a large variety of pathophysiological pathways (Anheim et al., NEJM, 2012).

Heimler syndrome (HS) is a rare recessive disorder characterized by sensorineural hearing loss, enamel hypoplasia, retinal pigmentation and nail abnormalities, for which no gene has been identified. We performed whole exome sequencing in eight families with HS and identified biallelic mutations in PEX1 or PEX6, in six affected families. Loss of function mutations in both genes are known to cause peroxisome biogenesis disorders (PBDs), such as Zellweger syndrome, which is a group of autosomal recessive disorders, characterized by developmental brain abnormalities, sensorineural hearing loss, retinopathy, and skeletal, craniofacial, and liver abnormalities. We analyzed plasma, erythrocytes and cultured skin fibroblasts from affected individuals for biochemical peroxisomal parameters but did not detect any significant aberrations. However, immunofluorescence microscopy of the fibroblasts revealed a so-called mosaic peroxisomal pattern compatible with a very mild peroxisomal dysfunction. The impaired peroxisomal biogenesis in the PEX1 or PEX6 mutant cells could be rescued by transfection of PEX1 or PEX6 cDNA respectively and by functional expression studies we demonstrated which of each mutant allele caused the mild mutant phenotype. Most of these mutations had not been reported previously in PBD patients.

Although individuals with HS share subtle clinical features found in PBDs, the overlap is minimal and the diagnosis was not suggested by routine plasma analyses used to detect PBDs. In conclusion, our findings illustrate the diagnostic utility of exome sequencing for rare syndromes and expand the phenotypic spectrum associated with PEX mutations.

C12.4

An in-frame deletion in *FOXL1* identifies the first gene causing autosomal dominant otosclerosis

N. Abdelfatah[1], *A. Mostafa*[1], *S. G. Stanton*[2], *M. B. Lucas*[2], *A. Griffin*[1], *V. Booth*[3], *C. Rowley*[3], *J. E. Besaw*[3], *L. Tranebjærg*[4], *N. Dahl Rendtorff*[4], *K. A. Hodgkinson*[1], *L. A. Little*[2], *A. Sangamanatha*[2], *S. Agrawal*[5], *L. Parnes*[5], *A. Batten*[6], *J. Houston*[1], *D. Galutira*[1], *T. Benteau*[1], *C. Penney*[1], *C. Negrijn*[1], **T. Young**[1];

Introduction: Otosclerosis, the most common cause of conductive hearing loss in adults, is characterized by the cementing of the stapes bone to the oval window, and is believed to be caused by dysregulation of bone remodeling in the otic capsule. Although considered sporadic, 10 distinct genetic loci (*OTSC1-10*) have been mapped in families with autosomal dominant forms, but no genes have been identified.

Materials and Methods: We used a combination of linkage, fine mapping and exome sequencing in a multiplex AD family from the island of Newfoundland, Canada.

Results: We identified a 15 bp in-frame deletion in the FOXL1 gene (c.976_990het_delGGGATCCCCTTCCTC) co-segregating in all relatives with surgically confirmed otosclerosis. This in-frame deletion in FOXL1 is predicted to cause the removal of 5 amino acids from the highly conserved C-terminus (NM_005250). Screening of >100 patients from Canada and Europe revealed a second family from Ontario, Canada, with the identical mutation in FOXL1 and shared ancestral haplotype.

Conclusions: Expression studies using human cells suggest that mutant FOXL1 causes dysregulation of cytokines, supporting the prevailing hypothesis that patients with otosclerosis undergo activated bone remodeling in the otic capsule. Interestingly, although not present in ethnically matched controls, the novel c.976_990het_delGGGATCCCCTTCCTC deletion in FOXL1 was recently reported at a frequency of 0.16% in Europeans and 0.09% in Africans. In summary, we report the identification of the first otosclerosis gene.

Congenital microcoria (MCOR) is a rare autosomal dominant disorder characterized by inability of the iris to dilate owing to absence of dilator pupillae muscle. So far, a dozen MCOR families are reported worldwide. By using whole-genome oligonucleotide array CGH, we have identified deletions at 13q32.1 segregating with MCOR in six families originating from France, Japan and Mexico. Breakpoint sequence analyses showed nonrecurrent deletions in 5/6 families. The deletions varied from 35 Kbp to 80 Kbp in size, but invariably encompassed or interrupted only two genes: TGDS encoding the TDP-glucose 4,6-dehydratase and GPR180 encoding the G protein-coupled receptor 180, also known as intimal thickness-related receptor (ITR). Unlike TGDS which has no known function in muscle cells, GPR180 is involved in the regulation of smooth muscle cell growth. The identification of a null GPR180 mutation segregating over two generations with iridocorneal angle dysgenesis which can be regarded as a MCOR endophenotype is consistent with the view that deletions of this gene, with or without the loss of elements regulating the expression of neighboring genes, are the cause of MCOR.

C12.6

A molecular network surrounding dysregulated H3K9 di-methylation in PRDM5-associated disease

Introduction: Brittle cornea syndrome (BCS) is an inherited connective tissue disease with a devastating ocular phenotype. Mutations in transcription factors *ZNF469* and *PRDM5* cause BCS types 1 and 2, respectively. PR domain containing 5 (PRDM5) is hypothesised to exert epigenetic effects on histone and DNA methylation, chromatin organisation, and microRNA regulation, however its role in epigenetic regulation is not fully elucidated. PRDM5-related disease offers an *in vivo* opportunity to observe a subset of epigenetic regulatory mechanisms in an inherited eye disease.

Methods and results: We report a retinal vascular phenotype in the eyes of two patients with PRDM5-associated disease, and through mining PRDM5 ChIP-seq data performed in murine MC3T3 cells and our expression microarray data performed on patient fibroblasts suggest a role for *PRDM5* in vasculogenesis. We confirmed *PRDM5* binding at a subset of vasculogenesis-related genes in skin fibroblasts by ChIP-QPCR. We examined PRDM5 interaction partners by pull-down and mass spectrometry and observed diminished interaction of a PRDM5 construct carrying a BCS-associated mutation with repressive complexes, including NuRD complex protein CHD4, and heterochromatin protein 1 binding protein 3 (HP1BP3). We investigated a role for HP1BP3 *in vivo*, identifying reduced HP1BP3 staining in patient retinas, and identifying H3K9 di-methylation as a molecular mechanism for transcriptional repression at a subset of vasculogenesis-related PRDM5 target genes. Western blotting studies on patient fibroblasts further suggested a role for dysregulated H3K9 di-methylation *in vivo.* **Conclusions:** These findings suggest a role for dysregulated H3K9 di-methylation in PRDM5-associated disease.

Recurrent 600kbp deletions and duplications at 16p11.2 are associated with autism, schizophrenia and extremes of BMI and head circumference. These rearrangements occur via non-allelic homologous recombination (NAHR) between *BOLA2*-containing directly oriented segmental duplications at BP4 (breakpoint 4) and BP5. Illumina sequencing of 2,551 humans, 86 great apes, a Neanderthal and a Denisovan showed that modern humans carry at least one additional copy of *BOLA2* (from 3 to 10 diploid copies) in contrast to apes and archaic hominins. Through Illumina and PacBio sequencing of large-insert clones from orangutan and chimpanzee, we identified three inversions in the human lineage after divergence from orangutan, affecting >1Mbp of sequence and 45 genes, together with the addition of ~1Mbp via segmental duplication. The latter includes a ~102kbp *BOLA2* segment that duplicated ~183kya, the time when *Homo sapiens* emerged as a species.

We sequenced four human haplotypes and discovered multiple ~102kbp tandem duplications in BP4 and BP5, likely leading to different NAHR predisposition. We are currently assaying *BOLA2* copy number and refining breakpoints in >125 patients with a BP4-BP5 deletion or duplication. *BOLA2* is ubiquitously expressed, present in all eukaryotes, and involved in the regulation of iron metabolism. Expression levels in human lymphoblastoids correlate with copy number (r=0.29), expression of genes on 16p13 and 19p13, and of genes encoding mitochondrial and ribosomal proteins.

These findings suggest that a possible advantage linked to the emergence of duplicated genes in the last 200,000 years of human evolution, underlies the predisposition to recurrent rearrangements at 16p11.2 associated with autism.

C13.3

Chromosomal contacts connect loci associated with autism, BMI and head circumference phenotypes

[1]*Center for Integrative Genomics, Lausanne, Switzerland,* [2]*EPFL, Lausanne, Switzerland,* [3]*Service de Génétique Médicale, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland,* [4]*Swiss Institute of Bioinformatics, Lausanne, Switzerland.*

We identified the cis- and trans-acting long-range chromosomal contacts of five genes located within the 16p11.2 600kb BP4-BP5 copy number variants (CNVs). Its deletion is one of the most frequent known etiologies of autism spectrum disorder (ASD), while this deletion and reciprocal duplication are associated with mirror phenotypes on BMI, head circumference and brain volume. We observed complex chromatin looping between genes located in the proximal 600kb BP4-BP5 and those mapping to the distal 16p11.2 220kb BP2-BP3 region, two loci separated by 650kb, successfully confirmed by reciprocal 4C, FISH, Hi-C and associations between active regulatory regions. Phenotyping of 137 unrelated carriers of distal 16p11.2 220 kb BP2-BP3 deletion and duplication showed that these CNVs are similarly associated with ASD and reciprocal impacts on BMI and HC.

Our results indicate that chromosomal contacts' maps could uncover functionally and clinically related genes. Consistent with this hypothesis, loci chromatin-contacted by our selected viewpoints are enriched for ASD genes (OR=2.15, P=1.65e-08). Furthermore, we uncovered 16p11.2 600kb BP4-BP5 chromatin loops with (i) the 1q21.1 cytoband, whose deletions and duplications were previously linked to micro- and macrocephaly, respectively; (ii) PTEN, mutations of which are associated with a macrocephalic-form of ASD; and (iii) the 2p15 cytoband. We enrolled 35 carriers of 2p15-16.1 deletion and duplication and showed that they similarly display mirror phenotypes on HC and weight.

Finally, we observe that genes differentially expressed in 16p11.2 BP4-BP5 CNV carriers are concomitantly modified in their chromatin interactions, suggesting that disruption of chromatin interplays participates in the observed phenotypes.

C13.2

The impact and activity of mobile elements within the genome

J. Y. Hehir-Kwa[1], *D. Thung*[1], *V. Guryev*[2], *W. P. Kloosterman*[3], *T. Marschall*[4], *K. Ye*[5], *J. A. Veltman*[1,6];

[1]*Radboud umc, Nijmegen, Netherlands,* [2]*University Medical Center Groningen, Groningen, Netherlands,* [3]*University Medical Center Utrecht, Utrecht, Netherlands,* [4]*Max-Planck-Institut für Informatik, Saarbrücken, Germany,* [5]*The Genome Institute Washington University, St Louis, MO, United States,* [6]*Maastricht University Medical Centre, Maastricht, Netherlands.*

Mobile genomic element insertions (MEIs) are DNA sequences that can be autonomously copied or moved through the genome, yet their highly repetitive sequence structure makes them difficult to detect and genotype. In addition to being a major evolutionary driver in changing the genomic architecture, MEIs can also directly resulted in pathogenic variation in a number of human diseases by inserting into functionally important regions and disrupting gene function, or indirectly by mediating deletions.

We have developed a method to identify both MEIs as well as gene retrotransposition insertions (GRiPs) in whole genome sequencing data. Using this tool we screened a cohort of 250 trios selected from the Dutch population and whole genome sequenced to a mean depth of 14x. In total 11,680 MEIs and 5 GRiPs were identified. The majority of the MEIs were rare Alu events (83%) with a frequency of less than 1% (56%). Per individual 1,200 MEIs were identified, including exonic insertions predicted to result in loss of function in known disease genes. In addition we identified and validated 5 de novo MEI events and used the trio design to estimate the genotype error rate (0.4%).

Due to developments in NGS it is now possible to perform genome wide identification of both MEI and GRiP events. The discovery of these events in large cohorts provides new insights into the role of genomic variation with positional effects.

C13.4

Single-cell allele specific expression (ASE) in T21: a novel approach to understand Down syndrome.

G. Stamoulis[1], *P. Makrythanasis*[2], *F. Santoni*[1], *A. Letourneau*[1], *M. Guipponi*[2], *M. Garieri*[1], *N. Panousis*[1], *E. Falconnet*[1], *P. Ribaux*[1], *C. Borel*[1], *S. E. Antonarakis*[1,2,3];

[1]*Department of Genetic Medicine and Development, University of Geneva Medical School 1211, Geneva 4, Switzerland, Geneva, Switzerland,* [2]*Geneva University Hospitals-HUG, Service of Genetic Medicine, 1211 Geneva 4, Switzerland, Geneva, Switzerland,* [3]*iGE3 Institute of Genetics and Genomics of Geneva, University of Geneva, 1211 Geneva 4, Switzerland, Geneva, Switzerland.*

Trisomy 21 is a model disorder of altered gene expression. We have previously used a pair of monozygotic twins discordant for T21 to study the global dysregulation of gene expression, without the noise due to genetic variation among individuals (Nature:508;345-350;2014). The majority of previous studies focused on aneuploidies were conducted on cell populations or tissues. Studies on gene and allelic expression behavior at the single cell level, may reveal important biological insights regarding the cellular impact of aneuploidy and elucidate the fundamental mechanisms of gene dosage. In this study we employed allele specific expression (ASE) using RNAseq from 352 single cell fibroblasts (172 Normal and 180 T21 cells) from the pair of monozygotic twins discordant for T21. A considerable number of heterozygous sites throughout the non-chr21 genome were expressed monoallelically (Normal: 73.2 % monoallelic in 559,134 observations, and T21: 78.8 % monoallelic in 573,670 observations). There was also considerable monoallelic expression for chr21 genes in Normal and surprisingly in T21 cells as well (Normal: 67,2 % monoallelic in 4,985 observations, and T21: 76.07 % monoallelic in 6,723 observations). This metric was used to classify genes on chr21 according to the level of monoallelic expression (9 monoallelic, 29 intermediate, 2 biallelic). We hypothesize that different classes of genes contribute with different mechanisms to the phenotypic variability of Down Syndrome. Furthermore we have made a preliminary observation that genomewide T21 cells showed more monoallelic expression than the normal cells, but more analysis is needed to confirm these results. This study provides a fundamental understanding of the allele specific expression behavior in T21.

C13.5

High incidence of mosaic chromosomal aneuploidies in human cell lines: a quantification of the frequency of the phenomenon

E. S. Dimitriadou[1], *M. Zamani Esteki*[2], *N. Van der Aa*[2], *T. Voet*[2], *J. R. Vermeesch*[1];

[1]*Laboratory for Cytogenetics and Genome Research, Department of Human Genetics, KU Leuven, Leuven 3000, Belgium., Leuven, Belgium,* [2]*Laboratory of Reproductive Genomics, Department of Human Genetics, KU Leuven, Leuven 3000, Belgium, Leuven, Belgium.*

Maintenance of a balanced euploid genome is a key requisite for the success of all multicellular organisms. Broken chromosomes trigger repair pathways and are known to block or delay mitosis. As a consequence, chromosome segregation is generally thought to accurately transmit intact chromosomes. Estimates of the whole chromosomal error rates derived from karyotyping and FISH studies of cell lines or stimulated white blood cells, range between 2-4x10-2 per cell division. The occurrence of segmental imbalances is estimated to be 5x10-4 per cell division. Sporadic studies of single cell genome wide CNV analysis suggested that the error rate might be higher than currently estimated. To obtain accurate measures of chromosomal error rates, we plated fibroblast and analyzed the genomes of two daughter cells following a single cell division, using array-based approaches. In total 152 cells (76 mitoses) from 5 different normal control fibroblast cell lines were analyzed. At least one imbalance was detected in 23 cells, giving a aneuploidy rate of 5.3-25% (median=15.1%) in the different cell lines tested. In conclusion, the chromosomal stability is more than 100 times lower than current dogma, showing that chromosomal instability is a common place and putting the efficacy of the DNA repair mechanisms and control checkpoints in question.

C13.6

Chromothripsis in healthy individuals affects multiple protein-coding genes and can result in severe congenital abnormalities in offspring

M. S. de Pagter[1], *M. J. van Roosmalen*[1], *A. F. Baas*[1], *I. Renkens*[1], *K. J. Duran*[1], *E. van Binsbergen*[1], *M. Tavakoli-Yaraki*[1], *R. Hochstenbach*[1], *L. T. van der Veken*[1], *E. Cuppen*[1,2], *W. P. Kloosterman*[1];

[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*Hubrecht Institute, Utrecht, Netherlands.*

Chromothripsis represents an extreme class of complex chromosome rearrangements (CCRs) with major effects on chromosomal architecture. Although recent studies have associated chromothripsis with congenital abnormalities, the incidence and pathogenic effects of this phenomenon require further investigation. Here, we analyzed the genomes of three families in which chromothripsis rearrangements were transmitted from a mother to her child. The chromothripsis in the mothers resulted in completely balanced rearrangements involving 8-23 breakpoint junctions across 3-5 chromosomes. Two mothers did not show any phenotypic abnormalities, although 3-13 protein coding genes were affected by breakpoints. Unbalanced but stable transmission of a subset of the derivative chromosomes caused apparently de novo complex copy number changes in two children. This resulted in gene dosage changes, which are likely responsible for their severe congenital phenotypes. In contrast, one child with severe congenital disease harbored all three chromothripsis chromosomes from his healthy mother, but one of the chromosomes acquired de novo rearrangements leading to copy number changes. These results show that the human genome can tolerate extreme reshuffling of chromosomal architecture, including breakage of multiple protein coding genes, without noticeable phenotypic effects. The presence of chromothripsis in healthy individuals affects reproduction and is expected to substantially increase the risk of miscarriages, spontaneous abortions and severe congenital disease.

C14.1

External Quality Assessment of Genetic Counselling: experiences with the first pilot assessment

C. M. A. van Ravenswaaij-Arts[1], *C. van Asperen*[2], *E. Dequeker*[3], *L. Tranebjaerg*[4], *L. Garavelli*[5], *B. Peterlin*[6], *B. Cope*[7], *H. Skirton*[8], *R. Hastings*[9], *ESHG Genetic Services Quality Committee;*

Genetics UzLeuven, Leuven, Belgium,* [4]*University of Copenhagen, Copenhagen, Denmark,* [5]*S. Maria Nuova, Reggio Emilia, Italy,* [6]*UMC Ljubljana, Ljubljana, Slovenia,* [7]*Genetic Alliance UK, London, United Kingdom,* [8]*University of Plymouth, Plymouth, United Kingdom,* [9]*John Radcliffe Hospital, Oxford, United Kingdom.*

Quality assessment has long been associated with laboratory, but not clinical, services. To address this gap, in 2012 the ESHG Genetic Services Quality Committee (GSQC) explored the needs for a European Quality Assessment (EQA) scheme for genetic counselling. All European national societies of human genetics were surveyed. All participating 15 countries expressed a need for an EQA for genetic counselling services.

A proposal for achieving an EQA for genetic counselling was launched at an ESHG satellite symposium in 2013. The working group wrote four case scenarios in the fields of cardiogenetics, oncogenetics, monogenetic disorders and dysmorphology. Each scenario started with a referral letter and consisted of multiple stages, to reflect an episode of clinical care. At each stage more information was given and a number of questions presented. For each question, consensus answers were obtained by the author of the case, a patient organisation and at least two other experts.

A total of 16 genetic centres from 11 countries participated in the pilot EQA

and all answers were reviewed by two assessors per case. The whole process was evaluated, both by the assessors and by the participating centres (post pilot EQA questionnaire). The results highlighted some differences in genetic counselling practice across Europe and indicated that few centres offered psychosocial support. The conclusion was that an EQA for genetic counselling is feasible and highly educational. A second exploratory pilot EQA will be run in 2015 to further improve the process. The EQA process will be demonstrated using one of the educational pilot cases.

C14.2

Hereditary breast and ovarian cancer syndrome: successful, large-scale implementation of a group-based approach to genetic counseling.

P. R. Benusiglio[1], *M. Di Maria*[1], *A. Jouinot*[1], *B. Claret*[2], *D. Boinon*[3], *D. Lejri*[1], *O. Caron*[1];
[1]*Gustave Roussy Cancer Campus. Département de Médecine Oncologique, Villejuif, France,* [2]*Gustave Roussy Cancer Campus. Département de Psycho-Oncologie, Villejuif, France,* [3]*Gustave Roussy Cancer Campus. Département de Psycho-Oncologie, Villejuif, France.*

Introduction. In the past two years, there has been a large increase in referrals to our cancer genetics clinic of patients with suspected BRCA1/2-associated hereditary breast and ovarian cancer syndrome (HBOC), probably due to the "Angelina Jolie effect". However, staffing has not increased in proportion, and dealing with the demand has proved challenging. A group-based approach to genetic counseling seemed an appealing way to increase efficiency. Methods. From 9-October-2014, we systematically invited referred patients aged 35-75, with a good performance status and in which assessment for HBOC was warranted, to group-based counseling. It consisted of a 30-minute group session with a genetic counselor and a cancer geneticist, followed by rapid face-to-face standard counseling, and genetic testing when appropriate. Patients completed a form assessing their general understanding of cancer genetics before and after the group session, and a custom-made satisfaction questionnaire before leaving the clinic. Results. As of 23-January-2015, 75 patients with a mean age of 50 had attended group-based counseling. The number of patients seen in a three-hour slot was 6, compared to 4 with traditional individual counseling. Cancer genetics understanding improved by an average of 3/10 points after the group session, and the average satisfaction score was 9.5/10. Conclusion. Large-scale, systematic group-based genetic counseling is feasible in patients with suspected HBOC. This novel approach has allowed us to increase efficiency in the context of an ever-increasing number of referrals, and to maintain waiting times of about a month between the referral and the consultation. Updated data including a greater number of patients will be presented at ESHG 2015.

C14.3

Experiences of systematic genetic testing involving women recently diagnosed with epithelial ovarian cancer: a qualitative study

H. E. Shipman[1], *M. Tischkowitz*[1,2], *S. Flynn*[3], *C. MacDonald-Smith*[4], *N. Hulbert-Williams*[3], *GTEOC Study team;*
[1]*East Anglian Medical Genetics Service, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,* [2]*Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom,* [3]*Chester Research Unit for the Psychology of Health, University of Chester, Chester, United Kingdom,* [4]*North Wales Cancer Treatment Centre, Betsi Cadwaladr University Health Board, Rhyl, United Kingdom.*

Newly available rapid genetic testing (RGT) for BRCA1/2 makes it possible to identify mutation carriers soon after cancer diagnosis. There are benefits for directing women's treatment and providing information for families, but there are ethical concerns about testing this group at this point. These women may be elderly, unwell and may have little or no family history of cancer. Those found to have a mutation then have the task of communicating this sensitive information to their families.

We explore the experiences of women recently diagnosed with epithelial ovarian cancer who have been offered RGT through a project considering the feasibility of integrating RGT into routine oncology services (The GTEOC Study). Using data collected from twelve semi-structured interviews with women that were analysed using Interpretive Phenomenological Analysis, we consider how individuals make sense of genetic testing within their broader cancer and life experiences.

Our results highlight the sensitivity of the timing of discussions about genetic testing during a woman's cancer journey. Women have much emotional work to do as they confront their cancer diagnosis, their own mortality and the impact on their family and others. Though genetic testing is welcomed during this time by the women we interviewed, the burdens and complexities are acknowledged. This foregrounds the necessity for appropriate support for this patient group. Our work contributes to current discussions about the ethical issues arising from the introduction of genetic testing in mainstream medicine.

C14.4

Sharing information with children and young people about adult-onset inherited conditions: Using evidence to improve services for parents and their children

K. Forrest Keenan, *L. McKee, Z. Miedzybrodzka;*
University of Aberdeen, Aberdeen, United Kingdom.

Background: A growing number of young people are undertaking predictive testing for adult-onset conditions. However, there is a lack of empirical evidence about their information and support needs. Aim: To produce the evidence for, and to develop materials to help parents and professionals in sharing information with young people about serious adult-onset genetic conditions.

Methods: Clinic observations and interviews with young people and parents; an analysis of practitioners' case notes and online web fora for young people; collaborations with patient groups and interviews with genetics professionals. We used two adult-onset inherited disorders as exemplars: Huntington's disease and Familial Hypercholesterolaemia.

Results: In both patient groups the process of genetic testing could be a positive and empowering experience for young people, but for some patients there were gaps in the provision of age-appropriate information and emotional support, resulting in poor experiences. Children and young people could question their own risk earlier than literature suggests. Genetics professionals used a range of strategies to support communication between parents and children, but one third gave limited advice and felt under-skilled in this area. Some parents also felt inadequate time was given to discussion of disclosure strategies. We helped patient groups develop evidence based materials for children and young people.

Conclusions: Practitioners should give serious consideration to parents concerns about disclosure even in treatable inherited conditions, and the provision of age-appropriate information. Facilitating family communication should be a goal of genetic counselling, but training for practitioners is needed.

KFK was funded by a CSO Fellowship, Scottish Government.

C14.5

Attitudes towards returning data to participants in sequencing research

A. Middleton[1], *C. Wright*[1], *H. Firth*[1], *M. Hurles*[1], *M. Parker*[2], *on behalf of the DDD study;*
[1]*Wellcome Trust Sanger Institute, Cambridge, United Kingdom,* [2]*Ethox, University of Oxford, Oxford, United Kingdom.*

Genome-wide sequencing in a research setting has the potential to reveal health-related information of personal or clinical utility for the study participant. There is increasing pressure to return research findings to participants that may not be related to the project aims, particularly when these could be used to prevent disease. This cross-sectional, web-based survey investigated the attitudes of 6944 individuals from 75 countries towards returning results from genome research. Participants included four relevant stakeholder groups: 4961 members of the public, 533 genetic health professionals, 843 non-genetic health professionals and 607 genomic researchers who were invited via traditional media, social media and professional email list-serve. Treatability and perceived utility of genomic data were deemed important with 98% of stakeholders personally interested in learning about preventable life-threatening conditions. Participants appeared to assign a value to genomic data, there was a sense of 'if the scientists know it, I'd like to know it too' - 59% were interested in being able to receive their raw sequence data, even though the majority would not do anything with this. 52% of participants felt it was important that genomic researchers kept reanalysing their data and had the ability to update them periodically with new findings; 85% of participants felt that if something serious was discovered they would like this information delivered to them directly by an appropriately trained health professional. This social studies study offers the largest dataset, published to date, of attitudes towards issues surrounding the return of results from sequencing research.

C14.6

Population-based Preconception Carrier Screening: how do potential users view a preconception test for 70 severe autosomal recessive diseases?

M. Plantinga[1], *E. Birnie*[1], *S. Kaplan*[1], *M. A. Verkerk*[2], *A. M. Lucassen*[3], *A. V. Ranchor*[4], *I. M. van Langen*[1];
[1]*University of Groningen, University Medical Centre Groningen, Department of Genetics,*

Groningen, Netherlands, [2]University of Groningen, University Medical Centre Groningen, Department of Internal Medicine, Groningen, Netherlands, [3]University of Southampton, Faculty of Medicine, Clinical Ethics and Law, Southampton, United Kingdom, [4]University of Groningen, University Medical Centre Groningen, Department of Health Psychology, Groningen, Netherlands.

Background
A preconception carrier screening (PCS) test can detect whether a couple has an increased risk of having a child with a monogenetic disease. Next-generation sequencing (NGS) allows the testing of many genes or diseases simultaneously. The University Medical Center Groningen (UMCG) developed an NGS PCS test for couples covering 70 very severe, autosomal recessive diseases simultaneously and screening for all variants. This is the first non-commercial population-based PCS test to be offered to prospective couples in a healthcare setting in Europe. So far, little is known about how potential users view such a population-based PCS test.
Methods
We examined potential users' intentions to undergo the test and preferences regarding who should offer the test. Data was collected in March 2014 by means of an online survey among 500 people belonging to the target population (people aged 18-40, with a partner and living in the Netherlands).
Results
One third of the respondents said they intend to take this test were it to be offered. They prefer this to be offered via their GP and via face-to-face pre-test consultation. Fifty-eight percent is willing to pay for the test, up to a cost of 5,000 euro. Testing for later onset, treatable diseases or even traits (e.g sportivity) is valued less. The UMCG will start an implementation study soon in which the PCS test is supplied via selected GPs in the north of the Netherlands. Our first aim is to measure the uptake, practical feasibility and psychological impact of offering the test.

C15.1
Genome-wide association study of 200,000 individuals identifies 18 genome-wide significant loci and provides biological insight into human cognitive function

T. Esko[1,2,3], *on the behalf of Social Science Genetic Association Consortium (SSGAC); [1]Estonian Genome Center, University of Tartu, Tartu, Estonia, [2]Boston Children's Hospital, Boston, MA, United States, [3]Broad Institute of Harvard and MIT, Cambridge, MA, United States.*

Educational attainment, measured as years of schooling, is commonly used as a proxy for cognitive function. A recent genome wide association study (GWAS) of educational attainment conducted in a discovery sample of 100,000 individuals identified and replicated three genome-wide significant loci. Here, we report preliminary results based on conducted in 200,000 individuals. We replicate the previous three loci and report 15 novel, genome-wide significant loci for educational attainment. A polygenic score composed of 18 single nucleotide polymorphisms, one from each locus, explains ~0.4% of the variance educational attainment. Applying data-driven computational tools, we find that genes in loci that reach nominal significance ($P < 5.0x10-5$) strongly enrich for 11 groups of biological pathways (false discovery rates < 0.05) mostly related to the central nervous system, including dendritic spine morphogenesis ($P=1.2x10-7$), axon guidance ($P=5.8x10-6$) and synapse organization ($P=1.7x10-5$), and show enriched expression in various brain areas, including hippocampus, limbic system, cerebral and entorhinal cortex. We also prioritized genes in associated loci and found that several are known to harbor genes related to intellectual disability (SMARCA2, MAPT), obesity (RBFOX3, SLITRK5), and schizophrenia (GRIN2A) among others. By pointing at specific genes, pathways and brain areas, our work provides novel biological insights into several facets of human cognitive function.

C15.2
Systematic phenotype-based deconvolution of intellectual disability disorders into biologically coherent modules

C. Zweier[1], *K. Kochinke[2], B. Nijhof[2], M. Fenckova[2], P. Cizek[3], F. Honti[4], S. Keerthikumar[3], M. A. W. Oortveld[2], T. Kleefstra[2], J. M. Kramer[2,5], C. Webber[4], M. A. Huynen[3], A. Schenck[2]; [1]Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, [2]Department of Human Genetics, Donders Institute for Brain, Cognition and Behaviour, Radboud university medical center, Nijmegen, Netherlands, [3]CMBI, Radboud Institute for Molecular Life Sciences, Radboud university medical centre, Nijmegen, Netherlands, [4]MRC Functional Genomics Unit, Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, United Kingdom, [5]Department of Physiology and Pharmacology, Schulich School of Medicine and Dentistry, Western University, London, ON, Canada.*

Intellectual disability (ID) disorders, due to their frequency and enormous genetic and phenotypic heterogeneity, represent a major unmet challenge in health care and diagnostics. A comprehensive and systematic understanding of ID disorders and their underlying biology is still limited. We established a curated database of 650 currently known ID genes, linked them to various functional datasets and classified them according to ID manifestation and severity and 27 associated core clinical features such as organic or neurological anomalies. Using this integrated resource we show that ID genes are substantially enriched in protein-protein interactions and co-expression, highest in the hippocampus. 86% of ID genes fall into 32 common Gene Ontology based molecular processes: metabolism and nervous system development among the largest, and hedgehog and glutamate signalling among the most enriched groups. Identification of highly enriched functional themes and phenotypes systematically revealed characteristic phenoprofiles of process-defined IDopathies including chromatin- and DNArepairopathies. Strikingly, classification of ID genes according to their associated clinical phenotypes efficiently breaks them down into subsets with significantly elevated biological coherence and allows ID genes to predict each other. Furthermore, we utilised custom-made datasets on ID gene function in Drosophila. Early onset behavioural and specific morphological wing phenotypes were characteristic for ID genes in general, and several fly phenotypes were particularly representative for specific human clinical phenotype classes. Our study and resource provide systematic insights into the molecular and clinical landscape of ID disorders and prove the utility of systematic human and cross-species phenomic analyses in highly heterogeneous genetic disorders.

C15.3
9.6% of mouse gene knockouts show abnormal neuroanatomy: a resource to identify genes and gene networks involved in ID in human

*B. YALCIN[1,2], **A. Mikhaleva**[1], V. E. Vancollie[3], M. Kannan[2], H. Whitley[2], A. Edwards[4], C. Wagner[2], J. Estabel[3], C. J. Lelliott[3], J. K. White[3], Sanger Mouse Genetics Project, D. J. Adams[3], D. A. Keays[5], J. Flint[4], Y. Herault[2], A. Reymond[1]; [1]Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland, [2]Institute of Genetics and Molecular and Cellular Biology, Illkirch, France, [3]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [4]Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, [5]Research Institute of Molecular Pathology, Vienna, Austria.*

Intellectual disability (ID) affects 1-3% of the general population. Genetic mutations account for about half of the currently undiagnosed cases, and despite recent successes in identifying some of the mutations responsible, it has been suggested that up to 1,000 further genes remain to be identified. To identify genes involved in brain malformation and potentially associated with ID, we are collaborating with the Sanger Mouse Genetics Project (MGP), allied to the International Mouse Phenotyping Consortium (IMPC), to systematically study the neuroanatomy of the MGP/IMPC knockout mouse strains. We are measuring a standardized set of 78 brain parameters across 22 brain regions to detect a variety of mechanisms that underlie brain malformation disorders, such as aberrant cell proliferation, neuronal migration defects or elevated cell death rates.
So far, we have assessed brain defects in 825 knockout mouse genes. These preliminary data yielded success with the identification of 40 known ID genes including Ap4e1, Cenpj, Chd7, Mcph1, Sc4mol and Ube3b demonstrating the pertinence of our approach. We also discovered 41 other genes including Mta1, Ccdc104, Caprin2 and Dusp3, which when disrupted caused modification of brain structures and thus are good candidate genes for ID.
Our study is the largest screen of brain morphology from the MGP/IMPC. It shows that we can detect abnormalities in about 10% of knockout mouse mutants, and that these translate into human pathology. This offers a complementary resource to human genetic studies.
The project is funded by the French National Research Agency and the Swiss National Science Foundation.

C15.4
Finding new connections in the transcriptional regulation of Lysine-specific demethylase 5C (KDM5C) a disease gene involved in syndromic and non-syndromic XLID

A. Padula[1], *L. Poeta[1], C. Shoubridge[2], A. Ranieri[1], K. Helin[3], J. Gecz[2], C. Schwartz[4], M. V. Ursini[1], H. vanBokhoven[5], M. G. Miano[1]; [1]IGB-CNR, Naples, Italy, [2]University of Adelaide, Adelaide, Australia, [3]University of Copenhagen, Copenhagen, Denmark, [4]Greenwood Genetic Center, Greenwood, SC, United States, [5]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

X-linked Intellectual Disability (XLID) is a group of heterogeneous disorders caused by mutations in genes on the X chromosome. Disease mutations in ~10% of X chromosome genes are implicated in causing XLID disorders in ~50% of known XLID disorders.
Mutations in Lysine-specific demethylase 5C (KDM5C) gene have been reported as an important cause of both syndromic and non-syndromic (XLID)

in males. KDM5C is a chromatin remodelling regulator with histone demethylase activity for di- and trimethylated histone 3 lysine 4 acting as transcriptional repressor during brain development and neuronal maturation. With Regulatory Element-1-Silencing Transcription factor (REST), a critical regulator of the spatio-temporal transition of neural progenitors to neurons, KDM5C co-occupies the promoters of a subset of REST target genes.
We identified a disease path, linking functionally KDM5C to another XLID/Epilepsy gene, encoding the homeotic transcription factor ARX, whose mutations impair severely KDM5C transcript regulation.
Furthermore, we analysed two additional XLID proteins that also bind KDM5C promoter. They are PHD Finger Protein 8 (PHF8), a H3K9 demethylase; and Zinc Finger Protein 711 (ZNF711), a transcriptional factor, which role is almost unknown. We observed that PHF8 and ZNF711, which co-occupy the target promoter, induce cooperatively the KDM5C stimulation. This activity seems to be ARX-independent and we propose that the transcriptional induction by ARX does not synergize with the action of the PHF8/ZNF711 complex. Remarkable, our findings open new perspectives towards the exploitation of rational strategies to treat the growing group of ID and cognition diseases that are caused by chromatin and/or transcriptional defects.

C15.5
HCFC1 is a dosage sensitive transcriptional coregulator of neurodevelopment that influences neural progenitor and neuronal cell function

L. A. Jolly[1,2], *L. S. Nguyen*[3], *D. Domingo*[1], *Y. Sun*[1], *S. Barry*[1,2], *M. Hancarova*[4], *P. Plevova*[5], *M. Vlckova*[4], *M. Havlovicova*[4], *V. M. Kalscheuer*[6], *C. Graziano*[7], *T. Pippucci*[7], *Z. Sedlacek*[4], *E. Bonora*[7], *J. Gecz*[1,2];

Initially we implicated HCFC1 in X-linked intellectual disability (XLID) by a non-coding, regulatory mutation. The single base change abolished binding of the YY1 transcription factor at a highly conserved sequence proximal to the HCFC1 transcription start site resulting in loss of transcriptional repression. We employed ex-vivo models of embryonic neural development to show that this change was likely pathogenic; over-expression of HCFC1 caused cell cycle exit and differentiation of neural progenitor cells (NPCs), and reductions in neurite growth of hippocampal neurons. Intriguingly, missense mutations that result in almost complete loss of HCFC1 have also been reported to cause Cobalamin type X (CblX), a VitaminB12 metabolic disorder with severe neurodevelopmental impairment including intractable epilepsy. We extended our studies to show that in contrast to over-expression, modest reduction (~50%) of Hcfc1 expression promoted the cell cycling of NPCs at the expense of differentiation, and enhanced neurite growth of neurons. We further identified four additional missense variants in HCFC1 that segregate with ID in four families. Three of these variants caused partial loss of function in multiple cell based assays, including complementation of neurite growth. In line with only partial loss of function, metabolic features of CblX were largely absent in affected individuals. Our identification and functional assessment of HCFC1 mutations together with descriptions of a broadened phenotypic spectrum reveals an emerging genotype-phenotype correlation, dependent also on HCFC1 abundance and not just function. Furthermore, we have identified relevant disease mechanisms of ID that converge on the behaviour of cells present during embryonic stages of brain development and Cobalamin metabolism.

C15.6
Clinical and experimental evidence establish a link between *KIF7* and *C5orf42*-related ciliopathies

R. Asadollahi[1], *J. E. Strauss*[2], *M. Zenker*[3], *O. Beuing*[4], *S. Edvardson*[5], *O. Elpeleg*[6], *P. Joset*[1], *T. M. Strom*[7], *D. Niedrist*[1], *B. Oneda*[1], *S. Azzarello-Burri*[1], *M. Papik*[1], *A. Baumer*[1], *K. Steindl*[1], *A. Schinzel*[1], *E. T. Stoeckli*[2], *A. Rauch*[1];

Joubert syndrome (JBTS) is a ciliopathy characterized by developmental delay, oculomotor apraxia, breathing abnormalities and a distinctive midhindbrain malformation on brain imaging known as molar tooth sign. It is genetically heterogeneous with >20 causal genes identified to date and its clinical and neuroradiologic findings overlap with other ciliopathies such as acrocallosal syndrome (ACLS). However, craniofacial manifestations of macrocephaly, prominent forehead and hypertelorism have been distinctive features of ACLS among ciliopathies. Here, we evaluated eight families with ACLS-like craniofacial appearance and other ciliopathy features by whole exome or targeted Sanger sequencing which revealed biallelic mutations affecting *KIF7*, the ACLS gene, or *C5orf42*, the JBST gene. Given the known role of KIF7 in primary cilia and Hedgehog signaling, we wondered if there was a functional connection to C5orf42 which's function has remained unknown. Therefore, we also assessed C5orf42 by evaluation of the primary cilia in affected individuals and *in ovo* RNAi silencing in chicken embryos. Consequently, in addition to the clinical overlap between *KIF7* and *C5orf42*-related craniofacial features, we found abnormal primary cilia in the *C5orf42*-patients and evidenced its role in craniofacial development, pathfinding of commissural axons and neural circuit formation in developing chicken embryos.

C16.1
Systematic evaluation of patients with idiopathic short stature using whole exome sequencing

C. T. Thiel[1], *N. N. Hauer*[1], *S. Schuhmann*[1], *E. Schöller*[1], *M. T. Wittmann*[1], *S. Uebe*[1], *A. B. Ekici*[1], *H. Sticht*[2], *H. Dörr*[3], *A. Reis*[1];
[1]*Institute of Human Genetics Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany,* [2]*Institute of Biochemistry Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany,* [3]*Department of Pediatrics and Adolescent Medicine Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany.*

Shortness of stature is a common medical concern in childhood and has an incidence of 3% in the general population. After excluding defects of the growth hormone pathway and recognizable syndromes the underlying cause remains unknown in approximately 70-80% of patients.
In some of these patients the underlying diagnosis is omitted by the lack of clinical features characteristic for known syndromic forms of short stature. To address this in patients with idiopathic short stature we thoroughly built a study group of more than 500 families with idiopathic short stature. We systematically selected 100 individuals where growth hormone defects, common genetic causes of short stature or copy number variations were excluded and performed whole exome sequencing. Variants were selected unbiased based on all modes of inheritance in agreement with the segregation in the families and their potential effect on protein function using our NGS Variant Analyzer software.
We confirmed mutations in known short stature genes in 11 patients. All these syndromes have been reported to be associated with further clinical issues providing mandatory medical guidance for these patients.
Furthermore, we recognized recessive, dominant and x-linked inherited variants in novel candidate genes involved in epigenetic modification, cell cycle regulation, ubiquitination and protein synthesis.
In conclusion, whole exome sequencing identified the underlying genetic defect in 11% of the patients with idiopathic short stature. As the clinical spectrum of most genetic defects is yet to be explored, an unbiased genetic analysis of patients with idiopathic short stature can establish a diagnosis in these cases.

C16.2
Mutations in the core NHEJ components LIG4 and XRCC4 result in microcephalic primordial dwarfism

Non-homologous end joining (NHEJ) is a vital cellular process repairing

DNA double strand breaks. Previously, mutations in NHEJ pathway components have predominantly been associated with severe combined immunodeficiency, consistent with the requirement for NHEJ during V(D)J recombination to ensure diversity of the adaptive immune system. In contrast, we recently described biallelic truncating mutations in *LIG4* as a common cause of microcephalic primordial dwarfism (MPD), a disorder of prenatal-onset extreme global growth failure; identifying a genotype-phenotype correlation where the severity of growth failure is related to disruption of the XRCC4 binding domain in LIG4. LIG4 is required for the final ligation step in NHEJ forming a complex with XRCC4 and NHEJ1. Given its candidacy, we have now identified biallelic *XRCC4* mutations in a further five families and provide confirmatory cellular studies establishing *XRCC4* as a disease causing gene. Both patient groups show similar anthropometric measurements with severe microcephaly and short stature as well as similar facial features. However, in contrast to LIG4 patients, pancytopenia leading to bone marrow failure has not been observed in XRCC4 patients and overt immunodeficiency is not apparent on clinical investigation despite reduced junctional diversification. These findings suggest differential developmental requirements for growth and immunity by specific components of the NHEJ pathway. We found *LIG4* and *XRCC4* mutations to be the second most common cause of MPD in a large patient cohort behind mutations in *PCNT* (MOPDII) highlighting the importance of NHEJ, and LIG4-XRCC4 binding in particular, in promoting normal growth.

C16.3
Loss-of-Function Mutations in WDR73 Are Responsible for Microcephaly and Steroid-Resistant Nephrotic Syndrome: Galloway-Mowat Syndrome

Galloway-Mowat syndrome is a rare autosomal-recessive condition characterized by nephrotic syndrome associated with microcephaly and neurological impairment. Through a combination of autozygosity mapping and whole-exome sequencing, we identified WDR73 as a gene in which mutations cause Galloway-Mowat syndrome in two unrelated families. WDR73 encodes a WD40-repeat-containing protein of unknown function. Here, we show that WDR73 was present in the brain and kidney and was located diffusely in the cytoplasm during interphase but relocalized to spindle poles and astral microtubules during mitosis. Fibroblasts from one affected child and WDR73-depleted podocytes displayed abnormal nuclear morphology, low cell viability, and alterations of the microtubule network. These data suggest that WDR73 plays a crucial role in the maintenance of cell architecture and cell survival. Altogether, WDR73 mutations cause Galloway-Mowat syndrome in a particular subset of individuals presenting with late-onset nephrotic syndrome, postnatal microcephaly, severe intellectual disability, and homogenous brain MRI features. WDR73 is another example of a gene involved in a disease affecting both the kidney glomerulus and the CNS.

C16.4
Mutations in PLK4, encoding a master regulator of centriole biogenesis, and its substrate, TUBGCP6, cause microcephaly, growth failure and retinopathy

Centrioles are microtubule-based structures that form the core of the centrosome and are essential for ciliogenesis. However, mutations in centriole biogenesis genes have been reported in primary microcephaly and Seckel syndrome, disorders without the hallmark clinical features of ciliopathies. Through linkage analysis and exome sequencing, we have identified mutations in the gene, PLK4, encoding PLK4 kinase, a master regulator of centriole duplication, in individuals with microcephalic primordial dwarfism. PLK4 individuals also demonstrated retinopathy, a phenotypic feature normally associated with cilium dysfunction. Two distantly related individuals are homozygous for a frameshift mutation, where detailed molecular characterization revealed a previously unrecognized alternative isoform which rescued the null allele. An additional mutation was identified in a large consanguineous family, where splicing altered the reading frame of the terminal exon. Using cellular and developmental systems we established that, through reduction in centriole number, PLK4 mutations resulted in aberrant growth and retinal phenotypes. Exome analysis and resequencing also identified multiple individuals with mutations in the substrate of PLK4, TUBGCP6, in individuals with microcephalic primordial dwarfism and additional congenital anomalies, including retinopathy, thereby extending the human phenotypic spectrum associated with centriole dysfunction. Furthermore, we establish that different levels of impaired PLK4 activity result in growth and cilia phenotypes, providing a mechanism by which microcephaly disorders can occur with or without ciliopathic features.

C16.5
Mutations in TUBGCP4 alter microtubule organization via the γ-tubulin ring complex γTuRC in autosomal recessive microcephaly with chorioretinopathy.

S. SCHEIDECKER;
Medical Genetics Laboratory, INSERM U1112, Institute of Genetics and medicine of Alsace (IGMA), University of Strasbourg, Strasbourg Medical School, Strasbourg, France.

Inherited congenital microcephaly is a clinically and genetically heterogeneous disorder. Autosomal dominant Microcephaly with or without Chorioretinopathy, Lymphoedema, or Mental Retardation (MCLMR) also known as Alzial syndrome has recently been attributed to mutations in KIF11. Autosomal recessive Microcephaly and Chorioretinopathy with or without Mental Retardation, abbreviated as MCMR, is a very rare entity recently described to be associated with TUBGCP6 mutations.
We have identified TUBGCP4 variants in individuals with autosomal recessive microcephaly and chorioretinopathy. Whole exome sequencing performed on one family with two affected siblings and independently on another family with one affected child revealed compound heterozygous mutations in TUBGCP4. Subsequent Sanger sequencing was performed on a panel of individuals with microcephaly and ophthalmic manifestations and one other patient was identified with compound heterozygous mutations in TUBGCP4. TUBGCP4 encodes the γ-tubulin complex protein 4, a component of the γ-tubulin ring complex (γTuRC) known to regulate the nucleation and organization of microtubules. Functional analysis of patient fibroblasts disclosed reduced levels of the γTuRC, altered nucleation and organization of microtubules, abnormal nuclear shape, and aneuploidy. Moreover, zebrafish treated with morpholinos against tubgcp4 were found to have a reduced head volume and eye developmental anomalies with chorioretinal dysplasia.
The identification of biallelic TUBGCP4 mutations described herein, as well as the very recent TUBGCP6 mutations, confirms the existence of autosomal recessive cases described as microcephaly and chorioretinopathy with or without mental retardation and provides evidence for an important role for the γTuRC in brain and eye development.

C16.6
From whole exome sequencing to functional studies in syndromic microcephaly: using zebrafish for variant testing

F. Cristofoli[1], *E. E. Davis*[2], *K. Devriendt*[3], *H. Peeters*[3], *H. Van Esch*[3], *J. R. Vermeesch*[1,3];

Leuven, Leuven, Belgium, [2]Center for Human Disease Modeling, Duke University Medical Center, Durham, NC, United States, [3]Center for Human Genetics, University Hospital Leuven, Leuven, Belgium.

Microcephaly (MC) is a clinical condition characterized by abnormal small head circumference for the respective age and sex which closely correlates with reduced brain volume and most of the times with intellectual disability. Many syndromes encompassing MC have been described and although several genes have been recently reported in literature, a massive number of unexplained cases still exist. We have collected and performed whole exome sequencing (WES) on 21 patients displaying syndromic forms of MC and on their parents for trio-based variant filtering. Since most of the index patients were sporadic, the majority of causative variants were suspected to be de novo. However, recessive models have also been taken into account. We were able to identify causative mutation in 10/21 patients. For the remaining cases, we found de novo mutations in 8 novel candidate genes. We used the zebrafish model to test the pathogenicity of candidate variants. The morphant model for one of our main candidates showed a 10% head size reduction, while preliminary mRNA overexpression data unexpectedly showed a slight head area increase. Our cohort was enriched with patients displaying de novo mutations in CASK, responsible for an X-linked syndrome of MC and pontocerebellar hypoplasia. CASK morphants displayed a pronounced head size reduction, while anti-acetylated tubulin staining revealed prominent cerebellar abnormalities. For both genes, rescue experiments and further functional assays are pending.

C17.1
RNF12 is essential for X-inactivation in female mouse embryonic stem cells, is required for female mouse development, and might be a target for future therapies to treat X-linked disorders in females: evidence from a mouse knockout model

T. S. Barakat[1,2], *J. Gribnau*[1];
[1]*Department of Reproduction and Development, Erasmus MC-University Medical Center, Rotterdam, Netherlands,* [2]*Laboratory of Embryonic Stem Cell Biology, MRC Center for Regenerative Medicine, School of Biological Sciences, University of Edinburgh, Edinburgh, United Kingdom.*

X-chromosome inactivation (XCI) in females is a crucial mechanism which equalizes X-linked gene-dosage between both sexes. In mice, a first wave of imprinted XCI occurs during cleavage stages of embryonic development, followed by X-chromosome reactivation (XCR) at the pre-implantation blastocyst, and subsequent random XCI (rXCI) in the post-implantation epiblast. rXCI can be simulated in differentiating mouse ES cells. We have previously shown that the X-encoded RNF12 protein act as a dosage-sensitive XCI-activator (PMID:19945382, PMID:21298085, PMID:24613346). When RNF12 becomes up-regulated during differentiation, it targets the pluripotency factor Rex1 for proteasomal degradation (PMID:22596162). As Rex1 is a repressor of the non-coding Xist RNA, which is crucial for initiating chromosome-wide gene-silencing, down-regulation of Rex1 by RNF12 allows female-specific Xist-expression and XCI-initiation in a stochastic manner (PMID:20083102).Here we present the generation and analysis of a novel Rnf12 knockout mouse model, and provide evidence that RNF12 is also crucial for iXCI and rXCI in vivo. Whereas Rnf12-/Y males are viable, Rnf12-/- female mice fail to undergo XCI leading to lethality at post-implantation. Rnf12-/+ animals inheriting the maternal knockout allele are lethal due to silencing of the paternal Rnf12 allele upon iXCI. Rnf12+/- females inheriting the paternal knockout allele are healthy but show an XCI-defect, with adult cells displaying XCR. This peculiar finding, together with our recent results on XCR in human induced pluripotent stem cells (Stem Cell Reports, in press), opens a new area of research which might lead to novel approaches for treating X-linked diseases, such as Rett syndrome, in females.

C17.2
Pattern of X chromosome inactivation across human tissues - insights from population-scale and single-cell RNA sequencing

T. Tukiainen[1,2], *A. Villani*[3,2], *A. Kirby*[1,2], *D. DeLuca*[2], *R. Satija*[2,4], *A. Byrnes*[1,2], *J. Maller*[1,2], *T. Lappalainen*[4,5], *The GTEx Project Consortium, A. Regev*[2], *K. Ardlie*[2], *D. MacArthur*[1,2];
[1]*Massachusetts General Hospital, Boston, MA, United States,* [2]*Broad Institute of Harvard and MIT, Cambridge, MA, United States,* [3]*Massachusetts General Hospital, Charlestown, MA, United States,* [4]*New York Genome Center, New York, NY, United States,* [5]*Columbia University, New York, NY, United States.*

Incompleteness and skewing of X chromosome inactivation (XCI) can result in biases in disease susceptibility and presentation between sexes and across individuals but the full extent and heterogeneity of XCI remains unclear. We have comprehensively profiled the landscape, regulation and variability of escape from XCI by deploying several complementary approaches based on high-throughput RNA sequencing.

Using detailed gene expression data from the GTEx consortium, we show that a large majority of previously reported escape genes demonstrate male/female expression differences detectable at population-level. For many of these genes sex-biased expression is present and directionally similar across the 38 tissues studied, a pattern distinct from autosomal sex-biased expression, suggesting XCI is tightly and uniformly regulated across human tissues. Notably, however, escape genes close to an edge of an escape domain (e.g. KAL1) show more tissue heterogeneity and subtle sex-bias.

To complement these observations and assess individual-level variability in escape we have analyzed single cell RNA-seq data across two tissue types, and assessed the allelic imbalance across the X chromosome from deep sequencing of 17 tissues from a female with non-random XCI. These analyses highlight well-known escape genes (e.g. USP9X), replicate novel candidates from the population-scale analyses (e.g. ZRSR2) and confirm variable escape genes (e.g. TIMP1) and elaborate the underlying dynamics. While finding little evidence for tissue-specific escape the analyses demonstrate tissue heterogeneity in expression from the inactive X (e.g. GYG2).

Together these analyses provide a comprehensive view of the landscape of escape from XCI in adult tissues, essential for understanding the impact of this process on sex differences and inter-individual variability.

C17.3
Genome wide DNA promoter methylation: Differences in human subcutaneous vs. omental visceral adipose tissue

M. Keller[1], *L. Hopp*[2], *X. Liu*[1], *K. Rohde*[1], *M. Klös*[1], *A. Dietrich*[3], *M. Schön*[4], *D. Gärtner*[4], *T. Lohmann*[5], *M. Dreßler*[5], *M. Stumvoll*[1,6], *P. Kovacs*[1], *H. Binder*[2], *M. Blüher*[6], *Y. Böttcher*[1];

Background: Differences in DNA methylation pattern between subcutaneous adipose tissue (SAT) and omental visceral adipose tissue (OVAT) may help, together with corresponding changes in the mRNA profile, to elucidate variances in metabolic activity. In the present study we examined genome wide promoter methylation and mRNA expression pattern in 80 paired human SAT and OVAT samples including lean as well as obese subjects.

Methods: DNA methylation analysis was performed using methylated DNA immunoprecipitation and subsequent hybridising on Affymetrix Human Promoter 1.0R tilling arrays. Expression profiles were generated using Illunima human HT-12 chips. All genes with at least 30% methylation difference between SAT and OVAT or lean and obese subjects in the same fat depot were taken forward to overlap analysis with corresponding mRNA expression levels.

Results: We identified 35 genes in the lean and 38 in the obese subgroup conferring negative correlation between DNA methylation and mRNA expression comparing SAT and OVAT. 37 genes were found in the SAT and 76 in the OVAT subgroup comparing lean and obese individuals. The gene lists included known candidate genes such as PPARG but also unexpected genes, e.g. BHMT.

Conclusion: To the best of our knowledge, we show the first genome wide epigenetic data set comparing SAT and OVAT in a considerably large cohort. We identified significant differences in genome wide DNA methylation pattern in paired human SAT and OVAT samples from lean and obese subjects with corresponding changes in mRNA levels. This work helped to identify novel interesting genes related to human obesity.

C17.4
Mapping genetic and epigenetic factors influencing human hippocampal gene expression

A. Hofmann[1], *H. Schulz*[2], *A. Ruppert*[3], *S. Herms*[1,3], *K. Pernhorst*[4], *C. Wolf*[5], *N. Kerbalai*[5], *O. Stegle*[5], *D. Czamara*[5], *S. Sivalingam*[1], *A. Hillmer*[6], *B. Pütz*[5], *A. Woitecki*[4], *S. Schoch*[4], *A. J. Forstner*[1], *B. Müller-Myhsok*[5], *M. M. Nöthen*[1], *T. Sander*[2], *A. Becker*[4], *P. Hoffmann*[1,3,7], *S. Cichon*[3,7];

Genome-wide association studies have detected multiple loci associated with psychiatric disorders. The majority of these associated variants are observed in noncoding regions and their functional effects are unclear. Novel

methods allow to systematically investigate the regulatory effects of genetic variants by screening the genome for correlations between allelic variants and gene expression (expression Quantitative Trait Loci / eQTLs) or DNA methylation (meQTLs). Several studies have investigated the occurrence of QTLs in human brain tissue; however the overlap of QTLs between these studies is relatively low.

We employed 150 fresh frozen hippocampal biopsy samples derived from surgery of patients with chronic pharmaco-resistant temporal lobe epilepsy and performed genome-wide SNP genotyping, expression and methylation profiling. Data from 115 brain samples was correlated using a linear regression model. To limit the effect of confounding factors, surrogate variables were included.

At a false discovery rate threshold of 5%, 641 RNA transcripts and 19,953 CpGs showed a genetic regulation by common variants in cis. Enrichment testing of our QTL data among the top hits from the public NHGRI GWAS catalogue revealed an overlap for brain disorders.

Overall, we present an integrative functional analysis to explore the effects of common DNA sequence variants on DNA methylation and mRNA expression. In contrast to all published studies, our samples were collected from fresh frozen and not post-mortem brain tissue. Therefore, the identified QTLs provide an extremely valuable resource for functional annotation of SNPs and will help guiding the interpretation of GWAS hits in genetically complex brain disorders.

C17.5

Analysis of monoallelic expression in human individual cells revealed novel imprinting genes.

C. Borel, *F. Santoni, M. Garieri, E. Falconnet, P. Ribaux, S. E. Antonarakis; University of Geneva Medical School, Geneva, Switzerland.*

Genomic imprinting is defined as the mutually exclusive expression of either the paternally or maternally inherited allele. Imprinted genes are implicated in the etiology of rare syndromes and have been associated with common diseases such as diabetes and cancer. We aim to identify novel imprinting genes using a Single-Cell (SC) RNA sequencing approach. The detection of average to low expressed genes allows a more comprehensive profiling of the allelic imbalance of each gene as previously reported (Borel et al, AJHG, 2015). From the proband of a family trio, 380 individual fibroblasts were RNA sequenced and more than 770'000 heterozygous SNVs were identified by WGS (25x). For each gene, we analysed the allelic specific expression using an in-house pipeline. We modeled the likelihood of a gene to be monoallelically expressed with a beta-binomial distribution and evaluated the significance of the aggregate monoallelic ratio (reads sum of the most frequent allele per site / total reads) with the log-likelihood test. Genes presenting with a significant (adjusted p-value <0.01) aggregate monoallelic ratio between 0.9-1 were retained. We were able to detect 634 putative imprinted genes and 16 known imprinted genes. We validated 118 of these genes in 165 SC fibroblasts from an independent individual; in addition, 19 were imprinted in 48 SC lymphoblasts from the same individual. A SC transcriptome analysis provides an unprecedented opportunity to discover the full repertoire of imprinted genes per cell type, and will contribute to the understanding of the molecular pathophysiology of genetic disorders. C.B. and F.S. contributed equally.

C17.6

Novel method reveals a large number of expression quantitative trait loci (eQTLs) influencing transcript levels in a Parent-of-origin fashion

A. F. McDaid[1], *T. Esko*[2], *L. Franke*[3], *Z. Kutalik*[1];
[1]*Institute of Social and Preventive Medicine (IUMSP), Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland,* [2]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [3]*University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

We investigate expression quantitative trait loci (eQTLs) and search for SNPs that have a parent-of-origin effect (POE) with respect to transcript levels in cis. We applied our recently published algorithm [Hoggart et al 2014] to tease out SNPs where the contribution of the maternal allele to the nearby gene expression is different to that of the paternal allele. In the case where each parent's allele has a different effect, the variance in the expression levels within the heterozygous group will be larger than the variance within either homozygous group. We used genome-wide genotyping and gene-expression data from the EGCUT and Groningen cohorts and ran the quicktest software to estimate the difference in effects.

Controlling the type I error at 5%, we selected 4,162 of the 59 million SNP-gene pairs, where we could reject the null hypothesis of no difference between paternal and maternal effects. We applied conservative pruning (based on LD) to end up with 495 candidate lead SNP-gene expression pairs, where the parents' effects are expected to be different. By combining the marginal effects from [Westra et al 2013] and our observed POE estimates for the differences between maternal and paternal effects we found that 135 of these 495 candidates exhibit classical POE, i.e. where the effect from one parent is exactly zero.

These 135 candidates are currently being validated in ~700 trios from the Framingham study to confirm that the expression levels differ between heterozygous individuals that inherited the two alleles from different parents.

Recently, we described *CHCHD10* as a novel gene responsible for mtDNA instability disorder by studying a large family with a late-onset phenotype including motor neuron disease, cognitive decline looking like frontotemporal dementia (FTD), cerebellar ataxia and mitochondrial myopathy with accumulation of multiple mtDNA deletions. Subsequently, other groups and ourselves, identified other *CHCHD10* mutations in several cohorts with frontotemporal dementia-amyotrophic lateral sclerosis (FTD-ALS) or with pure familial or sporadic ALS or late-onset spinal motor neuropathy (SMAJ).

Here, we show that CHCHD10 is a component of the mitochondrial inner membrane organizing system (MINOS) complex. The expression of *CHCHD10* mutant allele leads to MINOS complex disassembly and loss of mitochondrial cristae in patient fibroblasts. The abnormalities of the inner membrane are responsible for nucleoid disorganization leading to defect in mtDNA repair after oxidative stress, which explains the multiple mtDNA deletions found in patient muscles. Interestingly, the expression of *CHCHD10* mutant alleles inhibits apoptosis by preventing cytochrome *c* release. This result supports previous studies suggesting that, in some ALS models, motor neuron death can occur *via* caspase-independent apoptotic mechanism.

In conclusion, we show for the first time that mutations in a gene encoding a MINOS component are responsible for human disorder. Dissecting the cellular pathways disrupted by the expression of *CHCHD10* mutant alleles represents, therefore, a golden opportunity to gain powerful insight into the sequence of events that link mitochondrial dysfunction with neurodegenerative disorders.

Primary Coenzyme Q10 (CoQ10) deficiencies are rare, clinically heterogeneous disorders caused by recessive mutations in several genes encoding proteins involved in CoQ10 biosynthesis. CoQ10, a lipoidal quinone, is an essential component of the electron transport chain (ETC), shuttling electrons from complex I/II to complex III. By whole exome sequencing we identified five individuals carrying biallelic mutations in COQ4. The precise function of human COQ4 is not known, but it seems to play a structural role

in stabilizing a multiheteromeric complex, which contains most of CoQ10 biosynthetic enzymes. The clinical phenotypes of the five subjects varied widely, but four had a prenatal or perinatal onset with early fatal outcome. Two unrelated individuals presented with severe hypotonia, bradycardia, respiratory insufficiency and heart failure; two sisters showed antenatal cerebellar hypoplasia, neonatal respiratory distress syndrome, and epileptic encephalopathy. The fifth subject had early-onset but slowly progressive clinical course, dominated by neurological deterioration with hardly any involvement of other organs. CoQ10 amount was reduced in all available specimens from mutant subjects, often associated with decrease of CoQ10-dependent ETC complex activities and reduced oxygen consumption rate in cultured cells. The pathogenic role of all identified mutations was experimentally validated in a recombinant yeast model: oxidative growth, strongly impaired in strains lacking COQ4, was corrected by expressing a human wild-type COQ4 cDNA but failed to be corrected by expressing COQ4 cDNAs with any of the nucleotide variants identified in affected subjects. COQ4 mutations are responsible for early-onset mitochondrial diseases with heterogeneous clinical presentations associated with CoQ10 deficiency.

C18.3

MCT1 deficiency impairs ketone utilization and causes profound ketoacidosis upon catabolic stress

Wanders[2], **G. van Haaften**[1]*;*

[1]UMC Utrecht, Utrecht, Netherlands, [2]AMC, Amsterdam, Netherlands, [3]Childrens University Hospital, Dublin, Ireland, [4]Gazi University School of Medicine, Ankara, Turkey, [5]Sheffield Children's Hospital, Sheffield, United Kingdom, [6]Great Ormond Street Hospital, London, United Kingdom, [7]Department of Laboratory Medicine, Utrecht, Netherlands, [8]Southampton General Hospital, Southampton, United Kingdom, [9]MUMC, Maastricht, Netherlands, [10]Radboud university medical center, Nijmegen, Netherlands.

Ketoacidosis is a potentially lethal condition caused by an imbalance between ketone body production and ketone body utilization. Ketone bodies are mainly produced in the liver and used as an energy source in extrahepatic tissues. Currently only two genetic defects in ketone body metabolism are known, whereas most patients with recurrent ketoacidosis remained unresolved.

We performed targeted exome sequencing of homozygous genomic regions in a patient from consanguineous parents with recurrent massive ketoacidosis. We sequenced the main candidate gene and related genes in a cohort of 96 patients suspected of a ketolysis defect, followed by functional, biochemical and clinical characterization.

We identified a homozygous frameshift mutation in the monocarboxylate transporter 1 (MCT1/SLC16A1), a known transporter of monocarboxylates including lactate and ketones. Subsequent analysis of MCT1 and related genes in our cohort yielded 6 additional truncating mutations and 1 missense mutation in MCT1. We identified both homozygous and heterozygous inactivating mutations, correlating with the depth of ketoacidosis. Immunoblot analyses revealed reduced and absent levels of MCT1 in heterozygous and homozygous patients, respectively. A lactate transport assay in erythrocytes showed absence of transport in homozygous patients and reduced transport in heterozygotes.

We show that MCT1 deficiency is a novel cause of profound ketoacidosis. Our results indicate that MCT1 is pivotal for import of ketones in extrahepatic tissues. Contrary to the current concept of freely diffusing ketone bodies, our study shows that during catabolic stress, facilitated transport of ketones by MCT1 is essential to allow adequate ketone utilization and maintain acid-base balance.

Haemochromatosis type 4 is a rare form of primary iron overload transmitted as an autosomal dominant trait caused by mutations in the gene encoding the iron transport protein ferroportin 1 (*SLC40A1*). *SLC40A1* mutations fall into two functional categories (loss- versus gain-of-function) underlying two distinct clinical entities (haemochromatosis type 4A-B). However, the vast majority of *SLC40A1* mutations are rare missense variations, with only a few showing strong evidence of causality. The present study reports the results of an integrated approach collecting genetic and phenotypic data from 44 suspected haemochromatosis type 4 patients, with comprehensive structural (3D model) and functional annotations.[1,2] Causality was demonstrated for 10 missense variants, showing a clear dichotomy between the two haemochromatosis type 4 subtypes. Two subgroups of loss-of-function mutations were distinguished: one impairing cell surface expression and one altering only iron egress. A new gain-of-function mutation was identified, and the degradation of ferroportin on hepcidin binding was shown to probably depend on the integrity of a large extracellular loop outside of the hepcidin-binding domain. Eight further missense variations, on the other hand, were shown to have no discernible effects at either protein or RNA level; these were found in apparently isolated patients and were associated with a less severe phenotype. The present findings illustrate the importance of combining in-silico and biochemical approaches to fully distinguish pathogenic *SLC40A1* mutations from benign variants. This has profound implications for patient management.

Genetic defects are responsible for the majority of primary renal diseases leading to end-stage renal disease. The risk of recurrence after transplantation depends on the genotype. Genetic testing becomes increasingly important for proper clinical management and therapeutic and prognostic issues, but there is a need for novel comprehensive, time- and cost-efficient strategies. We analysed 605 unrelated patients by a customized NGS-panel of 347 genes for atypical haemolytic uremic syndrome (aHUS) and hereditary glomerular disorders (nephrotic syndrome, FSGS, Alport syndrome, MPGN, C3 glomerulopathies) which often show clinical and genetic overlap. The alternative complement pathway is typically overactivated in aHUS and C3 glomerulopathies, but genes implicated in coagulation and haemostasis play a pivotal role too. Secondary triggers (e. g., hypertension, pregnancy, transplantation, infection) and predisposing polymorphisms lower the threshold for disease onset. Our study represents the by far largest cohort analysed by comprehensive genetic testing. We present new disease genes and demonstrate that variations in more than one gene contribute to the phenotype with variable expressivity and incomplete penetrance. We show that detailed information on the genotype is crucial for decisions on transplantation, recurrence risk and treatment such as when and how long an expensive drug like the monoclonal antibody eculizumab should be given. The diseases discussed represent an interesting model that may help to explain basic genetic principles not confined to renal disorders and of relevance for all geneticists. We demonstrate that genetic testing assists in the decision-making process to treat patients adequately while handling public resources responsibly.

To search for novel sequence variants that confer risk of kidney stones, we conducted a genome-wide association study using 28.3 million sequence variants identified through whole genome sequencing of 2,636 Icelanders and subsequent imputation into 5,419 kidney stone cases, including 2,172 cases with a history of recurrent kidney stones, and 279,870 controls. In addition to replicating previous findings in an Asian population at *SLC34A1* (rs12654812[A] ,OR = 1.18, $P = 5.7\times10^{-11}$) we identified sequence variants associating with kidney stones at *ALPL* (rs1256328[T], odds ratio (OR) = 1.21, $P = 5.8\times10^{-10}$) as well as a suggestive association at *CASR* (rs7627468[A], OR = 1.16, $P = 2.0\times10^{-8}$). We specifically focused our analysis on coding sequence variants in 63 genes with preferential gene expression in the kidney. The strongest associations observed were of two rare missense variants SLC34A1 p.Tyr489Cys (OR = 2.38, $P = 2.8\times10^{-5}$) and TRPV5 p.Leu530Arg (OR = 3.62, $P = 4.1\times10^{-5}$) for recurrent kidney stones. We further tested the sequence variants identified in this study for association with biochemical traits involved in calcium-phosphate and purine metabolism, kidney function, acid-base and ion homeostasis in a large population set. The results demonstrate the role of sequence variants at genes involved in calcium-phosphate homeostasis in the pathophysiology of kidney stones in humans.

C19.1

Large-scale, high-throughput testing of cancer predisposition genes using the TruSight Cancer panel

S. Mahamdallie[1,2], *E. Ruark[1], A. Fowler[3], M. Münz[3], V. Cloke[2], A. George[1,4], S. Seal[1,2], G. Lunter[3], N. Rahman[1,2,4], Mainstreaming Cancer Genetics Programme;*

[1]Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom, [2]TGLclinical, Institute of Cancer Research, London, United Kingdom, [3]Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, [4]Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom.

Genetic testing of cancer predisposition genes is a major activity of Clinical Genetics, but gene testing in most countries remains very restricted with respect to the number of genes and number of people that can access testing. In collaboration with Illumina we developed an NGS pulldown panel called TruSight Cancer Panel (TSCP), which targets 97 cancer predisposition genes including *BRCA1* and *BRCA2*. TSCP requires only 50ng of input DNA and we multiplex to sequence 96 samples at a time on a HiSeq2500, generating median coverage of 500X. We have developed and validated a bespoke analytical pipeline that detects small and large variants, which runs overnight with no bioinformatic input.

To date we have processed >5000 individuals with TSCP and these data will be presented. Furthermore, TSCP has now been implemented in our accredited clinical testing laboratory, TGLclinical, as the test for *BRCA1* and *BRCA2* mutations, with all mutations validated by Sanger or MLPA as appropriate. 376 clinical reports using TSCP have been issued, including 42 with pathogenic mutations. Using our laboratory and analytical TSCP pipeline one person can process 96 samples from DNA to variant calling in eight working days. The average turnaround time from sample receipt to report issue is now 27 days. Expansion of clinical testing to other genes on the panel is underway. These data provide multiple insights into integration of NGS panel analysis in the clinical setting. This work was undertaken as part of the MCG programme (www.mcgprogramme.com), funded by the Wellcome Trust Grant 098518/Z/12/Z.

C19.2

Increasing accessibility and affordability of genetic testing through targeted clinical exome sequencing

S. Abbs[1], *H. Martin[1], K. Brugger[1], I. Delon[1], O. Spasic-Boskovic[1], G. Sagoo[2], F. Rodger[3], R. Littleboy[3], S. Mehta[1], S. Park[1], R. Armstrong[1], G. Woods[3], S. Holden[1], J. Campbell[4], C. Bennett[4], R. Sandford[1], E. Maher[3];*

[1]East Anglian Medical Genetics Service, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [2]PHG Foundation, Cambridge, United Kingdom, [3]Dept of Medical Genetics, Cambridge University, Cambridge, United Kingdom, [4]Department of Clinical Genetics, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

900 patients have been sequenced for 4813 clinically relevant genes using the Illumina TruSight One sequencing assay. This test has replaced numerous alternative diagnostic sequencing tests, providing a single laboratory workflow and financial savings.

Data is analysed for a panel of genes appropriate for the clinical presentation. To date 190 virtual gene panels have been developed, incorporating 1085 genes, averaging 7.9 genes per panel. Almost 1/3 of panels established (60) are single genes, requested for patients with homogeneous clinical presentations. Single gene analysis yields a higher mutation detection rate (40%) than panel testing (27%), however we will present data showing that panel testing would increase the diagnostic yield further if applied instead of single gene analysis.

Gene panels are established on demand. As long as the required gene(s) are captured and yield good sequencing coverage, a diagnostic test, which may be unavailable or unaffordable by alternative methodology, can be offered almost immediately. For example, we were able to offer rapid testing for a couple presenting in pregnancy, after having a child with a tentative diagnosis of Schwartz-Jampel syndrome. Sequence data was filtered for skeletal dysplasia and distal arthrogryposis gene panels. A biparentally inherited homozygous pathogenic HSPG2 variant was detected in the affected individual, confirming the diagnosis and enabling prenatal testing within 3 weeks of receiving the referral.

This "clinical exome" sequencing approach offers flexible testing at ~25% cost reduction over alternative tests, significantly increasing accessibility to genetic testing for patients with a huge range of genetic disorders.

C19.3

The RD-Connect platform includes the first 360 analysed exomes linked to phenotypic data and integrates user-friendly tools for rare disease variant prioritization

Around 300 million people worldwide are estimated to suffer from one of the 6000+ known rare diseases. However, rare disease research faces particular challenges because patient populations, clinical expertise, and research communities are small in number and highly fragmented. To overcome these challenges the EU FP7-funded RD-Connect project, in collaboration with Neuromics and EURenOmics, is building a platform to harmonise and securely integrate clinical data with biosample and -omics data. The genomics side of the platform already includes over 360 NGS exomes linked to detailed phenotypes stored in PhenoTips using the Human Phenotype Ontology. Exomes were processed with v1 of the RD-Connect standard analysis pipeline for genomics, which exceeds 99% precision and sensitivity when compared to the NIST reference set of calls for NA12878. The platform runs on a Hadoop cluster and uses technologies such as ElasticSearch, Postgres, Scala and Angular.js, making it highly configurable and efficient. The exomes can be combined in a very flexible manner and variants can be filtered and prioritized through the user-friendly front-end using the most common quality, genomic location, effect, pathogenicity and population frequency annotations, including CADD and ExAC. Moreover, additional tools can be

integrated at the database level or at the interface through API queries. To date, UMD Predictor, DiseaseCard, Alamut Functional Annotation (ALFA) and gene-disease relationships in nanopublication format have been integrated. The project aims to publicly release the first version of the platform during 2015 for authorized users and will gladly accept submissions from other projects in the future.

C19.4
Copy Number Analysis using Exon-level aCGH and Exome Sequencing in over 3,000 Parent-Offspring Trios from the Deciphering Developmental Disorders Project

T. W. Fitzgerald, *J. McRae, D. de Vries, M. Hurles;*
Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

The Deciphering Developmental Disorders (DDD) project is a family based study focused on rare genetic variants in patients with undiagnosed developmental delay. Copy number (CNV) discovery in the DDD project is achieved using a combination of exon-resolution array comparative genomic hybridization (exon-CGH) and whole exome next generation sequencing (WES) platforms. We have developed a new algorithm - CIFER (CNV Inheritance From Exome Resources) that uses trio WES for the validation and inheritance classification of CNVs detected using exon-CGH in probands. We screen the genomes of over 3,000 parent-offspring trios for potentially pathogenic CNVs to elucidate the genetic basis for numerous patient phenotypes from the DDD project. The inheritance patterns for CNVs across the patient cohort are explored and compared to current CNV mutation rate estimates from normal controls. An investigation into the potential for using WES as the sole source for CNV discovery comparing against and using exon-CGH as the gold standard is undertaken. By applying an automated CNV filtering pipeline we present the overall characteristics of CNVs predicted to have broad clinical relevance in approximately 10% of proband samples. We provide examples of recurrent CNVs in single known DD genes across multiple patients with similar phenotypes. Additionally by using association based testing and gene haploinsufficiency predictions we present initial findings into suggestive novel DD genes based on CNV frequency rates, inheritance patterns and patient phenotype similarities.

C19.5
Small exonic CNVs as causes of primary immunodeficiencies

A. Stray-Pedersen[1,2], *H. S. Sorte*[3], *T. Gambin*[1,4], *P. S. Samarakoon*[3], *S. Gu*[1], *L. R. Forbes*[5], *I. Chinn*[5], *Z. H. C. Akdemir*[1], *O. K. Rødningen*[3], *B. Yuan*[1], *P. M. Boone*[1], *A. Patel*[6], *S. J. Penney*[1], *W. Wiszniewski*[1], *S. N. Jhangiani*[1], *D. Muzny*[1,7], *R. A. Gibbs*[7], *R. Lyle*[3], *J. S. Orange*[5], *J. R. Lupski*[1,8,6];

Primary immunodeficiencies (PIDD) constitute a heterogeneous group of genetic diseases affecting the immune system. Mutations in more than 300 genes are known to cause PIDD and the subtype symptoms can be overlapping. Both disease severity, which can range from mild to life-threatening, and treatment options depend on the genetic aetiology. We examined the utility of whole exome sequencing (WES) to detect disease-causing single nucleotide variants (SNVs) and copy number variations (CNVs) in PIDD patients. Patients were recruited from Texas Children's Hospital (Houston, US) and Oslo University Hospital (Norway). As of February 2015, patients with extensive immunological and genetic testing from 258 families have been WES tested. PIDD-causing SNVs were identified in 100 of the families. A computational CNV prediction pipeline was applied to the exome data to identify PIDD-causing CNVs. The predicted PIDD-causing CNVs were validated using a custom array CGH (aCGH) platform with exon-level resolution. The same aCGH was also applied to a selection of the families with negative WES. PIDD-causing CNVs were identified in 10 families, involving MAGT1, SMARCAL1, DOCK8, IL7R, MYB, PGM3, DKC1, and FANCA. Five of the CNVs spanned between 1-4 exons and would not have been detected by traditional diagnostic aCGH, with a typical resolution of 50 kb. This study shows that exome sequencing is an efficient method to establish a genetic diagnosis for PIDD patients and that small exonic CNVs might be a neglected cause of PIDD.

C19.6
Whole genome sequencing as a clinical diagnostic tool for heterogeneous Mendelian disease

J. M. Ellingford[1], *S. Barton*[2], *S. Bhaskar*[2], *S. G. Williams*[2], *P. I. Sergouniotis*[3], *J. O'Sullivan*[1], *J. A. Lamb*[4], *R. Perveen*[1], *G. Hall*[2], *W. G. Newman*[2], *P. N. Background: Whole genome sequencing (WGS) enables the analysis of genome-wide genetic variation that can range from single nucleotide alterations to large structural genomic variants. WGS has become more affordable and presents dramatic opportunities for a potential shift in diagnostic services for genetic disease. This is exemplified by the recent commission of the 100,000 Genomes Project in England and the 'precision medicine' programme in the USA. However, diagnostic WGS pipelines are yet to be validated as a clinical tool in the context of heterogeneous genetic disease.
Methods: We surveyed the diagnostic yield of an accredited, conventional next-generation sequencing (NGS) diagnostic testing method for 537 patients with genetically and clinically heterogeneous single gene disorders (specifically, inherited-retinal-disease). A subset of 47 patients also underwent WGS, and we compare the diagnostic yield of a WGS pipeline to that achieved by the conventional NGS diagnostic test.
Findings: The WGS pipeline achieved similar sensitivity and specificity rates to the targeted NGS diagnostic testing method. Importantly, the WGS pipeline detected pathogenic variants that were not identified by current NGS diagnostics and, amongst the 47 patients, facilitated an 85% increase in diagnostic yield. If applied to the 537 patients surveyed, weighted estimates suggest that the WGS pipeline could provide a 27% increase in diagnostic yield.
Interpretation: We demonstrate the capability of a WGS pipeline to detect pathogenic genetic variants missed by current methodologies, and to identify essential modifications for current and future molecular diagnostic practice. We establish the potential utility of diagnostic WGS pipelines for clinically and genetically heterogeneous Mendelian disorders.

C20.1
Ethical and legal challenges of genomic cloud computing

E. S. Dove[1,2,3], *M. Phillips*[1], *Y. Joly*[1], *A. Tassé*[4], *B. M. Knoppers*[1,3];
[1]*McGill University, Montreal, QC, Canada,* [2]*University of Edinburgh, Edinburgh, United Kingdom,* [3]*Global Alliance for Genomics and Health, Toronto, ON, Canada,* [4]*Public Population Project in Genomics and Society, Montreal, QC, Canada.*

Genomic researchers are increasingly utilizing vast computer infrastructure and advanced software tools to store and perform comprehensive analyses of genomic data sets. Cloud computing is harnessed both to integrate data from multiple sources and to analyze data to solve biomedical problems. Cloud computing offers multiple advantages, including lower costs and the enablement of greater international collaboration and research efficiency. Yet, it also brings a number of new ethical and policy issues, particularly those concerning the protection of personal health data in an environment of transnational, multidirectional data flow. Because cloud computing affects multiple stakeholders situated across multiple jurisdictions, careful legal and ethical analysis is warranted. In this presentation, we will characterize and analyze the specific legal and ethical challenges emerging from cloud-based genome analysis based on our analysis of publicly available cloud service providers' Terms of Service. These challenges include: data control; data security and privacy; international data transfer; and, accountability. Additionally, in conjunction with the collaborative work of P3G-IPAC (Public Population Project in Genomics and Society - International Policy interoperability and data Access Clearinghouse) and the Global Alliance for Genomics and Health, we will present an international policy for cloud-based genomic research and clinical practice that sets an innovative but effective and ethically responsible approach to conducting genomic medical research in the cloud. Such a policy will robustly protect patient privacy and medical confidentiality, and also facilitate secure access to genomic and clinical data--even when up in the clouds.

C20.2

In utero treatment of Down syndrome - proceed with care

G. M. W. R. de Wert, *W. J. Dondorp;*
Maastricht University, Maastricht, Netherlands.

Non-invasive prenatal testing may well create an opportunity for *in utero* treatment of Down syndrome (IUTDS) by means of compounds improving neurogenesis (1). While research is still in its infancy, experts involved rightly stress the importance of an anticipatory ethical debate. Clearly, IUTDS would raise both conceptual and a cluster of normative issues, linked with research ethics, the ethics of prenatal screening and responsible parenthood.

First, the suggested conceptualization of such treatment as 'fetal personalized medicine' is debatable as this seems to presume a (rightly) contested view regarding the status of the fetus (as a 'person'). Second, future IUTDS will, obviously, be experimental for a longer period. What about the proportionality of possible harms and benefits, taking account of the fact that DS children with a somewhat higher IQ are not necessarily happier? Which criteria should be used to measure success? How to guarantee well-considered decisions of women who may prematurely consider such IUTDS to be evidence-based? Third, (how) would IUTDS change the ethics of NIPT for DS? While IUTDS could circumvent traditional 'pro life' criticism, objections may still come from 'disability rights' criticists - arguing that IUTDS reflects a problematic 'normalization' of people with mental retardation - and from feminists arguing that women may be pressurized to refrain from terminating affected pregnancies, undermining their reproductive rights.

This exploratory ethical analysis will scrutinize the main moral issues and contribute to agenda-setting for further debate

1. Bianchi D. From prenatal genomic diagnosis to fetal personalized medicine: progress and challenges. Nature Medicine 2012;18(7):1-11.

C20.3

Should children's carrier results be reported following diagnostic WES/WGS?

D. F. Vears[1,2], *K. Sénécal*[3], *J. Massie*[4,5], *P. Borry*[1];
[1]*Centre for Biomedical Ethics and Law, Leuven, Belgium,* [2]*Centre for Health Equity, University of Melbourne, Parkville, Australia,* [3]*Centre of Genomics and Policy, Mc Gill University, Montreal, QC, Canada,* [4]*Department of Respiratory Medicine, The Royal Children's Hospital, Parkville, Australia,* [5]*Department of Paediatrics, University of Melbourne, Parkville, Australia.*

The ACMG recommend that if children undergo whole genome/exome sequencing (WGS/WES) for diagnostic purposes, results for their predisposition to 24 genetic conditions, predominantly autosomal dominant familial cancer and vascular syndromes, should be reported to clinicians for discussion with the family. They suggest the possible negative psychological impacts from identifying children's genetic risks and the loss of their future autonomy, are outweighed by the potential benefits, both for the health of the child and also their parents.

Yet ACMG do not recommend disclosure of children's carrier status to families, despite the potential benefits to the child, due to the possible health implications for carriers of some X-linked conditions, such as Duchenne Muscular Dystrophy (DMD), and their parents, who may benefit from reproductive choices.

This paper explores the ethical implications of reporting incidental carrier results from diagnostic WGS/WES. We draw on data from qualitative interviews with 17 genetic health professionals and 33 parents of children with genetic conditions (cystic fibrosis, DMD and haemophilia), exploring the practices, views and experiences of carrier testing in children to inform this discussion. We consider these parents' reactions to learning their child's carrier status and their intentions to communicate carrier information to their children, and how this might impact on their abilities to manage incidental findings from diagnostic WES/WGS.

Finally, we draw conclusions about the appropriateness of conveying incidental carrier information from WGS/WES to families in contrast to the recommendations of international guidelines against performing carrier testing in siblings of children with genetic conditions.

C20.4

Informed consent for whole exome sequencing in pediatric disease diagnostics: parental decision-making processes, their ethical relevance and implications for policy development

C. Cornelis[1], *M. van Summeren*[2], *I. Bolt*[3], *A. Tibben*[4], *W. Dondorp*[5], *M. van Haelst*[6], *A. Bredenoord*[7], *M. Düwell*[8], *N. Knoers*[9];
[1]*University Medical Center Utrecht; Ethics Institute, Utrecht University, Utrecht, Netherlands,* [2]*Department of General Pediatrics, Wilhelmina Children's Hospital, University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Ethics Institute, Utrecht University, Utrecht, Netherlands,* [4]*Department of Medical Psychology, Leiden University Medical Center, Leiden, Netherlands,* [5]*Department of Health, Ethics & Society, Maastricht University, Maastricht, Netherlands,* [6]*University Medical Center Utrecht, Utrecht, Netherlands,* [7]*Julius Center, Department of Medical Humanities, University Medical Center Utrecht, Utrecht, Netherlands,* [8]*Ethics Institute, Department of Philosophy and Religious Studies, Utrecht University, Utrecht, Netherlands,* [9]*Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands.*

Introduction:
The empirical body of evidence on parents' decision-making processes for whole exome sequencing (WES) and return of unsolicited findings (UFs) in pediatric disease diagnostics is limited. Yet understanding these processes and the differences between them is needed for developing morally responsible policy.
Method:
Twenty semi-structured interviews were conducted with parents of children ages <1 – 17, after consenting to WES (trio-analyses), but prior to feedback of results.
Results:
Parental preferences for return of UFs, reasoning patterns, and difficulties experienced in decision-making diverged. Context-specific factors of persons' situations, such as uncertainty about whether their child will develop into an autonomous adult capable of making future disclosure decisions, and differences in persons' moral starting points clarify this divergence. Parents valued being given choices over most outcome categories of UFs for various reasons. One reason was that decisional discretion necessitates contemplation of the possible future consequences of hearing, or not hearing, certain results – thereby ensuring parents' confidence of having made a well-informed decision for WES. A need was sometimes also expressed by parents to understand the moral argumentation behind the center's policy choices regarding opt-ins and opt-outs for certain UFs, since seeing different arguments can help one weigh alternatives in a systematic manner, thus, adding to one's confidence about having decided responsibly.
Conclusion:
These insights inform ethical theorizing on how policy for WES and UFs should be structured in order to ensure persons' well-informed decision-making.
This project is funded by ZonMw (grant no. 70-73000-98-047) – The Netherlands Organization for Health Research and Development.

C20.5

A Human Rights Approach to International Data Sharing?

B. Knoppers, *E. Dove;*
McGill University, Montreal, QC, Canada.

Human rights are engrained in international law. They offer many advantages to translational and transnational genome science centred on data sharing. First, their universalizing force can overcome site-specific factors that drive a wedge between research initiative/funder data sharing policies and harmonization. Second, because human rights have both political and legal dimensions, they reach beyond the moral appeals of bioethics and can provide a more robust governance framework for the regulation of genomics research. If health care becomes a primary location for collecting the phenotypic and genetic data needed to create learning systems for research and clinical care, we need to reinforce the self-regulatory codes of ethics of genomic researchers, and clinicians with legally recognized human rights, that is, a *co*-regulatory system. Third, human rights belong to groups as well as individuals (creating a reciprocity between the individual and public level) and reach beyond classic negative duties (i.e. forbidding State actors from interfering with the rights of individuals), to positive, more progressive duties, thereby urging action by governments (and ideally, industry, funders, and researchers) to share the data, technologies and knowledge that are the fruits of our science to achieve a goal desired by all, such as health. Fourth, human rights can foster responsible protection in three critical areas: privacy; anti-discrimination, and procedural fairness. This presentation will use the *Framework for Responsible Sharing of Genomic and Health-Related Data* of the Global Alliance for Genomics and Health as a case study for harnessing human rights as mobilizing force for international data sharing.

C20.6

What's in it for me? A critical analysis of the notion of personal utility in genomic testing

E. M. Bunnik;
Erasmus MC, Rotterdam, Netherlands.

Observers have suggested that in the ethical evaluation of genomic tests, the criterion of clinical utility should be replaced or complemented with the cri-

terion of personal utility. These suggestions are commonly made from a liberalist vantage point, in which it is held that patients or consumers should be free to define the value of genomic tests for themselves and to access genomic tests - through the healthcare system or through commercial channels - that may lack clinical utility, strictly defined. A paradigmatic example is ApoE testing: while there are limited therapeutic options for Alzheimer's disease (i.e. clinical utility), many people prefer knowing their genetic risk to make life choices or to psychologically prepare for possible scenarios. Further, genomic tests for non-medical traits (e.g. ancestry, professional or sports-related testing) can be interesting or fun and thus have personal value for consumers. But does a 'consumer value' imply that there is personal utility in a genomic test? I will argue that genomic tests that lack predictive ability cannot have personal utility. Further, I will argue - descriptively and normatively - that the notion of personal utility should be demarcated narrowly in order for it to have a role in the ethical evaluation of genomic tests. I will set forth the conditions sine qua non of personal utility in genomic tests, including clinical validity and reasonable potential use. Often, the notion of personal utility is used to ethically justify genomic testing offers to the public; such justifications, I will point out, are flawed.

C21.1

Recurrent de novo p.Arg83Cys mutations in the acetyl CoA binding site of NAA10 are associated with atypical Cornelia de Lange syndrome

M. Ansari[1], *N. Akawi*[2], *H. Bengani*[1], *A. M. Meynert*[1], *I. Parenti*[3], *J. Pozojevic*[3], *D. C. Soares*[1], *C. Martin*[1], *A. Blatnik*[1], *H. Kayserili*[4], *S. Avci*[4], *S. Joss*[5], *K. Tatton-Brown*[6], *F. Elmslie*[6], *M. Suri*[7], *S. Mansour*[6], *K. S. Wendt*[8], *E. Watrin*[9], *F. J. Kaiser*[3], *M. S. Taylor*[1], *M. E. Hurles*[2], *D. R. FitzPatrick*[1];

[1]*MRC Institute of Genetics and Molecular Medicine, Edinburgh, United Kingdom,* [2]*Wellcome Trust Sanger Institute, Cambridge, United Kingdom,* [3]*Universität zu Lübeck, Lübeck, Germany,* [4]*Istanbul Medical Faculty, Istanbul, Turkey,* [5]*West of Scotland Genetic Services, Glasgow, United Kingdom,* [6]*St George's University of London, London, United Kingdom,* [7]*Nottingham University Hospitals, Nottingham, United Kingdom,* [8]*Erasmus MC, Rotterdam, Netherlands,* [9]*Institut de Génétique et Développement de Rennes, Rennes, France.*

Cornelia de Lange syndrome (CdLS) is a variable multisystem disorder with a broad phenotypic spectrum. Most typically-affected individuals carry *de novo* heterozygous loss-of-function mutations in *NIPBL*. Mutations in other components of the sister chromatid cohesion system, *SMC1A*, *HDAC8*, *SMC3* and *RAD21*, result in phenotypes that overlap with CdLS but which can be highly atypical. In the present study, a recurrent *de novo* mutation was identified in the X-linked gene, *NAA10* (c.247C>T [p.Arg83Cys]) in four unrelated female individuals through trio-based exome sequencing and re-sequencing. A fifth female was found to carry a *de novo* mutation affecting the adjacent codon (p.Arg82Gln). Three of these cases have a CdLS-like appearance, with the growth and dysmorphic features in all individuals being variable. Analysis of X-chromosome inactivation revealed complete skewing of X-inactivation in 3/5 cases and borderline skewing in the remaining two. *In vivo* analysis of a patient fibroblast cell line, only expressing the mutant allele, showed no obvious defects in cell division. Molecular modelling suggests that the p.Arg83Cys conversion is likely to alter binding of NAA10 to acetyl CoA. A significant reduction in auto-acetylation of NAA10 was observed in the presence of the p.Arg83Cys mutation *in vitro*. Furthermore, mouse embryonic fibroblast cell lines derived from CRISPR-induced p.Arg83Cys knock-in mouse embryos are being analysed for further characterisation of this mutation in relation to cohesin function. A detailed clinical comparison to published cases of *NAA10* mutations will also be presented. Our results identify recurrent *de novo* mutations in *NAA10* as a possible cause of CdLS-overlapping phenotypes.

C21.2

STAG1 haploinsufficiency is responsible for a new cohesinopathy with intellectual disability and characteristic facial features in four unrelated individuals

Cohesinopathies are rare disorders arising from a dysfunction in the cohesin pathway, which enables chromosome segregation and proper cell division. So far, seven genes from this pathway have been reported in human disease. Five of them are involved in autosomal dominant (NIPBL, SMC3, RAD21) or X-linked (SMC1A and HDAC8) Cornelia de Lange syndrome, and two of them in autosomal recessive Roberts (ESCO2) and Warsaw Breakage syndromes (DDX11). All are severe neurodevelopmental conditions characterized by intellectual disability, growth retardation, microcephaly, limb defects and facial dysmorphism.

STAG1 belongs to the STAG subunit of the core cohesin complex, which, along with three other subunits, mediates cohesion between sister chromatids. Here, we report an international series of four unrelated individuals, 3 males and 1 female, aged 8 to 33 years, referred for moderate to severe intellectual disability that could be attributed to STAG1 haploinsufficiency. Three had history of intrauterine growth retardation, two with prenatal-onset microcephaly, one with post-natal growth retardation. One individual had epilepsy, two had autistic features. The four patients shared common facial features, with widely spaced incisors, thin eyebrows, and high nasal bridge. The mechanism for haploinsufficiency was a small deletion encompassing STAG1 diagnosed by array-CGH in two individuals, an intragenic deletion in STAG1 found by whole genome analysis in one individual, and a missense heterozygous mutation (c.641A>G) revealed by exome analysis in the last patient. All the variants were shown to be de novo. This series provides evidence that STAG1 haploinsufficiency leads to a new cohesinopathy with a clinically recognizable phenotype.

C21.3

Wiedemann-Steiner Syndrome: Expanding the phenotypic spectrum associated with KMT2A (MLL) mutations

W. D. Jones[1], *M. McEntagart*[2], *C. Deshpande*[3], *T. Deciphering Developmental Disorders Project*[1], *M. A. Simpson*[4], *M. Hurles*[1], *J. Barrett*[1];

[1]*Wellcome Trust Sanger Institute, Cambridge, United Kingdom,* [2]*South West Thames Regional Genetics Service, London, United Kingdom,* [3]*Clinical Genetics, Guys and St Thomas' NHS Foundation Trust, Guy's Hospital, London, United Kingdom,* [4]*King's College London School of Medicine, London, United Kingdom.*

In 2012 members of our group reported that de novo mutations in the histone methyl-transferase MLL (renamed KMT2A) underlie a distinct phenotype of hypertrichosis, short stature, intellectual disability and a distinctive facial appearance consistent with a diagnosis of Wiedemann-Steiner syndrome in five individuals. Other phenotypic features observed were feeding difficulties, behavioural difficulties, skeletal abnormalities and cardiac defects.

We have now identified 39 individuals with mutations in KMT2A. Our cohort contains 37 sporadic individuals and a set of monozygous twins. In total 19 individuals with KMT2A mutations have undergone detailed clinical phenotyping by members of our group and we have detailed phenotype information for 20 further patients with KMT2A mutations. Recruitment to our study, sequencing and detailed phenotyping is on going.

Our study has shown that hypertrichosis, which was initially identified, as a typical feature is variable in individuals with KMT2A mutations. We have expanded the list of phenotypic abnormalities associated with KMT2A mutations and report novel features including seizures, renal abnormalities, plantar fat pads, ptosis, and malrotation of the bowel. Review of the facial appearance of individuals of KMT2A mutations shows that the facial phenotype evolves over time, clinical photographs will be presented at different time points to illustrate this progression.

In addition to the expansion and clarification of the clinical features, growth profile and mutational spectrum associated with KMT2A mutations, we will review the overlap with other conditions and compare the phenotype of individuals identified through non-targeted screening to those individuals identified following clinician phenotyping to define the characteristic phenotype that should prompt consideration of KMT2A testing.

C21.4

Mutations in the endothelin receptor type A cause mandibulofacial dysostosis with alopecia via a maxillary to mandibular transformation

The endothelin receptor type A (EDNRA) signaling pathway is essential for the establishment of mandibular identity during development of the first pharyngeal arch. We report four unrelated individuals with a novel syndrome, mandibulofacial dysostosis with alopecia (MFDA), who have de novo missense variants in EDNRA. The MFDA phenotype includes eyelid and ear dysplasia and hearing loss. Three of the four individuals have the same substitution in EDNRA, p.Tyr129Phe. Tyr129 is known to determine the selective affinity of EDNRA for endothelin 1 (EDN1), its major physiological ligand, and the p.Tyr129Phe variant increases the affinity of the receptor for EDN3, its non-preferred ligand, by two orders of magnitude. The fourth individual, previously described as having Johnson-McMillin syndrome, has a somatic mosaic substitution in EDNRA, p.Glu303Lys. The zygomatic arch of individuals with MFDA resembles that of mice in which EDNRA is ectopically activated in the maxillary prominence, resulting in a maxillary to mandibular transformation, suggesting that the p.Tyr129Phe variant causes an EDNRA gain of function in the developing upper jaw. Our findings highlight the importance of finely-tuned regulation of EDNRA signaling during human craniofacial development and suggest that modification of endothelin receptor-ligand specificity was a key step in the evolution of vertebrate jaws.

Many Mendelian disorders with isolated or syndromic short stature have been recognized but the spectrum of conditions with increased growth appears much more restricted. Among the latter, the 3q13.31 microdeletion (del3q13.31) syndrome is a multisystem disorder characterized by increased postnatal growth, hypotonia, intellectual disability, disturbed behavior and unusual face. Primrose syndrome is an overgrowth condition characterized by macrocephaly, hypotonia, intellectual disability, autism and other behavioral concerns. Facial signs resemble del3q13.31 syndrome. Individuals with Primrose syndrome also develop diabetes in adulthood, progressive muscle wasting, hearing loss and ectopic calcifications. We used a WES-based strategy to identify the Primrose disease gene. We report that mutations in ZBTB20, residing within the 3q13.31 microdeletion syndrome critical region, underlie this disorder. Eight different missense mutations affecting residues located in the N-terminal region of the DNA binding domain of the transcription factor were identified. Mutations were predicted to affect DNA binding, and biochemical data provided evidence for reduced interaction with DNA and transactivation activity of disease-causing mutants. Mutations were documented affect protein function through a dominant negative action. Our findings establish a genetic link between this disorder and the clinically related del3q13.31 syndrome, and delineate the impact of ZBTB20 functional dysregulation and haploinsufficiency on development, growth and metabolism.

C21.6
Mutations impairing GSK3-mediated MAF phosphorylation cause cataract, deafness, intellectual disability, seizures, and a Down syndrome-like facies.

Transcription factors operate in developmental processes to mediate inductive events and cell competence, and perturbation of their function or regulation can dramatically affect morphogenesis, organogenesis, and growth. We report that a narrow spectrum of mutations within the transactivation domain of the v-maf avian musculoaponeurotic fibrosarcoma oncogene homolog (MAF), a leucine zipper-containing transcription factor of the AP1 superfamily, profoundly affects development. Seven different de novo missense mutations involving conserved residues of the four GSK3 phosphorylation motifs were identified in eight unrelated individuals. The distinctive clinical phenotype, for which we propose the eponym Aymé-Gripp syndrome, is not limited to lens and eye defects as previously reported for MAF/Maf loss-of-function, but includes sensorineural deafness, intellectual disability, seizures, brachycephaly, distinctive flat facial appearance, skeletal anomalies, mammary gland hypoplasia, and reduced growth. Disease-causing mutations impair proper MAF phosphorylation, ubiquitination and proteosomal degradation, perturb gene expression in patient fibroblasts, and induce neurodevelopmental defects in an in vivo model. Our findings nosologically and clinically delineate a previously poorly understood recognizable multisystem disorder, provide evidence for MAF governing a wider range of developmental programs than previously appreciated, and uncover a novel example of protein dosage effect severely perturbing development.

C22.1
The secrets of GWAS are written in the reads

C. Wadelius[1], *M. Cavalli[1], G. Pan[1], H. Nord[1], O. Wallerman[1,2], E. Wallén Arzt[1], O. Berggren[3], I. Elvers[2,4], M. Eloranta[3], L. Rönnblom[3], K. Lindblad Toh[2];*
[1]Science for Life Laboratory, Department of Immunology, Genetics and Pathology, Uppsala, Sweden, [2]Science for Life Laboratory, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden, [3]Science for Life Laboratory, Department of Medical Sciences, Uppsala, Sweden, [4]Broad Institute of MIT and Harvard, Cambridge, MA, United States.

Genome-wide association studies (GWAS) have identified a large number of disease associated loci, but in few cases have the functional variant and the gene it controls been identified. To systematically identify candidate regulatory variants we sequenced ENCODE cell lines and used public ChIP-seq data to find allele-specific transcription factor binding. We found 15,644 candidate regulatory SNPs of which more than 20% were rare, allele frequency <1%, and showed evidence of larger functional effect than common SNPs. This high frequency of rare functional variants adds heterogeneity to GWA studies of traits and expression and may explain divergent GWAS results between populations and why SNPs with the highest association signal rarely are functional. The majority of allele specific variants (95%) were specific to one of the six studied cell types. By examining GWAS loci we found >600 allele-specific candidate SNPs, 184 of which were highly relevant in our cell types. Results were confirmed by luciferase assays, EMSA and stimulation of primary cells. Functionally validated SNPs support identification of an intronic SNP in MERTK associated to risk for liver fibrosis, a SNP in SYNGR1 affecting risk for rheumatoid arthritis and primary biliary cirrhosis as well as a SNP in the last intron of COG6 affecting risk for psoriasis. We propose that by repeating ChIP-seq experiments of 20 selected transcription factors in three to ten people most common polymorphisms can be interrogated for allele-specific binding, in different cell types and tissues. Our strategy may help to alleviate the current bottle neck in functional annotation of the genome.

C22.2

Optimal ancestry-matched imputation of GWAS association summary statistics using large reference panel of sequenced individuals

S. Rüeger[1,2], *Z. Kutalik*[1,2];

[1]*Institute of Social and Preventive Medicine, University Hospital (CHUV), Lausanne, Switzerland,* [2]*Swiss Institute of Bioinformatics, Lausanne, Switzerland.*

The ultimate goal of GWASs is to find disease-associated markers, preferably causal variants. GWASs use microarrays to interrogate tag SNPs, therefore many untyped variants need to be inferred through imputation, using the available genotyped SNPs. As demonstrated recently [Pasaniuc et al. (2014)], not only genotypes, but association summary statistics, generated by large meta-analytic studies, can be imputed.

We propose several improvements to state-of-the-art summary statistic imputation tools. We compute the optimal shrinking of the SNP-SNP correlation matrix, which flexibly adapts to the reference panel size, local LD structure, region size, etc. In addition, our method allows for summary statistics that are dervied from variable sample sizes. Finally, we search for the optimal linear combination of reference panel sub-populations in order to match their joint allele frequency distribution to that of the association studies. This is analogous to selecting the subset of the reference panel that best represents the individuals in the GWAS cohorts.

Our extensive simulation study, using UK10K whole genome sequencing data sets, showed that our optimized shrinkage constant significantly outperforms all previously proposed choices when the reference panel is small (<300). We also demonstrated the importance of ancestry weighted mixture using 1000 Genomes subpopulation panels combined with summary statistics simulated from our local CoLaus study (Firman et al., 2008). Finally, using cohort-level association summary data from the GIANT (Genetic Investigation of ANthropometric Traits) Consortium, we found that applying ancestry-matched imputation of individual cohort summary statistics before meta-analysis substantially outperforms the imputation of meta-analysed association summary statistics.

C22.3

A novel method and software tool for genome-wide multi-phenotype analysis of rare variants

M. Kaakinen[1], *R. Mägi*[2], *K. Fischer*[2], *M. Järvelin*[1,3], *A. P. Morris*[4], *I. Prokopenko*[1];

[1]*Imperial College London, London, United Kingdom,* [2]*University of Tartu, Tartu, Estonia,* [3]*University of Oulu, Oulu, Finland,* [4]*University of Liverpool, Liverpool, United Kingdom.*

Recently, genome-wide association studies (GWAS) have been expanded to analysis of low-frequency and rare variants (MAF≤5%, both denoted by RVs). Power for variant detection could also be increased by jointly analysing multiple correlated phenotypes. We have developed software for genome-wide Multi-phenotype Analysis of RVs (MARV), combining features from both RV burden tests and multi-phenotype analyses. Specifically, the proportion of rare variants at which an individual carries minor alleles within a gene region is modelled on linear combinations of phenotypes in a regression framework. MARV also implements model selection via the Bayesian information criterion (BIC). We have applied this new method on three correlated phenotypes: fasting insulin (FI), triglycerides (TG) and waist-to-hip ratio (WHR), using data from 4788 individuals from the Northern Finland Birth Cohort 1966. Individuals were genotyped on the Illumina370CNV array and imputed to the 1000 Genomes Project all ancestries reference panel (March 2012). FI/TG/WHR were adjusted for body mass index and three principal components to control for population structure. The following transformations were applied: natural logarithm for FI and inverse normal for the residuals of TG and WHR. We identified RV associations, at genome-wide significance ($p<1.7x10^{-6}$, Bonferroni correction for 30,000 genes) in *ZNF259*, which maps to a common variant GWAS locus for TG and coronary heart disease. Based on BIC, the model with TG and FI provided the best fit ($P_{model}=3.1x10^{-9}$), and stronger associations than in univariate analyses ($P_{TG}=6.7x10^{-8}$; $P_{FI}=0.13$). Using MARV, we demonstrate its ability to identify RV multi-phenotype associations with greater statistical significance than in univariate analyses.

Introduction: Whole-exome sequencing has revolutionized rare disease research. However, many cases remain unsolved due to the fact that ~100-1000 loss of function, candidates remain after removing common and non-pathogenic variants. Exomiser offers a suite of algorithms that address this problem by additionally combining gene-based measures of candidacy. hiPHIVE (Human Interactome PHenotypic Interpretation of Variants in Exomes) assesses each candidate gene by comparing the patient phenotype to existing knowledge from disease and model organism databases. For genes with missing data, a guilt-by-association approach is applied, based on the phenotypic similarity of near-by genes in a protein-protein association network. PhenIX is designed for use in a clinical diagnostic setting where only genes associated with existing Mendelian diseases are phenotypically compared with the patient signs and symptoms. ExomeWalker ranks exome candidates based on their proximity in protein-protein networks to genes shown, or suspected, to be associated with the disease.

Results: In benchmarking experiments with known disease mutations added to unaffected exomes, both hiPHIVE and PhenIX were able to detect the causative variant as the top hit in 97% of samples. Further experiments, where knowledge of the known disease-gene association was masked, revealed hiPHIVE could detect novel associations as the top hit in 87% of samples. Exomiser is freely available via download for command-line use or through our web interfaces.

Conclusions: We are applying Exomiser to the NIH Undiagnosed Diseases Program and detect causative variants as the top hit in most previously solved cases and have diagnosed several new cases including a novel association.

C22.5

Allele specific expression reveals common and rare regulatory variation acting in human substantia nigra and putamen

K. D'Sa*[1,2], *A. Ramasamy**[1,2,3], *S. Guelfi**[1,2], *J. Vandrovcova*[1,2], *J. A. Botía*[1,2], *D. Trabzuni*[1,4], *J. R. Gibbs*[5], *C. Smith*[6], *M. Matarin*[1], *V. Varghese*[2], *P. Forabosco*[2,7], *The UK Brain Expression Consortium (UKBEC), J. Hardy*[1], *M. E. Weale*[2], *M. Ryten*[1];

[1]*Reta Lila Weston Institute and Department of Molecular Neuroscience, UCL Institute of Neurology, London, United Kingdom,* [2]*Department of Medical & Molecular Genetics, King's College London, London, United Kingdom,* [3]*Jenner Institute, University of Oxford, Oxford, United Kingdom,* [4]*Department of Genetics, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia,* [5]*Laboratory of Neurogenetics, National Institute on Aging, National Institutes of Health, Bethesda, MD, United States,* [6]*MRC Sudden Death Brain Bank Project, University of Edinburgh, Department of Neuropathology, Edinburgh, United Kingdom,* [7]*Istituto di Ricerca Genetica e Biomedica, Cittadella Universitaria di Cagliari, Sardinia, Italy.*

Allele-specific expression (ASE) occurs when the two alleles of a transcribed polymorphic locus are differentially expressed. The advantages of ASEs are: (1) they are a within individual comparison, so this avoids potential confounding factors; and (2) they can be interrogated in small sets, even single samples, from rare tissues. ASEs can therefore help clinicians gauge the pathogenicity of rare variants obtained from exome sequencing.

As part of the UKBEC project, we applied ASE analysis to paired RNA and exome sequencing data from 84 substantia nigra and putamen samples ob-

tained from 53 neuropathologically normal post-mortem human brains. We analysed mRNA-enriched (but not mRNA-exclusive) total RNA, to explore gene expression in both pre-mRNA and mRNA.
7.83% of the heterozygous variants we studied were identified as ASE signals at a False Discovery Rate < 5%. We found 66% concordance with the lymphoblastoid cell line data of Lappalainen *et al.* (2013), giving strong validation considering the difference in tissues in both datasets. Signals that showed a reversal in direction of ASE between individuals were seen to be enriched for known imprinted genes. Additionally, 91 ASE sites that are also known risk loci for a range of disorders and phenotypes were also identified, of which 64.84% were exonic and 30.76% were intronic SNPs. Amongst ASE sites identified, 15% are risk loci for adult neurological disorders thus providing insights into these disorders and indicating the power of this approach.

C22.6
Evidence for directional dominance on complex traits relating to size and cognition in a wide range of human populations

P. Joshi[1], *T. Esko*[2], *H. Matteson*[3], *N. Eklund*[3], *I. Gandin*[4], *A. Jackson*[5], *T. Nutile*[6], *C. Schurmann*[7], *O. Polasek*[1], *J. F. Wilson*[1];
[1]*University of Edinburgh, Edinburgh, United Kingdom,* [2]*Estonian Genome Centre, Tartu, Estonia,* [3]*National Institute for Health and Welfare, Helsinki, Finland,* [4]*University of Trieste, Trieste, Italy,* [5]*University of Michigan, Ann Arbor, MI, United States,* [6]*Consiglio Nazionale delle Ricerche, Naples, Italy,* [7]*Mount Sinai, New York, NY, United States.*

Homozygosity has long been associated with rare, often devastating, Mendelian disorders and Darwin was one of the first to recognise that inbreeding reduces evolutionary fitness. However, the effect of the more distant parental relatedness common in modern human populations is less well understood. Genomic data now allow us to investigate the effects of homozygosity by measuring runs of homozygosity (ROH), however information is required on very large numbers of people to provide sufficient power. Here we use ROH in a study of 16 health-related quantitative traits in up to 354,224 individuals from 102 cohorts and find statistically highly significant associations between individual genome-wide summed ROH and four complex traits: height, forced expiratory lung volume in 1 second (FEV1), general cognitive ability (g) and educational attainment (nominal p<1 x 10-300, 2.1 x 10-6, 2.5 x 10-10, 1.8 x 10-10). In each case increased homozygosity was associated with decreased trait value, equivalent to the offspring of first cousins being 1.2 cm shorter and having 10 months less education. Similar effect sizes were found across four continental groups and in populations with different degrees of genome-wide homozygosity, providing convincing evidence for the first time that homozygosity, rather than genetic or environmental confounding effects, contributes to observed phenotypic variance. Directional dominance is predicted for traits under directional evolutionary selection, so this study provides evidence that increased stature and cognitive function have been positively selected in human evolution, whereas many important risk factors for late-onset complex diseases have not.

C23.1
TBK1 mutations cause amyotrophic lateral sclerosis and fronto-temporal dementia

Amyotrophic lateral sclerosis (ALS) is a genetically heterogeneous neurodegenerative disorder hallmarked by adult-onset loss of motor neurons and fatal paralysis. Mutations in 29 genes have been linked to ALS pathogenesis and are frequently also associated with fronto-temporal dementia (FTD). However, mutations in these genes explain less than 1/3 of ALS cases.
To evaluate the contribution of low-frequency variants in protein-coding genes to familiar ALS, we performed exome sequencing of 252 index cases and 827 control individuals. We performed gene-based rare variant analysis and identified a single exome-wide significant enrichment of loss-of-function (LoF) mutations in the gene TANK-binding kinase 1 (TBK1) in the patient group. Seven different LoF mutations were found in nine patients, whereas LoF variants were absent in controls and in 3,101 additional in-house exomes.
No enrichment of LoF mutations was detected using a targeted mutation screen of 1,010 sporadic cases and 650 Swedish control individuals.
Next, we recruited relatives from index mutation carriers to perform linkage analysis. Incomplete penetrance was observed in all pedigrees. Linkage analysis in 3 extended families using a dominant model with reduced penetrance resulted in a summary LOD score of 4.6 thus exceeding the genome-wide significance threshold.
In vitro experiments including patient-derived cell lines confirmed loss of expression of TBK1 LoF mutant alleles, or loss of interaction of the TBK1 coiled coil domain (CCD) with the TBK1 adaptor protein optineurin, an established ALS target.
In conclusion, we provide parallel evidence from association testing and linkage analysis that LoF TBK1 variants cause a monogenic form of ALS with FTD and reduced penetrance.

Non-progressive cerebellar ataxias (NPCAs) are a rare group of disorders, with only 7 genes/loci described, for autosomal recessive NPCAs. NPCAs manifest in infancy with abnormal gross motor development and hypotonia, followed by the appearance of ataxia. Dysarthria, intellectual disability and spasticity are often present.
We studied 17 patients from 4 families affected with NPCA, including the large Lebanese family previously described by Megarbane et al (1999) and localized to chromosome 9q34 (Delague et al, 2001; OMIM #213200). Homozygosity mapping and exome sequencing led to the identification of mutations in PMPCA in all patients: a homozygous p.Ala377Thr missense mutation in 16 patients, and compound heterozygous mutations, p.Ser96Leu and p.Gly515Arg, in one. We describe a founder effect for the p.Ala377Thr mutation, as patients from 3 a priori non-related Lebanese families share a common haplotype at the PMPCA locus.
PMPCA encodes α-MPP, the alpha subunit of mitochondrial processing peptidase (MPP), the primary enzyme responsible for the maturation of nuclear-encoded mitochondrial proteins. Analysis of cells from patients homozygous for the PMPCA p.Ala377Thr mutation and carriers, demonstrate that the mutation impacts both the level of α-MPP and the function of MPP. Indeed, this mutation impacts the maturation process of frataxin, the defective protein in Friedreich ataxia.
Our results definitely implicate PMPCA as the causal gene in this rare form of NPCA. This is the first time that the MPP enzyme, vital to life at the cellular level, has been associated with a clinical phenotype in humans. Disruption of mitochondrial protein precursor cleavage represents a new avenue for investigation of the pathogenesis of NPCAs.

Spinocerebellar ataxia type 28, from molecular hypothesis to human therapy

F. Maltecca[1], E. Baseggio[1], F. Consolato[1], D. Mazza[1], P. Podini[2], A. Puliti[3], F. Codazzi[1], A. Quattrini[2], **G. Casari**[1];

Spinocerebellar ataxia type 28 (SCA28) is a neurodegenerative disease caused by mutations of the AFG3L2 gene. The encoded protein assembles into multimeric complexes (the m-AAA proteases), which exert protein quality control in the inner mitochondrial membrane and participate to the regulation of mitochondrial morphology. The Afg3l2 haploinsufficient mouse recapitulates the symptoms of SCA28 patients, presenting a progressive decline in motor skills caused by dark degeneration of Purkinje cells (PC-DCD) of mitochondrial origin. In this work, we define the pathogenetic mechanism of SCA28 and provide the first evidence of a pre-clinical treatment of this disease. We demonstrated in cultured PCs that an inefficient buffering of stimulus-evoked Ca2+ peaks by Afg3l2-deficient mitochondria provokes an increase in cytoplasmic Ca2+ concentration, thus triggering PC-DCD. Proving this mechanism, we completely recover the ataxic phenotype of SCA28 mice by genetically reducing the metabotropic glutamate receptors mGluR1, and thus decreased Ca2+ influx in PCs. The same result has been successfully replicated by administration of an off-label therapy with ceftriaxone that favors the synaptic glutamate clearance. This treatment is effective when applied at both presymptomatic and after the ataxia onset in the preclinical model, thus representing a safe and immediately accessible therapy for presymptomatic carriers of AFG3L2 mutations and also SCA28 patients with overt symptoms.

C23.4

Homozygous truncating mutations in WDR73 cause a severe nephrocerebellar syndrome, part of the Galloway Mowat syndrome spectrum

DuPont Hospital for Children, Willmington, DE, United States, [16]University of Connecticut, Storrs, CT, United States.

We investigated 30 Amish individuals (1-28yrs) with a severe nephrocerebellar syndrome characterised by progressive microcephaly, visual impairment, stagnant psychomotor development, abnormal extrapyramidal movements, and steroid resistant nephrosis. Post-mortem neuropathology revealed micrencephaly and atrophic cerebellar hemispheres with a unique pattern of histological findings. Assuming autosomal recessive inheritance of a founder mutation we used autozygosity mapping and next generation sequencing to identify the underlying molecular cause, a homozygous frameshift variant in WDR73 (c.888delT; p.Phe296Leufs*26). Interestingly, a second truncating frameshift variant (c.1264_1270delATAAAAG) (NM_001080435.2) was also identified in the closely linked WHAMM gene, which was found to be homozygous in all but one affected individual. A further novel homozygous frameshift variant (WDR73 c.766dupC; Arg256Profs*18) was identified in a Bulgarian child with similar clinical features. Our functional studies revealed that wild type WDR73 protein is expressed in human cerebral cortex, hippocampus, and cultured embryonic kidney cells and interacts with α- and β-tubulin, heat shock protein 90 (HSP-90), and CAD; the mTORC1-regulated multi-enzyme complex. We show that WDR73 protein is concentrated at mitotic spindles and midbody microtubules during mitosis, and recombinant WDR73 mutant (p.Phe296Leufs*26, p.Arg256Profs*18) proteins are unstable displaying increased interaction with α- and β-tubulin and HSP-90. Together, our data confirm that mutation of WDR73 is responsible for a complex nephrocerebellar syndrome best classified as part of Galloway Mowat syndrome spectrum of disorders. However given that the phenotypical outcome of WHAMM mutation is currently unknown, patients doubly homozygous for WHAMM mutation in association with WDR73 mutation may exhibit a composite phenotype.

C23.5

Mutations in PDE10A, resulting in a loss of PDE10A activity cause a hyperkinetic movement disorder in humans and in a mouse model.

E. G. Sheridan[1], *R. Hinttala[2], J. Uusimaa[2], M. Kurian[3], N. Brandon[4], C. Diggle[1];*
[1]University of Leeds, Leeds, United Kingdom, [2]University of Oulu, Oulu, Finland, [3]University College LOndon, London, United Kingdom, [4]Astra Zeneca Neuroscience, Cambridge, MA, United States.

Clinical trials with phosphodiesterase 10A (PDE10A) inhibitors are currently underway in both Huntington's disease and Schizophrenia. PDE10A inactivates the critical intracellular signalling molecules Cyclic AMP and cyclic GMP; it is specifically expressed in the medium spiny neurons (MSNs) of the striatum.
In animal models PDE10A inhibitors ameliorate symptoms of schizophrenia, and the striatal pathology and clinical signs of HD, providing the rationale for these clinical trials in humans. However, very little is known about the role of PDE10A in man.
We observed two families with a very distinctive phenotype of a hyperkinetic movement disorder, variable mental retardation and abnormal skin pigmentation.
The pedigree structure of both families suggested a recessive disorder. Whole genome autozygosity mapping and exome sequencing revealed the presence of different homozygous mutations in PDE10A. Modeling of one of the mutations in cell lines showed that there was a reduction in protein levels and abnormal localization of PDE10A to the cytosol rather than the cell membrane where it is required for its activity.
We constructed a knock in mouse with one of the variants, this model animal displayed deficient motor control. The animal had reduced levels of PDE10A protein in the striatum, and furthermore there was a marked reduction in striatal PDE10A activity, and a loss of downstream signaling activity.
These data show that in humans congenital loss of PDE10 activity results in a movement disorder and variable cognitive impairment

C23.6

PLP1 mutations affecting *PLP1/DM20* alternative splicing causes Hypomyelination of Early Myelinating Structures

Inherited leukodystrophies represent a diagnostic challenge and many patients remain without a diagnosis. In this study we investigated the genetic etiology of the recently described X-linked disorder 'Hypomyelination of Early Myelinating Structures' (HEMS) in 16 patients diagnosed by brain MRI criteria. Using exome sequencing, we identified in all patients unusual hemizygous mutations in the *PLP1* gene, located either in exon 3B (1 deletion, 1 missense and 2 silent), which is spliced out in isoform DM20, or in intron 3 (5 mutations). The frameshift deletion led to truncation of PLP1, but not DM20. *In silico* analysis of effects of the mutations on splicing and secondary RNA folding showed that four mutations located deep in intron 3 were predicted to destabilize a long-distance interaction structure in the secondary *PLP1* RNA fragment involved in regulating *PLP1/DM20* alternative splicing. The other four mutations were predicted to alter *PLP1/DM20* alternative splicing, either by creating exonic splicing silencers motifs, a splice donor site or by affecting the local RNA structure of the *PLP1* splice donor site. *In vitro* studies confirmed a decreased *PLP1/DM20* ratio in patients'

fibroblasts and transfected immortalized immature oligodendrocytic cells. Intriguingly, in patients with HEMS, brain structures that normally myelinate early, are hypomyelinated, in contrast to Pelizaeus-Merzbacher disease, also caused by *PLP1* alterations. This suggests that *PLP1/DM20* alternative splicing is important for early myelination, probably by an impact on the *PLP1/DM20* ratio. Our data extend the phenotypic spectrum of *PLP1*-related disorders and support the need to include intron 3 in diagnostic sequencing.

Clinical experience with a SNP-based noninvasise prenatal test for 22q11.2 deletion syndrome

Z. Demko[1], *S. J. Gross*[1], *M. Stosic*[1], *A. Norvez*[1], *R. Dhamankar*[1], *K. N. Jinnett*[1], *P. Benn*[2];
[1]*Natera, Inc., San Carlos, CA, United States,* [2]*University of Connecticut Health Center, Farmington, CT, United States.*

Objective: In contrast to whole chromosome aneuploidy, microdeletion syndromes are smaller and thus harder to detect, and they occur with equal frequency in women of different maternal ages. Here we report on the clinical experience with our single-nucleotide polymorphism (SNP)-based noninvasive prenatal test (NIPT) for the microdeletion responsible for the 22q11.2 deletion syndrome (DiGeorge).
Method: 21,948 maternal blood samples received between February and August 2014 were analyzed for the 22q11.2 deletion. Cell-free DNA and maternal-specific DNA were isolated from the samples. 672 SNPs in a 2.91 Mb DNA segment commonly deleted in the 22q11.2 deletion syndrome were PCR-amplified, sequenced, and analyzed using a proprietary algorithm to determine fetal and maternal copy number at the interrogated region. Follow-up information was sought for all high-risk cases.
Results: In the study cohort, 97 (0.5%) patients were found to be at high risk for a 22q11.2 microdeletion, including two cases in which the mother was suspected to have the deletion. Fetal diagnostic confirmation was available for 58 high-risk cases: 11 were true positives and 47 were false positives, resulting in a positive predictive value (PPV) of 19%. Invasive testing decisions were available for 81 high-risk cases: 60.5% had invasive testing and 39.5% declined. Ultrasound abnormalities were confirmed for 81.8% of true-positive and 10.6% of false-positive cases. Follow-up is ongoing.
Conclusions: Despite the small size of the 22q11.2 microdeletion, this SNP-based NIPT was highly effective and may be considered as a first-line approach for the general pregnancy population, not just for high-risk patients.

PM01.02

Complete 46,XY female of 14 cases and review of the literature

S. Lee[1], *B. Lee*[1], *J. Park*[1], *E. Choi*[1], *Y. Lee*[1], *A. Oh*[1], *S. Park*[1], *M. Kim*[2], *H. Ryu*[1,2];
[1]*Laboratoy of Medical Genetics, Cheil General Hospital and Women's Healthcare Center, seoul, Korea, Republic of,* [2]*Department of Obstetrics and Gynecology, Cheil General Hospital and Women's Healthcare Center, Seoul, Korea, Republic of.*

Introduction : The individual of phenotypically female with 46,XY karyotype is caused by various abnormality such as gonadal formation and androgen synthesis and sensitivity during sexual development. XY female individuals are rarely found and have complex features. The degree of secondary sexual characteristics, level of hormone and presence or absence of Müllerian organ might be shown by various causes.
Materials and Methods : Cytogenetic analysis were performed in 9,472 female patients at Cheil General Hospital between September 1983 and December 2014. Clinical findings, basal hormone profiles, radiological readings were investigated. Additionally, DA-DAPI staining, CBG-banding, quantitative fluorescence-polymerase chain reaction analysis, fluorescence in situ hybridization were conducted to confirm the presence of Y chromosome and *SRY* gene.
Results : Among the 9,472 individuals, 14 cases found with complete 46,XY female (0.0015 %). Indications of 12 cases were primary amenorrhea (86 %) and two cases were agenesis of uterus and ovary cyst dysgeminoma respectively. Six cases had no uterus and high levels of testosterone. Four cases were performed gonadectomy. Four cases were familial. Only one case was diagnosed as androgen insensitivity syndrome.
Conclusions : Although further genetic testing and research is needed for an accurate diagnosis, the present report would be helpful for genetic counseling of XY female patient and their family, and understanding the one of the genetic etiology as the causal factor in amenorrhea.

PS01.03

aCGH in three fetus with severe intrauterine growth retardation (IUGR)

V. Gloning, *M. Shoukier, C. Daumer-Haas, C. Bagowski, S. Minderer, T. Schramm, K. Gloning;*
Praenatal-Medizin Muenchen, Munich, Germany.

Background:
The application of aCGH technology in prenatal diagnostics enables the detection of submicroscopic copy number changes that are associated with clinically significant outcomes.
Objective:

We report three cases of severe intrauterine growth retardation due to rare chromosomal aberrations diagnosed by aCGH. Prenatal and postnatal phenotypes are presented.
Methods and Results:
Fetal growth retardation as the leading finding was seen on ultrasound in the second/third trimester of pregnancy. In each case uterine artery Doppler was normal. With aCGH pathogenic submicroscopic copy number changes were identified, not detectable by cytogenetic chromosomal analysis: a) a terminal 11.4 megabase (Mb) deletion in 1q43q44, b) a 11 Mb duplication in 10p15.3p14 and a 1.9 Mb deletion in 17p13.3, c) a duplication in 14q11.2q12 (8.3 Mb) and deletion in 15q11.2q12 (3.2 Mb). While the copy number changes in cases a and b were de novo events, a pure deletion 1q43q44 in case a and a de novo translocation der(17)t(10;17)(p13;p13) in case b, the imbalances in case c resulted from an unbalanced inheritance of a reciprocal translocation t(14;15)(q12;q12). Beside growth retardation, the three young patients showed multiple dysmorphic features und further abnormalities after birth. For all, a distinct developmental delay/mental retardation is expected.
Conclusion:
aCGH should be adopted as a first-tier genetic test in fetus with idiopathic IUGR before routine G-banded karyotyping. The incremental information provided by aCGH allows prognosis prediction and hereby improves parental counselling.

PM01.04
Mutation analysis of androgen receptor gene:Multiple uses for a single test

A. Shojaei;
Department of Medical Genetics and Molecular Biology, Faculty of Medicine, Iran University of Medical Sciences,, Tehran, Iran, Islamic Republic of.

Abstract: Androgen receptor gene mutations are one of the leading causes of disorders of sex development (DSD) exhibited by sexual ambiguity or sex reversal. In this study, 2 families with patients whom diagnosed clinically as androgen insensitivity syndrome (AIS) were physically and genetically examined. This evaluation carried out by cytogenetic and molecular analysis including karyotype and sequencing of SRY and AR genes. In family1, two brothers and their mother were hemizygous and heterozygous respectively for c.2522G>A variant, while one of their healthy brother was completely normal hemizygous. Family 2 assessment demonstrated the c.639G>A (rs6152) mutation in two siblings who were reared as girls. The SRY gene was intact in all of the study's participants. Our findings in family 1 could be a further proof for the pathogenicity of the c.2522G>A variant. Given the importance of AR mutations in development of problems such as sex assignment in AIS patients, definitive diagnosis and phenotype-genotype correlation could be achieved by molecular genetic tests that in turn could have promising impacts in clinical management and also in prenatal diagnosis of prospect offspring.
grant:Tehran University of Medical Sciences/89033010820

PS01.05
Genome wide association analysis of Anti Müllerian Hormone (AMH) in about 1,300 caucasian women highlights 2 novel suggestive loci for fertility.

C. Barbieri[1], *M. Traglia*[1], *T. Nutile*[2], *S. Ulivi*[3], *L. Portas*[4], *C. Sala*[1], *C. Masciullo*[1], *M. Cocca*[3], *L. Pagliardini*[5], *P. Panina*[5], *M. Ciullo*[2], *P. Gasparini*[3], *A. La Marca*[6], *E. Papaleo*[5], *M. Pirastu*[4], *D. Toniolo*[1];

AMH is a dimeric glycoprotein, member of the TGF-β superfamily expressed in the growing follicles of the ovary. AMH concentration in serum essentially reflects the ovarian follicular pool. AMH levels vary broadly in women during reproductive life, until after 40 years old when the AMH level starts to decrease sharply, becoming undetectable after menopause. The discovery of genetic variants responsible for the high variability in AMH level could be a useful marker to predict fertility and age of menopause.
AMH levels were measured in serum of 850 healthy women collected by the Italian Network of Genetic Isolates (INGI) and of 461 fertile women collected by Obstetrics and Gynecology Unit of San Raffaele Hospital, Milano.
A meta-analysis for AMH adjusted for age of 1311 samples was performed on genotypes imputed to the low variants enriched 1000G panel. Two suggestive loci were identified: a locus on chromosome 6 already associated to menopause (MAF 0.017; p=2.081E-07) and a second novel locus on chromosome 11 (MAF 0.012; p= 1.34E-07). A subset of 941 women was genotyped by high-coverage exome chip. A SKAT meta-analysis was performed to highlight rare variants in the coding regions associated to AMH levels. A new locus on chromosome 16 reached a suggestive p-value of 2E-05.
Meta-analysis will be enlarged by additional samples in order to increase the statistical power of the analysis and confirm the suggestive loci.

PM01.06
BACs-on-Beads technology and next-generation sequencing for aneuploidy screening in trophectoderm cells of human blastocysts

[1]*Human Genetics Laboratory, Department of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol, Bangkok, Thailand,* [2]*Medical Genomic Center, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand,* [3]*BORN IVF CLINIC, Bangkok, Thailand.*

Introduction: Preimplantation genetic testing is a technique used to identify genetic defects in embryos created through in vitro fertilization (IVF) before pregnancy. Array comparative genomic hybridization (aCGH) was the first technology to be widely available for provide more information by analyzing all chromosomes at one time. However, the throughput and cost of aCGH may limit widespread application in clinical laboratories. The purpose of this study was to investigate the effectiveness of a new rapid aneuploidy screening test based on BACs-on-Beads (BoBs) technology and next-generation sequencing (NGS).
Materials and Methods: Trophectoderm (TE) samples of 10 blastocysts were subjected to analysis. The Karyolite™ BoBs kit was used to study aneuploidies involving any of the 24 chromosomes. Low-coverage whole genome sequencing was performed using the Ion Torrent PGM with 316 chip. The efficiency of these both approaches were estimated by comparing results obtained by aCGH.
Results: Whole genome amplification (WGA) products of TE cells were detected by both BoBs and NGS technology. One embryo (10.0%) was detected as euploid, while three embryos (30.0%) contained single chromosomal aneuploidy. Six of these (60.0%) were with multiple chromosomal abnormalities. The results from both technologies were compared with aCGH revealed that both methods were concordance 100% sensitivity and specificity.
Conclusions: Our study demonstrated both BACs-on-Beads technology and next-generation sequencing could be applied to accurately detect embryonic chromosomal abnormality with a flexible and cost-effective strategy and higher potential accuracy.

Maintenance of the methylation pattern on fresh and cultured Chorionic Villi (CV) in normal and Beckwith Wiedemann Syndrome (BWS)-suspected pregnancies

L. Paganini[1], *N. Carlessi*[1], *S. Gangiobbe*[1], *R. Silipigni*[2], *S. Guerneri*[2], *F. Lalatta*[3], *A. Cereda*[4], *S. Sirchia*[5], *M. Miozzo*[1], *S. Tabano*[1];
[1]*Division of pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,* [2]*Medical Genetics Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, Milano, Italy,* [3]*Clinical Genetics Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy., Milano, Italy,* [4]*Pediatric Unit, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy., Milano, Italy,* [5]*Medical Genetics, Department of Health Sciences, Università degli Studi di Milano, Milano, Italy., Milano, Italy.*

BWS is an imprinting-related disorder that can be prenatally suspected following established clinical guidelines. Molecular confirmation is commonly performed on amniocytes and the possibility to use fresh (CVF) and cultured (CVC) CV has never been investigated.
To verify whether CVF and CVC are eligible sources of DNA, we tested by pyrosequencing in normal pregnancies the methylation percentage at: ICR1, ICR2, H19 promoter, PWS/AS-ICR, MGMT and RASSF1A genes. We highlighted stable methylation levels at the imprinting-driving regions ICR1 (CVF: 45.38% ± 1.77; CVC: 45.04% ± 1.81), ICR2 (CVF: 44.32% ± 1.84; CVC: 43.67% ± 2.10) and PWS/AS-ICR (CVF: 43.70% ± 5.60; CVC, 43.15% ± 3.41). Conversely, H19 promoter was severely hypomethylated at both CVF (11.33% ± 1.92) and CVC (19.30% ± 4.30), and showed a significantly increased methylation after culture. In two unrelated and biallelic genes, the methylation remained stable at MGMT promoter and changed at RASSF1A.
As second step, we investigated ICR1 and ICR2 methylation level on both CVF and CVC of two BWS-suspected fetuses (P1 and P2). P1 showed hypomethylation at ICR2 both in CVF and CVC (CVF: 17.63% ± 0.88; CVC: 16,13% ± 0.18); P2 showed normal methylation profiles.
Taken together these findings suggest that: i) ICR1 and ICR2, but not H19,

are reliable targets for BWS prenatal methylation test in CV also after culture; ii) similarly, PWS/AS-ICR is steadily hemimethylated in CV from healthy pregnancies, independently from culture. Thus, methylation analysis of these regions represents a very useful tool for prenatal diagnosis of imprinting related syndromes.

CDKN1C mutations in familial and prenatally diagnosed Beckwith-Wiedemann syndrome cases.

L. Calzari[1], A. De Crescenzo[2], A. Mussa[3], M. Divizia[4], M. Police[5], S. Di Presa[6], S. Di Candia[7], L. Memo[8], C. Izzi[9], D. Melis[10], G. Ferrero[3], A. Riccio[10], L. Larizza[1], **S. Russo**[1];
[1]Istituto Auxologico Italiano, Milano, Italy, [2], Università Federico II, Napoli, Italy, [3]Università di Torino, Torino, Italy, [4]Istituto Neuroligo Gaslini, Genova, Italy, [5]Osp Moscati, Avellino, Italy, [6]IRCCS Burlo garofalo, Trieste, Italy, [7]Ospedale San Raffaele, Milano, Italy, [8]Ospedale San Martino, Belluno, Italy, [9]Spedali Civili, Brescia, Italy, [10]Università Federico II, Napoli, Italy.

CDKN1C (cyclin dependent kinase inhibitor 1) gene mapping within the 11p15.5 cluster of imprinted genes, encodes an inhibitor of several cyclin dependent kinases (Cdk) acting in the cell cycle G1 - S transition. The monoallelic maternal expression of CDKN1C is under the control of the IC2 imprinting centre through the antisense non coding KCNQ1OT1 transcript. The protein comprises three functional domains including from the N- to the C-terminus a CDK binding, a PAPA and a PCNA domain.

CDKN1C mutations underlie the Beckwith Wiedemann syndrome (BWS) accounting for 10% of sporadic cases and up to 40% of familial cases.

Here we report on the clinical and molecular characterization of ten BWS families, negative for the known 11p15 (epi)genetic alterations and 2 prenatal cases diagnosed because of omphalocele. Twelve distinct mutations were detected, including 6 stop, 3 frameshift, two missense mutations and one complex mutation, seven of which yet unreported. Most important 11/12 mutations were maternally transmitted allowing to provide the family with genetic counseling and to assess the recurrence in two subsequent prenatal diagnoses. The clinical presentation of the investigated cases was heterogeneous although severe in all the carriers of inactivating mutations, including one case born prematurely at 28th week also displaying psychomotor delay and another with autistic traits, not associated with de novo or inherited CNVs as shown by array CGH.

Conversely the two patients with a missense mutations, predicted to be damaging by several bionformatic tools, exhibited a mild phenotype

PS01.09

Expanded carrier screening of 311,688 individuals: the case for going beyond CF

I. S. Haque, *G. A. Lazarin, M. Raia, H. Bellerose, E. A. Evans, J. Goldberg;
Counsyl, South San Francisco, CA, United States.*

We report our experience performing expanded carrier screening for 98 recessive conditions on an ethnically-diverse group of 311,688 individuals primarily from the USA, using targeted genotyping and next-generation sequencing. Individuals of European ancestry comprise 65% of the sample. All tested diseases were categorized as "profound", "severe", or "moderate" by a recently published methodology [Lazarin et al., PLoS One 2014]. "Severe" diseases (e.g., cystic fibrosis) are those that cause intellectual disability or shorten lifespan to adolescence or earlier; "profound" diseases (e.g., Canavan disease) do both.

We find that in every ethnic group, there is a higher absolute risk of fragile X syndrome (FXS) than of spinal muscular atrophy, recommended for universal screening by the American College of Medical Genetics and Genomics; in European groups, FXS is at least 50% as common as CF, and has higher risk than CF in all non-European groups.

We find the absolute risk for "profound" disorders not on an ethnicity-specific panel to be 60-80% that of CF (classified as "severe") in all European populations. Non-CF "severe" disorders are even more common, from 3.9x CF risk in Ashkenazi to 99.3x in East Asians.

Our data show that the absolute risk for diseases in expanded carrier screening panels is comparable to or significantly higher than the risk detected by existing carrier screening guidelines, especially in non-Caucasian populations.

		Absolute risk relative to CF risk			
Ethnicity	Absolute risk of CF (1-in-X births)	Spinal muscular atrophy	Fragile X syndrome	Profound diseases	Severe diseases
African	12341	75%	300%	89%	518%
Ashkenazi	1745	14%	95%	131%	389%
Mixed/Other Caucasian	1473	16%	44%	63%	389%
Northern European	1622	19%	51%	60%	374%
Southern European	1987	29%	53%	80%	286%
Unknown	2371	23%	86%	75%	499%
Hispanic	4348	39%	115%	72%	656%
East Asian	143037	935%	911%	3554%	9926%
Southeast Asian	90603	806%	724%	925%	4680%
Middle Eastern	9522	103%	768%	106%	2623%
South Asian	7079	56%	248%	29%	1693%

p.Asn386Lys, a new putative cystic fibrosis mutation on a complex allele discovered during assisted reproduction explorations, with an unknown phenotypical impact

B. Herve[1], *E. Girodon[2], A. Taillandier[3], E. Mornet[3], M. Bailly[4], T. Bienvenu[2], B. Simon-Bouy[3], F. Vialard[1], D. Molina-Gomes[1];
[1]Laboratoire de Cytogénétique, CHI Poissy St Germain en Laye, Poissy, France, [2]Laboratoire de Biochimie et Génétique Moléculaire, AP-HP, Hôpital Cochin, Paris, France, [3]Service de Biologie Médicale, Centre Hospitalier de Versailles – Hôpital André Mignot, Le Chesnay, France, [4]Service de Biologie de la Reproduction, Gynécologie et Obstétrique, CHI Poissy Saint Germain en Laye, Poissy, France.*

Cystic fibrosis (CF) is an autosomal recessive genetic disease caused by mutations in the CF transmembrane conductance regulator (CFTR) gene. Almost 2,000 mutations have been described, resulting in CF and CFTR-related disorders including male infertility by congenital absence of the vas deferens (CBAVD). Here, we report a Portuguese couple undergoing assisted reproduction because of CBAVD. The man was compound heterozygous for the CF-mutation c.1000C>T (R334W) and the CFTR-RD associated complex allele c.[1210-34TG[13]T[5];3705T>G] (TG13T5;S1235R). The genotype was consistent with the phenotype. The partner carried three heterozygous variants: c.1727G>C (G576A) and c.2002C>T (R668C), which are known as a complex allele, per se not associated with CF but sometimes in association with a third mutation, resulting in a CF or CFTR-RD allele, and c.1158C>A (N386K), which was never reported previously. Family study led to characterize a new complex allele combining the three variants. Evaluation of a possible impact of the c.1158C>A (N386K) mutation by bioinformatic tools did not suggest an effect on splicing but showed a possible effect on the protein level. This mutation, in the context of a complex allele, was thus considered to be potentially associated with CF, although functional studies would help document such an effect. This makes genetic counseling cautious, with a 25% hypothetical risk for the couple of having a child with CF. This case report illustrates the interest of thorough CFTR gene studies in CBAVD couples requesting assisted reproduction in order to provide accurate genetic counselling.

PS01.11

An unusual presentation of a human chimera - case study and investigation of the underlying mechanism by SNP array analysis.

Human XX/XY chimerism, resulting from the fusion of two different zygotes, is a rare finding and is usually identified in newborns with ambiguous genitalia. In the present study we describe an apparently normal male age 34 years who presented with infertility. Sperm analysis revealed a low sperm count with decreased mobility, a diagnosis of severe oligoasthenoteratozoospermia was made. The proband is otherwise healthy and has received no blood or bone marrow transfusions. Karyotype analysis of peripheral blood and subsequent FISH analysis of buccal cells showed a mixture of 46,XY and 46,XX cells. Several mechanisms have been proposed for the formation of chimerism including 1) tetragametic chimera resulting from postzygotic fusion of two separate zygotes, 2) dispermic fertilization of either an oocyte and its second polar body, and 3) dispermic fertilization of two female gametes arising from parthenogenetic division of a single oocyte. Comparative QF-PCR studies of the proband and both parents provided evidence of a genetic contribution in the proband from two different sperm but no evidence of a genetic contribution from a second ovum, consistent with mechanism 2 or 3. A comparative genotyping SNP array analysis was undertaken to try to further elucidate the underlying mechanism in this case. This genetic diagnosis posed a challenging genetic counselling issue but has not fundamentally altered the proposed ICSI treatment for this individual's infertility.

Reliability of chromosomal microarray-based analysis in CVS for the detection of cryptic chromosomal abnormalities and fetoplacental discrepancies

A. Sánchez[1,2,3], *I. Mademont-Soler*[4], *E. Margarit*[1,2,3], *V. Borobio*[1], *S. Anna*[1,2,3];
[1]*Hospital Clínic, Barcelona, Spain,* [2]*IDIBAPS, Barcelona, Spain,* [3]*CIBERER, Barcelona, Spain,* [4]*Institut d'Investigació Biomèdica Josep Trueta, Girona, Spain.*

The study of chorionic villi samplings (CVS) by conventional cytogenetics reveals chromosomal abnormalities in 12% of cases, and in 1-2% of pregnancies mosaicism is observed. In order to increase the diagnostic yield, new molecular techniques that offer higher resolution have been developed, such as chromosomal microarray-based analysis (CMA). Similar to cytogenetically visible chromosomal abnormalities, cryptic chromosomal abnormalities (CCA) may also be presented as confined placental mosaics, contributing to misinterpretations. The purpose of the present work was to determinate the frequency of CCA and confined placental mosaicism of CCA in CVS, and to evaluate the reliability of the strategy used.
We performed CMA in CVS of 50 pregnancies with normal karyotype or a balanced familial rearrangement, in both trophoblast and mesenchyma. Twenty two per cent of them were referred for ultrasound abnormalities and 78% for abnormal first trimester screening.
In 94% of the CVS, CMA results could be obtained from both tissues. The overall frequency of reportable non-mosaic CCA was 8,5%, and in 2% of samples a CCA was only found in trophoblast. All the CCA were diagnosed in the abnormal first trimester screening group.
Although the cohort presented is relatively small, it seems that CCA and placental mosaicisms of CCA present a frequency similar to that of cytogenetically visible chromosomal abnormalities during the first trimester of pregnancy. However, CCA do not seem to be generally associated with ultrasound abnormalities in the first trimester. The strategy used is reliable for the detection of placental mosaicisms of CCA.

PS01.13

The cleavage-stage bovine embryo is a valuable model to study chromosome instability in early mammalian embryogenesis

In vitro fertilization (IVF) is a widely used infertility treatment procedure, but the IVF outcome may be influenced by the high rate of chromosome instability (CIN) found in human preimplantation embryos. Although CIN has been observed in recent studies, its precise etiology remains elusive. However, experimenting on human embryos is associated with ethical issues. In this study, we investigate the incidence of CIN in in vitro cleavage-stage bovine embryos, and provide substantial proof that bovine early embryogenesis is a valuable model for the study of underlying mechanisms leading to CIN in an in vivo research setting.
151 blastomeres from 25 cleavage-stage embryos were obtained on day 2 and day 3 post insemination (pi) and whole-genome amplified (WGA). Subsequently, the samples were hybridized on the Illumina Bovine HD BeadChip SNP arrays. We consequently applied a modified version of the siCHILD algorithm (siCHILD-bovine) and haplarithmisis for the data analysis.
From 25 embryos analyzed, 7 were uniformly diploid (28%), while 18 embryos had blastomeres with chromosomal anomalies (72%), of which 83% were mosaic. Out of 124 blastomeres available for the analysis, 31% were diploid, 47% had whole-chromosome abnormalities and 27% carried segmental aberrations. Moreover, segmental reciprocal gains and losses in sister blastomeres were identified in 3 embryos.
This study demonstrates that the nature of CIN in bovine cleavage-stage and human cleavage-stage embryos are comparable. Therefore, cattle can be employed as a model organism for CIN studies. Data acquired from such studies could be used to raise the success rate of human IVF outcome.

EasyChip 8x15K: a new and useful tool for anomalies detection in low risk pregnancies

V. Alesi[1], *L. Bernardini*[2], *M. Canestrelli*[1], *M. Dentici*[3], *G. Barrano*[1], *L. Sinibaldi*[2], *B. Dallapiccola*[3], *A. Novelli*[3];
[1]*san pietro FBF hospital, rome, Italy,* [2]*Mendel Laboratory, IRCSS Casa Sollievo della Sofferenza Hospital, rome, Italy,* [3]*Bambino Gesù Children's Hospital, rome, Italy.*

Microarray chromosome analysis is becoming a more and more routinely test and its use in prenatal diagnosis has been discussed, raising controversial opinions.
In order to limit incidental findings (IF) and variants of unknown significance (VOUS) we designed EasyChip, a low resolution oligo 8x15K array with a resolution of 3-4Mb on genomic backbone, 500Kb on subtelomeric portions and 250Kb on 43 syndromic regions.
Syndromic regions were selected considering morbidity, penetrance (>75%) and etiological mechanisms.
We evaluate EasyChip on 48 samples with known anomalies, and all the imbalances were detected: 22 syndromic regions (86.7Kb-33Mb); 29 subtelomeric regions (233.8Kb-40Mb); 7 backbone regions (1.9Mb-5.5Mb).
A prospective study was carried out on 32 cases of prenatal samples from low risk pregnancies, tested with both EasyChip and a higher resolution platform (4x180K/8x60K).
The only positive result detected by both the platforms was consistent with a female foetus presented with mosaicism 45,X/46X,i(X)(q10).
EasyChip did not detect 7 VOUS on genomic backbone, ranged 222.1-579 .6Kb, evidenced by high resolution platform.
EasyChip is a useful tool in prenatal diagnosis for screening purposes, associated with karyotype. It can support the standard cytogenetic analysis for detection of submicroscopic imbalances, which could be lost especially when working on not optimal quality samples. Moreover, it can detect cryptic imbalanced subtelomeric rearrangements and microdeletions/duplications within 43 specific regions associated with high morbidity syndromes.
Such a design has the advantage, over higher resolution platforms, to limit the detection of VOUS or IF, which complicate genetic counselling increasing parental anxiety, without providing certitude in pregnancy outcome.

PS01.15

Tissue-specific mosaicism for CNV in human miscarriages

A. A. Kashevarova[1,2], *N. A. Skryabin*[1,2], *T. V. Nikitina*[1], *E. A. Sazhenova*[1], *D. I. Zhigalina*[2], *I. Lebedev*[1,2];
[1]*Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Tomsk State University, Tomsk, Russian Federation.*

Introduction: Extensive load of somatic copy number variants (CNVs) has recently been shown in human placenta, suggesting that it may be critical for normal gestation. However, it is unclear weather the entire placenta or just certain placental cell types promote this phenomenon. Also it may occur that prevalence of CNVs in one cell type may be essential for normal development, while in another - responsible for embryolethality. We aimed to investigate CNVs in the only two placental tissues available from blighted ova - cytotropholast (CT) and extraembryonic mesoderm (EM).
Materials and Methods: Placental tissues of 10 euploid miscarriages were investigated using Agilent 180K microarrays.
Results: Altogether 198 CNVs were detected: 91 in EM and 107 in CT, 24 (26%) and 50 (47%) of them were unique respectively (p=0.0032). Microdeletions and microduplications were equally represented in EM (11 vs. 13), while microdeletions prevailed in CT (41 vs. 9). Unique microdeletions significantly more frequently were detected in CT (p=0.0014). The candidate developmentally important genes involved in tissue-specific CNV in EM are PTPN18 (cell growth, differentiation), CFC1 (embryonic development), OCLN (vascular integrity), WIST1 (cell lineage determination and differentiation), TBX10 (embryonic cell fate and organogenesis), in CT - CTNNA3 (inhibitor of trophoblast invasion), PTPRR (cell growth, differentiation), TSPAN8 (cell development, growth, motility), miR-296 (angiogenesis), PCGF1 (embryogenesis).
Conclusions: The presented profiling of CNVs may be the hallmark of abnormal pregnancy, specifically blighted ova, as according to Kasak et al. (2015) normal gestation whole-placental material is, on the contrary, characterized by the prevalence of duplications. This study was supported by Russian Foundation for Basic Research, 14-04-32047.

PM01.16

Cytogenetics evaluation among infertile couples in a Southern Iranian population; a targeted survey

D. Karim[1], *A. Nariman*[1], *S. Tabei*[1], *E. Aref-Eshghi*[2], *E. Zare*[3];
[1]*Department of Medical Genetics, Shiraz University of Medical Sciences,, Shiraz, Iran, Islamic Republic of,* [2]*Faculty of Medicine, Memorial University of Newfoundland, St John's, NL, St John's, NL, Canada,* [3]*Department of Medical Biotechnology, Arak University Of Medical Sciences, Arak, Iran, Islamic Republic of.*

Introduction: The role of cytogenetics service in diagnosis, risk management, and outcome of infertility is becoming more and more evident. An abnormal finding can have significant consequences to assisted reproductive techniques and fertility treatment, and provide a firm diagnosis to couples

with longstanding infertility. In the present study we investigated the status of cytogenetic evaluations performed on infertile couples from a southern population of Iran.
Methodology: Couples with a history of infertility were interviewed regarding their medical history, any referrals into cytogenetics clinic, and genetic counseling using a standard questionnaire.
Results: A total of 438 couples were included. The mean age was 24.8 ± 5.2 years. Consanguinity was found among 23.4% of the couples. The majority of the participants (98.3%) never performed any kind of cytogenetic testing and 97.2% of them were never referred for genetic counseling. Finally, 10% of the participants experienced at least one abortion and mental retardation in their familial history.
Conclusions: While chromosomal abnormalities are responsible for a significant portion of infertilities, miscarriages, and IVF/ICSI failure, just a negligible number of the infertile couples in our study are offered cyotogentics service. Our findings highlight a shortage accessibility of such services as well as a lack of education amongst the involved clinicians about the cytogenetic causes of infertility in our target population.

PS01.17
Identification and characterization of novel fetal specific differentially methylated regions on chromosomes 13, 18, 21 and X

M. Ioannides[1], *M. Hadjidaniel*[1], *E. Papageorgiou*[2], *P. Antoniou*[2], *S. Kyriakou*[1], *G. Koumbaris*[2], *P. C. Patsalis*[1,3];
[1]*The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus,* [2]*NIPD Genetics LTD, Nicosia, Cyprus,* [3]*Ministry of Health, Nicosia, Cyprus.*

DNA methylation is a conserved epigenetic mark that involves the addition of a methyl group on carbon 5 of cytosines present in CpG dinucleotides. Furthermore, tissue specific methylation patterns are investigated as biomarkers for cancer and cell-free fetal DNA using various methodologies. Our group has previously confirmed the presence of methylation variability on differentially methylated regions (DMRs) on chorionic villus sampling (CVS) and non-pregnant peripheral blood

samples (WBF). Despite the DNA methylation variability, the validated set of DMRs was clearly distinguished between CVS and WBF samples, enabling for robust tissue specific methylation identification. In this study we aimed to expand the prenatal panel of DMRs, utilizing custom 1 million ultra-high resolution aCGH chip designed for chromosomes 13, 18, 21 and X on normal/abnormal CVS and WBF. A subset of the identified DMRs was selected according to established criteria and confirmed by utilizing methylated DNA immunoprecipitation (MeDIP) and real-time quantitative PCR. In total we confirmed the differential methylation status in 99 regions on chromosomes 13, 18 and 21 and two on chromosome X; the majority of the DMRs were found to be located on genes and associated with diseases. Interestingly, four regions on chromosome 21 have been found to be correlated with genes that may play a role in the pathophysiology of Down syndrome. In conclusion, our work provides an expansion in the biomarker panel available for NIPT for Down syndrome and can eventually provide the starting point towards the development of assays towards the detection of all common chromosomal aneuploidies.

PM01.18
Study of genetics of human disorders of sexual development in Ukraine in the frame of SCOPES 2013-2016: Joint Research Projects

L. Livshits[1], *N. Gunkovska*[1], *G. Livshits*[1], *S. Chernushin*[1], *S. Kravchenko*[1], *O. Bolshova*[2], *V. Pampukha*[1];
[1]*Institute of Molecular Biology and Geneitcs (National Academy of Sciences of Ukraine), Kiev, Ukraine,* [2]*State Institution V.P.Komisarenko Institute of Endocrinology and Metabolism of the National Academy of Medical Sciences of Ukraine, Kiev, Ukraine.*

The project "Genetics of Human Disorders of Sexual Development" is funded by Swiss National Science Foundation and fulfilled by the University of Geneva Medical School (Switzerland), the Institute of Human Genetics (Poland), the Center of medical genetics and primary health care (Armenia) and the Institute of Molecular Biology and Genetics (Ukraine).
The goal is to identify mutations underlying unresolved DSD phenotypes - in novel DSD genes, or regulatory regions that lead to atypical gene expression. Identification of new genes involved in human sex determination and differentiation is carried out through exome sequencing and CGH microarray in parallel.
Ukrainian partner is participating in all stages preceding the exome sequencing: clinical data collecting (caryotype, family history, physical examination, ultrasound, hormonal status, surgery, histology), caryotyping, DNA samplings (proband, parents, siblings), SRY gene deletion detecting and SRY, SOX9, WT1, SF1, LHX9, RSPO1, FOXL2, WNT4, DMRT1, DMRT2 genes Sanger sequencing. During the first year a few main medical centres of Ukraine joined the project: Institute of endocrinology and metabolism of Komisarenko and Regional centres of medical genetics of Zaporizhzhya, Kherson, Chernigiv, Lutsk, Poltava, Zhytomyr, Khmelnitskyi.
For the first year Ukrainian part collected 38 DNA samples from 16 DSD cases - 15 of 46,XY DSD females and 1 of 46,XX DSD male.
We expect the research will provide the opportunity to develop new genetic tests for DSD diagnosis and to improve understanding of the molecular mechanisms of ovarian and testicular differentiation.
The results on the first cohort will be discussed in details.

Background Mutations in the ERCC2/XPD gene cause rare autosomal recessive NER (Nucleotide Excision Repair)- related diseases including trichothiodystrophy (TTD), cerebrooculofacioskeletal syndrome (COFS), Cockayne syndrome (CS) and xeroderma pigmentosum (XP), or a combination of XP/TTD, XP/CS or COFS/TTD. These diseases share a number of clinical features and encompass a wide spectrum of severity, in particular TTD, characterised by sulphur-deficient brittle hair, short stature, intellectual disability, microcephaly, facial dysmorphism and ichthyosis. To date, there have been few reports describing foetal cases with mutations in ERCC2. Case report We describe a male foetus, the second child of healthy unrelated parents, who died in utero at 28 weeks of pregnancy. The autopsy revealed severe harmonious intrauterine growth retardation (<3rd centile), delayed bone maturation, congenital ichthyosis, and facial dysmorphism including low insertion of the columella, beaked nose, large and low set ears, micrognathism and retrognathism and upslanted palpebral fissures. The hands showed retracted broad and tapering fingers with hypoplastic nails. Caryotype and array-CGH were normal. Exome sequencing revealed compound heterozygous nonsense and pathogenic missense mutations (p.Gln698* and p.Arg722Trp respectively) in ERCC2, that were consistent with the clinical features. One mutation was transmitted from each of the patient's parents, respectively. Functional studies are on going to test the patient's NER capacities, using standardized methods. Conclusion This case confirms the power of exome sequencing in the rapid identification of rare clinically non-recognisable diseases, in particular in the absence of clinical clues suggesting a diagnosis, as in severe congenital ichthyosis, a condition that includes several distinct subtypes with significant genetic heterogeneity.

PM01.20
Do people from the Jewish community prefer ancestry-based or pan-ethnic expanded carrier screening?

K. C. A. Holtkamp[1], *M. C. Van Maarle*[2], *M. J. E. Schouten*[1], *W. J. Dondorp*[3], *P. Lakeman*[2], *L. Henneman*[1];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands,* [3]*Maastricht University, Maastricht, Netherlands.*

Background: Ancestry-based carrier screening in the Ashkenazi Jewish po-

pulation entails screening for specific autosomal recessive founder mutations, which are rare among the general population. As it is now technically feasible to screen for many more diseases, the question arises whether this population prefers an ancestry-based offer or a pan-ethnic expanded carrier screening panel that goes beyond the diseases relatively frequent in their own population, and is offered regardless of ancestry.
Methods: An online questionnaire was completed by 145 individuals from the Dutch Jewish community (≥18 years) between April and July 2014.
Results: 64.8% were aware of the existence of ancestry-based carrier screening. Respondents were generally positive about screening and thought that several categories of diseases should be included. About half (54%) preferred pan-ethnic expanded carrier screening whereas 43% preferred ancestry-based screening. Reasons for preferring pan-ethnic screening included "everyone has a right to be tested", "fear of stigmatization when offering ancestry-based panels", and "difficulties with identifying risk due to mixed backgrounds". "Preventing high healthcare costs" was the main perceived barrier to pan-ethnic carrier screening among those in favour of ancestry-based screening.
Conclusion: These findings show that people from the Dutch Jewish community have a positive attitude regarding carrier screening in their community for a wide range of diseases. Costs were the main perceived barrier for pan-ethnic carrier screening panels. As costs of these panels are most likely to drop in the near future, it may be expected that these will receive more support in the future.
The study was funded by Netherlands Organization for Health Research and Development (grant no 209040001).

PS01.21

Detection of a novel mutation in FANCD2 gene in a fetus with unilateral kidney agenesis and anomalies of upper limbs

S. Ivanov[1], *R. V. Vazharova*[2,3], *L. Balabanski*[3], *S. Vragaleva*[4], *V. Dimitrova*[5], *M. Malinov*[3], *D. Toncheva*[6];
[1]Gynecology and Assisted Reproduction Hospital, Sofia, Bulgaria, [2]Department of Biology, Medical genetics and Microbiology, Faculty of Medicine, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria, [3]Gynecology and Assisted Reproduction Hospital „Malinov DM", Sofia, Bulgaria, [4]MC „Femina", Sofia, Bulgaria, [5]Department of Obstetrics and Gynecology, Medical University of Sofia, Sofia, Bulgaria, [6]Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria.

Congenital anomalies affect 1% to 2% of newborns, and approximately 4-5% of those children have abnormalities of urinary tract and kidneys and 10% - have upper-extremity abnormalities. Combining of homozygosity mapping using SNP arrays and sequencing of target regions has been successfully applied for identification of mutations causing many autosomal recessive diseases in patients diagnosed postnatally.
We used SNP array karyotyping and next generation sequencing to clarify the etiology of a polymalformative syndrome detected prenatally. On US scan at 18th g. w. the fetus of a second gravida was found to have: mild growth retardation, right kidney agenesis and absent radii and thumbs of both arms.
SNP karyotyping with Illumina Human CoreExome-12 revealed a homozygous chromosome region encompassing 6.1 Mb in 3p: arr[hg19] 3p26.1p25.3p25.2(6206901-12352468)x2hmz. The gene FANCD2 mapped in the region and was found to be a good candidate for the fetal malformative syndrome. We used TruSight Cancer gene panel (Illumina) and the MySeq sequencing system. The fetus was found to be homozygous for a novel hypomorphic mutation in FANCD2 gene: p.Leu699del and both parents were found to be carriers of the mutation.
The identification of an anomaly compatible with life during pregnancy is a challenge for both prospective parents and the doctor. The anomalies require an accurate diagnosis and communication of relevant information to the family. Certain anomalies occur in isolation, whereas others are associated with systemic conditions. Prognosis of the developing fetus and reproductive decisions of the family largely depend on the causes behind the disease.

PM01.22

Perinatal outcome of fetal echogenic bowel

T. Lanxner Battat[1], *E. Kachko*[2], *L. Novak*[3], *A. Koifman*[4];
[1]Soroka university Medical Center, Beer Sheva, Israel, [2]Clinical research center, Soroka university Medical Center, Beer Sheva, Israel, [3]Department of public health, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel, [4]Institute of Human Genetics, Soroka university Medical Center , Ben-Gurion University of the Negev, Beer Sheva, Israel.

Introduction: The aim of this study is to describe the association between fetal echogenic bowel (FEB) during the second trimester and adverse perinatal outcome and to compare additional findings that contribute to the pregnancy outcome
Material and methods: We conducted a retrospective case control study. Perinatal outcome of 262 cases of FEB, reported between 2007-2014, were compared to 2827 cases of pregnancies without abnormal sonographic findings.
Results: Of the 262 cases 36 cases (13.7%) were associated with maternal vaginal bleeding and 15 cases (8.6%) of 174 who underwent serology testing had evidence of CMV seroconversion during the pregnancy as oppose to 0.1% in both parameters in the control group. 73 cases (27.8%) had evidence of structural malformation. 122 cases underwent amniocentesis and karyotyping, three of which had chromosomal abnormalities (2.45%). The incidence of IUGR and fetal demise was 9.23% and 6.42% as oppose to 2.9% and 0.5% in the control group, respectively. Composite endpoint calculation demonstrated absolute risk increase for fetal demise, IUGR, SGA, low apgar score of 10% in the isolated FEB group as compared to isolated polyhydramnios group. Interestingly, elevated level of alpha-fetoprotein in the FEB group were significantly ($p<0.001$) associated with preterm delivery and fetal demise.
Conclusions: The presence of FEB is independently associated with an increased risk for IUGR and fetal demise. Elevated aFP in addition to FEB contributes to adverse perinatal outcome. This information should be considered when counseling patients after FEB is diagnosed.

Gene discovery in lethal fetal malformation phenotypes - the value of human knockouts

I. Filges[1], *E. Bruder*[2], *M. Schubach*[3], *S. Biskup*[4], *O. Lapaire*[5], *I. Hoesli*[5], *S. Schulzke*[6], *S. Tercanli*[7], *P. Miny*[1];
[1]Medical Genetics, University Hospital Basel, Basel, Switzerland, [2]Pathology, University Hospital Basel, Basel, Switzerland, [3]Medical Genetics, University Hospital Charité, Berlin, Germany, [4]CeGaT GmbH, Tübingen, Germany, [5]Obstetrics and Gynecology, University Hospital Basel, Basel, Switzerland, [6]Neonatology, University Children's Hospital Basel, Basel, Switzerland, [7]Centre for Ultrasound and Fetal Medicine, Basel, Switzerland.

Prenatal ultrasonography identifies an increasing number of undescribed malformation phenotypes. Little attention has been paid to using whole exome and genome sequencing strategies for gene identification in fetal disorders that are lethal in utero, because they are extremely rare, may appear to be sporadic, and Mendelian inheritance can be easily missed. Some lethal phenotypes, however, indicate an error of early development implying a major malfunction of a gene with a crucial role in cellular and developmental processes.
Hypothesizing that truncating autosomal recessive variants are an important cause of early human lethality, we select families with phenotype recurrence in sibs who died during pregnancy or after birth because of their malformations. We correlate the malformation pattern, confirmed by autopsy, to developmental pathways in embryogenesis. Genes with homozygous or compound heterozygous variants will be considered candidates. Those harboring truncating variants will be prioritized, since loss of function variants are more likely to be causal compared to other variant classes.
We present two novel prenatal malformation patterns indicative of the disruption of pathways involved in ciliary and midline defect phenotypes. The role in cell division of candidate genes identified suggests a link to these developmental pathways. Causality is supported by cross-species phenotyping.
Identifying mutations implicated in early fetal development will improve recurrence risk counseling and allow prenatal diagnosis for future pregnancies in affected families. Lethal fetal phenotypes may represent an important model to study the genetic basis of natural human knockouts and the roles of genes for which little to nothing is known.

PM01.24

Microarray analysis of fetal cells isolated from maternal blood

A. Grabowska[1,2], *M. Bik-Multanowski*[1,2], *J. J. Pietrzyk*[1,2];
[1]Department of Medical Genetics, Chair of Pediatrics, Jagiellonian University Medical College, Cracow, Poland, [2]University Children's Hospital of Cracow, Cracow, Poland.

Introduction: Limitations of contemporary techniques of prenatal diagnosis necessitate the need to develop new non-invasive prenatal test. The presence of microchimerism state during each pregnancy opened up new possibilities for fetal genome analysis. Despite of many studies there is still no consensus protocol for identification of fetal cells in the maternal blood. We aimed to compare the expression of maternal and fetus genomes to determine potential fetal microchimeric cells markers.
Materials and Methods: The experimental material consisted of 5 ml of peripheral blood from women in the second trimester of pregnancy, who under-

went amniocentesis procedure. Analysis was based on CD34 positive cells. Cells were isolated from blood samples and were subsequently cultured to obtain the targeted line of hematopoietic colonies. After the incubation period, single erythroid colonies were collected and analyzed by means of microarray technology using GeneChip Human Gene 1.0 ST Array.
Results: The analysis showed statistically significant differences in the expression of 958 genes between maternal and fetal cells. Most of the genes (n = 591) showed higher expression in the fetus relative to the expression of the mother's genome. A total of 367 genes showed decreased expression in the fetus. Initial protocols were developed for culture and identification of fetal cells in the maternal blood.
Conclusions: The use of cell culture enables multiplication of the cells and reduces the volume of maternal blood sample necessary for the analysis. Transcriptome analysis of cells shows expression of specific genes, which may be used as markers for the identification of fetal cells.

PS01.25
First Report of Prenatal Diagnosis for Severe Genodermatoses in Egypt

K. S. Amr, *G. El Kammah, M. Farag, H. Nasr, K. Gaber;*
National Research Centre, Cairo, Egypt.

Introduction: Genodermatoses are mostly severe inherited disorders. A great success in identifying responsible genes & characterizing mutations within such genes paved the road for DNA-based prenatal diagnosis. Examples of severe genodermatoses candidate for prenatal diagnosis include autosomal recessive congenital ichthyosis (ARCI), Xerodema pigmentosa (XPA), Sjögren-Larsson syndrome (SLS) and papillon lefeuvre syndrome (PLS) where clinical severity affects span &/or quality of life hence urging prenatal diagnosis.
Materials and methods: The study included five amniotic samples (AF) from carrier mothers descending from five pedigrees with history of affected sibs with severe genodermatoses including; two mothers of previous ARCI cases, one XPA, one SLS and one PLS. DNA was extracted from AF samples by QIA gene extraction kit followed by mutational screening for XPA, TGM1, ALDH3A2 and CTSC genes.
Results: prenatal diagnosis was successfully performed in all cases. For the family with history of XPA, the fetus was found to be heterozygous carrier for E111X mutation; For ALDH3A2 gene the fetus was affected for E331X nonsense mutation; for TGM1 gene the two fetuses were heterozygous carriers for R264W, R143H missense mutations. The fifth AF sample PLS showed homozygous wild type genotype.
Conclusion: The high incidence of consanguinity & consequently AR rare disorders combined with the lack of curative therapy, points to the importance of implementing preventive programs. Prenatal diagnosis and genetic counseling represent an important step in prevention & alleviating the burden of severe genodermatoses on the family & community.

PM01.26
Incremetal yield of Array Comparative Genomic Hybridization above karyotyping in Fetal Increased Nuchal Translucency - A systematic review and meta-analysis

A. Borrell[1], *M. Grande*[1], *F. Jansen*[2], *Y. Blumenfeld*[3], *A. Fisher*[4], *A. Odibo*[5], *M. Haak*[2];
[1]*Institute Gynecology, Obstetrics and Neonatology.Hospital Clínic Barcelona, Barcelona, Spain,* [2]*Leiden University Medical Center, Department of Obstetrics and Fetal Medicine, Leiden, Netherlands,* [3]*Department of Obstetrics & Gynecology, Stanford University School of Medicine, Stanford, CA, United States,* [4]*Elliot Health System, Manchester, Manchester, NH, United States,* [5]*Department of Obstetrics & Gynecology, Division of Maternal Fetal Medicine, University of South Florida, Tampa, FL, United States.*

Objective: To perform a systematic review of the literature and meta-analysis and estimate the incremental yield of genomic microarray over karyotyping in fetuses with increased nuchal translucency (NT) diagnosed by first trimester prenatal ultrasound.
Method: All articles identified in PubMed and Ovid, from January 2009 to September 2014 describing copy number variants (CNVs) in fetuses with increased NT were included. Search terms were: fetal or prenatal, nuchal translucency or cystic hygroma or ultrasound anomaly, array comparative genomic hybridization or copy number variants, with related search terms. Case reports and studies using conventional comparative genomic hybridization were excluded.
Results: Seventeen publications met the inclusion criteria for the analysis. A 5% (95% CI 2.0-8.0) incremental yield by microarray was obtained pooling the results. Stratified analysis demonstrated a 4% (95% CI 2.0-7.0) incremental yield for isolated NT and 7.0% (95% CI 2.0-12) when other malformations are present.
Conclusion: The review found that the use of genomic microarray provides a 5% incremental yield in fetuses with increased NT and normal karyotype.

PS01.27
Role of hereditary thrombophilia and antiphospholipid syndrome in pregnancy complications and recurrent miscarriages in IVF programs

S. Zhukovskaya, *S. J. Zhukovskaya, K. Mosse, N. Rumiantsava;*
Center of Reproductive Medicine, Minsk, Belarus.

Introduction: Screening for hereditary thrombophilia and APS in women undergoing IVF proved to reduce miscarriage and pregnancy complications risk, to minimize thrombotic complications.
Materials and Methods: 420 women with pregnancy loss or preterm birth after IVF were examined for hereditary thrombophilia and APS. Women diagnosed with these conditions were administered antiaggregant therapy (aspirin, low-molecular-weight heparin), high doses of folic acid (5 mg daily), vitamin B12 (in cases of MTHFR gene polymorphism and elevated homocysteine concentration).
Results: 232 women (55.2%) were diagnosed with thrombophilia - 145 of them had hereditary thrombophilia (34.5%), 41 of them presented elevated homocysteine levels (9.8%); APS was found in 87 women (20.7%). The structure of hereditary thrombophilia carriers (145 cases): heterozygous mutation 1691G>A Leiden in F5 gene - 11 women (7.6%), heterozygous polymorphism G20210A in F2-prothrombine gene - 6 (4.1%), compound heterozygous carriers of 1691G>A Leiden + G20210A - 3 (2.1%), homozygous carriers of 677T/T in MTHFR gene - 38 (26.2%), compound heterozygous carriers of 677T + 1298C in MTHFR gene - 87 (60%). IVF with appropriate thrombotic complications prophylaxis was performed for 145 women with hereditary thrombophilia, 67 cases resulted in pregnancy (46.2%). Pregnancies ended with term birth - 46 (68.7%), preterm delivery (32-36 weeks) - 12 (17.9%), reproductive failures - 9 (13.4%), which included 5 miscarriages in 1st trimester (7.5%), 3 in 2nd trimester (4.4%), 1 ectopic pregnancy (1.5%).
Conclusion: Screening for hereditary thrombophilia and APS reduces risk of miscarriages and pregnancy complications in IVF procedures; and should be widely recommended, especially for women with thrombotic complications or reproductive failures in anamnesis.

PM01.28
Association of a HRG polymorphism with ovarian reserve and response to ovarian stimulation in women undergoing assisted reproductive treatment

D. Tohlob[1,2], *S. Roberts*[3], *C. Cerra*[1,4], *P. Pemberton*[5], *L. Mohiyiddeen*[4], *W. Newman*[1,6];
[1]*Manchester center for genomic medicine, University of Manchester, Manchester, United Kingdom,* [2]*Clinical Pathology Departement, Faculty of medicine, Mansoura university, Mansoura, Egypt,* [3]*Centre for Biostatistics, Institute of Population Health, Manchester Academic Health Sciences Centre (MAHSC), University of Manchester, Manchester, United Kingdom,* [4]*Department of Reproductive Medicine, St. Mary's Hospital, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [5]*Department of Clinical Biochemistry, Central Manchester Foundation Trust, Manchester, United Kingdom,* [6]*Central Manchester University Hospitals NHS Foundation Trust,Manchester Academic Health Sciences Centre (MAHSC), Manchester, United Kingdom.*

Histidine-rich glycoprotein (HRG) is a plasma protein involved in many biological processes, including fibrinolysis, coagulation, apoptosis and angiogenesis. These processes are important in oocyte development
and pregnancy. In a recent Swedish study, a homozygous variant in *HRG*, c.633C>T was associated with poor ovarian response during the assessment of women undergoing assessment for *in vitro* fertilization (IVF).[1]
The aim of our study was to investigate whether *HRG* c.633C>T is associated with the ovarian reserve markers follicle stimulating hormone (FSH), antral follicle count (AFC), and anti-Mullerian hormone (AMH) and ovarian response (number of eggs retrieved, and gonadotropin dose required) to controlled ovarian hyper-stimulation.
We genotyped *HRG* c.633C>T in 517 women, attending a tertiary referral centre for reproductive medicine, undergoing their first cycle of controlled ovarian hyper-stimulation for IVF/ICSI. We found no evidence of any significant difference (p value <0.05) in FSH, AFC, AMH, the number of eggs retrieved, or the gonadotropin dose used between individuals with different *HRG* genotypes.
These results indicate that this variant does not provide clinically relevant data on which to base the individualization of the treatment of women undergoing IVF/ICSI.

Genetic associations for hypospadias: review of current knowledge and replication

L. F. M. van der Zanden[1], *N. van Leeuwen*[1], *R. R. Makkinje*[2,3], *W. F. J. Feitz*[4], *N. Roeleveld*[1,5];
[1]*Department for Health Evidence, Radboud university medical center, Radboud Institute for Health Sciences, Nijmegen, Netherlands,* [2]*Department of Human Genetics, Radboud university medical center, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands,* [3]*Department of Psychiatry, Radboud university medical center, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands,* [4]*Department of Urology-Pediatric urology, Radboudumc Amalia Children's Hospital, Radboud university medical center, Nijmegen, Netherlands,* [5]*Department of Pediatrics, Radboudumc Amalia Children's Hospital, Radboud university medical center, Nijmegen, Netherlands.*

Background
Hypospadias is a common congenital malformation of the male external genitalia with a multifactorial etiology. We identified all genetic associations reported for hypospadias and tried to replicate the most promising ones.
Methods
After a thorough literature search and SNP selection, we used Taqman assays to genotype seven SNPs in 816 Caucasian nonsyndromic hypospadias patients and 668 population-based controls derived from the AGORA data- and biobank in the Netherlands.
Results
When excluding studies using microarrays performed after our SNP selection, 36 polymorphisms in *DGKK* and 67 polymorphisms in 16 other genes were identified. We already examined *DGKK* successfully in our cohort and this gene was also associated with hypospadias in several other Caucasian populations, but much less strong in a Chinese. Many of the polymorphisms in other genes were found not to be associated with hypospadias, had a MAF<2% in Caucasians, or were repeats or deletions, while four SNPs had already been studied in our cohort. Therefore, we selected seven SNPs in the genes *HSD17B3*, *ESR1*, *ESR2*, *ATF3* and *MAMLD1* for this study. None of the SNPs was associated with hypospadias, with the possible exception of rs944050 in *ESR2* (OR=1.5, p=0.045). This association was in the same direction as in a Swedish study and in the opposite direction compared to a Japanese study.
Conclusions
Summarizing all currently reported genetic association studies on hypospadias shows that risk polymorphisms differ between populations. This stresses the importance of studying generalizability of genetic association results and points towards the need for gene-environment interaction analyses.

PM01.30

A family with deafness-infertility syndrome presenting in two generations

P. Skiba, P. Karpinski, M. Sasiadek, **K. Pesz**;
Wroclaw Medical University Department of Genetics, Wroclaw, Poland.

Only few families with deafness and infertility syndrome, a contiguous gene deletion syndrome at 15q15.3 locus, have been described so far.
It is rare and inherited as an autosomal recessive trait (homozygous for the deletion females present with deafness whereas males with infertility and deafness).
We present a family with two generations affected by sensorineural hearing loss (mother and two sons). Both sons were diagnosed with infertility, one of them had a child through assisted reproductive technology.
Using the array CGH method the deleted region in the proband has been described to encompass 55 kb. It includes the gene *CATSPER2* and a major part of *STRC*, linked to infertility and deafness, respectively. The mother of the proband has also a homozygous deletion in the region whereas the father is a heterozygote.
For confirmation of the deletion a PCR was performed for an STR marker and no products have been found in the proband and the mother.
The genotypes and the phenotypes of all affected individuals in the family are discussed in detail.
A family with deafness-infertility syndrome presenting in two generations

PM01.32

Recurrent microdeletions at Xq27.3-Xq28 are not associated with infertility of males from the Czech Republic

B. Chylikova[1], *I. Hrdlicka*[1], **K. Veselá**[1], *K. Rezabek*[2], *F. Liska*[1];
[1]*Institute of Biology and Medical Genetics, Prague 2, Czech Republic,* [2]*Department of Obstetrics and Gynaecology, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague 2, Czech Republic.*

Introduction: Genetic causes of male infertility are hypothesized to involve multiple types of mutations, from single gene defects to complex chromosome rearrangements. Recently, several recurrent X-chromosome microdeletions (located in subtelomeric region of the long arm) were reported to be associated with male infertility in Spanish and Italian males (Lo Giacco et al., 2014). The aim of our study was to test their prevalence and infertility association in population of men from the Czech Republic.
Materials and Methods: 146 males with idiopathic nonobstructive infertility were compared to 109 males with normal fecundity. X-chormosome microdeletions were assessed by +/- PCR with three primer pairs for each region Xcnv64 (Xq27.3), Xcnv67 (Xq28) and Xcnv69 (Xq28). The latter microdeletion was also complemented with amplification across the deleted region, dividing the deletion into three types.
Results: We detected presence of Xcnv64 in 10 patients and 12 controls, Xcnv69 in 5 patients and 4 controls (3, 1 and 1 patient vs. 3, 1 and 0 control for types A, B and C respectively). Thus the frequency was comparable in patient and control groups (Fisher´s exact test P>>0.05). The patient with Xcnv69 type C deletion also carries Xcnv64 deletion. This may indicate a more extensive rearrangement with putative causal potential.
Conclusion: Association of X-chromosome microdeletions at Xq27.3 and Xq28 with male infertility could not be confirmed for Czech males. One patient may carry a larger rearrangement that will be further dissected.
Supported by Ministry of Health of the Czech Republic grant No. NT/12269-5

PS01.33

Maternal plasma microbiome detection by analyzing sequencing data of non-invasive prenatal test

H. Wang, *F. Jiang, Y. Wang, Y. Gao;*
BGI Shenzhen, Shenzhen, China.

Introduction
MPS-based non-invasive prenatal test not just supply an effective method for detecting chromosome abnormality, but accumulate large amount of sequence data of plasma cell free DNA. Main purpose of this research is unfolding the plasma microbiome through using NIPT sequencing data. A whole scene of exogenous organism in human blood would be presented, together with exploring differences between T21-positive and T21-negtive samples.
Materials and Methods
A cohort of 40,934 plasma samples undergone NIFT test was obtained. Sequencing reads mapped on human reference were filtered out. The remaining non-human reads were assembled to contigs by five different pipelines. Contigs were annotated by Nucleotide database and then classified into different taxonomy groups. Each sample's raw reads were then remapped to the constructed reference contig set. Clustering analysis was performed. Moreover, non-human sequence abundance of trisome 21 samples and normal samples were calculated separately.
Result
15,350 contigs being annotated on nucleotide database constructed a reference set and classified into 16 taxonomic categories. The non-human rate of T21-positive group and T21-negtive group did not show significant difference. However, remap rate of Trisomy 21 samples was lower than that of non-trisomy samples. In addition, cluster analysis showed a remarkable correlation between microbiome abundance distribution and sampling geography locations.
Conclusions
This research built a reference set of plasma microbiome and demonstrated the complexity of plasma microbita. Moreover, differences of the microbiome between T21-positive and T21-negtive samples would supply evidences for enhancing the prenatal test and assisting the detection of some other diseases.

PM01.34

Hsa-let-7c miRNA as a potential biomarker for congenital heart disease

O. Biro, *B. Nagy, J. Schönleber, J. Rigo Jr, L. Lazar;*
Semmelweis University, 1st Dept. of Obstetrics and Gynecology, Budapest, Hungary.

Background: Congenital heart defects (CHD) are the most common fetal malformations and often correlated with chromosomal abnormalities. There is a great need for biomarkers which could detect CHD early with high accuracy. The miRNAs are short, non-coding RNA molecules that play important role in regulation of eukaryotic gene expression. Let-7c miRNA is located on the human chromosome 21 and broadly expressed by the major types of cardiovascular cells. Recent studies revealed the possible role of let-7c in heart development; therefore we hypothesize that it can be associated with CHD.
Purpose: Based on our previous results, let-7c is significantly upregulated

in the circulation of mothers who has fetuses with CHD. In this study, our aim was to analyze the let-7c expression in diseased fetal heart samples to confirm the miRNA's importance in pathogenesis of CHD.
Patients and methods: We have collected heart samples from fetuses with CHD and/or trisomy 21 and from healthy controls. Total-miRNA was isolated from the left ventricles; the quality was checked by UV-VIS spectrometry. Total-miRNA samples were reverse-transcribed. RT-PCR was performed on the cDNA templates using let-7c specific primers. U6 snRNA was used as control.
Results: We found significant differences in the let-7c concentrations between the control and the diseased fetal heart samples: 0.0021±0.00075 ng/µl vs. 0.031±0.041 ng/µl ($p<0.05$). The highest expression was observed in the cases of trisomy 21 with accompanying CHD. According to our studies elevated let-7c expression is associated with CHD and may be ideally suited as a biomarker for the disease.

PS01.35

The genetic stability of human blastocysts can be effectively predicted by the copy number of mitochochondrial DNA detected by next generation sequencing (NGS)

f. f. wang[1], *k. Tan*[2], *X. Y. Yin*[1], *Y. Q. Tan*[2], *G. Vajta*[1], *F. Gong*[2], *J. Wang*[1], *B. Xiong*[3], *W. Wang*[1], *G. Lin*[2], *G. X. Lu*[4];
[1]BGI-Shenzhen, Shenzhen, China, [2]Central South University, Institute of Reproduction and Stem Cell Engineering, Changsha, China, [3]Reproductive and Genetic Hospital of CITIC-Xiangya, Reproductive center, ChangshaHunan, China, Changsha, China, [4]Reproductive and Genetic Hospital of CITIC-Xiangya, Reproductive center, Changsha, China.

Summary answer
Is the copy number of mitochondrial DNA (mtDNA) correlated to the genetic stability and developmental potentiality of blastocysts?
Whole genome amplification of single-cell and next generation sequencing (NGS) can be used to analyze embryo genome and mtDNA.
Study design, Participants/materials, setting, methods
A retrospective study was performed at the Reproductive and Genetic Hospital of CITIC-Xiangya, and BGI-Health, China, involving 440 couples with indications to in vitro fertilization treatment, 1528 blastocysts were biopsied and frozen embryo transplant was carried out using embryos with balanced genome. Embryos were subjected to preimplantation genetic diagnosis/screening using next generation sequencing (NGS-PGD/PGS) between October 2011 and September 2014.
Main results and the role of chance
The sequencing data covered 5.5% ± 1.2% of the whole human genome and 98.7% ±3.1% of mtDNA.The copy number of mtDNA in euploid blastocysts was significantly lower than that of the chromosomally abnormal blastocysts(291.46 vs 317.39,$P<0.001$). Significantly reduced copy number of mtDNA was also found in blastocysts from young women (age≤35 years) comparing to blastocysts from the aged women(300.07 vs 322.07,$P=0.002$). Similarly, The copy number of mtDNA also correlated to the development rate of the embryo and the blastocyst quality, blastocysts with higher ranking contained considerably fewer copies of mtDNA than blastocysts with lower ranking and poor development($P<0.001$).
Limitations
Complete pregnancy outcomes could not be obtained as some blastocysts were not transferred yet. Future data collection is warranted.

PM01.37

Utilization of noninvasive prenatal screening and its relevance to clinical practice: Update on clinical outcome metrics on over 85,000 cases

P. Taneja, *H. Snyder, E. de Feo, K. Kruglyak, M. Halks-Miller, K. Curnow, S. Bhatt; Illumina, Redwood City, CA, United States.*

Objective: The
verifi® noninvasive prenatal screen (NIPS) has been available through Illumina's accredited clinical lab since February 2012. Professional societies have published statements supporting the use of NIPS and recommend continued test performance monitoring. In follow-up to Illumina's first published clinical experience paper (Futch et al, June 2013), this study highlights continued efforts to provide clinically relevant metrics for chromosomes 21, 18, and 13.
Method: Outcome information (karyotype or birth outcome) was requested from providers for singleton samples reported as aneuploidy detected (AD) or suspected (AS) for chromosomes 21, 18, or 13. Voluntary outcome reporting was encouraged for all discordant outcomes.
Results: Of 86,658 cases, 85,298 (98.4%) met inclusion criteria for NIPS result reporting, 101 (0.1%) were cancelled for technical reasons and 1259 (1.5%) were cancelled for administrative reasons. Average turn-around-time was 3.3 business days. Of 85,298 reported samples, there were 2,142 (2.5%) positive results: 1,858 AD (2.2%) and 284 AS (0.3%); AS results have significantly decreased since 2012. Informative clinical outcomes were available for 851 (39.7%) positive samples. Of 85,298 reported samples, 108 (0.13%) AD cases were reported as putative false positives; 15 (0.02%) false negatives were reported. The observed overall (all chromosomes) positive predictive value was 94.2% for AD samples and 88.9% for AD/AS samples combined. The overall observed negative predictive value was over 99.9%.
Conclusion: Test modifications have facilitated a refinement in borderline result classification, and improvements in turn-around time and cancellation rates.Information about clinical performance of NIPS aids in appropriate pre- and post-test counseling.

Based on a statistical analysis of low coverage genome sequencing data, non-invasive prenatal testing of aneuploidies is being provided in a growing numbers of countries. It has proved a major improvement versus classic screening strategies but still requires invasive procedures when positive. Using five hundred samples included in our French multicenter study, we aim to validate two different published bioinformatics tools for aneuploidy calling. All patients included had an indicated invasive sampling to achieve fetal karyotype in parallel.
WISECONDOR (WIthin SamplE COpy Number aberration DetectOR) and RAPIDR (Reliable Accurate Prenatal non-Invasive Diagnosis R package) both require a reference set of euploid samples. RAPIDR establishes a baseline for confrontation with unknown samples. WISECONDOR uses a "within sample" normalization algorithm made from the reference set and preventing from inter-individual variation. They both use a bin segmentation approach to take into account the GC-content bias. Different QC metrics are used. Fetal fraction, a well-known cause for false negative, can be estimated for male pregnancies via RAPIDR. WISECONDOR uses an inter-chromosomal concordance test to reduce technical noise. A training set of 50 samples has shown comparable performances regarding False Negative and False Positive rates for main aneuploidies (T21, T18, T13). The study will focus on the practicality for use in routine diagnosis (time of calculation, necessary resources, setting up), reliability of QC metrics and potential discrepancies.
Both applications were initially developed using data from Illumina dye sequencing technologies. In this study we will demonstrate that semiconductors sequencing data fit to these two turnkey methods.

PM01.38

False negative NIPT results for trisomy 13, 18 and 21: risk figures derived from cytogenetic investigations in chorionic villi

D. Van Opstal, *M. Srebniak, J. Polak, F. de Vries, C. van den Berg, R. H. Galjaard; Erasmus MC, Rotterdam, Netherlands.*

Background: Non-invasive prenatal testing (NIPT) demonstrated a small chance for a false positive and false negative result. This is partly due to the fact that the fetal DNA in maternal plasma is derived from the cytotrophoblast of chorionic villi (CV). This cytotrophoblast is not always representative for the fetus because of its embryonic origin (trophoblast) and the existence of chromosomal mosaicism. Therefore, accurate cytogenetic studies in CV involve the investigation of both cytotrophoblast (STC-villi) and mesenchymal core, the latter having the same embryonic origin as the fetus itself. We calculated the risk for a false negative trisomy 13, 18 and 21 NIPT result of a biological nature based on our experience with CV.
Me**thods :** All cases of fetal trisomy 13, 18 and 21 among 5967 CV samples of

pregnancies at high risk that were cytogenetically investigated in our centre between January 2000 and December 2011, were retrospectively studied for the presence of a normal karyotype or mosaicism < 30% in STC-villi.
Results: 404 cases of trisomies 13, 18 and 21 were found amongst 5967 samples. Of these 404 cases, 14 (3,7%) had a normal or low mosaic karyotype in STC-villi and therefore would potentially be missed with NIPT. It involved 2 % (5/242) of all trisomy 21 cases and 7.3% (9/123) of all trisomy 18 cases.
Conclusion: In 1:426 (14/5967) NIPT samples of patients at high risk, a trisomy 18 or 21 will be missed due to the biological phenomenon of absence of the chromosome aberration in the cytotrophoblast.

PS01.39
Identification of 22q11 microdeletions by noninvasive prenatal testing (NIPT) - one year of clinical experience

R. M. McCullough[1], *T. Boomer*[1], *J. Wardrop*[1], *J. Hume*[1], *W. B. Paxton*[1], *N. Dharajiya*[1], *J. Saldivar*[1], *T. Monroe*[2], *D. H. Farkas*[3];
[1]*Sequenom Laboratories, San Diego, CA, United States,* [2]*Sequenom Laboratories, Morrisville, NC, United States,* [3]*Sequenom Laboratories, Grand Rapids, MI, United States.*

Introduction: NIPT for fetal aneuploidies has become routine practice in pregnancy management. A whole genome approach enables detecting subchromosomal events by employing a novel algorithm that uses low coverage sequencing data. The output for detected fetal microdeletion events is akin to data from conventional microarray analysis of invasive testing.
Methods: Maternal blood samples submitted to Sequenom Laboratories were subjected to DNA extraction and library preparation followed by whole genome massively parallel sequencing. Sequencing data were analyzed using an algorithm to detect subchromosomal events such as 22q11 microdeletions. Results: The MaterniT21® PLUS test identified 32 cases with a 22q11 deletion. For twenty-one cases diagnostic invasive testing was performed and for all cases the 22q11 deletion was confirmed. Eleven cases did not have invasive testing results available. Seven of these cases had clinical findings of complex heart defects or Tetralogy of Fallot consistent with the NIPT result. For the remaining four cases, no clinical signs were identified and outcomes were pending. Thus far no confirmed false positives have been identified. One of the confirmed cases was a twin gestation where one twin was positive for the 22q deletion.
Conclusion: It is imperative when testing for rare conditions that tests perform with the utmost specificity to yield high positive predictive values. By using a whole genome sequencing approach, we have demonstrated that this objective is achievable. This abstract provides further evidence to broaden the scope of non-invasive testing to detect subchromosomal deletion/duplication events and the potential to derive fetal karyotypes in the future.

PM01.40
When isochromosomes and noninvasive prenatal testing (NIPT) collide: The technical and clinical challenges of piecing together puzzling cases

T. A. Boomer[1], *N. D. Loia*[2], *L. Bensen*[3], *M. N. Strecker*[4], *J. Wardrop*[1], *T. J. Monroe*[5], *R. McCullough*[1], *J. Saldivar*[1], *N. Dharajiya*[1];
[1]*Sequenom Laboratories, San Diego, CA, United States,* [2]*New Jersey Perinatal Associates, Livingston, NJ, United States,* [3]*St. Joseph's Hospital - Perinatal Assessment Unit, Tucson, AZ, United States,* [4]*CombiMatrix, Irvine, CA, United States,* [5]*Sequenom Laboratories, Morrisville, NC, United States.*

Background: Noninvasive prenatal testing (NIPT) uses circulating cell free DNA for the evaluation of fetal chromosomal abnormalities. Whole genome sequencing combined with advanced bioinformatics enables detailed interrogation of a variety of complex chromosomal changes. Here we highlight three cases involving isochromsomes and relate their NIPT results to diagnostic and clinical outcomes.
Case 1: mos 47,XX,+i(18)(p10)[3]/46,XX[16]
NIPT performed at 12 weeks gestation indicated Trisomy 18. CVS chromosomes revealed a mosaic marker chromosome and microarray detected an 18p duplication. Fetal ultrasound was normal. Amniocentesis chromosomes revealed mosaicism for a supernumerary isochromosome 18p. NIPT traces corroborated duplication of 18p.
Case 2: idic(Y)(q11.2)[15]
NIPT performed at 12 weeks gestation indicated Turner Syndrome. Fetal ultrasound showed male genitalia. Amniocentesis chromosomes and microarray revealed an isodicentric Yp. Discordant NIPT results may suggest the placenta is mostly 45,X, though traces reflect presence of Yp material.
Case 3: 46,X,i(X)(q10)[13]/45,X[7]
NIPT performed at 10 weeks gestation indicated Turner Syndrome. Fetal ultrasound was normal other than a clubbed foot. Amniocentesis chromosomes revealed a mosaic karyotype including an isochromosome Xq. NIPT traces show no evidence of segmental abnormality and may suggest the placenta is mostly 45,X.
Conclusions: Isochromosomes arise from an error in centromere division during meiosis or mitosis. Most are de novo and mosaic in origin, consequently having variable impact on developing embryologic tissues. As NIPT reflects placenta tissue, results may be concordant or discordant with amniocentesis studies. NIPT can lend insight into the timing and origin of such complex events and help explain inconsistencies between testing modalities.

PM01.42
Comparison of NIPT clinical performance in 72,382 high-risk pregnant women and 40,287 low-risk pregnant women

Y. Gao, *H. Zhang, F. Jiang, F. Chen, W. Wang;*
BGI, Shenzhen, China.

NIPT has been applied in prenatal screening for fetal aneuploidy with remarkable advances. However, clinical data from large scale of NIPT practice in the general population has not been reported. We prospectively analyze NIPT performance in 147,314 pregnancies with singleton and twins from 508 hospitals from January 1, 2012 to August 31, 2013, which is the largest clinical experience to-date. NIPT sensitivity and specificity were validated by karyotyping confirmation for positive cases and clinical follow-up of negative cases, showing comparable if not better performance comparing to previous studies in small scale of high-risk population in detecting T21, T18, and T13. A performance comparison was also performed between the high-risk group and the low-risk group, which were divided based on maternal age, prenatal screening results, nuchal translucency measurement, family history and previous pregnancy of aneuploidy, showing the equivalent effectiveness of NIPT in the low-risk population as in the high-risk population. In the total population, NIPT false positive and false negative results were investigated for their corresponding reasons. Biological factors such as maternal background and mosaicism were the major reasons causing NIPT false positive and false negative results. Our data supports the use of NIPT in the general population to screen for T21, T18, and T13.

PS01.43
Non-Invasive Prenatal Testing for the most common aneuploidies (trisomies 21, 18, and 13) using a semiconductor-sequencing platform: a French multicenter pilot study

Combined first-trimester screening has improved prenatal screening for trisomy 21. However the number of unnecessary invasive diagnostic procedures still remains high. Non-Invasive Prenatal Testing (NIPT) using massively parallel sequencing of cell-free fetal DNA from maternal plasma, which is now part of the prenatal landscape, should drastically diminish the risk associated with invasive techniques. Several publications have established NIPT's effectiveness using mainly the Illumina sequencing technology.
A French consortium of seven academic hospitals collaborates to validate a common protocol and to evaluate the efficiency and reliability of NIPT of the most common chromosomal aneuploidies using a semiconductor-sequencing platform. Indeed many French laboratories are already equipped with this technology.
A total of 500 pregnant women (between 12.3 and 35 weeks of gestation) who presented a high risk of aneuploidy and underwent fetal karyotyping were included in a prospective study. 15 % of these patients presented a fetus with one of the most common aneuploidies: trisomies 21, 18 and 13. The NIPT results matched the fetal karyotyping results in all of the cases: all trisomies were detected. The analysis of whole genome sequencing data (including notably librairies quantification, total raw reads per sample, estimate of plasma fetal DNA fraction) enabled us to establish the quality criteria

required for its use in routine diagnosis.
NIPT using a semiconductor-sequencing platform is a rapid and cost-effective alternative technology, and represents an attractive approach for large scale population NIPT.

Validation of abnormal non-invasive prenatal testing (NIPT) by conventional testing technologies - Tel Aviv Medical Center experience

M. Goldstein[1], *A. Bar-Shira[1], D. Barel[1], S. Simchoni[1], H. More[1], D. Konik[1], T. Naiman[1], I. Kaplan-Ber[1], A. Orr-Urtreger[1,2], Y. Yaron[1,2], A. Reches[1];*
[1]The Genetic Institute, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]The Sackler Faculty of Medicine,Tel Aviv University, Tel Aviv, Israel.

Accurate assessment of fetal aneuploidy risk is important for genetic counseling in order to facilitate informed reproductive choices while avoiding unnecessary pregnancy loss due to invasive testing. Recent non-invasive prenatal testing (NIPT) using cell free DNA screens for common aneuploidies and some microdeletion syndromes. This technology is offered in Israel since 2012 as an out-of-pocket service. Abnormal results are usually followed-up with invasive testing. We hereby describe our experience with such cases.
During the years 2013-2014, twenty one women underwent invasive testing in our institution due to abnormal NIPT results. These included 10 cases at risk for trisomy 21, 5 for sex chromosome aneuploidy (SCA), 2 for trisomy 13, one for trisomy 18 and 3 for a suspected microdeletion. QF-PCR was performed in 14 of the 18 cases at risk for aneuploidy, all cases underwent full karyotyping. Chromosome microarray analysis (CMA) was performed for cases at risk for microdeletions.
The overall rate of discordant results in our series was 40%. The highest detection rate was for Down syndrome with a positive predictive value (PPV) of 90%. The PPV for SCA was 60% (3 of 5). None of the 3 cases suspected for trisomies 13 and 18 were confirmed by karyotyping. Likewise, none of the 3 cases suspected for microdeletion were detected by CMA.
Validation of abnormal NIPT results by conventional invasive procedures remains the gold standard and is essential for establishing fetal status, also demonstrating the importance of physician education regarding the limitations of NIPT.

PS01.45

Massively Parallel Sequencing (MPS) reliably identifies trisomy 21, 18, and 13 in maternal plasma with low-level fetal cell-free DNA fractions.

S. Bono, *F. Pizzuti, M. Mariano, A. Polverari, S. Duca, G. Cottone, A. Nuccitelli, M. Sessa, F. Spinella, M. Baldi, F. Fiorentino;*
GENOMA GROUP, Rome, Italy.

Noninvasive prenatal testing (NIPT) detects common fetal aneuploidies by analyzing cell-free DNA (cfDNA). Current methods use massive parallel sequencing (MPS) or targeted sequencing. Several studies have reported that NIPT accuracy is substantially affected by low-level of fetal fraction (FF), referred as to the fetal component of total (maternal + fetal) cfDNA. Targeted sequencing-based NIPT approaches use a 4% FF cut-off, below this value a redraw is requested. However, data describing the limit of detection (LOD) at low FFs is lacking. Here, we determine the LOD for a MPS-based NIPT.
Serial dilutions were made using 26 confirmed fetal aneuploidy samples with a known FF. Each aneuploidy sample was mixed with a euploid sample to create 6 samples with effective aneuploid FFs of 1-4%. Additionally, NIPT was performed on 1998 pregnancies with confirmed outcomes. Fetal fraction was determined in aneuploid and male samples using MPS tag counting.
Dilution experiments revealed a LOD of 2% for Trisomy (T) 21, and 1.5% for T18 and T13. All (26/26) aneuploidy pregnancy samples were detected; 15.4% (4/26) had a FF of 2-4%, none were <2%. Of 1056 euploid male samples, 23 (2.2%) had a FF <2% and 64 (6.1%) had a FF between 2-4%. All NIPT data were concordant.
Our MPS-based NIPT detected aneuploidies down to 2% FF; 6% of samples had a FF in the 2-4% range. Assay LOD should be determined prior to clinical application, as this establishes an appropriate cut-off that lowers the risk of false negative results and avoids unnecessary test cancellations.

PM01.46

Non invasive prenatal diagnosis (NIPD) of RHD using cell free fetal DNA (cffDNA) from maternal plasma as a method for targeted anti RhD prophylaxis

M. Madjunkov[1,2], *S. Madjunkova[3,2], M. Mircevska[3], T. Madgett[4], N. Avent[4], D. Plaseska-Karanfilska[3];*
[1]Clinic of gynecology and obstetrics, Medical faculty, Skopje, Macedonia, The Former Yugoslav Republic of, [2]Department of Clinical Pharmacology, Toxicology and Genetics, The Hospital for Sick Children, Toronto, ON, Canada, [3]Macedonian Academy of Sciences and Arts, Research Center for Genetic Engineering and Biotechnology "Georgi D. Efremov", Skopje, Macedonia, The Former Yugoslav Republic of, [4]School for Biological and Biomedical sciences, University of Plymouth, Plymouth, United Kingdom.

Introduction: RhD blood group incompatibility between an RhD-negative mother and an RhD-positive fetus followed by allosensitization and production of maternal anti-D antibodies is still the major reason for hemolytic disease of the fetus and newborn (HDFN). Routine antenatal and postnatal anti-D prophylaxis has reduced the risk of RhD alloimmunization to 0.05-0.4%. However about 10-20% of RhD-negative mothers would receive unnecessary prophylaxis. Non-invasive diagnostic methods employing cell free fetal DNA (cffDNA) from maternal blood overcome the risks associated with invasive procedures used for fetal RHD genotyping.
Materials and Methods: We aimed to evaluate the results from non-invasive fetal RHD typing using cffDNA from maternal plasma in a group of 24 RhD-negative women with confirmed singleton pregnancy before receiving their first prophylactic dose of anti-RhD-IgG. RHD genotyping was done using real-time PCR amplification of exon 5 and 7 of RHD gene.
Results: Of the 24 RhD-negative pregnant women 5 (20.8%) were in the first trimester (7±2 GW) and 19 (79.1%) were in their second trimester (20.4±2.6 GW). 20.8% (5/24) were in their third pregnancy and in the second trimester. Non-invasive fetal-RhD typing showed that 20.8% (5/24) of the fetuses were RHD negative. Three of them were in the second trimester and 2 in the first trimester, but to mothers in their second and third pregnancy.
Conclusions: These results although limited, clearly show that non-invasive fetal-RhD typing using cffDNA from maternal plasma can be used as a method in clinical practice for targeted anti-RhD prophylaxis and improvement of management of RHD fetomaternal incompatibility.

PS01.49

Experiences of high-risk pregnant women who were offered a choice between non-invasive prenatal testing, invasive testing or no follow-up test

R. V. van Schendel[1], *G. C. M. L. Page-Christiaens[2], L. Beulen[3], C. M. Bilardo[4], M. A. de Boer[1], A. B. C. Coumans[5], B. H. W. Faas[3], I. M. van Langen[4], K. D. Lichtenbelt[2], M. C. van Maarle[6], M. V. E. Macville[5], D. Oepkes[7], E. Pajkrt[6], L. Henneman[1];*
[1]VU University Medical Center, Amsterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]Radboud University Medical Center, Nijmegen, Netherlands, [4]University Medical Center Groningen, Groningen, Netherlands, [5]Maastricht UMC+, Maastricht, Netherlands, [6]Academic Medical Center, Amsterdam, Netherlands, [7]Leiden University Medical Center, Leiden, Netherlands.

Objective: The TRIDENT study evaluates the implementation of non-invasive prenatal testing (NIPT) in the Dutch healthcare system. Here we report on the preferences and experiences of high-risk pregnant women who were offered a choice between NIPT, invasive testing or no follow-up test.
Methods: A nationwide prospective cohort study among pregnant women at high-risk for fetal aneuploidy because of first-trimester screening results (risk >1:200) or medical history. Questionnaires were completed after counselling (n=1,106, 86% response) and after test-results (n=686, 67% response), at seven (of the eight) prenatal diagnostic centres.
Results: The majority of respondents (92%) preferred NIPT, 5% invasive testing, 2% were unsure, and 1% declined testing. Main reason to prefer NIPT was safety for the child (92%). Of the 60 women preferring invasive testing, 52% did so because of test-accuracy, 25% desired more rapid test-results, 5% because it provides more information, and 18% reported other reasons. Most women (92%) felt that they made a well-informed decision, and 75% reported that this decision was easy to make. Intention to terminate the pregnancy for Down syndrome was lower among women choosing NIPT (58%) vs. invasive testing (87%). Women were highly satisfied with NIPT. However, 64% perceived the waiting time for NIPT results (mean:11 days (range 5-32)) as too long, while 3% in retrospect would have preferred a different follow-up test, mostly to avoid the long waiting time.
Conclusion: Most pregnant women felt they could make an informed decision. The majority prefers NIPT, mainly because it has no miscarriage risk. Reducing turnaround time for test-results is our next challenge in meeting women's needs.

PM01.50

Non-invasive prenatal testing (NIPT) of aneuploidy by means of next-generation sequencing (NGS) in high-risk pregnancies of fetal abnormalities. The first experience in Russia.

E. Shubina[1], **E. Baranova**[2], *N. Karetnikova[1], D. Korostin[1], A. Ekimov[1], A. Gus[1], V. Bakharev[1], N. Tetruashvili[1], D. Trofimov[1], G. Sukhikh[1];*
[1]Federal State Budget Institution „Research Center for Obstetrics, Gynecology and

Perinatology" Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation, [2]Federal State Budget Institution, Moscow, Russian Federation.

Introduction: General prenatal screening estimates only indirect markers, such as fetal ultrasound and maternal serum biomarkers. Chorionic villus sampling or amniocentesis are highly precision but carry a risk of 1-3% of cases procedure-related miscarriage. Non-invasive prenatal testing is actively put into practice after discovered fetal cell-free DNA in maternal blood. Objective: To evaluate the possibility of using non-invasive prenatal testing of aneuploidy by means of next-generation sequencing (NGS) in high-risk pregnancies of chromosomal fetal abnormalities. Materials and Methods: Chorionic villus sampling or amniocentesis was done on 200 pregnant women at 11-14 (n=165) or 17-20 (n=35) weeks of gestation due to abnormal maternal serum screening, increase in nuchal translucency and advanced maternal age. Pregnant women also donate blood samples before having the invasive test. NIPT samples were analyzed using low-coverage whole-genome sequencing of plasma cell-free DNA. Z-score was used for fetal aneuploidy detection and the results were validated by karyotyping confirmation. Results: Aneuploidies were confirmed in 17 of 17 T21-positive cases, 8 of 8 T18-positive cases, and 1 of 2 T13-positive cases. 2 false negative cases were identified, both T21 cases, and 1 false positive case - T13. The principal factor contributing to NIPT false positive result was placental mosaicism, whereas false negative results were due to low fetal fraction (<4%).
Conclusions: At this time, NIPT may be an option for women classified as high-risk of aneuploidy, especially in pregnant women with advanced age. Additional studies are needed to introduce NIPT into the routine workflow of prenatal care.

PS01.51
Non-invasive prenatal screening plus (NIPS+) for fetal trisomy 2 and trisomy 5 mosaicism cases

H. Chia-Cheng[1,2], *L. Tzu-Hung*[3], *S. Yi-Ning*[1,3,4];
[1]*Sofiva Genomics, Co., Ctd., Taipei, Taiwan,* [2]*Graduate Institute of Medical Genomics and Proteomics, National Taiwan University College of Medicine, Taipei, Taiwan,* [3]*Dianthus Maternal Fetal Medicine Clinic, Taipei, Taiwan,* [4]*Department of Obstetrics and Gynecology, School of Medicine, Taipei Medical University, Taipei, Taiwan.*

Background: Non-invasive prenatal screening plus (NIPS+) has been proven to be a powerful method for the routinely detection of trisomies 21, 18 and 13. However, few cases have been reported about other rare aneuploidies. Here we describe two cases of fetal trisomy 2 mosaicism and trisomy 5 mosaicism identified by NIPS+.
Methods: We sequenced cell free DNA isolated from maternal plasma obtained at 13 and 22 weeks of gestation from two health pregnant woman with a singleton pregnancy. The sequenced data were mapped to human genome sequence (hg19). Z-scores were calculated for all the 23 pairs of chromosomes.
Results: Z-score increasing significantly of chromosome 2 and 5 were observed in these two cases and the Z-score values were 2.80 and 10, respectively. The results were confirmed by karyotyping of amniotic fluid cells and showed 47,XY,+2 and 47,XY,+5[5]/46,XY[35] mosaicism karyotypes.
Conclusion: This study show NIPS+ can provide information on other rare chromosomal abnormalities. It can provide useful information for the further investigation and practice of NIPS+.

PM01.52
Noninvasive detection of fetal aneuploidies using targeted sequencing of paired homologous regions

T. J. Jensen[1], *S. K. Kim*[1], *G. Hogg*[1], *C. K. Ellison*[1], *Y. Sun*[1], *J. Fox*[1], *H. Tao*[1], *E. McCarthy*[1], *B. Sagoe*[1], *M. Abdellatef*[1], *A. R. Mazloom*[1], *J. Tynan*[1], *T. Burcham*[2], *D. van den Boom*[2], *M. Ehrich*[2];
[1]*Sequenom Laboratories, San Diego, CA, United States,* [2]*Sequenom, Inc., San Diego, CA, United States.*

Current clinical laboratory offerings for noninvasive prenatal testing (NIPT) determine the presence or absence of fetal aneuploidies using aligned sequence read counting methods or by leveraging single nucleotide polymorphisms (SNPs). We hypothesized that using the relative abundance of paired homologous regions may enable an alternative way to detect fetal aneuploidies noninvasively. This study describes the evaluation of paired homologous regions for the detection of trisomy 21 (T21) and trisomy 18 (T18). Assays for 1,060 amplification targets were designed to determine fetal aneuploidy status, fetal sex, and the proportion of fetal DNA present in a sample. Circulating cell free (ccf) DNA was extracted from the plasma of pregnant female donors and all target regions were co-amplified in a single reaction. Amplified products were evaluated using massively parallel sequencing (Illumina) and homolog ratios were determined based on the read depth from each homolog. We measured the performance of the developed assay in a blinded set of 480 ccfDNA samples with fetal genotypes orthogonally validated by the MaterniT21® PLUS Laboratory Developed Test. Samples were sequenced at a mean depth of 2.3 million reads per sample with 432 (90%) assayed samples returning a result. Using orthogonal NIPT results as a reference for each individual, we detected 31/31 T21 samples and 14/16 T18 samples. No false positive results were observed. This study introduces a novel NIPT aneuploidy detection approach using targeted sequencing of paired homologous regions and establishes proof of concept for a low-cost, highly scalable method for the identification of selected fetal aneuploidies with performance and non-reportable rates similar to some other published methods.

PS01.53
Discordant results for sex chromosomal aneuploidies from noninvasive prenatal testing

R. RAYNOVA, *I. Bradinova, K. Vladimirova, A. Savov;*
National Genetic Laboratory,University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria.

In the human fetus sex chromosome aneuploidies (SCA) have the same prevalence as the common autosomal aneuploidies 21, 18, 13. Non-invasive prenatal testing (NIPT) of cell-free fetal DNA (cffDNA) for fetal aneuploidy risk assessment has been shown to be both highly sensitive and highly specific for trisomy 21. However, it is less sensitive for trisomies 18, 13 and sex chromosome aneuploidies. Discrepancies between positive NIPT result and fetal karyotype on chorionic villus sampling or amniocentesis may occur. The source of aneuploidy may be due to maternal mosaicism, maternal malignancy, true fetal mosaicism, a demised co-twin, an anembryonic sac, confined placental mosaicism.
We present two cases of a 31-year-old woman, pregnant in 18 gestational weeks and a 34-year-old woman, also pregnant in 18 gestational weeks. Both were referred to our Unit for amniocentesis due to positive NIPT for SCA: risk for monosomy X, for the first patient and risk for Kleinfelter's syndrome for the second. The ultrasound scans were unremarkable.
DNA was extracted from uncultured amniocytes, amplified with commercial QF-PCR kit and analyzed on ABI 3130. Karyotyping was performed on cultured amniocytes using standard protocol.
QF-PCR and cytogenetic analysis showed normal results, SCA were excluded.
Both pregnancies were still ongoing, with no pathological findings on fetal morphology ultrasound scans. Cytogenetic and molecular-genetic analyses are to be done after delivery to reveal the source of the discordant results. We expect maternal mosaicism and confined placental mosaicism to be the main causes.

PM01.54
Noninvasive Prenatal Testing after discovery of fetal malformation by ultrasound: two years of experience in France

G. VIOT, *C. BERNABE DUPONT, L. LOHMANN, P. ERNAULT, F. JACQUEMARD;*
American Hospital of Neuilly, NEUILLY sur SEINE, France.

Detection of fetal DNA in maternal blood allows non-invasive prenatal testing (NIPT) of aneuploidy with very high sensitivity and specificity. Using NGS, this approach can be proposed to women with higher age, with history of trisomy, with positive test for aneuploidy or in case of parental balanced translocation involving chromosomes 13-18-21.
From January 2013 to December 2014, 2304 tests were carried out in your unit mainly because of advanced maternal age or abnormal first trimester screening (FTS). For 91 women (3.9%), fetal DNA was proposed while scan detected fetal malformations (28.5%: thick nuchal translucency; 21.4%: soft signs of trisomy 21; 12.85%: intrauterine growth retardation; other: 37.27%). For 2 cases, the result was positive for trisomy 21.
Classically, fetal DNA testing is not a good option in case of ultrasonic malformations. For all these women, we granted the request for specific reasons: refusal of patients to perform an invasive procedure due to the risk of induced miscarriages, risk of premature delivery or history of premature labor, decision to continue the pregnancy whatever the outcome, assisted procreation history. Genetic counseling is mandatory before testing. Test limitations were explained. Ultrasound evaluation in our unit was also performed. Clinical evaluation of newborns and follow-up were always practiced after birth.
In some specific situations, NIPT can be performed after genetic counseling and explanation of its limitations. In the near future, it appears important to evaluate the help of this non-invasive approach, mainly after discovery of soft signs in favor of Down syndrome.

PS01.55

Novel homozygous NLRP7 mutation in a Cypriot patient with recurrent hydatidiform molar pregnancies

T. Delikurt[1], I. Touitou[2], G. Sarrabay[2], **V. Christophidou-Anastasiadou**[1,3]*, G. A. Tanteles[1];*
[1]The Cyprus Institute of Neurology and Genetics; Clinical Genetics Clinic, Nicosia, Cyprus, [2]Laboratory of Rare and Autoinflammatory Diseases, Montpellier, France, [3]Makarios Medical Center; Clinical Genetics Clinic, Nicosia, Cyprus.

Hydatidiform mole (HM) is an aberrant human pregnancy associated with abnormal embryonic development and has, in the majority of sporadic cases, a multifactorial basis. In Western countries, HM occurs once in every 600 pregnancies, however, this rate has been reported to be higher in other parts of the world including the Middle East. Recurrent hydatidiform molar (RHM) pregnancies are rare and are defined by the occurrence of at least two HM pregnancies in the same patient. Recently, mutations in two different genes namely, NLRP7 and KHDC3L have been identified as a cause of familial RHM pregnancies. We present a 37 year old Cypriot patient with a history of four (three of which were histologically confirmed) HM pregnancies. NLRP7 mutation analysis revealed that the index case was homozygous for the p.Leu820Cysfs*29 (c.2458delC) mutation in exon 7 of this gene. This is a novel mutation, not previously reported in the literature. To our knowledge, this is the first Cypriot case with a history of RHM pregnancies in which a causative maternal-effect in the form of NLRP7 homozygosity has been identified.

PM01.56

First successful story of preimplantation genetic diagnosis for pantothenate kinase-associated neurodegeneration

B. Panthan*;*
Ramathibodi Hospital, Bangkok, Thailand.

Here we report the first successful story of Preimplantation Genetic Diagnosis (PGD) for Pantothenate Kinase-Associated Neurodegeneration (PKAN). We received a referral from Pediatric Neurologist concerning genetic diagnosis and reproductive option for the couples bearing the first child affected by this particular disorder. A 2-year-old Thai boy was born from non-consanguineous parents, developed dystonia and neurological deterioration after the age of 1 and died within 1 year after establishing clinical diagnosis. DNA sequencing of *PANK2* in the patient's leukocytes revealed novel homozygous g.21738G>C, whereas the parents were identified as carriers. Genetic counseling for PGD was performed to the couples and the ethical clearance was done. *In-Vitro* fertilization (IVF) and Intra Cytoplasmic Sperm Injection (ICSI) with PGD was performed. All of embryos were biopsied in the cleavage stage and subsequently performed for whole-genome amplification. Genetic status was diagnosed with the linkage analysis using family-specific short-tandem repeat markers and direct mutation testing using SNaPSHOT Mini-sequencing. The aneuploidy screening was performed by Next-Generation Sequencing-based strategy. There were seven embryos from these couples: two likely affected, three likely carriers, one likely unaffected and one failed in the target genome amplification. Aneuploidy screening was done before making decision of embryo transfer and only one unaffected embryo passed the screening. Thereafter, this embryo was transferred in frozen thawed cycle and the pregnancy was successful. The confirmation was done by amniocentesis, which showed the consistent result to PGD. At 38 weeks of gestational age, a healthy male baby was born.

PS01.57

Algorithm for efficient analysis of perinatal samples: a three-year prospective study

K. Wou*[1], Y. Hyun[2], D. Chitayat[1,3,4], K. Chong[1,3,4], S. Keating[2], P. Shannon[2], E. Kolomietz[2];*
[1]Department of Obstetrics and Gynecology, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [2]Department of Pathology and Laboratory Medicine, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [3]The Prenatal Diagnosis and Medical Genetics Program, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [4]Department of Pediatrics, Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.

Objective: To evaluate the performance of a clinical algorithm for direct genetic analysis done on fetal/neonatal tissue.
Methods: Study samples consisted of tissues obtained from miscarriage, stillbirth and neonatal demise during the time period from July 1st, 2011 to June 30th, 2014. QF-PCR analysis was the initial test performed on all specimens followed by chromosomal microarray analysis done on the normal QF-PCR specimens.
Results: A total of 1071 of 1195 submitted specimens were confirmed as of true fetal origin. Of those 1071 informative specimens, 30.8% yielded abnormal results. Of the latter, 57.6% had abnormal QF-PCR and 42.1% had abnormal microarray result. Autosomal trisomies were detected in 61.2%, 7.6% had triploidy, 9.1% had monosomy X, 1.5% had sex-chromosome aneusomies, 5.8% were molar pregnancies and 14.2% had copy number variants (CNV) including microdeletions/microduplications and cryptic unbalanced rearrangements (Table 1). The highest diagnostic yield was observed in the 1st trimester specimens 67.9%, followed by 20.3% in the 2nd and 9.2% in the 3rd trimester. We confirmed that maternal age is correlated with the likelihood of autosomal trisomies but not with triploidy, sex chromosome aneusomies, molar pregnancy, or CNVs.
Conclusion: This algorithm, based on uncultured specimens, has replaced standard cytogenetic analysis method in testing of perinatal samples and resulted in a substantially higher diagnostic yield and improved diagnostic rate. Establishing the cause of a miscarriage and stillbirth has clinical and reproductive implications and results in changes in the management of future pregnancies, such as the decision to undertake preimplantation genetic testing.

PM01.58

Introducing CMA (chromosomal microarray) analysis into the advanced IVF lab

T. Frumkin*[1], T. Shwartz[1], T. Cohen[1], V. Gold[1], S. Peleg[1], L. Malki[1], B. Almog[1], D. Ben-Yosef[1], Y. Yaron[2], A. Amit[1], A. Reches[2], M. Malcov[1];*
[1]Racine IVF Unit, Department of Ob/Gyn, Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv, Tel Aviv, Israel, [2]Prenatal Diagnosis Unit, Genetic Institute, Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv, Tel Aviv, Israel.

Introduction It is widely accepted that a main cause for IVF failure is aneuploidity of the embryos. It is also claimed that normal morphokinetics of early embryos, as demonstrated by the EmbryoScope, are correlated with normal chromosomal constitution. Introducing CMA technique to the IVF lab is aimed to contribute a reliable and objective test for the selection of embryo with the best prognosis. This may enable the transfer of a single embryo without decreasing pregnancy rates.
Aim To assess the additive prediction value of CMA for embryo selection, compare to the known morphokinetic parameters.
Material and methods For CMA analysis 21 PGD embryos, that were not suitable for transfer, were re-biopsied on day 5-6. Single cells were subjected to whole genome amplification followed by array hybridization (BlueGenome, 24 sure+) and scanning. CMA results were compared with morphokinetic parameter: PB localization, timing and synchronization of cells division and EmbryScope's score.
Results CMA results of 21 analyzed embryos were divided into 5 groups: normal chromosomal constitution (3), X monosomy (2), unbalanced translocation (6), single trisomy (3) and chaotic chromosomal constitution (7). Two out of 3 normal euploid embryos were graded with very low morphokinetic score and 7 embryos with chaotic chromosomal constitution were graded with various scores.
Conclusion This preliminary study demonstrates that the ploidity of cleavage stage embryos can still be determined only by an invasive CMA method. We suggest that timing and synchrony of cell cycles are probably dissatisfactory morphokinetic parameters for predicting embryo chromosomal constitution; however, other parameters may be better ones.

PS01.59

Clinical utility of blastocyst biopsy and vitrification for Preimplantation Genetic Diagnosis by haplotyping (PGH) and sequencing for Marfan syndrome caused by a de-novo FBN1 mutation.

P. Renwick*[1], J. Ward[1], E. Ronaldson[1], J. Campbell[2], C. Ogilvie[1];*
[1]Centre for Preimplantation Genetic Diagnosis, Guy's Hospital, London, United Kingdom, [2]Viapath Genetics, Guy's Hospital, London, United Kingdom.

Background
PGH for monogenic disease requires prior construction of haplotypes around the gene of interest using appropriate family members with known disease status to assign phase to the haplotypes prior to undergoing IVF to generate embryos for testing. In the absence of affected relatives, mutation-carrying haplotypes cannot be identified.
We have therefore developed a strategy for de novo mutations which assigns phase during the PGD cycle; this strategy is facilitated by our blastocyst biopsy and vitrification programme.
Methods
Grand-parental samples were used to construct haplotypes for each partner, leaving phase to be set during the case. Nine eggs were collected; four blastocysts were biopsied and vitrified. Due to allele drop out, phase can only be accurately set when the mutation is present. Three embryos, arrested at earlier stages with visible cells, were therefore collected to optimise finding the mutation in a sibling embryo. Samples underwent MDA-based whole

genome amplification and tested using linked FBN1 polymorphic markers, in conjunction with DNA sequencing of the de novo maternal c.2719C>T allele.
Results
Of the 7 tested samples, 3 were heterozygous for the mutation; linkage confirmed their presence on the same maternal haplotype. Two of the four biopsied embryos carried the opposite maternal FBN1 haplotype and will be replaced in frozen embryo transfers.
Conclusion
Our blastocyst biopsy and vitrification programme has enabled a novel strategy for PGD for carriers of de novo mutations. Extensive work up on gametes or sacrifice of viable embryos in a cycle, required by previous approaches, has been circumvented.

PM01.60
The first experience with detection of aneuploidy using next-generation sequencing within preimplantation genetic diagnosis

I. Soldatova, *L. Krautova, M. Putzova, S. Horackova, I. Maresova, R. Kren, J. Mika, D. Stejskal;*
GENNET, Prague, Czech Republic.

Due to rapid development of genetic methods evolved in routine check of embryos suitable for transfer after preimplantation genetic diagnosis (PGD) of monogenic diseases, we have introduced the next-generation sequencing (NGS) for detection of aneuploidies. Our aim is to join the both methods together for routine examination and to increase probability to transfer healthy embryos without chromosomal aneuploidies and unaffected alleles of monogenic disease from parents.
The products derived from MDA of the embryos five days of age were subjected to the PGD analysis and sequenced in the next step using Ion Proton Sequencing machine and Ion Fragment Library Kit.
From June 2014 we have analysed twenty one families undergoing the PGD of monogenic diseases with the aneuploidy detection using the NGS sequencing. Till now the total number of biopsied embryos has been sixty-six; forty-three embryos have been concluded as suitable for the transfer after the PGD but this number of embryos was decreased to thirty-one by the reasons of the NGS results. Twelve embryos were eliminated after NGS - : one triploid embryo , one embryo with trisomy of chromosome 21, two embryos with monosomy of chromosome 4, two embryos with monosomy of chromosome 16, two embryos with trisomy of chromosome 16, one embryo with monosomy of chromosome 18 in mosaic form and two chaotic embryos.
We concluded to involve NGS after the PGD during IVF is effective and suitable. Thereby, we are able to decrease risk of abortions after IVF caused by the aneuploidies of the transferred embryos.

PS01.61
Shallow whole genome sequencing is well suited for the detection of chromosomal aberrations in human blastocysts during preimplantation genetic diagnosis

A. Dheedene[1], *L. Deleye*[2], *D. De Coninck*[2], *T. Sante*[1], *C. Christodoulou*[3], *B. Heindryckx*[3], *E. Van den Abbeel*[3], *P. De Sutter*[3], *D. Deforce*[2], *B. Menten*[1], *F. Van Nieuwerburgh*[2];
[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Laboratory of Pharmaceutical Biotechnology, Ghent University, Ghent, Belgium,* [3]*Department for Reproductive Medicine, Ghent University Hospital, Ghent, Belgium.*

Introduction: Preimplantation genetic diagnosis (PGD) for chromosomal rearrangements is widely used to avoid transferring embryos with genomic aberrations. Currently, genomic microarrays are predominantly used for the detection of unbalanced structural abnormalities and aneuploidies in embryos from parents at risk. In this study we evaluate whether massive parallel sequencing (MPS) can be used in PGD for detecting chromosomal abnormalities.
Materials and Methods: 15 patients with a balanced structural rearrangement were included in the study: 8 reciprocal translocations, 4 Robertsonian translocations, 2 inversions and one insertional translocation. Whole genome amplification and microarray analysis (24sure+, Illumina) was performed on 47 trophectoderm samples from the cohort. In the current study, low coverage MPS on a Nextseq 500 (Illumina) and Ion Proton (Life Technologies) instrument was performed in parallel for those 47 amplified samples. Aberrations were detected using the QDNAseq algorithm.
Results: An average read count per sample of 11 and 10 million was obtained on the Nextseq 500 and the Ion Proton instrument respectively. In total, 6 normal and 41 abnormal embryos were analysed. All aberrations previously detected with arrayCGH could be readily detected in the MPS data and were correctly identified. The smallest detected abnormality was a 5 Mb deletion/duplication hence equaling or even exceeding the resolution of the routinely used microarrays.
Conclusions: This study demonstrates that MPS on a Nextseq 500 or Ion Proton instrument can be applied for the detection of chromosomal abnormalities in PGD embryos. MPS can serve as a more cost-effective and flexible technology for PGD.

PM01.62
Human placental genome is enriched in somatic genomic rearrangements

L. Kasak[1], *K. Rull*[1,2], *P. Vaas*[1,2], *P. Teesalu*[1,2], **M. Laan**[1];
[1]*University of Tartu, Tartu, Estonia,* [2]*Women's Clinic, Tartu University Hospital, Tartu, Estonia.*

Placenta is a temporary, but an indispensable organ in human pregnancy. Similarly to cancer, it is characterized by highly invasive nature facilitating effective implantation of the embryo and its function to support fetal nutrition, growth and development. Rapid multiplication and invasiveness of cancerous cells is facilitated by rearrangements in their genomes. So far only cancerous tissues have been described with high profile of somatic copy number variations (CNVs).
We hypothesized that similarly to cancer, somatic genomic rearrangements are promoted to support placental function. We report for the first time an extensive load of somatic CNVs, especially duplications, in the human placental genomes across gestation and suggest that this phenomenon may be critical for placental development and function to guarantee the normal progression of pregnancy. Identified placental somatic CNVs were significantly enriched in genes involved in cell adhesion, immunity, development, cell cycle. Overrepresentation of imprinted genes in somatic duplications suggested that amplified gene copies may represent an alternative mechanism to support parent-of-origin specific gene expression. The discovery may have clinical implications as placentas from pregnancy complications exhibited altered CNV profiles. Also, in prenatal testing based on cell-free DNA shed into the maternal circulation by the placenta, extensive placental somatic CNVs and mosaicism may interfere with the reliable detection of fetal CNV profile.

Investigation of the polygenic genetics of Pre-eclampsia and its relationship with other phenotypes

N. O. Williams[1], *F. Dudbridge*[2], *S. Chappell*[3], *C. Franklin*[1], *R. McGinnis*[1], *On behalf of the InterPregGen Consortium;*
[1]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom,* [2]*London School of Hygiene and Tropical Medicine, London, United Kingdom,* [3]*University of Nottingham, Nottingham, United Kingdom.*

Pre-eclampsia (PE) is a potentially life-threatening disorder characterised by hypertension and proteinuria after the 20th week of pregnancy. Although no single-locus PE associations have been replicated or achieved genome-wide statistical significance in PE mothers or offspring ("fetal cases"), we evaluated evidence for shared DNA variants responsible for PE and 6 other disease phenotypes of Wellcome Trust Case-Control Consortium 1 (WTCCC1) by using polygenic score analysis (PGSA) and genome-wide complex trait analysis (GCTA) methods (Nature 460:748-752,2009; AmJHumGenet 88:76-82,2011). For PGSA, GWAS SNPs with p-values below specific cut-points were identified in PE "Discovery" meta-analysis results from combined totals of 3830 maternal or 2650 fetal PE cases and ~47,000 controls from the InterPregGen Consortium, deCODE, and ALSPAC. For GCTA, individual-level SNP GWAS genotypes from InterPregGen (1900 maternal or 1000 fetal UK cases, 5500 UK controls) were tested for correlation with WTCCC1 phenotypes (~2000 UK cases, 3000 UK controls for each disease). Both PGSA and GCTA found significant evidence ($p<0.001$) for shared genetic variants responsible for the WTCCC1 Hypertension phenotype and maternal PE despite strict exclusion of pre-pregnancy hypertensives from our maternal cases. No significant evidence of variant sharing between maternal or fetal PE and any other WTCCC1 phenotype was observed by PGSA or GCTA. GCTA indicates that maternal and fetal PE arise from large numbers of causative variants spread throughout the genome with the heritability contributed by each chromosome being approximately proportional to chromosome length (maternal PE $r^2=0.86$; fetal PE $r^2=0.59$).

Design of a preconception carrier-screening panel including more than 200 genes associated to recessive and X-linked disorders. Our experience sequencing DNA samples from 48 Spanish healthy semen donors

J. Lezana[1], *C. Palma*[1], *J. Lopez*[1], *I. Manrique*[1], *P. Carrasco*[1], *S. Carmona*[1], *C. Torres*[1], *S. Zamora*[2], *A. Yoldi*[2], *A. Vaquero*[2], *J. Ramirez*[2], *J. Castilla*[2], *J. Lopez*[1];
[1]*MGC Genetaq, Malaga, Spain,* [2]*Ceifer, Granada, Spain.*

Introduction:
Next-generation sequencing (NGS) methods allow genetic testing for many disorders with high fidelity, quick turnaround time and a lower cost.
Materials and Methods:
DNA from 48 healthy semen donors, with previous negative studies for the most prevalent genetic disorders in Spain: Fragile X syndrome type 1, spinal muscular atrophy and cystic fibrosis (32 common mutations).
Design and testing of a NGS gene panel including 203 genes for recessive and X-linked disorders genes (106 complete coding and splicing region analysis, 97 partial analysis). Paired-end sequencing, alignment with BWA, and variant calling using GATK.
Results:
Mean coverage: 308,76X (SD=62,62). Regions with >20X coverage: 99,53% (SD=0,22).
Pathogenic variants (PV) and likely pathogenic variants (LPV) per donor: 2,04 (SD=1,50).
Variants of uncertain clinical significance (VUCS) per donor: 6,69 (SD=2,44).
Thirty nine donors presented at least 1 PV/LPV. All of them presented VUCS.
Most PV/LPV were found in: *CFTR* (12 donors), *CYP21A2* (10), *BTD* (7), *PCCB* (5), *DUOX2* (4), *SLC12A3* (4), *POMGNT1* (4), *PAH* (3).
Most of *CFTR* PV/LPV were low penetrance variants or associated to non-classical phenotype. High rate of *CYP21A2* PV/PPV could be due to co-capture of pseudogene and false positive calls because of the methodology employed. *BTD* variants obtained were associated with mild phenotype, consistent with population allele frequencies described.
Conclusions:
Taking together all these results, some aspects should be considered: the need to fully analyze *CFTR* and to confirm the results with gold-standard methodology for genes with pseudogenes or high homology sequences, whether or not to analyze genes associated to mild phenotypes, and the high number of VUCS obtained.

PS01.65

Contribution of chromosomal abnormalities and genes of the major histocompatibility complex to early pregnancy losses

I. Tkach[1], *K. Sosnina*[1], *N. Huleyuk*[1], *O. Terpylyak*[1], *D. Zastavna*[1], **H. Akopyan**[1], *A. Weise*[2], *N. Kosyakova*[2], *T. Liehr*[2];
[1]*Institute of Hereditary Pathology, NAMS of Ukraine, Lviv, Ukraine,* [2]*Jena University Hospital, Friedrich Schiller University, Institute of Human Genetics, Jena, Germany.*

Background: Pregnancy losses (PL) in 60% to 80% of the cases are associated with chromosomal abnormalities in embryos or fetuses. Immunologic factors contribute to PL especially at the early stages of gestation. In particular, 45% of cases of the early pregnancy losses (EPL) are accompanied by immunologic intolerance to the fetus. One of the main factors involved in immune responses is the major histocompatibility complex (MHC) encoded by human leukocyte antigen (HLA) gene locus.
Aims: The determination of chromosomal abnormalities in samples from EPL and allelic polymorphism of HLA-DRB1 and DQA1 genes in couples with RM.
Methods: Banding cytogenetic analysis; interphase mFISH analysis with the probe panel for chromosomes 13, 14, 15, 16, 17, 18, 21, 22, X and Y; DNA extraction by salting method, PCR, agarose gel electrophoresis.
Results: Cytogenetic and molecular-cytogenetic investigations of EPL material identified karyotype anomalies in 32.4% of cases with prevalence of autosomal trisomy - 42.65%, triploidy - 30.38% and monosomy X - 19.11%. Complex analysis of frequency and distribution of allelic variants of genes HLA-DRB1 and HLA-DQA1 allowed to establish alleles DRB1*0301, DRB1*1101-1104 and DQA1*0501 to be aggressor alleles in women with RPL. The cumulative homology of allelic polymorphism of more than 50% of HLA-DRB1 and HLA-DQA1 loci between partners increases the risk of RPL by almost four times. Conclusion: Detected chromosome aneuploidies in samples from products of conception and changes in the MHC genes can cause the failure of a couples reproductive function and can lead to an early fetal loss.
This work was partially supported by the West-Ukrainian BioMedical Research Center grant.

Since the publication of the Royal College of Obstetricians and Gynaecologists green top guidelines for the investigation and treatment of couples experiencing recurrent miscarriages, many UK regional genetics laboratories have implemented the proposals and have ceased offering parental karyotyping but instead are offering a range of genetic testing strategies for tissues from 3rd and subsequent miscarriages. The range of tests offered includes QF-PCR, subtelomere MLPA, karyotyping and array CGH. Combinations of these tests are also being used to investigate later gestation pregnancy losses and fetal losses where phenotypic anomalies have been noted. The ACGS scientific subcommittee has instigated an audit of the outcomes of these tests with respect to gestational age and the presence or absence of fetal anomalies. The data is being used to examine the clinical utility of this testing in i) providing a likely cause for the pregnancy loss, ii) identifying couples with a balanced rearrangement where there is a risk of recurrence, iii) identifying which couples may benefit from prenatal genetic testing or PGD, and iv) establishing the proportion of cases where there is substantial risk of a future affected live born child. Outcomes have been measured in terms of failure rates, diagnostic yield and the significance of genetic findings to the management of future pregnancies for couples. The evidence to date supports the development of a more targeted and consistent approach to genetic testing of fetal loss.

PS01.67

Early pregnancy loss and polymorphism in xenobiotics detoxification genes

K. Saraev, *A. Rodionov, E. Mashkina;*
Southern federal university, Rostov-on-Don, Russian Federation.

Pregnancy loss and other pregnancy complication can be connected with environmental and lifestyle risk factor, among which effect of chemical compounds is the strongest. Effects of xenobiotics can be modified by allele variants of xenobiotic detoxification enzymes phase I or II. A total of 71 women with early pregnancy loss and 101 control patients were examined by a case-control methodology. The *Ile462Val CYP1A1*, *Arg47His ADH1B*, *Glu487-Lys ALDH*, *I105V GSTP1* polymorphisms were genotyped by allele-specific polymerase chain reaction. Our data demonstrated that the heterozygous *Glu487Lys ALDH* genotypes rate were higher in the pregnancy loss patients (12.71%) compared to the control group (2.0%). There was no difference between two groups detected for other polymorphisms. However, presence of polymorphic variants of genes of 1st and 2nd detoxification phases can have additive effect and cause multifactorial pathology risk increase. It is shown, that combination of polymorphic variants of *ALDH2* и *GSTP1* genes in genotype results in 5 fold pregnancy loss risk increase. Combination of polymorphic variants of *ALDH2, ADH1B u GSTP1* genes in genotype results in 9 fold pregnancy loss risk increase. The results demonstrated that combination of allele variants of 1st and 2nd detoxification phases in woman genotype increases the risk of early pregnancy loss. This study was supported by the federal assignment № 6.98.2014/K from Russian Ministry of Science and Education.

PM01.68

Blastocyst trophectoderm biopsy and Preimplantation Genetic Diagnosis/Screening for aneuploidy using Array-Comparative Genomic Hybridization: one-year results

I. Loddo[1], *F. M. R. Pileio*[2], *C. Liuzzo*[1], *S. Briuglia*[1], *C. Salpietro*[1];
[1]*UOC Genetics and Pediatric Immunology, University of Messina, Messina, Italy,* [2]*GATJC*

IVF, Gioia Tauro, Italy.

Introduction: Preimplantation Genetic Diagnosis/Screening (PGD/PGS) is the earliest form of prenatal diagnosis and allows identification of genetic abnormalities in embryos produced in vitro, prior to their transfer into the uterus.
The identification and transfer of embryos with normal set of chromosomes allow to increase the implant rate per transfer and significantly reduce the likelihood of miscarriage.
Materials and Methods: Array-CGH is performed on trophectoderm cells. The biopsy of blastocyst during the fifth or sixth day of culture, ensures a remarkable accuracy of the results of the genetic analysis, a significant reduction in the risk of mosaicism, and the absence of impairment in regular embryonic development.
Results: During the last year 690 embryos were processed from ICSI cycles performed on 313 infertile couples. In 11% of cases there weren't clear results due to detection of DNA fragmentation or low concentration of DNA. There was a result in 91% of embryos analyzed. Of these: 63% were found to be normal; 37% were found with chromosomal abnormalities.
The pregnancy rate obtained by the transfer of embryos undergoing PGD, resulted to be free of chromosomal abnormalities, was 14.6% higher, compared to the transfer of embryos without PGD.
Conclusions: The intention of the PGD/PGS is to improve live births rates after IVF treatment. PGD/PGS offers one more chance during IVF treatment to increase the selection of embryos for certain groups of patients, including those with advanced maternal age, repeated failure of IVF cycles, repeated miscarriages in parents with normal karyotype or carriers of balanced translocations.

PS01.69

Premature ovarian failure (POF/POI) and array-comparative genomic hybridization (aCGH)

A. Beke[1], *H. Piko*[2], *I. Haltrich*[3], *J. Csomor*[4], *A. Matolcsy*[4], *J. J. Rigo*[1], *V. Karcagi*[2], *G. Fekete*[3];
[1]*1st Dept. of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary,*
[2]*National Institute of Enviromental Health, Dept. of Molecular Genetics and Diagnostics, Budapest, Hungary,* [3]*2nd Dept. of Pediatrics, Semmelweis University, Budapest, Hungary,*
[4]*1st Dept. of Pathology and Cancer Research, Semmelweis University, Budapest, Hungary.*

Background: One of the frequent reasons of the unsuccessful conception is the premature ovarian failure/primary ovarian insufficiency (POF/POI) that is defined as the loss of functional follicles below the age of 40 years, and the incidence of this abnormality is 0.1% among the 30-40 years age group. Among the genetic causes the most common one involves the X chromosome, as in Turner syndrome, partial X deletion and X-autosome translocations.
Methods: Here we report a case of a woman referred to genetic counselling because of POF. Genetic testing of the 27 year old female patient was carried out due to suspected POF/POI. Molecular and cytogenetic analyses were performed. We evaluated the FMR1 gene analysis using Southern blot technique and Primed PCR. We performed the FISH method and the standard cytogenetic analyses by G-banding also. In order to detect the exact breakpoints, we used a special cytogenetic array ISCA plus CGH array.
Results: We detected a large 67.355 Mb size deletion on the X chromosome at the critical region (ChrX q21.31-q28) which is associated with the POF/POI phenotype. At this region the concerned genes were those ones that the different studies published as POF/POI associated (POF1B; BHLHB9; DACH2; DIAPH2, FMR1; FMR2; XPNPEP2; PGRMC1, CENP1, BCORL1).
Conclusions: We conclude that the karyotyping is definitely helpful in the evaluation of POF patients to identify the non submicroscopic chromosomal rearrangement, and using the array CGH technique we can contribute to the most efficient detection and mapping of exact deletion breakpoints of the deleted Xq region.

Objectives
Since 2013, samples for prenatal diagnosis in Belgium are analysed by Chromosomal Microarray Analysis. Interpretation of prenatal copy number variants (CNV) remains difficult given the limited phenotypic information. An Ad Hoc Committee tries to resolve uncertain cases based on literature and experiences with similar variants. A Belgian MicroArray Prenatal (BEMAPRE) database studies the association between laboratory, ultrasound and postnatal data.
Method
Our database was customised in consultation with the Centers for Medical Genetics to import, consult and extract genotype-phenotype data. Prenatal cases in which a pathogenic CNV/UV(unclassified variant) >400kb was detected, are imported. Phenotypic data are added postpartum and at the age of 2-3 years. Meta-analysis is performed based on genotype-phenotype data from hundreds of cases.
Results
Reporting policy is determined by classification of CNVs (benign, UV and pathogenic). If UVs have intragenic deletions/duplications in a known gene; are mentioned in literature and/or databases; consist of deletions/duplications covering more than 18 genes or comprise an X-linked gene in a XY fetus, likeliness of pathogenicity is evaluated. In case of strong arguments for pathogenicity, parents are tested. They are reported if parental phenotype is potentially divergent or if de novo. Known pathogenic variants, risk factors with high penetrance or ultrasound anomalies and actionable incidental findings are reported. Since 2013, 7875 arrays were performed; 293 (3.72 %) were reported as pathogenic.
Conclusions
The BEMAPRE database is a source of scientific, clinical and ethical studies; allows easy communication among Belgian genetic centers and will be made available to other scientists. Most recent data are presented.

PS01.71

Chromosomal Microarray (CMA) for prenatal referrals with abnormal ultrasound scan findings: experiences of moving to a frontline NHS diagnostic service in the West Midlands, UK

S. J. Hamilton[1], *G. K. Hall*[1], *M. Drozniewska*[1], *F. S. Togneri*[1], *S. K. Allen*[1], *D. Williams*[2], *D. J. McMullan*[1];
[1]*West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom,*
[2]*Department of Clinical Genetics, Birmingham, United Kingdom.*

Prenatal testing by CMA has been established in the West Midlands Regional Genetics Laboratory (WMRGL) at Birmingham Women's Hospital (BWH) since 2009 via involvement in a local project (243 referrals) and the MRC-funded EACH project (125 referrals), with cytogenetic analysis performed concurrently on all samples tested as a stipulation of project criteria
From October 2014, all patients in the West Midlands presenting with abnormal ultrasound scan (USS) findings and/or an NT measurement of >3.5mm have been offered CMA instead of karyotyping, following exclusion of common aneuploidy by QF-PCR. To date >200 CMA analyses have been performed using the ISCA v2.0 8x60k platform.
Only CNVs interpreted to be clearly linked to USS findings or CNVs which are determined to be clearly pathogenic, irrespective of USS, are reported. Gene content and evidence of overlapping CNVs/syndromes in the literature are the main criteria used to assign pathogenicity classifications. Abnormality rate for reportable anomalies is 9.6%. CNVs considered to be sub-microscopic (likely to be undetected by karyotyping) were observed in 4.9% of referrals, consistent with larger published studies.
Decisions regarding clinical reporting and assignment of pathogenicity remain challenging in the current absence of a National UK consensus and within the fast turn-around-times mandated in the prenatal setting. A local review panel including both Consultant Clinical Scientists and Consultant Clinical Geneticists is therefore convened virtually to support clinical reporting. Several complex cases highlighting the need for this approach will be discussed, as will issues encountered in rolling out array-based testing across the whole West Midlands.

PM01.72

Prenatal detection of a mosaic structurally abnormal chromosome 18

S. L. Britton;
Institute of Medical Genetics, Cardiff, United Kingdom.

Prenatal detection of a mosaic structurally abnormal chromosome 18
Prenatal detection of true mosaicism involving an autosomal structural imbalance is a rare occurrence. An amniotic fluid sample was received at 20 weeks gestation following abnormal ultrasound scan findings including bi-

lateral ventriculomegaly, possible neural tube defect and a cardiac anomaly. QF-PCR analysis showed no evidence of aneuploidy for chromosomes 13 or 21. However, the chromosome 18 markers, D18S978 and D18S390, were trisomic and there was marked skewing of D18S391 towards the trisomic range. However, the centomeric marker D18S1002 gave a normal result. Fluorescence in situ hybridisation (FISH) studies using the chromosome 18 centromeric probe showed two signals with no evidence of mosaicism. Together, the QF-PCR and FISH findings were suggestive of a mosaic, structurally abnormal chromosome 18. The QF-PCR result for chromosome 18 was reported as being uninterpretable.
Subsequent cytogenetic analysis identified a mosaic, structurally abnormal chromosome 18 in 26% of cells examined. The complex nature of the imbalance could not be fully characterised by G-banding. FISH studies with a wcp18 showed that no other chromosome was involved in the rearrangement and 18p and 18q subtelomeric probes showed that there was both loss of 18q and gain of 18p material. Array CGH was used to further characterise the abnormality. The parental karyotypes were normal indicating that the abnormality had arisen *de novo* in the fetus. Such cases present counselling dilemmas in terms of the uncertainty in predicting the level and distribution of abnormal cells in the fetus.

PS01.73

Non-invasive versus invasive prenatal diagnosis: What do pregnant couples choose?

S. L. van der Steen[1], **S. R. Riedijk***[1], K. E. M. Diderich[1], D. Van Opstal[1], M. Polak[2], M. F. C. M. Knapen[1], J. M. J. Cornette[1], K. Prinsen[1], A. T. J. I. Go[1], A. Tibben[3], R. J. H. Galjaard[1];*
[1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus University, Rotterdam, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands.

Non-invasive versus invasive prenatal diagnosis: What do pregnant couples choose?
Background: Women at increased risk of common trisomies can opt either for non-invasive prenatal testing (NIPT) or invasive prenatal diagnosis (PND) using a SNP array at 0.5 Mb resolution. Array detects more clinically relevant anomalies, and anomalies with variable penetrance and expression, while NIPT only aims to detect trisomy 13, 18 and 21.
Research questions: What do pregnant couples with an abnormal first trimester screening result choose: NIPT or array? Which motivations do pregnant couples have for this choice?
Method: Pregnant women (N=183) and 59 of their partners participated after they were counselled by an obstetrician. Individually, women and their partners filled out a questionnaire assessing anxiety, ambivalence and informed choice, that was previously designed and published.
Results: Eighty-four percent of the women chose NIPT and 16% chose array. The main reason for choosing NIPT was to prevent the risk of a miscarriage and not wanting to test for 'more than necessary'. Women who opted for an array were inclined to obtain more genetic information to be 'prepared for the future', and to mobilise adequate care if needed. Most mentioned they preferred a quicker test result that was completely certain.
Conclusion: While most participants chose NIPT over invasive PND with array, our study shows that for a significant number of pregnant women and their partners, the opportunity to learn more about the health of their unborn child might outweigh the miscarriage risk of an invasive procedure. It therefore seems justified to keep offering this choice.

PM01.74

Audit of prenatal samples referred for specific molecular tests to the Wessex Regional Genetics Laboratory between 2012 and 2014

S. Thomas, *A. Callaway, K. Ellis, M. Bateman;*
Wessex Regional Genetics Laboratory, Salisbury, United Kingdom.

Prenatal testing is a significant component of Molecular Genetic Diagnostic Laboratories because of the wide range of tests required and the rapid reporting time. The WRGL received 86, 80 and 91 prenatal referrals for specific molecular tests in 2012, 2013 and 2014 respectively.
There was a slight excess (55%) of amniotic fluid compared to CVS. The tests most frequently requested were DGV (n=51), sequencing (49 referrals for 34 different genes), UPD (n=39), CF (n=38), and skeletal dysplasia (n=29).
Across all referrals, 49/257 results were abnormal. However, pick up was 0/21 for cases with an apparently de novo mutation in a previous pregnancy, 15/46 for recessive conditions and 21/47 for dominant and X-linked conditions. Of 139 referrals with an "intermediate" risk, 11 were affected: this category mainly comprised abnormal scans (9/101) and inherited Robertsonian translocations (0/32).
Abnormal scans accounted for 42% of all referrals, increasing from 34% in 2012 to 45% in 2014; pick-up rate also increased from 0/29 in 2012 to 2/31 in 2013 and 7/41 in 2014. The most common tests indicated by an abnormal scan were DGV (n=47), skeletal dysplasia (n=26) and CF (n=20). Five DGV referrals were affected, three with skeletal dysplasia and one with BWS. There were no positive CF cases referred with echogenic bowel. AF comprised the majority of abnormal scan referrals (88%) in contrast most cases referred through family history were received as CVS (68%).
Additional referrals from abnormal scans, technological advances and increases in the number of genetic tests available are all likely to affect the future delivery of prenatal genetic testing.

PS01.75

Primary ovarian failure in two women with Xq deletion

V. JAUFFRET*[1], C. RAVEL[2], E. CHEROT[1], C. DUBOURG[3], M. BLAYAU[3], M. P. BEAUMONT-EPINETTE[3], S. ODENT[4], M. A. BELAUD-ROTUREAU[1], S. JAILLARD[1];*
[1]Service de Cytogénétique et Biologie Cellulaire, CHU de Rennes, Rennes, France, [2]Service de Biologie de la Reproduction, CHU de Rennes, Rennes, France, [3]Service de Génétique Moléculaire et Génomique Médicale, CHU de Rennes, Rennes, France, [4]Service de Génétique Clinique, CHU de Rennes, Rennes, France.

Primary ovarian failure (POF) is a pathology characterized by an absence of the normal ovarian function before the age of 40 years. It can be suspected by amenorrhea or premature menopause. Aetiologies are heterogeneous and chromosomal abnormalities can represent 15 to 20 % of reported causes. Nine critical regions (Premature Ovarian Failure POF 1 to 9) were described among which POF1 and POF2 loci localized on the long arm of chromosome X (respectively Xq26-Xq28 and Xq13.3-Xq21.1). Among candidate genes involved in ovarian development localized in these regions, besides *FMR1* (Xq27.3), we can pinpoint *DIAPH2* (Xq22), *XPNPEP2* (Xq25) and *ZFX* (Xp22.2-p21.3) genes.
Karyotype, DNA microarray and fluorescent *in situ* hybridization were performed in two women presenting POF.
The first patient presented a terminal 14.4 Mb Xq27.2q28 deletion including POF1 with *FMR1* as the principal candidate gene. The second patient presented an interstitial 8,4 Mb Xq23.2q22.1 duplication including *DIAPH2* in POF2 and a terminal 53,5 Mb Xq22.1q28 deletion including POF1. These two rearrangements are the result of an inversion-duplication-deletion mechanism not mediated by non-allelic homologous recombination (NAHR).
The presence of a Xq deletion involving POF1 in these two patients consolidates the role of this region in the occurrence of a POF. Furthermore, no case of inversion-duplication-deletion of the long arm of chromosome X in women presenting POF has been reported in literature. Loss of function of the *DIAPH2* gene has already been described as responsible of POF. Nevertheless, the role of duplications involving POF2 and *DIAPH2* remain to be established.

PM01.76

The modifier gene of *Prokineticin 1* variant in human early pregnancy

M. Su*;*
Department of Obstetrics and Gynecology, National Cheng-Kung University Hospital, Tainan, Taiwan.

Aim: One common missense variant of PROK1-V67I was suggested to play as a modifier in PROK1-PROKR system of human early pregnancy. To explore the modifier mechanism of PROK1-V67I, we studies for functional comparison in gene expression level and cell functions of V67I and its wild type (WT) in transiently transfected cells.
Material and Methods: We investigated transcript expression of V67I and WT in HTR-8/SV neo and HEK293 cells using quantitative RT-PCR, and protein levels of cell lysate and supernatant of culture medium in HTR-8/SV neo, JAR and Ishikawa and HEK293 cells using ELISA method. Transiently V67I- or WT-transfected HTR-8/SV neo and HEK293 cells were used to evaluate cell proliferation, cell invasion, tubal formation, and intracellular calcium mobilization.
Results: The gene expression level of both transcript and protein were down-regulated in all cell lines, ranging from 20% to 70% compared with WT. The ligand activities of V67I and WT on cell proliferation, cell invasion, calcium influx and tubal formation were of no difference. Both PROK1 allele promoted cell invasion and induced intracellular calcium influx activities, whereas they have no significant effect on cell proliferation, and tubal formation. In conclusion, the common variant of PROK1 (V67I) may play as a modifier in PROK1-PROKR system through down-regulation of PROK1 expression. Our investigation may provide a general modification mechanism for impact on disease severity of PROK1-related pathophysiology.

PS01.77

The Baby Bio Bank: a collection of biological samples and medical data from 2500 families affected by recurrent miscarriage, preterm

birth, intrauterine growth restriction and pre-eclampsia available to researchers internationally

*N. SOLANKY[1], **S. Abu-Amero**[1], K. Rogers[2], S. White[2], A. Perez Miranda[1], W. Baird[1], C. Williamson[2], M. Johnson[2], L. Regan[2], G. Moore[1];*
[1]Institute of Child Health, UCL, London,, United Kingdom, [2]Imperial College, London,, United Kingdom.

The Baby Bio Bank is a unique collection of over 55000 biological samples collected from pregnancies complicated with recurrent miscarriage, preterm labour, fetal growth restriction, preeclampsia and uncomplicated pregnancies, available to researchers internationally interested in understanding pregnancy complications. Samples are being taken from the three key members of the family, mother, father and baby, allowing hereditary factors from both parents to be tracked
Mothers and their partners were recruited from antenatal clinics and wards from participating hospitals across London. Blood samples for DNA, serum and plasma, were collected from all consenting participants, plus urine from the mother. On the birth of the baby, we collected placental tissue, membranes, umbilical cord and cord blood. As all the samples are intended for DNA, RNA and protein isolation, they were collected, processed and stored to the highest possible scientific standards. Quality control audits followed by downstream applications such as real-time PCR and sequencing have shown clearly that the samples are of high quality and can be used with confidence by researchers.
The biological specimens have restricted value without clinical information. We include clinical information relating to factors affecting pregnancy such as parental height, weight and relevant medical history such as diabetes, hypertension and smoking. Importantly, we also collect fetal outcome data such as gestational age, birthweight and mode of delivery.
We have successfully recruited over 2500 participants and interested researchers are able to apply to use the samples and data. More information on the Baby Bio Bank is available at http://www.ucl.ac.uk/babybiobank including the Baby Bio Bank protocol and information about the application procedure.

PM01.78
Association study of differentially expressed genes regulatory SNPs and preeclampsia: results of a pilot study in Russia

E. Trifonova[1], *T. Gabidulina[2], V. Serebrova[1], V. Stepanov[1];*
[1]Institute for Medical Genetics, Tomsk, Russian Federation, [2]The Institute for Obstetrics and Gynecology, Tomsk, Russian Federation.

Preeclampsia is a pregnancy-specific disorder that leads among the causes of maternal and infant morbidity and mortality worldwide. Prevention, early detection, and specific treatment of preeclampsia are hindered by the fact that the etiology has remained unknown. Current consensus implicates placental and endothelial dysfunction, inflammation and genetics in development of preeclampsia. Our prior genome-wide transcriptional profiling of placental tissue led to a novel set of 63 preeclampsia candidate genes. In this report, we present preliminary study on the role of regulatory sites in some of these genes in the genetic susceptibility to preeclampsia. We analyzed 48 regulatory SNPs (rSNPs) in 23 differentially expressed genes in 519 patients with preeclampsia and 718 women with uncomplicated pregnancies from Russian, Buryat and Yakut populations using MassArray iPLEX (Sequenom). We have detected significant associations for preeclampsia with 15 rSNPs in 11 genes (CORO2A, NDRG1, SASH1, BHLHE40, PLIN2, SYDE1, LHB, HK2, INHA, ZNF175, PPP1R12C). These genes were associated with such biological processes as synthesis and functional activity of hormones, protein binding, ligand-receptor interaction and binding with DNA. Interestingly, only one gene (CORO2A) has been associated with preeclampsia in all three populations. These results demonstrate a significant role of genetic variability of the differentially expressed genes regulatory sites in the formation of susceptibility to pre-eclampsia in different ethnic groups. Nevertheless, the clinical significance of these findings remains to be determined. This work was supported by the Russian Foundation for Basic Research (grant №14-04-01467).

PS01.79
Autosomal gene defects investigation of male infertility in germ cell aplasia cases

G. Koc[1], *A. Ozdemir[2], G. Girgin[1], T. Avcilar[1], D. Kirac[3], K. Ulucan[4], C. Akbal[5], A. Guney[1];*
[1]Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, [2]Department of Urology, Zeynep Kamil Women and Children Training and Research Hospital, Istanbul, Turkey, Istanbul, Turkey, [3]Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey, Istanbul, Turkey, [4]Marmara University, Faculty of Dentistry , Istanbul, Turkey, Istanbul, Turkey, [5]Marmara University, Faculty of Medicine, Department of Urology, Istanbul, Turkey, Istanbul, Turkey.

Sertoli-cell-only (SCO) syndrome, also called germ cell aplasia, describes a condition of the testes in which only Sertoli cells line the seminiferous tubules and is diagnosed by testicular biopsy. SCOs is considered as irreversible infertility. SCO syndrome, a histological diagnosis, consists of multifactorial reasons including Y microdeletions, kleinefelter syndrome, cystic fibrosis gene mutations, XYY syndrome, cryptorchidism, radiation, cytotoxic drugs and viral infections. The etiology of the disease is currently unknown on the other hand it is believed that autosomal gene defects could lead to SCOs. The aim of this study is detecting autosomal genetic defects and determining candidate genes in SCOs infertile men. Single nucleotide polymorphism + comparative genomic hybridization microarray technology (SNP+CGH array) was performed on 39 SCOs infertile patients in the study. Array CGH compares the patient's genome against a reference genome and identifies uncover deletions, amplifications, ploidy abnormalities and loss of heterozygosity (LOH). We examined a link between defected spermatogenesis genes and infertility. Detected amplifications and deletions in several genes are namely, SHBG, COL1A1, HOXD9, SYCE1, EMX2, EMX2OS, CATSPER2 and loss of heterozygosity in several genes are namely SPATA gene family (SPATA18, SPATA17, SPATA16, SPATA12, SPATA4, SPATA2), TSSK gene family (TSSK3, TSSK4, TSSK6), DNALI1, DNAH5, DNAH11, SPAG16, SPAG8, DMRT1, DMRT2, FSHR, LHCGR, GNRHR, SPACA1, SPACA3, TSGA10, SMCP, KIT, TCTE3, TEX14, FGF8. Amplifications and deletions were detected on some of the genes who play a role in epigenetic changes. Epigenetic genes (H19, KCNQ1, IGF2, CDKN1C) are expected to be linked with male infertility.

PM01.80
Detection of sex chromosome aneuploidies using quantitative fluorescent PCR

B. Nagy, *O. Biro, G. R. Nagy, L. Lazar, J. Schönleber, J. Rigo Jr;*
Semmelweis University, 1st Dept. of Obstetrics and Gynecology, Budapest, Hungary.

Background: Aneuploidies are the most frequent chromosomal abnormalities at birth. Autosomal aneuploidies cause serious malformations like trisomy 21, trisomy 18 and trisomy 13. However sex chromosome aneuploidies are causing less severe syndromes. For the detection of these the "gold standard" method is the cytogenetic analysis of fetal cells, karyograms shows all numerical and structural abnormalities, but it takes 2-4 weeks to get the reports. Molecular biological methods were developed to evercome on the long culture time, FISH and quantitative fluorescent PCR were introduced. In this work we show our experience with a commercial kit for the detection of sex chromosome aneuploidies.
Methods: We analysed 20.173 amniotic fluid samples in a period of 2006-2013 in our department. A conventional cytogenetic analysis was performed on the samples. We checked the reliability of quantitative fluorescent PCR and DNA fragment analyis on those samples where sex chromosomal aneuploidy was diagnosed.
Results: From the 20.173 amniotic fluid samples we found 50 samples with sex chromosome aneuploidy. There were 19 samples showing 46, XO, 17 samples with 46, XXY, 9 samples with 47, XXX and 5 samples with 47, XYY karyotypes. The applied quantitative fluorescent PCR and DNA fragment analyses method is suitable to detect all abnormal sex chromosome aneuploidies.
Conclusions: Quantitative fluorescent PCR is a fast and reliable method for detection of sex chromosome aneuploidies.

PS01.81
Clinical outcomes for patients with single-nucleotide polymorphism (SNP)-based noninvasive prenatal testing (NIPT) suggestive of fetal sex chromosome trisomy

T. McKanna[1], *M. Stosic[1], K. O'Brien[2], Z. Demko[1], S. J. Gross[1];*
[1]Natera, Inc., San Carlos, CA, United States, [2]Quest Diagnostics, Nichols Institute, San Juan Capistrano, CA, United States.

Objective: To determine the clinical outcomes for patients within a general screening population who received an NIPT result indicating a fetal sex chromosome trisomy (SCT).
Method: 51,884 consecutive cases were collected from participating clinics over 10 months. Isolated cell-free DNA was amplified and sequenced at 19,488 SNPs covering chromosomes 13, 18, 21, X, and Y; data was analyzed using a proprietary algorithm. Follow-up information was sought for suspected SCT cases.
Results: 65 (0.1%) clinical samples were identified by NIPT as suggestive of SCTs: XXX, XXY, or XYY. All were low-risk for fetal aneuploidy at other interrogated chromosomes. Mean maternal age was 33.9 years and mean gestational age was 15.3 weeks. Karyotype information was available for 19 cases: 17 true positives (5 XXX, 9 XXY, 3 XYY) and 2 false positives (XXX).

This resulted in an overall positive predictive value (PPV) of 89.5%, with PPVs for XXX, XXY, and XYY of 71.4%, 100%, and 100%, respectively. Of the 46 patients without confirmation, 25 declined invasive testing, and no data is available for the remainder. Information about invasive confirmation decisions was available in 44 cases: 17 (38.6%) had invasive confirmation and 27 (61.4%) declined; two of the cases that declined invasive confirmation had genetic testing at birth. Follow-up is ongoing.
Conclusions: Results of this SNP-based approach for SCTs demonstrate good PPVs in clinical practice. Confirmation rate for these disorders in a clinical setting was limited as invasive testing was pursued in less than half of cases where invasive testing decisions were known.

PM01.82
Why is there a relatively low uptake of prenatal diagnosis for sickle cell disease?

P. Lakeman[1], *K. F. L. Douma*[2], *A. Zwagemaker*[3], *H. E. Peters*[3], *K. C. A. Holtkamp*[4], *L. Henneman*[4], *C. L. Harteveld*[5], *M. Peters*[3];
[1]*Academic Medical Center, Department of Clinical Genetics, Amsterdam, Netherlands,* [2]*Academic Medical Center, Department of Medical Psychology, Amsterdam, Netherlands,* [3]*Academic Medical Center, Emma Children's Hospital, Department of Paediatric Haematology, Amsterdam, Netherlands,* [4]*VU University Medical Center, Department of Clinical Genetics, Section of Community Genetics, EMGO Institute for Health and Care Research, Amsterdam, Netherlands,* [5]*Leiden University Medical Center, Department of Clinical Genetics, Hemoglobinopathies lab (LDGA), Leiden, Netherlands.*

Background: In the Netherlands, each year 40 to 60 children with sickle cell disease (SCD) are born. The uptake of prenatal diagnosis (PND) for SCD is relatively low: an estimated 5 to 7.5% of couples at risk choose PND. Does this reflect an informed choice? The aim was to explore factors affecting this uptake.
Methods: Factors involved in reproductive decision-making of couples at risk for offspring with SCD were explored by: a) performing semi-structured interviews with 21 parents of a child identified with SCD after symptoms (n=13) or by neonatal screening (n=8) (2009); and b) analysing 15 papers (PubMed;1988-2013).
Results: Factors resulting in refraining from PND for SCD were: having no experience with SCD, not experiencing SCD as severe, fear for miscarriages, keeping the child's diagnosis (and own carrier status) secret, fear for stigmatization, religion, a strong wish to have a child, as well as insufficient knowledge about SCD amongst couples at risk and care providers. Those who considered PND, had experience with disease symptoms, were in early pregnancy (when pregnant) instead of later gestational age, wanted to be prepared before birth, had higher socio-economic status, more often single marital status, and more extensively adopted the Dutch culture.
Conclusion: Lack of understanding about the severity of SCD, perceiving high risks for obstetric complications and cultural aspects resulted in refraining from PND for SCD. Improving knowledge among couples at risk and care providers is important and counselling should be repeated. Future non-invasive testing might influence the uptake for PND for SCD.

PS01.83
Prenatally suspected and after the birth confirmed Simpson-Golabi-Behmel syndrome: familial case

E. Benusiene[1,2], *S. Tumene*[3,2], *A. Matuleviciene*[1,2], *R. Meskiene*[1,2], *V. Kucinskas*[1,2];
[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Center for Medical Genetics, Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania,* [3]*Clinic of Obstetrics and Gynecology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.*

We present fetal ultrasound, newborn clinical and molecular testing findings in a case of Simpson-Golabi-Behmel syndrome (SGBS) diagnosed prenatally and confirmed after the birth. In the first pregnancy (2009), ultrasound examination at 29 weeks of gestation revealed fetal macrosomia (parameters>99‰), macroglossia, depressed nasal bridge, hypertelorism, nephromegaly, clinodactyly and polyhydramnios.
The differential diagnosis between overgrowth syndromes was performed, but most of these syndromes share the same pathological findings, so it was difficult to differentiate them prenatally. However, after comprehensive literature analysis, we notice specific phenotype sings in mother as suspected mutation carrier (Golabi and Rosen, 1984) and fetal facial 3D evaluation, gender, absence of omphalocele and CNS structural defects enabled to concentrate on SGBS as the most probable diagnosis. Since the molecular genetic testing of GPC3 and GPC4 genes in Lithuania was impossible at that moment, genetic counselling after delivery was recommended.
Child (male) was born at 34 weeks of gestation via s/c. After the birth breathing insufficiency, macrosomia, macrocephaly, broad forehead, hypertelorism, depressed nasal bridge, macrostomia, macroglossia, midline grooves under the lower lip, epicanthus, low-set ears, clinodactyly, brachydactyly, polythelia, cryptorchidism and hypotonia were observed. These symptoms coincided with SGBS diagnosis, so molecular genetic testing of GPC3 gene was performed. Deletion of exons 5-8 in GPC3 gene was detected.
In 2011 the same mother gives birth to a healthy son. The third pregnancy (2012) ended in miscarriage at the 13th week of gestation after CVS. Sonography of fetus showed increase NT (3.1mm), enlarge liver and diaphragmatic hernia. The familial mutation was detected.

PM01.84
Prenatal whole genome SNP array diagnosis: relevance of unexpected abnormal results in pregnancies with and without ultrasound anomalies

M. Joosten, *K. E. M. Diderich, D. Van Opstal, L. C. P. Govaerts, S. R. Riedijk, A. K. E. Prinsen, F. A. T. De Vries, R. J. H. Galjaard, M. I. Srebniak;*
Erasmus MC, Rotterdam, Netherlands.

Background: We routinely perform SNP array analysis as a first-tier test for all prenatal indications. Array detects more clinically relevant anomalies including pathogenic aberrations that are not related to the indication. The chance of finding these so-called unexpected diagnoses (UD) is one of the reasons that the use of array in prenatal diagnosis is controversial. We will show the relevance of detecting UDs, based on the nature, prevalence, counseling and outcome of the affected pregnancies.
Methods: In 2010-2014 3,326 patients were referred for prenatal SNP array testing (Illumina): 1,682 pregnancies with and 1,644 without ultrasound anomalies. All cases of UD were discussed in a multidisciplinary team consisting of laboratory specialists and clinical geneticists before disclosure. All patients received pre- and post-test counseling. Psychological help was available if required.
Results: In 1:208 (16/3,326) cases an UD was found. Eleven were severe early-onset untreatable diseases. In 9/11 severe cases (e.g. Duchenne muscular dystrophy, Angelman syndrome) the UD helped the couples in making a decision about the course of their pregnancy. In 1 case the UD (22q11 deletion) was found later in the pregnancy when termination was no longer a possibility. In this case delivery was transferred to a tertiary hospital. No severe late-onset diseases were detected.
Conclusion: We will show that in the great majority the UD was relevant for counseling and pregnancy management. This adds another reason to the known recommendations to use SNP array for all prenatal indications.

PS01.85
Molecular cytogenetic examination of female somatic gonadal cells in cryopreserved ovarian tissues: detection of chromosomal aneuploidy and mosaicism.

J. Chrudimská[1], *T. Borgbo*[2,3], *M. D. Libik*[1], *L. Dvořáková*[1], *H. Zůnová*[4], *J. Drabova*[5], *N. Ptáková*[1], *M. Macek jr.*[1], *C. Y. Andersen*[3], *M. Macek sr.*[1];
[1]*Charles University - 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic,* [2]*Aarhus University, Aarhus, Denmark,* [3]*Rigshospitalet, Copenhagen, Denmark,* [4]*University of Chemistry and technology Prague, Prague, Czech Republic,* [5]*University Hospital Motol, Prague, Czech Republic.*

We studied somatic ovary cells (SOCs) by molecular cytogenetic methods since they have an important role in nurturing of oocytes.
DNA from ovarian tissue cells of females in their reproductive age (women 29 +/-0.,8 years) who had their ovarian tissue cryopreserved and consented to research was subjected chromosomal aneuploidy screening by VeriSeq (Illumina), MLPA (Subtelomeric mix, MRC Holland), QF-PCR (Devyser) and arrayCGH examinations (24Sure V3, Illumina).
VeriSeq detected low level mosaicism in 4/39 cases (10.3%) with monosomy of chromosome 19, trisomy 4, 21 (isolated) and combined with trisomies 4, 12. QF-PCR did not confirm trisomy 21 mosaicism revealed by VeriSeq, since it is below the detection limit of QF-PCR. On the other hand, MLPA (subtelomeric mix) revealed duplications/deletions of long and short arms in 5/36 (13.9 %): dupl. chrom. 21p (gene STCH), associated in 2/5 cases with del. chrom. 16p (DECR2), in 2/7 with deletion of chromosome 16q (GAS8), in 1/5 with dupl. chrom. 2p/3p (ACP1), including del. chrom. 13p (PSPC1). All suspective results will be expanded by centromeric mix and verified by a-CGH, including low level mosaicism from the VeriSeq assay.
Although the biological significance of these observations is currently not clear, our pilot study indicates that molecular cytogenetic testing in SOCs could provide additional evidence on the genetic quality of cryopreserved ovaries and thus improve outcomes of assisted reproduction from this tissue. Supported by FNM00064203, CZ.2.16/3.1.00/24022, NF-CZ11-PDP-3-003-2014, LD14073 and IGA NT13770.

PM01.86

Nuclear envelope remodelling during human spermiogenesis involves somatic B-type lamins and a spermatid specific B3 lamin isoform

R. Elkhatib[1], *G. Longepied[1], M. Paci[1], V. Achard[2], J. Grillo[2], N. Levy[1], M. Mitchell[1], C. Metzler-Guillemain[1,2];*
[1]Inserm - Aix Marseille Université UMR_S910, Marseille, France, [2]APHM Hôpital La Conception, Marseille, France.

The nuclear lamina (NL) is a filamentous protein meshwork, composed essentially of lamins, situated between the inner nuclear membrane and the chromatin. Evidence from rodents suggests a role for the NL during spermiogenesis. The mouse spermatid NL is composed of the ubiquitous lamin B1 and the spermatid-specific lamin B3, an N-terminally truncated isoform of lamin B2. To explore the NL in human spermatids, we used RT-PCR on RNA extracted from spermatozoa (remnants of spermatid transcripts) and immunofluorescence on human testis to reveal a lamin B3 transcript present in human spermatids, and B-type lamins as the only lamins detectable in human spermatids. Unlike the mouse, we detected lamin B2 expression in human spermatids. Like the mouse proteins, we show that human lamin B3, but not lamin B2, induces nuclear deformation, when ectopically expressed in HeLa cells. We detected B-type lamins at the nuclear periphery in human spermatids, except in the region covered by the acrosome, and as spermatids mature the B-type lamins recede towards the flagellum. Only lamin B1 remains detectable on 33-47% of ejaculated spermatozoa. On spermatozoa selected for normal head density, however, this fell to <6%, suggesting that loss of the NL signal may accompany sperm nucleus compaction. We also show that the presence of lamin B2 transcripts is variable in human spermatozoa samples. The similarities between lamin expression during human and rodent spermiogenesis, strengthens evidence that the NL and lamin B3 have conserved functions during the remodelling of the mammalian spermatid nucleus.

PS01.87

Familial cases of severe oligozoospermia associated with a homozygous nonsense mutation in a meiotic gene of unknown function

M. J. Mitchell[1], *E. Streichemberger[1], G. Longepied[1], V. Delague[1], C. Metzler-Guillemain[1,2], N. Levy[1], A. Megarbane[3];*
[1]Inserm - Aix Marseille Université UMR_S910, Marseille, France, [2]APHM Hôpital La Conception, Marseille, France, [3]St Joseph University, Beirut, Lebanon.

Gametogenesis is central to human biology, ensuring the faithful and efficient transmission of genetic and epigenetic information to the next generation. An estimated 10% of couples have difficulty conceiving their own child and in 40% of cases there is evidence of a male cause, most often reduced sperm production. Assisted reproductive techniques provide solutions for many couples, but in most cases the primary cause of infertility, and the consequences for future generations, remain undetermined, with only a handful of causal mutations identified.
We have studied a consanguineous family in which five of the six sons have severe oligozoospermia, 0.05x106 sperm per ml (normal = > 20x106). Genome-wide linkage analysis identified a critical region of homozygosity, containing 134 genes (LOD score Z=3.1 at θ=0.01). Sequencing the entire region revealed a single coding variant that was homozygous in the five oligozoospermic sons, heterozygous in the father and absent from public databases. The variant, p.Glu101Ter, is in a gene of unknown function that we have termed OZF13 (Oligozoospermia factor 13), and is predicted to prevent expression of the protein. We have sequenced OZF13 in 100 infertile men with severe oligozoospermia or azoospermia and identified a unique missense variant affecting a conserved amino acid. In human and mouse, we show that OZF13 predominates in the testis and localises to the cytoplasm of spermatocytes. We conclude that OZF13 is required for efficient progression through meiosis, and we have created a mouse model to study the effects of OZF13 loss on spermatogenesis and gamete quality.

PM01.88

Could teratological counseling be used as an effective method in the prevention of unnecessary pregnancy losses among women exposed to diagnostic radiation

M. Seven[1], *E. Fenercioglu[1], E. Koparır[2], E. Kirtas[1], H. Ulucan[1], E. Kirat[1], A. Koparır[1], M. Demir[1];*
[1]Istanbul University Cerrahpasa Medical School, Istanbul, Turkey, [2]Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey.

Women are commonly exposed by radiation in the radiology and nuclear medicine departments being unaware of their pregnancies. In such situations, mothers have often deep concern about possibility of having baby with the congenital anomalies. Moreover, families are usually faced to make the decision for termination. In this study, the risk of the congenital anomalies due to radiation exposure was calculated and the importance of „teratological counseling" was demonsrated to avoid unnecessary pregnancy terminations. 139 pregnant women with the history of radiation exposure were evaluated via medical records, retrospectively. Fetal radiation dose was given between 0.01-10.30 (Med. 0.75±1.59 R) to women exposed to radiation for diagnostic purposes, being unaware of their pregnancy. 65% of those pregnant women were suggested to terminate their pregnancy while others were also adviced that their babies may have congenital abnormalities at some level before admitted for teratological counseling. Only 6 women terminated their pregnancy following teratological counseling. Of remaining 133 pregnants, 3 were terminated for medical purposes while 4 were resulted as spontaneous abortion. Remaining 126 pregnancies lasted as normal birth and none of the babies had abnormalities checked by physical examination. In conclusion, we suggest that teratological counseling is necessary to reduce the anxiety of families and it is an effective method to prevent unnecessary pregnancy terminations.

PS01.89

Comparison of microRNA expression in chorionic tissue of healthy and trisomic fetuses

I. Svobodová, *S. Pospisilova, E. Pazourkova, M. Korabecna, A. Horinek;*
General faculty hospital in Prague, Prague 2, Czech Republic.

Recently, there is an effort to associate specific pregnancy pathologies, especially risk of preeclampsia, with particular miRNAs in plasma, which could serve as biomarkers for the detection of the corresponding pathology and so enable its early diagnosis. Direct miRNA analysis in the trisomic placental tissue is an unexplored topic yet.
The aim of this study was to compare physiological and pathological gravidities at level of placental miRNAs expression.
The chorionic villi samples (CVS) collected for the purposes of invasive prenatal diagnosis between 11^{th}-14^{th} gestational weeks from patients with increased fetal trisomy risk were examined. We supposed the differences in presence and concentration of the specific miRNAs between the group of 16 CVS samples with cytogenetically confirmed fetal trisomy of 21, and 10 samples with normal karyotype. The expression of 381 miRNA pattern (TaqMan® Array Human MicroRNA A Cards) was determined using real-time PCR technology in both groups of samples. The results were then statistically evaluated via ExpressionSuite and qBase software. Mammalian small nuclear RNA U6 in combination with small nucleolar RNA RNU48 was used as endogenous controls for appropriate results normalization.
The nonparametric Mann-Whitney test was applied to the both group's expression data.
The group of 20 miRNAs which were significantly elevated in placental tissue of trisomic pregnancies was determined. The p-values ranged from 0.008 to 0.05. The miRNA which most significantly differed between both groups was miR-542-5p. The current results will be subsequently verified in maternal circulation.
Supported by the Ministry of Health of the Czech Republic RVO VFN64165.

PM01.90

Azoospermia and trisomy 18p syndrome: a fortuitous association? A patient report and a review of the literature

G. Jedraszak[1], *H. Copin[2], M. Demailly[3], C. Quibel[2], M. Gallet[2], M. Benkhalifa[2], A. Receveur[2];*
[1]Laboratoire de génétique moléculaire - CHU d'Amiens, AMIENS, France, [2]Laboratoire de Cytogénétique et Biologie de la Reproduction - CHU d'Amiens, AMIENS, France, [3]Service d'Urologie et Transplantation - CHU d'Amiens, AMIENS, France.

Complete, isolated trisomy of the short arm of chromosome 18 is very rare. To date, only 24 cases of trisomy 18p have been reported in the literature, making it difficult to define a potentially associated phenotype. However, the available evidence suggests that few clinical features are shared by these patients: only variable intellectual disability, variable facial dysmorphism and epilepsy are reported in a few patients. Although three inherited cases of trisomy 18p have already been reported, all were of maternal origin.
We report on a patient carrying an isolated complete trisomy 18p translocated to the short arm of chromosome 14 and presenting with facial dysmorphism, mild intellectual disability and non-obstructive azoospermia.
Chromosomal abnormalities are more frequent in infertile men with poor sperm quality than the general population. Both numerical and structural chromosomal aberrations have been already reported within the context of azoospermia. To our knowledge, this is the first patient with trisomy 18p to present a fertility impairment due to totally altered spermatogenesis and azoospermia. Although fertility disorders were not mentioned in the four previous reports of men with trisomy 18p, none of the latter had children.

We suggest that azoospermia is a previously uncharacterized feature of trisomy 18p syndrome. We further hypothesize that two mechanisms could be responsible of the fertility impairment: a meiotic synapsis defect due to the additional 18p arm that blocks meiosis, and/or overexpression of a gene located on the 18p chromosome involved in the normal testicular development.

PS01.91

Case report: male patients with normal phenotype and various Y-chromosome rearrangements

K. Goldmann;
Centre for Reproductive Genetics, Munich, Germany.

Introduction
Chromosomal rearrangements of the Y-chromosome are known causes for male infertility. Microdeletions in the azoospermia factor (AZF) regions are found in up to 15% of azoospermic or severely oligospermic men (1).
Material & Methods
Here we present data from four patients with normal phenotype, but abnormal sperm count and infertility. For all patients, we performed conventional karyotyping and revealed various rearrangements affecting the Y-chromosome. For more detailed analysis, we performed diagnostics on either molecular-cytogenetic or molecular genetic level.
Results
Screening of the AZFa, AZFb, and AZFc revealed a partial deletion of AZFb in one patient, a partial deletion of AZFb and AZFc in the second one and in the third one, we revealed a complete deletion of AZFb and AZFc. Here, none of the 36 most common mutations in CFTR-gene were found. These data are in concordance with the previously diagnosed oligozoospermia and azoospermia respectively. Interestingly, we could determine a deletion of the PAR2 in two patients using FISH and additionally a duplication of the PAR1 in one of those. We performed SNParray analysis in two patients to determine the constitution of the Y-chromosome. Analysis of one revealed an unclear deletion pattern in the region Yq11.223-q11.23. The analysis of the other one resulted in a huge deletion on Yq11.221-q12.
Conclusions
We will provide detailed case comparison which shows, that performing additional FISH and SNParrays can help to clarify the aberration status of the Y-chromosome.

SLC24A5 recent albinism gene (OCA6): detection of a homozygous mutation in two patient from French Guiana

E. Lasseaux[1], *A. Bertelotti*[2], *C. Plaisant*[1], *A. Trimouille*[1], *F. Morice-Picard*[1], *C. Rooryck-Thambo*[1], *D. Lacombe*[1], *P. Brousse*[2], *P. Couppie*[2], *B. Arveiler*[1];
[1]*CHU Bordeaux, Bordeaux, France,* [2]*A. Rosemon Hospital Dermatology Departement, Cayenne, France.*

Oculocutaneous albinism (OCA) is an autosomal recessive disorder characterized by hypomelanosis of the skin, hair, and eyes, associated with reduced visual acuity, nystagmus, and photophobia. Recently, two new types of albinism non syndromic have been identified OCA6 (SLC24A5) and OCA7 (C10orf11).(1)
Cases : Two women, aged 22 and 65 years, lived in a village along the Maroni River in South America. They were not from the same family. They had a particular albinism, with similar clinical ophtalmologic characteristics : brown iris, photophobia, reduced visual acuity and nystagmus,but their hair was blond at birth and become darker with age. Their skin was light brown. They were sensitive to the sun exposure and might turn brown. The second patient had a significant pachydermia with age (2).
We analyzed these patients by Next Generation Sequencing technology with a panel of genes involved in syndromic and non syndromic OCA (TYR, OCA2, TYRP1,SLC45A2, GPR143, HPS 1 to 6, SLC24A5, MITF, PAX3, SOX10, EDN3, EDNRB). We found the same homozygous variant in these two patients, c.521G>A/ p.Arg174Lys in exon 5 of SLC24A5 gene. This variant had never been described before in the literature. This variant was not reported in the international database of mutations HGMD. There is no frequency data in ESP, EXAC, dbSNP. The prediction software Polyphen and Mutation taster predicted this variant as probably damaging.
Our finding of a novel homozygous mutation in SLC24A5 in two patients from french Guiana strengthens the importance of screening this gene in OCA (3).

The COL4A4 p.Gly533Asp mutation is prevalent in Czech Romani families with Alport syndrome

P. Plevova[1], *P. Turska*[1], *P. Vojta*[2], *A. Balcar*[1], *D. Cerna*[1], *J. Dusek*[3], *J. Stepankova*[4], *J. Nemeckova*[5], *E. Zemankova*[6];
[1]*Department of Medical Genetics, University Hospital Ostrava, Ostrava, Czech Republic,* [2]*Institute of Molecular and Translation Medicine, Palacký University, Olomouc, Czech Republic,* [3]*Department of Pediatrics, 2nd Medical Faculty of the Charles University and University Hospital Motol, Prague, Czech Republic,* [4]*Department of Nephrology, Institute of Clinical and Experimental Medicine, Prague, Czech Republic,* [5]*Department of Medical Genetics, University Hospital Brno, Brno, Czech Republic,* [6]*Gennet Lab, s.r.o., Pribram, Czech Republic.*

Introduction: Alport syndrome is characterized by progressive hereditary nephritis, hearing loss and ocular anomalies. The disease is caused by *COL4A5, COL4A3* and *COL4A4* gene mutations.
Materials and Methods: Twelve patients with hematuria and sensorineural hearing loss were included, in whom carriership of p.Gly624Asp *COL4A5* mutation (the most frequent one in Czech patients) was excluded. Sequencing of the whole coding sequence of the *COL4A3*, *COL4A4* and *COL4A5* genes was performed using either Sanger sequencing on ABI3130 (1 patient) or the ALPORT MASTR kit (Multiplicom) with subsequent next generation sequencing at Illumina platform (11 patients). MLPA was performed to detect genomic *COL4A5* and *COL4A3* rearrangements. In one patient wholegenome SNP array was performed.
Results: Five of the twelve patients carried c.1598G>A, p.Gly533Asp mutation in *COL4A4* gene in either homozygous (4 patients) or heterozygous (1 patient) state. All the homozygots also carried the same 44 polymorphisms in *COL4A3* or *COL4A4* genes in homozygous state. MLPA excluded deletion of *COL4A3*, thus making deletion of the whole region unprobable. SNP array showed loss of heterozygosity of 250 Mb at various sites of the genome of one patient due to consanguinity, including 48 Mb at 2q32.1 to 2q37.1 region (*COL4A3* and *CO4A4* genes are localised at 2q36.3). All the patients with the mutation were of Romani origin.
Conclusion: The *COL4A4* p.Gly533Asp mutation is prevalent in Czech Alport syndrome patients of Romani origin, consanguinity being responsible for its frequent occurrence in homozygous state.

Phenotypic and genotypic findings in a large cohort of patients with eye anomalies

S. L. Broadgate[1], *N. Chassaing*[2], *R. J. Holt*[1], *P. Calvas*[2], *N. K. Ragge*[1,3];
[1]*Oxford Brookes University, Oxford, United Kingdom,* [2]*CHU Toulouse, Service de Génétique Médicale, Toulouse, France,* [3]*Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom.*

Anophthalmia, microphthalmia and coloboma (AMC) are genetically heterogeneous conditions responsible for ~25% of childhood blindness. We aimed to identify causative genes in 311 AMC subjects recruited through a UK national study. Clinical phenotyping and genetic analysis were performed using various methods: single gene sequencing, MLPA, aCGH, custom panel and exome sequencing. Our cohort was subdivided into phenotypic subgroups for analysis: 56 participants (18%) had bilateral anophthalmia/severe microphthalmia, 37 (12%) had bilateral microphthalmia (+/- coloboma), 175 (56%) had unilateral anophthalmia/microphthalmia (+/- contralateral defects), and 43 (14%) had other phenotypes e.g. isolated colobomas or Peters' Anomaly. Thirty-four of the 56 severe cases received a diagnosis, including deletion/mutations in: SOX2 (15 [27%]), OTX2 (7 [14%]), VSX2 (3 [5.4%]), ALDH1A3 (2 [3.6%]), TFAP2A (2 [3.6%]), FOXE3 (2 [3.6%]), also one each: PAX6, STRA6, BMP7, GJA8. SOX2 (7.4%), OTX2 (3.5%) and FOXE3 (1.6%) were the most common causative genes identified, with VXS2, BMP7, CHD7 and TFAP2A each accounting for 1%. Seventy-two participants who initially received single gene screening proceeded to 187 targeted gene sequencing. Pathogenic variants in known genes were found in 5 (including CHD7 and FOXE3); a further 51 had variants of unknown significance (VUS) in known/candidate genes. Of 15 participants with whole exome analysis; 3 had pathogenic variants in known genes (including PAX6 and BCOR) and 9 had VUS. This study represents the largest reported phenotype-genotype study of patients with eye anomalies. To date, 21.5% of participants have a definitive diagnosis and a further 24.4% have VUS and are undergoing further analysis.

PM02.04

Novel variants in OLFM2 in patients with developmental eye disease

R. J. Holt[1], *S. A. U. İşeri*[2], *S. Broadgate*[1], *R. G. Dunn*[3], *A. Gallagher*[4], *C. Ogilvie*[5], *N. K. Ragge*[1,6];

[1]*Oxford Brookes University, Oxford, United Kingdom,* [2]*İstanbul University, Istanbul, Turkey,* [3]*Guy's and St Thomas' NHS Trust, London, United Kingdom,* [4]*Worcestershire Acute Hospitals NHS Trust, Worcester, United Kingdom,* [5]*Kings College London, London, United Kingdom,* [6]*Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom.*

Microphthalmia, anophthalmia and coloboma are developmental anomalies of the eye and occur in approximately 3 in 10,000 births. They are a heterogeneous group of genetic conditions, with 111 genes identified based on published case reports and genetic databases. We identified a heterozygous de novo deletion of chromosome 19p13.2 affecting a minimum of 46kb spanning regions of Olfactomedin 2 (OLFM2) and collagen, type V, alpha 3 (COL5A3) by array CGH in a patient with bilateral microphthalmia and cloudy vascularised corneas. While COL5A3 has not been implicated in mammalian eye function, Olfm2 is expressed in the retina and ganglion cells during mouse eye development. OLFM2 has also been implicated in open-angle glaucoma and elevated intraocular pressure in a Japanese population. Therefore, we screened the exons and flanking regions of OLFM2 for variants in a cohort of 261 patients with developmental eye anomalies using LightScanner® technology, with subsequent validation by Sanger sequencing. We identified novel mutations in three members of this cohort. These included two variants in the 5' untranslated region (UTR) of OLFM2 and an intronic C>A 20bp 5' of exon 5. Of the 5' UTR variants, one is a 4bp insertion/deletion and the second is a G/C substitution, both occurring approximately 60bp 5' of translation start site, separated by only 4bp and predicted to affect transcription factor binding.

We suggest that OLFM2 is a new gene for eye developmental anomalies, in particular associated with microphthalmia, and should be included when considering eye genes to screen in these conditions.

SF3B2, a novel candidate gene for autosomal dominant retinitis pigmentosa, encodes a component of the U2 small nuclear ribonucleoprotein

C. Van Cauwenbergh[1], *M. Karlstetter*[2], *K. Vleminckx*[1,3], *G. Manes*[4], *T. Langmann*[2], *C. Hamel*[4], *European Retinal Disease Consortium (ERDC), B. P. Leroy*[5,6], *F. Coppieters*[1], *E. De Baere*[1];

[1]*Center for Medical Genetics, Ghent University, Ghent, Belgium,* [2]*Department of Ophthalmology, University of Cologne, Cologne, Germany,* [3]*Department of Biomedical Molecular Biology, Ghent University, Ghent, Belgium,* [4]*INSERM U1051, Institut des Neurosciences de Montpellier, Montpellier, France,* [5]*Dept of Ophthalmology, Ghent University Hospital, Ghent, Belgium,* [6]*Division of Ophthalmology, The Children's Hospital of Philadelphia, Philadelphia, PA, United States.*

The aim of this study was to identify and functionally characterize a novel candidate gene for autosomal dominant retinitis pigmentosa (adRP). Ten individuals of a Belgian adRP family in which known adRP loci were excluded underwent genome-wide linkage analysis, resulting in two novel candidate loci with a maximum LOD score of 1.7. Whole exome sequencing in two affected individuals (HiSeq, Illumina) revealed a missense variant c.2417A>G p.(Tyr806Cys) in the SF3B2 gene encoding the splicing factor 3b, subunit 2. The Tyr residue is highly conserved, several predictions suggest an effect on protein function. The change is predicted to disrupt a phosphorylation site. The variant co-segregates with adRP and is absent in 300 controls. No additional SF3B2 mutations were found in 472 unrelated adRP patients (ERDC consortium). Ubiquitous expression of SF3B2 was demonstrated in human tissues, including retina and RPE. Localization in perinuclear and nuclear areas was shown in 661W mouse cells. Sf3b2 knockdown in Xenopus was performed using targeted injection of a splicing blocking morpholino (GeneTools), showing gross developmental anomalies affecting the eye.

In conclusion, SF3B2 was identified as a novel candidate gene for adRP. SF3B2 is required for binding of the U2 small nuclear ribonucleoprotein (snRNP) to the branchpoint and is involved in early spliceosome assembly. Protein-protein interactions have been identified between SF3B2, SNRNP200 and PRPF8, two proteins implicated in adRP. So far, of the seven known adRP genes involved in splicing, six encode components of the U4/U6-U5 triple small nuclear ribonucleoprotein (tri-snRNP) complex. Our study potentially involves other components of the spliceosome apart from the tri-snRNP complex in adRP.

Autosomal recessive nonsyndromic hearing loss due to TMPRSS3 mutations in Slovenia

K. Trebusak Podkrajsek[1,2], *G. Klancar*[1], *J. Kovac*[1], *T. Battelino*[1,2], *S. Battelino*[3,2];

[1]*University Medical Centre Ljubljana, University Children's Hospital, Ljubljana, Slovenia,* [2]*Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia,* [3]*University Medical Centre Ljubljana, Department of Otorhinolaryngology and Cervicofacial Surgery, Ljubljana, Slovenia.*

Introduction: Autosomal recessive nonsyndromic hearing loss (ARNSHL) is usually prelingual, nonprogressive and severe to profound. Up to date it was accounted to mutations in 55 genes (Hereditary Hearing Loss Homepage, http://hereditaryhearingloss.org), where the number is still rising. TMPRSS3 gene mutations account for less than 1 % of autosomal recessive nonsyndromic hearing loss (ARNSHL) in Caucasians. In Slovenians, 26.6 % of congenitally deaf patients and 11 % of progressive hearing loss patients had biallelic GJB2 mutations, where other genetic causes of ARNSHL were not exploited so far.

Material and Methods: Targeted next generation sequencing in the index family with congenitally deaf parents and their son was performed initially, followed by Sanger sequencing of selected TMPRSS3 region in 35 patients with ARNSHL and no mutation identified in GJB2 or GJB6 genes.

Results: Next generation sequencing in the index family revealed that a son and his mother were homozygous for TMPRSS3 c.208delC (p.His70Thrfs*19) variant. Father was digenic compound heterozygote for the same variant and common GJB2 c.35delG variant. Additionally, we identified 3 patients homozygous for TMPRSS3 c.208delC in a cohort of ARNSHL patients.

Conclusions: TMPRSS3 mutations detected in altogether 13,1% of the studied patients seem to be an important cause of ARNSHL in Slovenia resulting in uniform phenotype with profound congenital hearing loss and satisfactory hearing and speech recognition after cochlear implantation.

Behr syndrome (MIM#210000) is characterized by early-onset optic neuropathy associated with ataxia, spasticity, peripheral neuropathy and developmental delay. Although this disorder is believed to be inherited in an autosomal recessive pattern, it might be heterogeneous encompassing several etiologies. Recently, we reported two brothers affected with adult-onset Behr-like syndrome caused by a heterozygous mutation in the optic atrophy 1 (*OPA1*) gene. Heterozygous mutations in *OPA1*, a gene encoding for a dynamin-related GTPase involved in mitochondrial dynamics and mtDNA maintenance, are the main causes of autosomal dominant optic atrophy (DOA). As many as 20% of persons carrying heterozygous OPA1 mutations are affected with the so-called 'DOA plus' consisting in optic neuropathy associated with extra-ocular signs including deafness, ataxia, peripheral neuropathy and mitochondrial myopathy with multiple mtDNA deletions.

We here report four children affected with early-onset Behr syndrome caused by compound heterozygous *OPA1* mutations. These four children are affected with a strikingly similar early-onset neurological syndrome associating severe optic neuropathy (4/4), cerebellar ataxia with cerebellar atrophy at MRI (4/4), peripheral neuropathy (4/4), digestive involvement (2/4) and deafness (1/4).

To date, compound heterozygosity in OPA1 has been proven in 6 patients (including those reported here) all affected with severe early-onset syndromic optic atrophy.

Intriguingly, the same variant p.Ile382Met, involving a highly conserved residue in the OPA1 GTPase domain, was recurrently found in five of six patients in this series. Although the p.Ile382Met mutation on its own might have only mild consequences, it may combine with another mutation to induce a severe pathological condition which is consistent with a semi-dominant mode of inheritance.

Novel gene identified by exome sequencing analysis in a Colombian family affected by autosomal recessive congenital cataract

L. C. Hernandez[1], *O. A. Moreno*[1], *A. Fernandez*[2], *M. C. Lattig*[1];
[1]*Universidad de los Andes, Bogota, Colombia,* [2]*Hospital Militar, Bogota, Colombia.*

Congenital cataract is a Mendelian disorder that affects the eye lens, a non-vascular transparent tissue, causing distortions of the light giving an opaque appearance and loss of transparency that leads to vision problems. This condition is the worldwide leading cause of visual impairment and blindness for children (Chan, Wai H. et al. 2012). Several genes are known to be responsible for the autosomic dominant type of cataract, the most common in the world population. However recessive inheritance has also been reported and it is usually associated with other ocular conditions that worsen the vision making it difficult to treat (Kondo, Y., et al. 2013). In this study, a family of healthy parents and three affected children with zonular, nuclear congenital cataract (two sons and one daughter) is described. Exome sequencing using SureSelect Human All Exon 50Mb V4 (50X depth) was performed to uncover the genes responsible for the condition in the family. Bioinformatic analysis using the reference genome GRCh37 did not find variants in any of the known genes, however we did identify a novel homozygous variant P.Gly377fs in exon 7 of the SLC37A4 gene (NM_001164280.1). According to polyphen (Adzhubei IA. et al. 2010) this variant is considered damaging. Mutations in this gene have been found in patients with glycogen storage disease, however the individuals in our family show no clinical manifestations of the disease. We might speculate that an abnormal glucose homeostasis caused by this mutation might lead to an accumulation of sorbitol forming a sugar cataract.

Choroideremia (CHM) is an X-linked chorioretinal dystrophy affecting 1 in 50,000 people. Typically, males develop initial symptoms from night blindness to peripheral visual field loss leading to complete blindness. Female carriers are generally asymptomatic, although mild symptoms can be observed. It is caused by mutations in the *CHM* gene that encodes Rab escort protein 1 (REP-1), an essential component of Rab geranylgeranyl transferase (Rab GGTase) that controls cellular trafficking in secretory and vesicular pathways.

We characterized 33 out of 45 unrelated families with clinical diagnoses of CHM. The molecular diagnostic pipeline followed include haplotype analysis, direct sequencing, RNA studies, combined MLPA and qF-PCR, CGH arrays, cytogenetic studies and, in a family, whole exome sequencing. The mutational spectrum included complete or partial deletions of *CHM* gene being the most frequent mutations identified (13 families; 39%). Among them, exon 9 deletion was recurrent affecting three families (10%). Secondly, most pathogenic alleles carried nonsense mutations (11 families; 33%). Mutation p.Arg293* was the most frequent one, being present in four families (12%) from diverse geographical origins: Spanish, Portuguese and Polish. Frameshift p.Thr175fs* mutation was found in one Spanish and one Portuguese families.

Our diagnostic pipeline allowed us to achieve the molecular characterization in 73% of cases. The remainder cases should be clinically reviewed. Alternatively, other mutations in uncovered regions or in other genes can be the cause. To identify the causative mutations in CHM patients is essential in patient management and to the improvement of therapies focused on correcting the primary genetic defect.

Mutations in Collagen, type XVII, alpha 1 (COL17A1) cause Epithelial Recurrent Erosion Dystrophy (ERED)

A. E. Davidson[1], *F. Jonsson*[2], *B. Byström*[2], *L. J. Backman*[2], *T. G. Kellgren*[2], *S. J. Tuft*[1,3], *T. Koskela*[4], *P. Rydén*[2], *O. Sandgren*[2], *P. Danielson*[2], *A. J. Hardcastle*[1], *I. Golovleva*[2];
[1]*UCL Institute of Ophthalmology, London, United Kingdom,* [2]*Umeå University, Umeå, Sweden,* [3]*Moorfields Eye Hospital, London, United Kingdom,* [4]*Koskelas Eye Clinic, Umeå, Sweden.*

Epithelial recurrent erosion dystrophy (ERED) is an autosomal dominant condition associated with painful corneal epithelial erosions, typically starting within the first decade of life. Between attacks the corneal epithelium either appears normal or there are a small number of epithelial micro-cysts, consistent with a healing epithelial erosion. Sub-epithelial haze may then progress over several decades, which can lead to central corneal scaring. Our goal was to identify the genetic cause of ERED. A large, genealogically expanded, ERED pedigree of northern Swedish origin was identified and whole exome sequencing (WES) was performed using DNA from disparate branches of the family. A novel, non-synonymous COL17A1 variant, c.2816C>T, p.(Thr939Ile), was found to co-segregate with disease in the extended pedigree. COL17A1 encodes collagen type XVII alpha 1, a structural component of hemidesmosomes (multi-protein complexes that provides attachment for basal epithelial cells to the underlying basement membrane) and thus represents an excellent candidate gene for ERED. Previously, in a family with a similar ERED-like phenotype, disease was shown to be linked to Chr10q23-q24 encompassing COL17A1, but the authors reported that no mutation was identified (Sullivan, et al., 2003). Our re-evaluation of this data suggested that the synonymous COL17A1 variant, c.3156C>T p.(Gly1052Gly), that co-segregated with disease could create a cryptic splice donor site. We experimentally confirmed that this synonymous variant leads to aberrant pre-mRNA splicing of the COL17A1 transcript in vitro, and we suggest that both of these ERED-like corneal dystrophies are allelic and can be attributed to mutations in COL17A1.

STX3: A novel gene linked to autosomal recessive congenital cataract, intellectual disability phenotype in a consanguineous Tunisian family

M. Chograni[1], *F. S. Alkuraya*[2], **H. Chaabouni-Bouhamed**[1];
[1]*Faculte de medecine University Tunis Elmanar, Tunis, Tunisia,* [2]*Department of Genetics, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.*

Introduction

One-third of congenital cataract cases have a genetic cause. Today about 39 loci are involved in isolated or primary cataracts; several complex syndromes including cataract with multiple anomalies and intellectual disability have been mapped. Here is the first report of gene identification in inherited congenital cataracts associated only with intellectual disability.

Materials and Methods

A total of 3 affected patients and 2 unaffected parents belonging to a consanguineous Tunisian family with congenital cataract associated to intellectual disability were analysed.

Homozygosity mapping, a successful method in identifying genetic defects in consanguineous families, we carried out a genome wide scan for the five members.

Moreover, we used the integrated Systems Tool for Eye gene discovery (iSyTE) for the identification of lens specific genes with high or low expression.

Results

GWS identified 2 homozygous candidate regions at chromosome 11 (p11.2-p11.12) and (q11-q13.1). These regions were analysed by the iSyTE allowing the identification of less-highly expressed lens disease-associated genes to non-syndromic congenital cataract. Four genes (STX3 (11q12.1), CCDC86 (11q12.2), SLC3A2 (11q12.2) and SLC15A3 (11q13)) were selected according to their early expression in lens development. All exons, exon-intron junctions were sequenced. By analyzing the results we identified a novel missense mutation c.122A>G in STX3 gene which results in p.E41G. Bioinformatics analysis suggested a deleterious effect of this mutation on protein structure and function.

Conclusion

We report for the first time a missense mutation of a novel lens specific gene STX3 in a phenotype associating AR congenital cataract and intellectual disability. This study highlighted the genetic heterogeneity of congenital cataract.

Application of custom-designed high resolution CGH array in diagnosis of patients with congenital eye malformations

L. Rodrigues Jacy da Silva[1,2,3], F. Blanco-Kelly[1,2], C. Villaverde[1,2], N. Reyes[1,2], C. Velez[1,2], E. Guillen-Navarro[4], J. Rosell[5], M. Trujillo-Tiebas[1,2], C. Ayuso[1,2], **M. Corton**[1,2]*;*
[1]Instituto de Investigacion Sanitaria-Fundación Jiménez Díaz University Hospital (IIS-FJD-UAM), Madrid, Spain, [2]Centre for Biomedical Network Research on Rare Diseases (CIBERER), ISCIII,, Madrid, Spain, [3]University of Mogi das Cruzes, Sao Paulo, Brazil, [4]University Hospital Virgen de la Arrixaca, Murcia, Spain, [5]University Hospital Son Espases, Palma de Mallorca, Spain.

Introduction: Congenital eye malformations are very highly heterogeneous conditions displaying a wide spectrum of overlapping phenotypes that can occur isolated or taking part of a syndrome. They include pan-ophthalmic disorders such as anophthalmia, microphthalmia (A/M) and aniridia, and also anomalies restricted only to the anterior or posterior segment. Our aim was to design and validate a customized high-resolution CGH array to search for rearrangements across eye developmental genes causing ocular malformations.
Material and Methods: A custom whole-genome oligonucleotide CGH array (Agilent, 4x180K format) was designed to cover all exonic, intronic and regulatory regions from 160 eye developmental genes and the WAGR-related locus at 11p13, using 130K probes. In addition, 44K thousand backbone probes were added to cover the remained non-target genomic regions.
Forty-eight patients with several phenotypes were analysed, including syndromic and isolated forms of A/M, aniridia, coloboma, anterior segment dysgenesis and nerve optic hypoplasia that mostly were previously tested by MLPA for PAX6 or SOX2 deletions.
Results: In 4 patients, our custom aCGH allowed detect larger 11p13 deletions than the previously found by MLPA and then, refined chromosomal breakpoints. In a syndromic patient with bilateral anophthalmia, a 14q22.3-q23.2 microdeletion was detected encompassing OTX2 and SIX6, both genes associated with A/M and septo-optic dysplasia. Non-polymorphic copy number changes were also found at several candidate chromosomal regions. Rearrangements ranged from 6.2Mb to 55kb.
Conclusions: Our custom aCGH represents an accurate tool for the analysis of genomic rearrangements in eye developmental diseases.

PS02.15

Spectrum of mutations and genotype-phenotype correlation in TGFBI-associated corneal dystrophies

C. J. Evans[1]*, A. E. Davidson[1], N. Carnt[2], N. Veli[2], S. J. Tuft[2,1], A. J. Hardcastle[1];*
[1]UCL Institute of Ophthalmology, London, United Kingdom, [2]Moorfields Eye Hospital, London, United Kingdom.

Autosomal dominant gain-of-function mutations in *TGFBI* are responsible for a diverse range of corneal dystrophies including Reis-Bücklers (RBCD), Thiel-Behnke (TBCD), granular (GCD) and lattice corneal dystrophies (LCD). Here we investigated the spectrum of *TGFBI* mutations in patients with a corneal dystrophy attending Moorfields Eye Hospital. In total, 58 unrelated probands with a suspected *TGFBI*-associated corneal phenotype were screened for mutations by direct sequencing. The most commonly identified mutations occurred at two known mutation hotspot residues of the TGFBI protein, Arg-124 and Arg-555. The mutations included c.370C>T; p.(Arg124Cys) in 17 probands, c.1664G>A; p.(Arg555Gln) in 16, c.1663C>T; p.(Arg555Trp) in 11 and c.371G>A; p.(Arg124His) in 5 patients. The phenotypes associated with each mutation were LCD, TBCD, GCD1 and GCD2, respectively. However, the hotspot mutation c.371G>T; p.(Arg124Leu) associated with an RBCD phenotype was only observed in one proband. Interestingly, the c.1868G>A; p.(Gly623Asp) mutation was identified in 4 patients, with clinical features of RBCD, LCD or both, indicating a lack of genotype-phenotype correlation. Two probands with LCD had c.1859C>A; p.(Ala620Asp) and c.1877A>G; p.(His626Arg) mutations and one proband with RBCD had a c.1874T>A; p.(Val625Asp) mutation. One patient with LCD, who was mutation negative for *TGFBI*, had a mutation in *GSN* that resulted in a re-diagnosis to Meretoja syndrome. In summary, a limited spectrum of *TGFBI* mutations is responsible for the majority of *TGFBI*-associated corneal dystrophies. Mutations affecting residues Arg-124 and Arg-555 show strong genotype-phenotype correlation, whereas mutations affecting other residues show more variable phenotypic expression.

PM02.16

Identification of deafness genes in Israeli Jewish and Brazilian families using Next Generation Sequencing platforms

F. T. A. Martins[1,2]*, Z. Brownstein[1], M. Birkan[1], M. Sokolov[1], O. Isakov[3], H. Baris-Feldman[4], M. Frydman[5], R. Sharony[6], N. Shomron[3], E. L. Sartorato[2], K. B. Avraham[1];*
[1]Department of Human Molecular Genetics and Biochemistry, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [2]Human Molecular Genetics Lab, Molecular Biology and Genetic Engineering Center, University of Campinas, Campinas, Brazil, [3]Department of Cell and Developmental Biology, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [4]Genetics Institute, Rambam Health Care Campus, Haifa, Israel, [5]Danek Gartner Institute of Human Genetics, Sheba Medical Center, Tel Hashomer, Israel, [6]Genetic Institute, Meir Medical Center, Kfar Saba, Israel.

Introduction: One in every 500 individuals presents severe to profound sensorineural hearing loss. According to the World Health Organization, hearing loss is the most common sensory impairment. It is estimated that 60% of congenital hearing loss may be due to genetic mutations, with high genetic heterogeneity. Over 80 genes are known to be involved in hearing loss. Traditional diagnostic techniques have become slow and costly for screening this large number of genes. High-throughput platforms based on Next Generation Sequencing (NGS) have provided an optimal solution for diagnostics.
Materials and Methods: We employed Targeted Genomic Enrichment (TGE) and massively parallel sequencing to capture the exons of 284 genes associated with deafness in humans and mice. We performed whole exome sequencing (WES) on a portion of the families. A bioinformatics workflow was implemented, providing an output of potential causative variants. The segregation of a subset of variants was examined in families and controls. When relevant, functional analysis was performed.
Results: One Brazilian and 67 Israeli Jewish families were evaluated. Variants in over 20 genes, including TMC1, POU3F4, MYO6, and MYO15A, were identified, solving 38% of the cases in the Jewish Israeli population. A MYH9 mutation segregated with deafness in the Brazilian family.
Conclusions: These results demonstrate that diagnostics for deafness can be performed optimally using NGS, leading to a better understanding of the genetic profile of hearing impaired populations and mechanisms of hearing loss.
This work was supported by NIH/NIDCD grant R01-DC011835 and São Paulo Research Foundation (FAPESP), project number 2013/05823-5.

PS02.17

A genome-wide association study provides evidence of sex-specific involvement of Chr1p35.1 (ZSCAN20-TLR12P) and Chr8p23.1 (HMGB1P46) with diabetic neuropathic pain

M. Weihua[1]*, H. A. Deshmukh[1], L. A. Donnelly[1], Wellcome Trust Case Control Consortium 2 (WTCCC2), Surrogate markers for Micro- and Macro-vascular hard endpoints for Innovative diabetes Tools (SUMMIT, N. Torrance[1], A. D. Morris[2], H. H. Colhoun[1], C. N. A. Palmer[1], B. H. Smith[1];*
[1]University of Dundee, Dundee, United Kingdom, [2]University of Edinburgh, Edinburgh, United Kingdom.

Neuropathic pain is defined as pain arising as a direct consequence of a lesion or a disease affecting the somatosensory system and it affects around 1 in 4 diabetic patients in the UK.The purpose of this genome-wide association study was to identify genetic contributors to diabetic neuropathic pain.
We obtained a GWAS dataset of 6,927 diabetic individuals from the Genetics of Diabetes Audit and Research Tayside (GoDARTS) project and accessed the prescription history of these individuals. Cases of neuropathic pain were defined as diabetic patients with a multiple prescription history of at least one of five drugs specifically indicated for the treatment of neuropathic pain. Controls were diabetic individuals who were not prescribed any of these drugs, nor amitriptyline, carbamazepine, or nortriptyline. Those who had one use of the five specific neuropathic pain drugs were further excluded from controls. Logistic regression analyses were performed to test genetic associations, adjusting with covariates.
Overall, 961 diabetic neuropathic pain cases and 3,260 diabetic controls were identified. We found a cluster in the Chr1p35.1 (ZSCAN20-TLR12P) with a lowest P value of 2.74 x 10-7 at rs71647933 in females and a cluster in the Chr8p23.1, next to HMGB1P46 with a lowest P value of 8.02x 10-7 at rs6986153 in males. The narrow-sense heritability of neuropathic pain from the overall dataset was 14.7%. Sex-specific narrow sense heritability was higher in males (30.0%) than in females (14.7%).
This GWAS on diabetic neuropathic pain provides evidence for the sex-specific involvement of Chr1p35.1 (ZSCAN20-TLR12P) and Chr8p23.1 (HMGB1P46) with the disorder, indicating the need for of further research.

PM02.18

Comprehensive evaluation of the FBN1, LTBP2 and ADAMTSL4 genes in 207 patients with ectopia lentis

B. L. Callewaert[1], *S. Van Nuffel*[1], *L. De Potter*[1], *E. De Bals*[1], *J. De Backer*[1], *O. Vanakker*[1], *H. Van Esch*[2], *M. Biervliet*[3], *J. Désir*[4], *J. Vandenende*[5], *A. De Paepe*[1], *B. Leroy*[1], *P. Coucke*[1];
[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Center for Human Genetics, University Hospital Leuven, Leuven, Belgium,* [3]*Center for Medical Genetics, University Hospital Brussels, Brussels, Belgium,* [4]*Department of Medical Genetics, Hôpital Erasme, Université Libre de Bruxelles, Brussels, Belgium,* [5]*Center for Medical Genetics, University Hospital Antwerp, Antwerp, Belgium.*

Ectopia lentis (EL) can occur isolated or within a syndromal constellation. The most prevalent cause of congenital EL is Marfan Syndrome (MFS), which requires a lifelong cardiovascular follow-up. Because of the evolving phenotype, FBN1 testing is often requested in children with EL. In patients without an FBN1 mutation, the absence of a definite diagnosis may cause psychological distress and unnecessary examinations. Recently, mutations in LTBP2 and ADAMTSL4 have been implicated in congenital glaucoma and microspherophakia with EL, and EL et pupillae, respectively.
We analyzed the FBN1, ADAMTSL4 and LTBP2 genes in 207 probands referred for EL over a period of 22 months using a step-wise PCR-based next-generation sequencing approach. One hundred fifty-four probands harbored an FBN1 mutation (of which 47 fulfilled the 2010 Ghent criteria for MFS) and 53 did not (of which 9 patients fulfilled the criteria). Of these 53 patients, four harbored biallelic mutations in ADAMTSL4 (c.767_786del; c.2237G>A, c.2021_2022delCT, c.2977C>T, c.963dup). One proband had a homozygous LTBP2 mutation (c.4964A>G; p.Tyr1655Cys). In another proband only one heterozygous LTBP2 mutation (c.3850C>T, p.Arg1284Cys) was found.
FBN1 is the primary gene to screen in EL (mutation detection rate 75%) but if negative should be followed to include ADAMTSL4 and LTBP2 as this reveals a final diagnosis for 11% of the remaining patients (and even up to 15% if the MFS criteria are not met). Our prospective data further indicate that a FBN1 mutation is found in 92.2% of all patients fulfilling the 2010 Ghent criteria for MFS.

PS02.19

Clinical utility of targeted Nextgen sequencing and array CGH panels along with mitochondrial genome analysis for inherited eye diseases

S. P. Shankar[1,2], *J. Yan*[1], *Z. Whitt*[1], *B. Bunke*[1], *C. d. Silva*[1], *S. Richards*[1], *M. Hegde*[1], *J. J. Alexander*[1];
[1]*Emory University School of Medicine, Atlanta, GA, United States,* [2]*Department of Ophthalmology, Emory University School of Medicine, Atlanta, GA, United States.*

Introduction: Next generation sequencing (NGS) panels are increasingly used in molecular diagnosis of genetically heterogeneous eye diseases. We report the yield of these tests in a clinical setting.
Materials and methods: We custom designed a comprehensive panel that included NGS and array comparative genome hybridization (aCGH) for 208 nuclear genes and mitochondrial genome sequencing. We also offered targeted nextgen panels for specific conditions such as retinitis pigmentosa. 222 individuals with eye diseases were tested using comprehensive or targeted nextgen sequencing, mitochondrial genome testing and/or array CGH panels.
Results: We found pathogenic variants in 71/222 (32%) individuals. Of these positive results, 59 were identified by comprehensive or targeted nextgen panels alone, 12 individuals had pathogenic copy number variants identified on aCGH, of which 6 were for dominant conditions and 6 for a second recessive change. In 10 of these individuals, one definitive pathogenic variant was identified, the second was a variant of unknown significance. Another 14 individuals had variants that need additional analysis to determine significance. No pathogenic mitochondrial variants related to eye disorders were found in 99 individuals that had testing. .
Conclusions: Nextgen sequence analysis alone identified ~27% conclusive pathogenic molecular finding and when complemented with aCGH identified an additional 7-8% contributory disease-causing variation but none from the mitochondrial genome sequence analysis. Therefore, complete mitochondrial genome sequencing should be reserved only for individuals with suspected syndromic mitochondrial disorder. The most efficient and cost effective testing is a clinical phenotype driven targeted Nextgen sequencing panel with reflex to aCGH in those that have negative sequencing results.

PS02.21

Genetic and molecular analysis of the GJB2 gene in Moroccan population with non syndromic hearing loss

l. bouguenouch[1], *m. abbassi*[1], *H. Sayel*[1], *k. belhassan*[1], *M. ridal*[2], *M. Alami*[2], *k. ouldim*[1];
[1]*Unit of medical genetics and oncogenetics, CHU Fes, fes, Morocco,* [2]*ORL department University Hospital Hassan II Fes, fes, Morocco.*

Non syndromic sensorineural hearing impairment is inherited in a predominantly autosomal recessive manner in up to 70% of cases. The gene more often involved is GJB2, encoding the gap junction protein Connexin 26. To date, no clinical characterization of the *D F N B 1* inner-ear defects has been reported in our population, which precludes the provision of prognostic information and genetic counseling.
The aim of our study was to determine the prevalence and spectrum of GJB2 mutations, in Moroccan patients and estimate the carrier frequency of the 35delG mutation in the general population.
Genomic DNA was isolated from 60 families/unrelated patients with recessive or sporadic deafness. Molecular studies were performed using PCR and direct sequencing to screen for GJB2 mutations.
Of the 34 cases of family deafness, 9 patients had the 35delG homozygous mutation with a frequency of 26.47%. In sporadic cases the frequency was 15,4 %. We also identified two other mutations: G200R and G59R.
Our data suggest that *GJB2* mutations are the leading cause of moderate-to-profound congenital inherited deafness in Moroccan population. The absence of genetic alterations in the other cases (78.34%) clearly suggests the involvement of other genes that require further genetic analysis.

PM02.22

Multi-Trait Genome-wide Association Studies (GWAS) to investigate hearing function and interactions with BMI and blood pressure

D. Vuckovic[1], *M. P. Concas*[2], *M. La Bianca*[3], *M. Pirastu*[2], *P. Gasparini*[4], *G. Girotto*[1];
[1]*DMS - University of Trieste, Trieste, Italy,* [2]*Institute of Population Genetics, National Research Council of Italy, Sassari, Italy,* [3]*Medical Genetics - IRCCS Burlo Garofolo, Trieste, Italy,* [4]*DMS - University of Trieste/IRCCS Burlo Garofolo, Trieste, Italy.*

The genetic bases of complex traits such as Normal Hearing Function (NHF) and Age-Related Hearing Loss (ARHL) are largely unknown. Multivariate GWAS is a new and powerful tool for detecting candidate genes. Here, it was applied to simultaneously analyse hearing thresholds and also combine them with Body Mass Index (BMI) and Blood Pressure (BP), as potentially interacting traits.
A meta-analysis of 2059 subjects from isolated cohorts of Italy and Central Asia were analysed by multivariate linear mixed model regression (Zhou&Stephens 2014) and results were combined, based on inverse-variance weights (R-package MultiMeta). After adjusting for sex, age and relatedness, the following traits were tested: (a) 4 HT (0.5, 2, 4, 8 kHz); (b) HT and BMI and (c) HT and BP.
Preliminary results for HT (a) identified the following top SNPs: rs181948008 (p=4e-09) within *CYP4B1* gene, rs1523730 (p=3.04E-07) close to *CNTNAP2* a gene located within the deafness locus DFNB13 and rs72984055 (p=2.27E-07) within *MMP20* (other metalloproteinases were already involved in hearing loss). In order to investigate previous epidemiological data in which higher BMI was associated with poorer hearing (Curhan et al. 2013), a genome-wide analysis (b) was performed revealing suggestive association with rs62418085 (p=2.47E-07) located within *PRIM2*, a gene already associated with fatty acid levels. Up-to-date results will be presented and discussed.
In conclusion, the multivariate approach can give significant boost in statistical power for correlated traits and allows investigating genetic bases for different related traits.

PS02.23

New mutation found within OTOR gene involved in deafness in two Sudanese families from Al-Jazirah state- Sudan: using Next Generation Sequencing (NGS)

S. M. O. Sarour[1], *A. M. Zayed*[2], *M. O. M. Ibrahim*[1], *D. E. M. Albadry*[3], *M. M. Hassan*[4,5], *O. E. Yousif*[6], *M. A. Salih*[7,8];

The next generation sequencing technology (NGS) is one of most promising and cost effective alternative for whole genome exome sequencing, which was used to identify unknown mutations among hearing loss patients. New and possibly pathogenic mutations were screened using NGS (target genes sequencing) for hearing impairment panel including more than 80 genes. Knowing the fact of high rates of false positive pathogen predictions of

found SNPs, different prediction models were combined to enhance prediction power. Two female patients within two Sudanese families from Al-Jazirah state, displayed hearing loss, and Non-synonymous variant were detected and the SNP caused an amino acid substitution in the protein encoded by gene OTOR (OMIM #606067). Then, bioinformatics tools were used to support the significance of this mutation, and also confirmed the genotype-phenotype co-segregation in family members, in addition searched for the SNP that cause mutation within a control exons target SNPs (not founded). The involvement of OTOR in hereditary hearing impairment has not been observed in the Sudanese population so far.

Gene panel testing in non-syndromic hearing loss: validation on a British Asian cohort

*S. Boardman[1], **L. A. Mavrogiannis**[1], L. Crinnion[2], C. M. Watson[2], R. S. Charlton[1];*
[1]Leeds Genetics Laboratory, Leeds, United Kingdom, [2]Translational Genomics, Leeds, United Kingdom.

DFNB1, effectively the connexin 26 gene *GJB2,* is the leading genetic cause of non-syndromic hearing loss and testing is integrated in mainstream clinical pathways. However, the list of deafness genes is long - and still expanding - while the *DFNB1* detection rate in most diagnostic streams is in the range of 10%-20%; it can be as low as 5% in British Asians. We explored the possibility of gene panel testing using a custom-designed HaloPlex targeted genomic capture kit (Agilent Technologies) to obtain the coding regions of the majority of non-syndromic deafness genes: 67 genes were included, amounting to 270 kb, with design coverage of over 97%. For validation we sequenced 59 anonymised samples of local British Asian children with suspected genetic hearing loss and no causative *DFNB1* changes through an established pipeline of massively parallel sequencing on Illumina instruments. With structured data filtering and conservative variant evaluation criteria we identified pathogenic or likely pathogenic mutations, verified by Sanger sequencing, in 15 cases within *GIPC3*, *LHFPL5*, *LOXHD1*, *MYO15A*, *MYO3A*, *OTOF*, *PCDH15*, *STRC*, and *TMIE*. Actual average aggregate coverage exceeded 90% at a depth of 30x. The dataset enabled definition of the analytical and clinical scope of the workflow for service consideration, predicting a 6-fold increase in yield compared to *DFNB1* testing, while at the same time sampling the mutation background of non-*DFNB1* deafness in British Asians.

Etiology of hearing loss in a Newborn Screening Program

K. C. Costa[1,2], *T. Pereira[2], M. Pomilio[1], S. M. S. Costa[1], E. L. Sartorato[1];*
[1]Centro de Biologia Molecular e Engenharia Genética da Universidade de Campinas -UNICAMP, Campinas, Brazil, [2]Associaçao Terapeutica de Estimulação Auditiva e de Linguagem, Jundiai, Brazil.

Introduction: The Newborn Hearing Screening Program (NHSP) is a way to promote early diagnosis of hearing impairment[1]. Concomitantly with early diagnosis and intervention, it is important to search for the primary cause. In developed countries about 50% of the causes of isolated deafness have a genetic origin. In Brazil most of cases are due to environmental factors, such as congenital infections, perinatal asphyxia, kernicterus and meningitis[2].
Objective: To investigate the causes of hearing loss diagnosed at NHSP.
Method: Retrospective study of records of 21 deaf diagnosed from August 2003 to July 2014. Results of laboratory tests, imaging and genetic testing were analyzed.
Results: Twenty four children had a sensorineural hearing impairment, 20 were bilateral. Eight cases of newborns remained in Newborn Intensive Unit. One case showed craniofacial anomalies and 2 patients had inner ear malformations. In 3 newborn the hearing loss was due to perinatal asphyxia. Two newborns had history of infectious disease. Considering the genetic factors, 4 individuals had a history family of deafness; 3 newborns were from consanguineous family, 4 newborns were homozygous for 35delG in the *GJB2* gene, and 2 presented the A827G mutation in the *MTRNR1* gene. Three cases the etiology remains unknown.
Conclusion: The early etiological research hearing impairment contributes to support and assist disabled hearing and their families and also for assistance in public health measures.

Hearing loss is the most common sensory disorders and can affect up to 1/500 newborns. Before NGS platform could be implemented in diagnostic labs, the molecular diagnosis of non syndromic hearing loss (NSHL) was relying solely on the screening for mutations at the DFNB1 locus. Recently, we have developed a panel consisting of 71 genes known to be involved in ARNSHL, ADNSHL and X-linked NSHL. The libraries were generated with Illumina Nextera Rapid Capture Custom Enrichment or Nimblegen SeqCap EZ Choice and run on an Illumina MiSeq platform.
All NSHL patients, referred over the last 10 years and negative for DFNB1 mutations (more than 500) are currently being tested. The strategy applied is as follow: when recessive inheritance is suspected only the patient is tested by NGS; when dominant inheritance is suspected, a minimum of three relatives (the patient, affected and control family members) are tested. In all cases, validation and segregation analyses of the potential pathogenic variants is performed by Sanger sequencing.
Although X-linked HL is considered as rare, we've already identified mutations in the 3 known genes (POU3F4, SMPX and PRPS1) in 3 different families. In addition, mutations in the myosins genes are recurrent, whereas some of the other HL genes are scarcely involved. These results herald major NSHL molecular diagnosis improvements, which will directly benefit patients and families.

PS02.27

Genetically related hearing loss- results of exome sequencing in Polish patients.

A. Pollak[1], *U. Lechowicz[1], A. Podgorska[1], P. Stawinski[1], J. Kosinska[2], M. Oldak[1], H. Skarzynski[3], R. Ploski[2];*

Hearing loss is an extremely heterogenic trait, approximately 50-60% of cases of hearing loss are due to genetic factors. The genes responsible for the occurrence of hearing loss usually encode proteins located in the inner ear. Majority of patients with autosomal, recessive deafness harbour mutations in only one gene- GJB2. Mutations in other genes, which products are directly involved in the hearing process, may also result in hearing loss. To date, approximately 300 genes involved in the processing of auditory information has been described, and still the new one are discovered. Efficient search for variants in the gene structure requires the use of the most modern techniques of molecular biology, such as the next-generation sequencing. Here we present the results of whole exome sequencing (WES) performed on 15 individuals suffered from familiar, prelingual hearing loss. All exome sequencing was performed on HiSeq 1500 using Illumina exome enrichment kits.

Identification of novel genes and mutations associated with hearing loss in the Middle Eastern Arab population by next generation sequencing

N. Danial-Farran[1,2], *Z. Brownstein[1], A. Abu-Rayyan[3], M. Sokolov[1], M. Birkan[1], M. Sagi[4], N. Shomron[5], S. Shalev[2], K. B. Avraham[1];*

Introduction: One in one thousand newborns suffer from congenital hearing loss, making it the most prevalent sensory disorder in humans. To date, hundreds of mutations in more than 80 genes are associated with a hearing disability. Next Generation Sequencing (NGS) has improved the diagnostic

yield dramatically. The Middle Eastern population, comprised of different ethnic groups and known to exhibit high rates of consanguinity, has benefited from NGS. Furthermore, as many mutations first identified in this population have been subsequently found worldwide, this population is instrumental in determining genes crucial for hearing.
Materials and Methods: We applied targeted genomic enrichment along with massively parallel sequencing, encompassing 284 genes that included 121 human genes and 163 human orthologues of mouse deafness genes, on 91 families of Arab descent. One family underwent whole exon sequencing (WES).
Results: This research uncovered novel mutations in 23 known deafness genes. A novel gene, *SLC25A21*, associated with hearing loss was detected by WES. We were able to determine the causative mutation for deafness in 32% of our population.
Conclusions: NGS is an optimal technology for genetic diagnosis of hearing loss. Challenges remain in the search for mutations responsible for deafness: to identify the causative variant, particularly when several variants exist and segregate in the family; to detect structural variations and regulatory elements and to prove their involvement in hearing impairment; and to prove mutations in a novel gene causes hearing loss by relevant functional assays.

PS02.29
The contribution of GJB2 gene mutations to development of early onset hearing loss in affected group of patients in Lithuanian population.

V. Mikstiene[1], *J. Byckova*[2], *E. Gradauskiene*[2], *E. Lesinskas*[2], *A. Utkus*[1];
[1]*Department of Human and Medical Genetics, Faculty of Medicine,Vilnius University, Vilnius, Lithuania,* [2]*Centre of Ear, Nose and Throat Diseases, Vilnius University Hospital Santariškių clinics, Vilnius, Lithuania.*

Congenital hearing loss (CHL) is one of the most common traits diagnosed 1/1000 newborns. Genetic factors contribute to 2/3 of CHL cases in industrialized countries. Mutations of GJB2 gene are a major cause of CHL worldwide.
The aim of the study is to establish the contribution of GJB2 gene mutations to development of early onset HL in affected group of patients in Lithuanian population.
Objectives: to determine the incidence and structure of GJB2 mutations in patients affected with early onset nonsyndromic HL, to analyze audiologic features, genealogies and perform genotype - phenotype analysis.
Methods: Clinical data and GJB2 gene sequencing results were obtained from a retrospective collection of 133 patients (122 unrelated probands) with early onset nonsyndromic HL compiled in VUH Santariškiu clinics 2010-2014. Statistic summary, homogeneity tests, and logistic regression analysis were employed for the assessment of genotype-phenotype correlation.
Results: Our findings show high proportion of GJB2-positive patients (60.1%) in the study group. Most prevalent GJB2 mutations were c.35delG and c.313_326del14 (67.6% and 25.8% of mutated alleles). The statistical analysis revealed significant differences between GJB2-positive and GJB2-negative groups in disease severity (p=0.02), symmetry (p=0.04), and family history (p=0.0035). The probability of identifying GJB2 mutations in patients affected with profound/severe vs moderate/mild HL and positive vs negative family history estimated to be 2.773(95%CI 1.26-6.192;p=0.0116) and 3.235(95%CI 1.478-7.436;p=0.0418) respectively.
Conclusion: The findings of the study quantified the impact of GJB2 mutations to the development of HL and are useful for setting up the principles for the prediction of disease course in Lithuanian population.

Hereditary Hearing Loss (HHL) is an extremely genetically heterogeneous disorder that prompted us to develop a powerful diagnostic algorithm characterized by screening of 113 HHL genes by targeted re-sequencing followed, in negative cases, by whole exome sequencing to detect causative mutation in new genes. Thanks to this strategy we identified PSIP1/LEDGF as a novel gene causing sensorineural progressive HHL restricted to the medium-high frequencies and a variable eye phenotype (i.e. uveitis, optic neuropathy) in an ltalian pedigree. Further clinical examinations of the affected members showed normal amplitude of the ABR indicating no involvement of the auditory nerve while VEP indicated some differences in terms of visual acuity and optic nerve functionality.
A frameshift deletion leading to a premature stop codon (c.1554_1555del, p.E518Dfs*2, p.T519X) with truncation of the last 12 amino acids and segregating with the disease was detected. Our additional studies using different methodological approaches (i.e. cDNA analysis, RNA Seq, immunolabeling, etc.) demonstrate that: 1) this deletion does not lead to mRNA degradation 2) Psip1 is expressed in the nuclei of all hair cells and supporting cells of both mouse cochlea and vestibular system with the exclusion of the auditory nerve.
Recently, PSIP1 was described as a transcriptional co-activator regulated by miR-135b in cells of the mouse inner ear and as a possible protector against photoreceptor degeneration. Present findings strongly suggest an important role of PSIP1 in HHL as well as in eye defect and further highlight the reliability of our strategy to study the genetic basis of HHL

PS02.31
A Next Generation Sequencing amplicon-based strategy to explore Inherited Retinal Degeneration complexity

V. Artusi[1], *L. Chiesi*[2], **I. Bernardis**[1], *E. Tenedini*[1], *L. Artuso*[1], *G. M. Cavallini*[2], *A. Percesepe*[3], *V. Marigo*[4], *E. Tagliafico*[1];

Inherited Retinal Degeneration (IRD) are a group of eye disorders, characterized by photoreceptors degeneration which include: Retinitis Pigmentosa, Stargardt disease, Usher Syndrome and Leber congenital amaurosis. The high genetic heterogeneity, the incompleteness of disease specific databases and the elevated number of genes involved in IRD, often hamper the correct molecular diagnosis and patients stratification.
To clarify IRD molecular profile, we used a next Generation Sequencing (NGS) strategy and designed a custom AmpliSeq panel (Life Technologies), containing the coding sequences of 72 disease related genes, for a total of 1649 amplicons.
An in-house bioinformatic pipeline was optimized to filter synonymous variants and polymorphism and to annotate variants with prediction algorithm (dbNSFP) and disease specific databases (LOVD eye diseases, Retina International, RPGR database).
A cohort of 40 samples was selected (29 patients, 11 healthy relatives). They underwent a complete ophthalmologic examination (visual acuity, anterior segment and fundus examination, ERG and/or EOG, OCT), as well as a genetic counselling.
Possibly causative mutations were detected in 62% patients (n=18). We found mutations in 8 genes. The most recurrent gene was mutated in 38% (n=7) of patients. The remaining seven genes harboured lower frequencies with just one or two patients mutated. Overall, seven genes were inherited with an autosomal recessive pattern and one gene was X-linked.
Of note, less than 21% of variants have been already described in specific databases. These preliminary results highlight the need to further explore the molecular complexity and heterogeneity of RD in order to translate these analyses into clinical practice.

ZNF469 has been associated with Brittle cornea syndrome and central corneal thickness. The latest study also revealed that rare heterozygous mutations in *ZNF469* determine keratoconus (KTCN) susceptibility etiology. KTCN is a degenerative disorder of the eye characterized by stromal thinning and protrusion of the cornea, resulting in severe impairment of visual function. To investigate the contribution of *ZNF469* to KTCN, we Sanger sequenced *ZNF469* in 42 Polish KTCN patients and 49 Polish individuals with high myopia (HM) as a control group. The average number of *ZNF469* variants per individual was 40.59520 and 40.26531 for KTCN and HM, respectively (Wilcoxon Rank Sum test, p = 0.3601). Moreover, the average number of nonsynonymous variants was 16.30952 and 16.0 for KTCN and HM, respectively (Wilcoxon Rank Sum test, p = 0.3724). All identified variants were previously reported. Minor allele frequency (MAF) was determined based on the whole exome sequencing results from 268 Polish patients without ocular abnormalities. Among missense variants, only one (rs528085780) has MAF ≤ 0.01 and has been identified in one patient with sporadic KTCN. However, the resulting Arg1864Lys substitution was not predicted to be deleterious based on different prediction algorithms and conservation scores. Summarizing, we have not found a significant enrichment of pathogenic variants in *ZNF469* in KTCN patients. High prevalence of *ZNF469* variants identified in our KTCN group is typical for a common genetic variation observed in general population. Genetic factors different than variation in *ZNF469* are responsible for KTCN development.

PS02.33

Multiplex detection of mitochondrial variants by MALDI-TOF MS in Brazilian patients with hereditary optic neuropathy

E. L. Sartorato, *P. do Amor Divino Miranda, M. Amaral-Fernandes, A. Marcondes, A. T. Maciel-Guerra, R. M. Alves, S. M. Silva-Costa;*
Universidade Estadual de Campinas, Campinas - SP, Brazil.

Leber's hereditary optic neuropathy (LHON) is a mitochondrial disease characterized by bilateral loss of vision. Over 95% of LHON cases are associated with one of three main mitochondrial DNA (mtDNA) mutations, G11778A, T14484C, and G3460A. Other mutations appear in 5% of cases. The objectives of this study were: to determine the frequency of LHON mutations, to identify mitochondrial haplogroups in Brazilian patients and to evaluate the usefulness of iPLEX Gold/MALDI-TOF MS technology in detecting LHON mutations. We analyzed a total of 101 patients, 67 with LHON clinical diagnosis and 34 with optic neuropathy of unknown etiology. The techniques used were PCR-RFLP, direct sequencing and iPLEX Gold/MALDI-TOF MS. The frequency of the LHON mutations observed was 83% for G11778A and 17% for T14484C. Our findings contributed to confirm the LHON clinical diagnosis of 36 patients (36%) and allowed to clarify the diagnosis of 12 patients (35%) with optic neuropathy of unknown etiology. The most frequent haplogroups were of African origin: L1/L2 and L3. The frequency of the LHON mutations and haplogroups found in the study are relatively different from other published data in other parts of the world. Furthermore, the iPLEX Gold/ MALDI-TOF MS technology platform proved to be a very accurate and efficient method to screening of the mutations and identification of the haplogroups related to LHON. The platform combined with other techniques was important to elucidate approximately 35% of the cases studied.

PM02.34

Two cases of duplication 6p25.3, expanding the phenotype of FOXC1 duplication syndrome

P. VANDE PERRE, *A. Vigouroux, L. Bouneau, D. Dupin-Deguine, D. Bourgeois, P. Calvas;*
Service de Génétique Médicale, Hôpital Purpan-CHU de Toulouse, TOULOUSE, France.

Loss of function due to mutations in the *FOXC1* gene are known causes of dysgenesis of the anterior segment of the eye. Very few is currently known about duplications involving the whole *FOXC1* gene. Only two families have been previously described in which FOXC1 duplication is associated with iris hypoplasia (MIM 308500). No further phenotypic features being reported (*Nishimura, 2001*). This Copy Number Variant (CNV) is very rarely reported in the major databases as only two cases are noted in Decipher with only one phenotype available.

We report two additional unrelated cases with complete *FOXC1* duplication found by array CGH. The first patient displays a 4Mb duplication of the region 6p25.3, and a 7Mb deletion in the region 12p13.33p13.31. She presented with dysgenesis of the anterior segment of the eye and a keratoconus, intrauterine and post natal growth retardation, atrial septal defect, developmental delay, dysmorphic features and inner ear malformation.

The second patient displays an isolated duplication of the region 6p25.2p25.3 spanning 1,195 Mb. She had a congenital strabismus, unilateral ptosis with amblyopia, bilateral neurosensory deafness, developmental delay, behavioral disturbances, and dysmorphic features.

Both patients displayed overlapping phenotypic features with the ones previously described.

Further investigations are needed to determine the frequency of such characteristics and their consistency in *FOXC1* duplication syndrome. This duplication appears to be linked to developmental abnormalities as well as a loss of function mutations. This suggests that the normal development of at least the eye requires no more than two copies of the *FOXC1gene*.

PS02.35

Identification of a new case of colobomatous microphthalmia with recessive null mutations in TNEM3 by targeted gene analysis

O. Patat[1], *N. Ragge*[2], *D. Geneviève*[3], *J. Kaplan*[4], *P. Calvas*[1], *N. Chassaing*[1];
[1]*CHU Toulouse, Toulouse, France,* [2]*Le Gros Clark Building - University of Oxford, Oxford, United Kingdom,* [3]*CHU Montpellier, Montpellier, France,* [4]*Hôpital Necker-Enfants Malades, Paris, France.*

Microphthalmia and anophthalmia are the most severe malformations of the eye. Analysis of the genes currently associated to microphthalmia or anophthalmia leads to the identification of a pathogenic mutation in only 25% of cases. By combination of autozygome and exome analysis, a homozygous loss of function mutation in the TNEM3 gene (previously named ODZ3) was reported in two sibs with isolated bilateral colobomatous microphthalmia from a consanguineous Saudi family (Aldahmesh MA et al., Genet Med 2012). ODZ3 is strongly expressed in the optic stalk in vertebrates. Mice partially knocked down for the gene ODZ3 (lacking only the transmembrane domain) have morphologically normal eyes but impaired binocular vision. A new generation sequencing approach targeted on a panel of 180 genes definitely or possibly implicated in microphthalmia or anophthalmia was performed on a cohort of 96 patients, and identified a third patient harboring a TENM3 homozygous null mutation (c.2968-2A>T). This patient had bilateral colobomatous microphthalmia, with anterior chamber malformation and chorioretinal coloboma, associated with mild intellectual disability. The identified mutation (c.2968-2A>T) affects a consensus acceptor splice site. This result supports the role of TNEM3 in human microphthalmia. The three patients described to date with homozygous TENM3 loss of function mutations present with a similar phenotype of bilateral colobomatous microphthalmia.

PM02.36

Whole exome sequence analysis of 106 families with microphthalmia, anophthalmia and/or coloboma (MAC)

K. A. Williamson[1], *M. Ansari*[1], *H. Bengani*[1], *A. Seawright*[1], *U. Project*[2], *V. van Heyningen*[1], *D. R. FitzPatrick*[1];
[1]*MRC Human Genetics Unit, MRC Institute of Genetics and Molecular Medicine at the University of Edinburgh, Edinburgh, United Kingdom,* [2]*Wellcome Trust Sanger Institute, Cambridge, United Kingdom.*

Whole exome sequencing (WES) was performed on 106 MAC families that comprised two extended pedigrees, 22 trios, 12 affected-relative pairs, and 70 singletons. Samples were pre-screened for mutations in *SOX2*, *OTX2* and *PAX6* (paired domain): the major genes in severe bilateral MAC.

Sample preparation was performed in-house or at the Wellcome Trust Sanger Institute as part of the UK10K project, which generated 75 of the exomes. Sequence alignment/variant filtering were performed as previously described (PMID24462371). Targeted resequencing of more than 400 unrelated MAC cases was performed to identify additional/recurrent alleles of the exome-indicated genes.

Pathogenically significant variants are identified and validated in 22 genes to date, including the confirmed eye genes listed. Analyses to identify *de novo* mutations indicate genes newly associated with developmental eye defects.

Gene	Pathogenic genotypes: exome	Pathogenic genotypes: resequencing
FOXE3	1 AR singleton	-
STRA6	1 AR singleton	-
ALDH1A3	4 AR singletons	3 cases
RARB	1 AD singleton	4 AD cases
MAB21L2	1 affected-relative pair	3 cases
YAP1	2 cases	-
ADAMTS18	1 AR singleton	-
FZD5	1 extended pedigree	-
BMP7	2 cases	-
ACTG1	2 cases	-
GJA8	1 singleton	3 cases
SOX2	1 singleton (CNV)	-

The cohort size has facilitated the identification of variants in genes with a known or novel association with MAC. Mutations in confirmed eye genes account for 17% of WES MAC cases.

PS02.37
Isolated microphthalmia with coloboma of optic nerve mapped to a locus on chromosome 2.

R. Proskorovski[1], *Y. Perez*[1], *L. Gradstein*[2], *O. Birk*[1];
[1]*The Morris Kahn Laboratory of Human Genetics and the Genetics Institute, Soroka Medical Center, Ben-Gurion University, Beer Sheva, Israel,* [2]*Department of Ophthalmology, Soroka Medical Center and Clalit Health Services, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel.*

Large kindred of the Jewish Iranian inbred Mashhad community presented with an apparently autosomal recessive phenotype of severe microphthalmia and coloboma of optic nerve. Homozygosity mapping using Affymetrix 250K SNP arrays identified a single ~2.5Mb disease-associated locus on chromosome 2 between rs4672834 and rs517656411. Multipoint LOD score was calculated and yielded a score of 3.2 at D2S433. Interestingly, ABCB6 (MIM# 614497), encoding an ATP-binding cassette and known to be associated with autosomal dominant microphthalmia, lies within the defined locus. However, Sanger sequencing of ABCB6 and its promotor revealed no mutations. Whole exome sequencing was performed and data analysis is being processed.

PS02.39
Interplay between SOX10 and p54NRB:molecular and cellular consequences in the context of Waardenburg syndrome and related disorders

A. Kavo, *A. Chaoui, V. Baral, Y. Watanabe, L. Lecerf, V. Pingault, N. Bondurand; IMRB, INSERM U955, Team 6, Creteil, France.*

SOX10 is a transcription factor (TF) with a crucial role in Neural Crest (NC) development. Mutations within this member of the SOX family were first associated with Waardenburg-Hirschsprung disease (WS4, deafness, pigmentation defects and intestinal aganglionosis). Variable phenotypes that extend beyond the initial limits of this syndrome and incomplete penetrance of each feature are now reported. In addition to WS4 or WS2 (Waardenburg syndrome without Hirschsprung disease), some patients present with central and/or peripheral myelination defects. While an escape from the NMD pathway was proposed to explain the severe phenotypes in case of truncating mutations, no mechanism has been anticipated for missense mutations so far. In vitro studies confirmed deleterious effects of the latter on the main SOX10 functions, while about half of the resulting proteins are redistributed in nuclear bodies (foci) of undetermined nature and function.
Here, we report that p54NRB (NONO) interacts with SOX10 and acts in synergy with it to activate the expression of several target genes during NC development. Interestingly, p54NRB co-localizes with all foci forming SOX10 mutants . However, siRNA experiments indicated that p54NRB is not essential for their formation. Two other members of the DBHS protein family also co-localise with SOX10 mutants, raising the possible paraspeckles nature of the foci or the re-localisation of the DBHS members in other sub-nuclear compartments. Of note, WT SOX10 protein is also sequestrated in foci, leading to altered synergistic activity between this TF and p54NRB. We speculate that the dominant negative effect we observe could contribute or be at the origin of the neurological phenotypes observed in patients.

PM02.40
Next-generation sequencing of the ABCA4 gene reveals a high frequency of complex alleles and novel mutations in Polish patients with retinal dystrophies

A. Ścieżyńska[1], *D. Oziębło*[2], *A. Ambroziak*[3], *M. Korwin*[3], *K. Szulborski*[3], *M. Krawczyński*[4], *P. Stawiński*[2], *J. P. Szaflik*[3], *R. Płoski*[5], **M. Oldak**[2,1];
[1]*Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland,* [2]*Department of Genetics, World Hearing Center, Institute of Physiology and Pathology of Hearing, Warsaw, Poland, Warsaw, Poland,* [3]*Department of Ophthalmology, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland,* [4]*Department of Medical Genetics, University of Medical Sciences, Poznan, Warsaw, Poland,* [5]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland.*

Variation in the ABCA4 locus has emerged as the most prevalent cause of monogenic retinal diseases. Using next-generation sequencing targeting ABCA4, the first such approach in Polish patients with Stargardt disease (STGD, n=76) and cone-rod dystrophy (CRD, n=16), together with a Polish population exome data (n=594), we disprove the pathogenic status of p.V552I and provide more evidence against a causal role of six further ABCA4 variants as drivers of the phenotype under a recessive paradigm. Our study identifies 12 novel potentially pathogenic mutations (four of them recurrent) and a novel complex allele p.[(R152*; V2050L)]. In one third (31/92) of our cohort we detected the p.[(L541P; A1038V)] complex allele, representing an unusually high level of genetic homogeneity for ABCA4-related diseases. A combination of p.[(L541P; A1038V)] and/or a truncating change always resulted in an early disease onset. The comprehensive, population-specific study expands our knowledge on the genetic landscape of retinal diseases.
This work was supported by the Polish National Science Center grant no. N N402 591640 (5915/B/P01/2011/40) and the Medical University of Warsaw grant no. 1M15/PM11D/14.

PS02.41
Identification of four novel NHS protein-truncating mutations in families with X-linked cataract (CXN) and Nance-Horan syndrome (NHS) reflects the variable expressivity of the disease

S. Cheong[1], *P. Liskova*[2], *V. Plagnol*[3], *I. Russell-Eggitt*[4], *A. J. Hardcastle*[1];
[1]*Institute of Ophthalmology (UCL), London, United Kingdom,* [2]*Institute of Inherited Metabolic Diseases and First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic,* [3]*Genetics Institute, University College London, London, United Kingdom,* [4]*Great Ormond Street Hospital for Children, London, United Kingdom.*

Nance-Horan Syndrome (NHS) and X-linked cataract (CXN) have previously been reported to be allelic disorders, caused by NHS protein truncation and aberrant *NHS* transcription, respectively. In this study, five families diagnosed with NHS and one CXN family were recruited. All coding exons and splice sites of the *NHS* gene were PCR amplified and Sanger sequenced. Whole exome sequencing (WES) was performed for *NHS*-mutation negative patients. The WES dataset was filtered for rare variants (minor allele frequency ≤0.01) in congenital cataract genes, with reference to Cat-Map and GenomeTrax. Direct sequencing of *NHS* coding exons revealed mutations in 4 families; two novel frameshift mutations, p.(Val1187fs*1187) and p.(Leu256fs*284), and a segmental deletion of Xp22.13 encompassing *NHS*. Although the segmental deletion also disrupted four neighbouring genes *SCML1*, *SCML2*, *BEND2* and *RAI2*, this family did not present a clinically distinct phenotype, compared to families with disruption of *NHS* alone. Interestingly, a nonsense mutation, p.(Q175*), was identified in a CXN family lacking any of the extra-ocular phenotypes observed in NHS patients. WES analysis of *NHS*-negative patients did not reveal any variants in a common candidate gene. Further investigation of the WES data is required, although a mutation in a non-coding region or copy number variation of the *NHS* gene cannot be fully excluded. This study suggests the possible genetic heterogeneity of an NHS-like cataract-dental syndrome. Variable disease expression observed in the CXN family with an *NHS* stop mutation demonstrates that the phenotype-genotype correlation may not be as constricted as originally suggested.

PM02.42
Towards the genetic homogeneity of neonatal severe pseudocoloboma of the central retina with early-onset optic atrophy (LCA9).

I. Perrault[1], *O. Xerri*[1], *X. Gérard*[1], *O. Roche*[1,2], *J. Kaplan*[1], *J. Rozet*[1];
[1]*INSERMU1163, Institut IMAGINE, Paris Descartes University, Paris, France,* [2]*Department of Ophthalmology, Necker Hospital., Paris, France.*

Introduction: NMNAT1 encodes a homohexameric NAD- synthesizing enzyme as well as a chaperone that protects against neuronal activity-induced degeneration. NMNAT1 mutations cause a highly specific Leber congenital amaurosis phenotype characterized by severe neonatal neurodegeneration of the central retina with early-onset optic atrophy. The purpose of this study was to search for copy number variations (CNV) and mutations affecting 5' regulatory elements or splicing of the gene in 22 single heterozygote index cases with the NMNAT1 phenotype.
Results: Three unique CNVs, i.e. a 1-exon duplication, a 1-exon deletion and a two exon-deletion were identified in 3/22 patients. In addition, 5 distinct variants lying in the 5'UTR of the gene were identified in 10/22 individuals. 1/5 UTR variant was shared by 6/10 individuals originating from the French Indian Ocean Island, La Réunion. This variant was undetectable in all available patient cDNAs (3/6), supporting down regulation or instability of the mutant mRNA. mRNA from 2/10 other individuals harboring other UTR variants were available which analysis was consistent with similar mRNA defects.
Conclusion: Here, we report that at least 13/22 LCA individuals with single heterozygote NMNAT1 mutations carried a second disease allele undetected by Sanger sequencing of the NMNAT1 exome. This result suggests that severe neonatal neurodegeneration of the central retina with early-onset optic atrophy is pathognomonic of NMNAT1 mutations. In-depth molecular ana-

lysis of the gene and surrounding regulatory elements should be considered in all patients harboring this highly specific LCA phenotype.

PS02.43
Cone structure and function investigation in family with an RP1L1 mutation

M. Bertelli[1], *L. Ziccardi*[2], *A. Nicoletti*[1], *P. E. Maltese*[1], *M. Lombardo*[2];
[1]*Magi's Lab Human Medical Genetics Institute, Rovereto (TN), Italy,* [2]*Fondazione G.B. Bietti IRCCS, Rome, Italy.*

Screening by next generation sequencing for retinal dystrophies in a 23 year-old female with intense photophobia and progressive bilateral visual loss, identified a RP1L1 gene mutation: p.Arg45Trp. The same genetic variant was found in three family members. To examine cone structure and function in all family members, we obtained high-resolution retinal images of the cone mosaic with a flood-illumination adaptive optics (AO) retinal camera, over 2 years. Best corrected visual acuity (BCVA), contrast sensitivity function (CSF), combined SLO and SD-OCT imaging, MP1 microperimetry and multifocal electroretinography (mfERG) were also performed.
The complementary use of objective tools for analysis of *en face* and *cross-section* high-resolution views of the photoreceptor layer confirmed an asymptomatic phenotype in two family members and detected a mild phenotype in the proband's father. Our findings led to diagnosis of occult macular dystrophy (OMD) in this family.
RP1L1 gene mutations associated with OMD and the p.Arg45Trp variant have been reported in ethnically diverse families with different occult macular dystrophy segregation patterns. Using new high-resolution adaptive optical imaging, we detected a heterogeneous phenotype with different central cone morpho-functional abnormalities across family members harboring the p.Arg45Trp variant. The different phenotypes in this family may be ascribed to incomplete penetrance of the RP1L1 gene variant. Although we found only this variant analysing 61 genes, we cannot exclude that mutations in other genes might contribute to the phenotype.

PM02.44
Functional characterization of two novel splicing mutations in the SLC45A2 gene associated with Oculocutaneous Albinism Type IV

L. Straniero[1], *V. Rimoldi*[1], *G. Soldà*[1], *L. Mauri*[2], *E. Manfredini*[2], *E. Andreucci*[3], *S. Bargiacchi*[4], *S. Penco*[2], *G. P. Gesu*[2], *A. Del Longo*[5], *E. Piozzi*[5], *R. Asselta*[1], **P. Primignani**[2];
[1]*Humanitas University - Humanitas Clinical and Research Center, Rozzano (Milan), Italy,* [2]*Medical Genetics Unit – Department of Laboratory Medicine, Niguarda Ca' Granda Hospital, Milan, Italy,* [3]*Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy,* [4]*Medical Genetics Unit, Department of Clinical and Experimental Biomedical Sciences ,Mario Serio', University of Florence, Florence, Italy,* [5]*Pediatric Ophthalmolgy Department, Niguarda Ca' Granda Hospital, Milan, Italy.*

Oculocutaneous albinism (OCA) is characterized by hypopigmentation of the skin, hair and eye, and by ophthalmologic abnormalities caused by a deficiency in melanin biosynthesis. OCA is an autosomal recessive inherited condition and four principal forms (OCA1-4) are recognized based on the presence of mutations in *TYR*, *OCA2*, *TYRP1* and *SLC45A2* genes respectively.
In this study, we investigate the molecular basis of OCA4 in one Italian albino patient. Sequencing analysis of the *SLC45A2* gene identified two hitherto-unknown putative splicing mutations. The first one lies in the consensus sequence of the donor splice site of *SLC45A2* intron 5 in compound heterozygosity with a synonymous transition involving the last nucleotide of exon 3. *In-silico* prediction of the effect of both mutations on splicing shows a score reduction for the mutant splice sites and indicate the possible activation of newly-created splice sites. The effect on splicing of these two novel mutations is going to be investigate using an *in-vitro* hybrid-minigene approach to lead to the demonstration of their causative role and to the identification of aberrant transcript variants. Although the in-vitro characterization of splicing mutations may not completely represent the splicing events that really occur in vivo, it certainly provides a strong support to the pathogenic role of the identified variants.

PS02.45
OPA1 testing in optic atrophy: a 5-year service summary

L. A. Mavrogiannis, **D. J. Cockburn**, *R. S. Charlton;*
Leeds Genetics Laboratory, Leeds, United Kingdom.

OPA1, a nuclear gene encoding a mitochondrial dynamin-related GTPase, is the major cause of autosomal dominant optic neuropathy, manifesting in a spectrum ranging from isolated optic atrophy to complex multi-system neurological disease. We have been providing comprehensive clinical testing for *OPA1* in the UK and internationally since 2009, using a combination of amplicon-based massively parallel sequencing, Sanger sequencing, and MLPA dosage analysis. Full screens have been performed on 290 apparently unrelated consecutive cases/families, with requests originating from Clinical Genetics, Ophthalmology, Neurology, and specialist tertiary centres. Pathogenic or likely pathogenic outcomes were seen in 66 cases/families - a working detection rate of 23%, which may indicate more relaxed clinical filtering and/or increased affordability of testing recently, nevertheless remaining relatively high. Local testing for familial mutations was carried out in 40 individuals. All 84 sequence and structural changes encountered, including 42 novel ones, have been recorded and evaluated systematically, comprising a curated set for data filtering and scoring. Apart from established polymorphisms, they have also been deposited in relevant clinical databases, adding to the publically available mutation/variation spectrum of *OPA1*.

PM02.46
The hearing phenotype associated with an in-frame deletion in FOXL1 causing autosomal dominant otosclerosis

S. Stanton[1], *M. Lucas*[1], *A. Griffin*[2], *N. Abdelfatah*[2], *S. Agrawal*[1], *L. Parnes*[1], *A. Batten*[2], *K. Hodgkinson*[2], *T. Young*[2];
[1]*Western University, London, ON, Canada,* [2]*Memorial University, St. John's, NL, Canada.*

Introduction: Clinical otosclerosis, a bone remodeling disease of the human temporal bone, involves hearing loss, usually with a conductive impairment associated with fixation of the stapes. Other regions of the otic capsule may also be involved, with variable clinical presentation and progression.
Materials & Method: Subjects were a multiplex AD family from the island of Newfoundland identified with a 15 bp in-frame deletion in the FOXL1 gene, and an Ontario proband identified with the same mutation from a cohort of 32 Ontario cases with surgically confirmed otosclerosis. Phenotype data included retrospective data acquisition from clinical charts (Newfoundland and Ontario) and prospective measures (Ontario) including behavioural audiometry, middle ear analyses (immitance and middle ear muscle acoustic reflexes) and otoacoustic emissions.
Results: Phenotype analyses revealed a bilateral hearing loss in the Newfoundland proband, initially conductive in nature and later progressing to a mixed hearing loss. Newfoundland relatives with surgically confirmed otosclerosis (n=6) also exhibited a bilateral impairment, primarily of the conductive or mixed types; 2 cases did not undergo surgery and were considered non-penetrant. The Ontario proband presented with a profound mixed loss in the right ear, and a mild sensorineural hearing loss in the left ear; acoustic middle ear muscle reflexes were absent despite normal middle ear compliance.
Conclusions: Subjects with the FOXL1 mutation exhibit the hallmark features of clinical otosclerosis. Physiological measures of middle ear function can be used to supplement the behavioural phenotype, and may enable early detection of otosclerotic pathology.

PS02.47
PRDM12 is an epigentic regulator and a cause of congenital insensitivity to pain

c. G. woods, *A. Chen, m. nahorski, f. stafford;*
cambridge institute of medical genetics, cambridge, United Kingdom.

We report a new Mendelian disorder causing painlessness and an inability to sense temperature. Presentation is with temperature instability, self mutilations and frequent accidents and corneal trauma. The condition has similarities to HSAN4 and HSAN5 with the following important differences: there is a loss of small myelinated, not small unmyelinated, nerves; itch is not a feature; and mental retardation is rare. We found bi-allelic mutations in the histone methyletransferase PRDM12. We will describe the phenotype and genotype of this new condition, and how to distinguish it from similar disorders. As we have found that PRDM12 is expressed in post-natal nociceptors it si likely to be a new analgesic target.

PM02.48
Expanding the genotypic spectrum in Perrault syndrome

L. A. M. Demain[1], *J. E. Urquhart*[1], *J. O'Sullivan*[1], *S. G. Williams*[1], *S. S. Bhaskar*[1], *E. Jenkinson*[1], *C. M. Lourenco*[2], *A. Heiberg*[3], *S. H. Pearce*[4,5], *K. J. Munro*[6,7], *R. O' Keefe*[8], *W. G. Newman*[1];
[1]*Manchester Centre for Genomic Medicine, Institute of Human Development, University of Manchester, Manchester, United Kingdom,* [2]*Clinics Hospital of Ribeirao Preto, University of São Paulo, São Paulo, Brazil,* [3]*Section for Clinical Genetics, Department of Medical Genetics, Oslo University Hospital, National hospital, Oslo, Norway,* [4]*Institute of Genetic Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom,* [5]*Endocrine Department, Newcastle upon Tyne Hospitals, Newcastle upon Tyne, United Kingdom,* [6]*School of Psychological Sciences, University of Manchester, Manchester, United Kingdom,* [7]*Central Manchester University Hospitals NHS Foundation Trust,*

Manchester Academic Health Science Centre, Manchester, United Kingdom, [8]Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.

Perrault syndrome is a rare autosomal recessive disorder characterised by sensorineural hearing loss (SNHL) in both sexes and primary ovarian insufficiency in 46, XX karyotype females. Perrault syndrome is genetically heterogeneous with variants in five genes reported to date, *HSD17B4*, *HARS2*, *LARS2*, *CLPP* and *C10orf2*. Subsequent to the original discovery studies, no further cases of Perrault syndrome due to variants in these genes have been reported. Here we present four families affected by Perrault syndrome with novel and previously reported mutations in *HSD17B4, LARS2* and *C10orf2*. The proband from each family was whole exome sequenced and the mutations confirmed by Sanger sequencing. A female from family P1 was compound heterozygous for a known and novel mutation in *HSD17B4*, c.46G>A, p.(Gly16Ser) and c.244G>T, p.(Val82Phe), respectively. Two families (P2 and P3) had biallelic mutations in *LARS2*. The affected female and male in P2 were homozygous for c.1565C>A, p.(Thr522Asn), previously associated with Perrault syndrome. Family P3 consisted of an affected female and male, who were compound heterozygous for c.1565C>A, p.(Thr522Asn) and c.351G>C, p.(Met117Ile). Affected members of both families showed a low frequency SNHL an unusual audiometric configuration previously described in Perrault syndrome caused by *LARS2* mutations. A further affected female (family P4) with significant neurological disability was compound heterozygous for mutations in *C10orf2*, c.968G>A p.(Arg323Gln) and c.1196A>G p.(Asn399Ser). These cases independently confirm *HSD17B4*, *LARS2* and *C10orf2* as causative of Perrault syndrome.

PS02.49

Association of novel mutation p.W325X (c.977G>A) in the POU3F4 gene with perilymphatic Gusher-deafness syndrome (DFNX2) in Yakut family (Eastern Siberia)

[1]Yakut Scientific Center of Complex Medical Problems, Yakutsk, Russian Federation, [2]M.K. Ammosov North-Eastern Federal University, Yakutsk, Russian Federation, [3]Republican Hospital # 2– Center of Emergency Medicine, Ministry of Public Health of the Sakha Republic, Yakutsk, Russian Federation, [4]Republic hospital №1 – National Center of Medicine, Sergelyakhskoe shosse 4, Yakutsk, Russian Federation, [5]Institute of Chemical Biology and Fundamental Medicine, Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation, [6]Novosibirsk State University, Novosibirsk, Russian Federation, [7]Institute of Humanitarian Research and Indigenous Peoples of the North, Siberian Branch of the Russian Academy of Sciences, Yakutsk, Russian Federation, [8]Institute of Cytology and Genetics, Novosibirsk, Russian Federation, [9]Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation, [10]Bashkir State University, Ufa, Russian Federation.

The most rare causes of deafness in the world are X-linked and mitochondrial forms of hearing impairment (1-2%). For the first time, we revealed identical abnormalities of inner ear in two brothers from Yakut family (Eastern Siberia) with presumably X-linked recessive deafness that are typical for the perilymphatic Gusher-deafness syndrome (DFNX2, MIM304400) caused by mutations in the POU3F4 gene (MIM 300039). Computed tomography studies demonstrated an abnormal dilatation of the internal acoustic canal (IAC) as well as an abnormally wide communication between the IAC and the inner ear compartment in both brothers. Parents had no any temporal bone anomalies. To determine whether mutations in the POU3F4 gene (Xq21.1) are responsible for the hearing loss in these patients, we sequenced the single exon of the POU3F4 gene. We identified novel nucleotide substitution c.977G>A in POU3F4 in hemizygous state in both probands, in the heterozygous state in their mother, and c.977G>A was absent in their father. Transition c.977G>A leads to stop codon (p.W325X) in the POU-homeodomain of human transcription factor protein. Segregation of inner ear malformations and novel mutation c.977G>A (p.W325X) in the POU3F4 gene with deafness in studied Yakut family confirmed association of the POU3F4 gene with clinical phenotype of perilymphatic Gusher-deafness syndrome (DFNX2, OMIM 304400). Study was supported by RFBR (#14-04-01741_A, 14-04-9010_Bel_A, 15-44-05106-r_vostok_a), Governmental contract # 6.656.2014/K, SBRAS Integration project #92 and Grant of the Head of the Republic of Sakha (Yakutia) for young scientists, experts and students for 2015 years (RG#76 from 02.06.2015).

Genome-wide association study and targeted re-sequencing: a new combined approach to investigate the genetic causes of Age-related Hearing Loss (ARHL)

A. Morgan[1], *D. Vozzi[2], D. Vuckovic[1], M. La Bianca[2], A. D'Eustacchio[2], M. Concas[3], M. Pirastu[3], P. Gasparini[1], G. Girotto[1];*

[1]University of Trieste, Trieste, Italy, [2]IRCCS Burlo Garofolo, Trieste, Italy, [3]Institute of Population Genetics, National Council of Research, Sassari, Italy.

ARHL is a degenerative disease affecting millions of people worldwide. To date, very few potentially causative genes have been described. Based on our previous GWAS and expression data, a custom targeted re-sequencing panel of 46 ARHL candidate genes was designed and used for screening 500 ARHL Italian patients coming from both inbred and outbred populations using Ion Torrent PGM™ technology. Data were filtered according to allele frequency and to pathogenicity prediction (i.e. in silico predictor tools). Twenty-one mutations located in 14 different genes (8 frameshift, 2 stop gain and 11 missense) affecting 49 patients were detected. All mutations were absent in controls coming from the same populations as well as in any public database (or present at a very low frequency MAF≤0,003). Missense mutations were predicted to be highly damaging. Both scenarios were present: different mutations in the same gene as well as the same mutation in different patients. In some cases, human phenotype resembles that of already existing mice models. For example, a) 3 novel heterozygous frameshift deletions were detected in XIRP2 in patients showing a very similar phenotype to that recently described in mice (Francis et al. 2015); b) a heterozygous missense mutation was detected in four patients showing a high-frequency HL in WBP2 gene, similar to that described in the corresponding mouse model (Buniello et al. 2014). Complete results will be presented. These findings demonstrate the usefulness of our approach (GWAS+ Expression studies + Mutation screening) further supporting the potential role of these genes in causing ARHL.

PS02.51

New candidate genes associated with primary congenital glaucoma

S. Carmona[1,2], M. Simões[2], H. Froufe[2], F. Santos[2], E. SIlva[1], **C. Egas**[2,3];

[1]Faculty of Medicine, University of Coimbra, Coimbra, Portugal, [2]Biocant - Transfer Technology Association, Cantanhede, Portugal, [3]CNC.IBILI, University of Coimbra, Coimbra, Portugal.

Primary congenital glaucoma (PCG) is an ocular inherited autosomal recessive disease, associated with CYP1B1 mutations. However, some of the patients do not have CYP1B1 mutations. This study aims to identify novel genes causative of PCG in these patients.

Whole exome sequencing was performed in three unrelated patients and one trio. After annotation and variant filtration according to the autosomal recessive disease model, rare variants with a pathogenic functional impact were selected.

The comparison of variants shared by the four patients did not identify a common mutated gene. The four samples had 4, 9, 5 and 8 altered genes, respectively. None of these genes were previously associated with glaucoma, except an RNASEH2C gene variant, mutated in one patient and confirmed in the trio analysis. This gene has been associated with Aicardi-Goutières syndrome, characterized by severe neurological abnormalities together with congenital glaucoma. However, the patient does not have a typical phenotype. According to in silico previsions, this mutation leads to the loss of a donor splice site, creating a longer protein. Studies are underway to characterize the RNASEH2C mutation in this family.

Since no common mutated gene was found in our study and other reported studies, we suggest that PCG may be caused by mutations in different genes, consistent with an autosomal recessive model, or by an alternative model such as the polygenic, with heterozygous variants in different genes.

Heterozygous RARB missense mutations causing microphthalmia: Four further cases to add to this emerging phenotype

D. R. FitzPatrick[1], **R. J. Martin**[2], *J. A. Goodship[2];*

[1]MRC Human Genetics Unit, Edinburgh, United Kingdom, [2]Northern Genetics Service, Newcastle upon Tyne, United Kingdom.

Background

RARB (Retinoic Acid Receptor B) plays an important role in eye development. Compound heterozygous loss of function mutations in RARB have been associated with PDAC syndrome (pulmonary hypoplasia/agenesis, diaphragmatic hernia/eventration, anophthalmia/microphthalmia, and cardiac defect). Three unrelated subjects with microphthalmia and dia-

phragmatic hernia have been described with de novo, gain of function missense mutations affecting the same codon of RARB (Arg387). Two of these patients (both with p.Arg387Cys substitutions) died in utero and after a few hours of life respectively. The third patient (p.Arg387Ser) was 16 years old when his case was described in the literature.
New cases
We describe four new cases of missense RARB mutations at Arg387 in patients with microphthalmia/anophthalmia. One patient is an adult male of normal intelligence and a p.Arg387Ser substitution. He does not have a known diaphragmatic hernia. The other three patients all have p.Arg387Cys substitutions.
These four cases add to an emerging phenotype associated with RARB missense mutations.

PS02.53

Recessive RHO mutation E150K and SAMD7 regulatory variants in a consanguineous family with retinitis pigmentosa

K. Van Schil[1], *M. Karlstetter*[2], *A. Aslanidis*[2], *B. P. Leroy*[1,3], *F. Coppieters*[1], *F. Depasse*[4], *T. Langmann*[2], *E. De Baere*[1];
[1]Center for Medical Genetics, Ghent University and Ghent University Hospital, Ghent, Belgium, [2]Department of Ophthalmology, University of Cologne, Cologne, Germany, [3]Department of Ophthalmology, Ghent University and Ghent University Hospital, Ghent, Belgium, [4]Department of Ophthalmology, Queen Fabiola Children's University Hospital, Brussels, Belgium.

Purpose
To identify the genetic cause of a retintis pigmentosa phenotype observed in a Turkish consanguineous family.
Methods
Homozygosity mapping was performed for five sibs, two of which are affected. Functional analysis of non-coding SAMD7 variants was performed by luciferase assays and electroporation assays in mouse retinal explants with SAMD7 CBR-reporter constructs (Hlawatsch et al. 2013).
Results
Homozygosity mapping revealed two candidate genes, namely RHO and SAMD7. A homozygous RHO mutation (c.448G>A, p.E150K) was found in the two affected sibs, while all other sibs were heterozygous carriers.
No coding SAMD7 mutations were found. Interestingly, sequencing of the SAMD7 promoter and an enhancer in the two affected sibs revealed four homozygous variants located in the binding regions of the CRX transcription factor. The variants are known SNPs, with a low MAF of 1,6 %. The first three SNPs are located in a CRX-binding region called CBR1, while the fourth SNP is located in CBR2. The combined SAMD7 CBR1/CBR2 mutated construct showed a significantly decreased SAMD7 reporter activity compared with the WT construct.
Conclusions
A rare recessive RHO mutation (E150K) was found in consanguineous RP patients, consistent with previous reports (Kumaramanickavel et al., 1994; Azam et al., 2009 and Zhang et al., 2013). Moreover, functional analysis of four variants located in non-coding, CRX-binding regions of SAMD7, suggested a regulatory and synergistic effect on SAMD7 expression. As Samd7 has recently been identified as a novel Crx-regulated transcriptional repressor in retina (Hlawatsch et al., 2013), we hypothesize that these SAMD7 variants might have a modifying effect on the retinal phenotype observed in this family.

Molecular diagnosis of complex Eye disorders by Next Generation Sequencing

G. Shariati[1,2], *M. Mohebi*[3,1], *M. Sedaghat*[4,1], *A. Saberi*[1,5], *N. Mazaheri*[1,6], *M. Hamid*[7,8], *M. Sarvari*[1], *M. Mohammadi Anaei*[7], *J. Zeighami*[1], *H. Galehdari*[1,6];
[1]Narges Medical Genetic diagnosis Lab, Ahvaz, Iran, Islamic Republic of, [2]Department of Genetics, Jondishapour Medical University, Ahvaz, Iran, Islamic Republic of, [3]Internal Medicine, Jondishapour Medical University, Ahvaz, Iran, Islamic Republic of, [4]Department of Endocrinology, Jondishapour Medical University, Ahvaz, Iran, Islamic Republic of, [5]Jondishapour University, Medical School , Genetics Department, Ahvaz, Iran, Islamic Republic of, [6]Department of Genetics, Shahid Chamran University, Ahvaz, Iran, Islamic Republic of, [7]Narges Medical Genetic diagnosis Lab, Ahwaz, Iran, Islamic Republic of, [8]Department of Biotechnology, Pasteur Institute, Tehran, Iran, Islamic Republic of.

Molecular detection of diseases such as eye disorders is very challenging. Hunting the right gene in these complex disorders is like finding the needle in the haystack. Nevertheless, modern sequencing platforms known under collective name Next generation sequencing or NGS is a huge help to solve this problem. We also could be able identifying disease causing mutations by NGS in different and unrelated retinopathy cases. In One case, the PRPH2 gene was homozygous mutated at nucleotide c.582-1(G>A) in 2 affected children of related parents. This change is a splice site variation that leads to vitelliform macular dystrophy. Further, we found in other family in the CRB1 gene mutation at c.T2106G (p.Y702X) causing macular dystrophy. Third case showed pathogenic mutation in the CNGA3 gene at c.A827G (p.N276S) causing achromatopsia type 2. A affected male was mutated in the gene TULP1 at position c.1450A>C (T484P) causing Leber Congenital Amaurosis (LCA) or RP type 14 and further affected female was positive for a change in the RDH12 gene at c.81delT (p.A27fs). Mutations in this gene cause Leber Congenital Amaurosis. All mentioned mutations are unreported. To validate pathogenic nature of these changes, we analyzed the mutations by Sanger sequencing and some predicting software. In addition, missense mutations were compared for protein structure changes with mutated and wild type amino acid. In all cases we observed significant difference in protein folding, which might influences the biological function. Furthermore, over 100 normal population samples were tested with negative results for each case.

PM02.56

Two missense mutations in SALL4 in a patient with microphthalmia, coloboma and optic nerve hypoplasia

E. Ullah[1,2], *R. Lao*[3], *P. Tang*[3], *E. Wan*[3], *T. Bardakjian*[4], *P. Kwok*[3], *A. Schneider*[4], *M. Ansar*[1,5], **A. Slavotinek**[2];
[1]Department of Biochemistry, Faculty of Biological Sciences, Quaid-i-Azam University, Islamabad, Pakistan, [2]Department of Pediatrics, University of California, San Francisco, San Francisco, CA, United States, [3]Cardiovascular Research Institute, University of California, San Francisco, San Francisco, CA, United States, [4]Division of Medical Genetics, Einstein Medical Center, Philadelphia, PA, United States, [5]Center for Statistical Genetics, Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States.

There are four human homologues of the D. Melanogaster Sal gene that are highly conserved, C2H2 double zinc finger transcription factors. Mutations in SALL1 causes Townes-Brocks syndrome, SALL2 and SALL3 have not been associated with human disease and mutations in SALL4 cause a phenotypic spectrum that includes Okihiro/Duane-radial ray syndrome, acro-renal-ocular syndrome and Holt-Oram syndrome. As part of our studies into the etiology of anophthalmia, microphthalmia and coloboma (AMC), we used exome sequencing with a trio approach in a Caucasian female with unilateral microphthalmia and coloboma, bilateral optic nerve hypoplasia, a ventricular septal defect, atrial septal defect and growth delays. Prior investigations included normal array CGH and both parents reportedly had no clinical features. We found two sequence variants in SALL4 - c.575C>A, predicting p.Ala192Glu and c.G2053G>C, predicting p.Asp685His (NM_020436). Both variants were verified using Sanger sequencing and predicted to be damaging with three software programs; the first was paternally inherited and the second was maternally inherited. Only p.Ala192Glu was present in normal controls (6/121,266). Structural eye defects have been infrequent in individuals with SALL4 mutations. In two families diagnosed with acro-renal-ocular syndrome, segmental disc dysplasia and hypoplasia and retinal coloboma were found with a SALL4 deletion and cataract, iris and choroidal colobomas, microphthalmia and microcornea were reported with heterozygosity for a frameshift mutation. As Sall4 regulates Bmp4, we speculate that altered BMP4 expression could be responsible for the eye defects and conclude that haploinsufficiency for SALL4 should be considered as a rare cause of AMC.

An augmented ABCA4 screen targeting non-coding regions reveals a deep intronic founder causal variant in Belgian Stargardt patients

M. Bauwens[1], *F. Coppieters*[1], *J. De Zaeytijd*[2], *N. Weisschuh*[3], *S. Kohl*[3], *K. Dahan*[4], *F. Depasse*[5], *M. De Rademaeker*[6], *B. Loeys*[7], *F. Meire*[5], *T. de Ravel*[8], *W. Steyaert*[1], *S. De Jaegere*[1], *B. P. Leroy*[2,9], *E. De Baere*[1];
[1]Center for Medical Genetics, Ghent University, Ghent, Belgium, [2]Dept of Ophthalmology, Ghent University Hospital, Ghent, Belgium, [3]Molecular Genetics Laboratory, Institute for Ophthalmic Research, University of Tuebingen, Tuebingen, Germany, [4]Institut de Pathologie et de Génétique, Centre de génétique humaine, Gosselies, Gosselies, Belgium, [5]Department of Ophthalmology, Queen Fabiola Children's University Hospital, Brussels, Belgium, [6]Center for Medical Genetics, Free University of Brussels, Brussels, Belgium, [7]Center for Medical Genetics, University of Antwerp and Antwerp University Hospital, Antwerp, Belgium, [8]Center for Human Genetics, Leuven University Hospitals, Leuven, Belgium, [9]Division of Ophthalmology, The Children's Hospital of Philadelphia, Philadelphia, PA, United States.

Autosomal recessive Stargardt disease (STGD1) is hallmarked by a large proportion of patients with a single heterozygous causative variant in the disease gene ABCA4. Braun et al. (2013) reported deep intronic variants of ABCA4, prompting us to perform an augmented screen in 131 Belgian STGD1 patients with one or no ABCA4 variant to uncover deep intronic causal ABCA4 variants.
All 131 prescreened patients underwent targeted resequencing of four deep

intronic ABCA4 regions using next-generation sequencing (Miseq, Illumina), revealing a second variant in 28.6% of cases. Twenty-six percent of these carry the same causal variant c.4539+2001G>A (known as V4). Haplotyping in V4 carriers showed a common region of 63 kb, suggestive of a founder mutation. Genotype-phenotype correlations indicate a moderate-to-severe impact of V4 on the STGD1 phenotype.
The remaining patients in whom no second ABCA4 mutation was identified underwent targeted resequencing of the entire genomic regions of ABCA4, BEST1 and PRPH2 (~ 500 kb in total) (HaloPlex Target Enrichment System, Agilent Technologies). Variant filtering was based on minor allele frequency, conservation score, splicing predictions and regulatory potential. Preliminary data in a pilot group show that the standard filtering yields approximately 130 variants per patient that require further investigation.
In conclusion, causal variant V4 occurs in a high fraction of Belgian STGD1 patients and represents the first deep intronic founder mutation in ABCA4. This emphasizes the importance of augmented molecular genetic testing of ABCA4 in STGD1. Finally, resequencing of the complete ABCA4 gene in the remainder of the STGD1 patients will allow us to identify novel deep intronic and non-coding mutations.

PM02.58
Association between telomere length and telomerase polymorphisms in young adults with cataract.

M. Fernández-Prieto[1,2], *V. Rivero-Gutiérrez*[3], *J. Fernández-Mateos*[1,2], *C. Egido-Turrión*[1], *A. Sánchez-Jara*[3], *L. de Juan-Marcos*[3,2], *R. González-Sarmiento*[1,2];
[1]*Molecular Medicine Unit. Department of Medicine. University of Salamanca., Salamanca, Spain,* [2]*Institute of Biomedical Research of Salamanca (IBSAL)., Salamanca, Spain,* [3]*Department of Ophthalmology, University Hospital of Salamanca, Salamanca, Spain.*

INTRODUCTION: Telomeres cells shortening during aging suggests that telomere length could be a biomarker of aging and age-relate morbility. Telomerase compensates this shortening maintaining telomere ends by addition of desoxyribonucleic acid (DNA). Acquired cataract is one of the most common age-related eye diseases but it is also present in a reduced number of young people.
OBJETIVES: The aim of this report was to analyze the prognostic value of telomere length in young patients with cataracts and evaluate the effect of polymorphisms in telomerase genes on the susceptibility to develop cataract in these subjects.
PATIENTS AND METHODS: Telomere length was measured by quantitative polymerase chain reaction in peripheral blood leukocytes of 112 cases and 112 controls classified in two groups (60 years).
To detect telomerase polymorphisms TERT1327C>T and TERC63G>A, TaqMan quantitave PCR method was used.
RESULTS: Our results indicate that young population with cataracts has shorter telomeres than the same cohort of healthy subjects ($p<0.01$) and similar to the older patients with cataracts. The onset of cataracts in younger adults may serve as an in vivo marker of primary aging and at the same time could alert us to other pathologies associated with telomeric shortening as cardiovascular diseases or cancer.
We found a statistically significant association between GG homozygous of TERC63G>A rs2293607 polymorphism and an increased telomere shortening in healthy subjects ($p=0.015$).
Thus, our results suggest that the development of cataracts in young people could be associated to a premature molecular aging.

Introduction: Recessive mutations of the TMPRSS3 gene cause non-syndromic hearing impairment (HI) but knowledge on their spectrum in Caucasians is limited. The purpose was to search for pathogenic TMPRSS3 variants in Polish Caucasian HI patients.
Materials and Methods: A strategy of iterative cycles of TMPRSS3 gene sequencing (initiated by whole exome sequencing in one subject performed on HiSeq 1500- Illumina) combined with focused mutation screening which we termed Iterative Sequencing and Variant Screening (ISVS) was applied to ~2200 unrelated HI patients recruited among patients from Institute of Physiology and Pathology of Hearing. Approx. 600 control subjects were also studied.
Results: We found 43 (1.88%) probands with 14 different rare TMPRSS3 variants. We also found a genotype-phenotype correlation with truncating mutations causing more severe HI with earlier onset than missense mutations. The p.A90T variant previously linked with HI had high prevalence in controls (~6%) indicating that is non-pathogenic.
Conclusions: TMPRSS3 mutations are rare but distinct cause of HI in Polish population. The more severe phenotype associated with truncating mutations confirms previous findings.

Introduction: Usher Syndrome is a rare autosomal recessive disease causing sensorineural hearing loss, retinitis pigmentosa and, sometimes, vestibular dysfunction. It is a genetically heterogeneous disorder, with more than 10 associated genes, being *USH2A* the most common mutated gene.
The recent CRISPR technology is based on a nuclease (Cas9) that cuts the double DNA strand at a specific locus via a guide RNA. Upon cleavage, the target locus undergoes a damage repair either by the error-prone nonhomologous end-joining (NHEJ) or the high fidelity homologous recombination (HDR) pathway.
Materials and Methods: We have generated different constructs of CRISPR/Cas9 RNA-guided nucleases targeted to two prevalent mutations located at exon 13 of the *USH2A* gene: c.2999delG and p.C759F. These constructs were transfected into HEK293 cells, and each nuclease efficiency was tested by sequencing and also with the T7 endonuclease assay.
Later on, we repeated the transfection with the most efficient nuclease together with a template to induce HDR repair.
Results: The present study shows the first steps of an approach of gene therapy based on this CRISPR technology, applied to two characteristic mutations responsible for Usher Syndrome.
Conclusions: The pathological features of this syndrome represent a great disadvantage for the patients, since communication nowadays relies largely on audiovisual media, and there is still no medical treatment, except for the hearing aids or cochlear implants for the hearing impairment.
Therefore, repairing of specific mutations by gene editing is an interesting strategy that can be performed using the CRISPR technology.

PS02.61
A targeted next-generation sequencing diagnostic panel for Usher Syndrome

M. E. Shanks, *E. Packham, J. P. Williams, P. Clouston, A. H. Nemeth, S. Downes, A. Seller; Oxford Medical Genetics laboratory, Oxford, United Kingdom.*

Introduction: Usher syndrome is a phenotypically and genotypically heterogeneous autosomal recessive condition comprising both hearing loss and Retinitis Pigmentosa (RP). We have designed a targeted next-generation sequencing panel for the thirteen genes currently associated with Usher syndrome; *ABHD12, CDH23, CIB2, CLRN1, DFNB31, GPR98, HARS, MYO7A, PCDH15, PDZD7, USH1C, USH1G* and *USH2A*. *USH2A* is the most common cause of type II Usher syndrome and is also a common cause of non-syndromic RP.
Method: The genes associated with Usher syndrome are captured using Agilent's Haloplex enrichment technology and sequenced on an Illumina MiSeq. A custom bioinformatics pipeline has been designed for alignment, variant calling, annotation and filtering of variants.
Results: To date 16 patients have been referred with a clinical diagnosis of Usher syndrome. The majority, 11 patients, have two pathogenic USH2A variants – including 3 dosage variants. A further 2 patients have only 1 pathogenic *USH2A* variant. Pathogenic variants were also detected in *MYO7A* and *GPR98*.
USH2A is also tested as part of our Retinitis Pigmentosa diagnostic screen and 10/89 RP patients were found to have two pathogenic *USH2A* variants.
Conclusions: A molecular diagnosis of Usher syndrome was made in 81%

of Usher referrals; 69% in the *USH2A* gene and of these 13% have a copy number variants; confirmed by MLPA. *USH2A* variants are also present in 11% of our RP cohort.

PM02.62
Molecular genetic examination of hereditary deafblindness in Czech patients

J. Sabova[1,2], *O. Mazal*[1], *M. Simandlova*[2], *D. Raskova*[3], *D. Grecmalova*[4], *A. Krepelova*[2], *R. Pourova*[2];

Deafblindness is a rare disorder characterized by combination of hearing and visual impairment. Usher and Stickler syndromes are the most frequent genetic syndromes associated with deafblindness. Usher syndrome is an autosomal recessive disorder responsible for up to 50% cases of hereditary deafblindness. It is divided into three clinical subtypes and is caused by mutations in 11 genes, most frequently in USH2A gene. Stickler syndrome is an autosomal dominant disorder of connective tissues characterized by hearing impairment, eye abnormalities, with possibility of other congenital defects. Mutations in collagen genes, most frequently in COL2A1, are responsible for Stickler syndrome.
In our study we investigated 30 patients from 16 families with Usher syndrome and 17 patients from 9 families with Stickler syndrome from the Czech Republic. We analysed USH2A and COL2A1 genes using Sanger sequencing as a prescreening and we detected mutations in 2 families with Usher syndrome and 2 families with Stickler syndrome. NGS screening of negative patients will follow.
Here we present two cases: The first case is a 50-years-old male with bilateral hearing loss and retinitis pigmentosa. Double heterozygosity of known pathogenic mutation c.11864G>A (Trp3955Ter) and novel mutation c.14621C>G (Ser4874Ter) in USH2A gene confirmed the diagnosis of Usher syndrome in this patient. The second case is a 20-years-old female showing bilateral retinal detachment, experienced by her father and paternal grandfather as well. Identification of a known pathogenic mutation c.1597C>T (Arg533Ter) confirmed the diagnosis of Stickler syndrome.
Supported by a project for conceptual development of research organization 00064203 and 64204.

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT) are some of the most common malformations observed during pregnancy. We describe a case of prenatally detected fetal hyper-echogenic kidneys that led to diagnosis of a familial condition.
Materials and Methods: A 34 year old primipara was referred to our institution due to fetal hyperechogenic kidneys at 24 weeks gestation. Her husband has mature-onset diabetes of the young (MODY).
Results: Non-invasive prenatal testing (NIPT) showed low risk for aneuploidy. No other malformations were seen. Fetal ultrasound and MRI were highly suggestive of bilateral renal dysplasia. Amniocentesis with chromosomal microarray analysis (CMA) revealed a 1.5Mb microdeletion on chromosome 17q12 including the TCF2/HNF1B gene. Chromosome 17q12 microdeletion is a well described contiguous-gene deletion syndrome, with variable phenotype. The deletion varies in length but most cases harbor the common 1.5Mb deletion. The TCF2/HNF1B gene is the major causative gene. Features include a wide range of manifestations including neurological, skeletal, hair & nails and endocrine (including MODY). Renal involvement is the hallmark feature, described in over 90% of cases ranging from fetal hyperechogenic or multicystic dysplastic kidneys to pelvic dilatation, recurrent infections and abnormal renal function. Normal kidneys have been described. Parental CMA analysis demonstrated that the deletion was inherited from the father, thus providing a molecular basis for MODY.
Conclusions: Genetic consultation in such prenatal settings is difficult, due to the variable phenotype and penetrance, especially the risk for neuro-developmental disorders, and the fact that it is often inherited from a mildly affected parent.

Introduction: Familial visceral myopathy (FVM) is a rare heritable and heterogeneous condition due to impaired smooth muscle function. We identified a family segregating eleven individuals with a spectrum of visceral symptoms involving the small intestine, colon, biliary tract, urinary tract and uterus.
Material and Methods: Whole exome sequencing was conducted on DNA samples from four affected individuals. Target enrichment was performed using the Agilent SureSelect Human All Exon 50Mb kit. Samples were loaded on an Ion PI chip and sequenced on the Ion Proton System using Ion PI Sequencing 200 Kit (200 bp read length
Results: Whole exome sequencing revealed a novel heterozygous tandem base substitution c.806_807delinsAA (p.Gly269Glu) in ACTG2, encoding smooth muscle actin gamma-2, in affected family members.
Conclusions: Variants in ACTG2 were recently identified in familial visceral myopathy with intestinal pseudo-obstruction as well as with the congenital megacystics-microcolon-intestinal hypoperistalsis (MMIH) syndrome. In our family, eight affected members presented with severe complications from the biliary and/or the urinary tracts in addition to gastrointestinal pseudo-obstructions. Furthermore, all affected mothers had a history of assisted deliveries due to poor progress during labor and weak uterine contractions. The variable involvement of multiple smooth muscle dependent organs in our family, including the biliary tract and the uterus, add to the phenotypic spectrum associated with ACTG2 missense variants.

Introduction
Alport syndrome (AS) is an inherited renal disorder characterized by hematuria, progressive renal failure, hearing loss, and ocular abnormalities. The disease is genetically heterogeneous and associated with mutations in type IV collagen that forms a distinct network in the glomerular basement membrane (GBM). Fifteen percent of patients with AS have autosomal recessive inheritance caused by pathogenic mutations in either COL4A3 or COL4A4 genes, located in 2q36-37.
Subjects and methods
Genetic analysis was performed on a 28-year-old male patient who had, since the age of 3 years-old, presented nephrotic syndrome and persistent microhematuria. He fulfilled four of the AS clinical diagnostic criteria: a positive family history of hematuria, proteinuria, hearing loss, and typical electron microscopy abnormalities of the GBM. The entire coding sequence and flanking intronic regions of the COL4A3/A4 genes were analyzed by PCR and direct sequencing reaction. Afterwards, sixteen members of his family (8 males and 8 females) were included in the analysis.
Results
A novel heterozygous mutation (c. [998G>A]+[=]; p.[G333E]+[=]) in exon 18 of the COL4A3 gene was found in the proband and it was confirmed in eleven members of the family.
Conclusion
Among relatives of members who carried the novel mutation, the clinical phenotype of AS was variable. All of them presented hematuria, and 6 of 12 also had proteinuria and hearing loss. The identification of new mutations and their correlation with clinical phenotype are important to offer an early treatment and genetic counselling.

PM03.04
Further evidence for digenic inheritance in Alport syndrome: combined mutations in collagen IV and slit diaphragm genes

Anna, Como, Italy, [11]Pediatric Nephrology and Dialysis Unit, Santobono Children's Hospital, Naples, Italy, [12]Renal Division, Department of Medicine, University Hospital Freiburg, Freiburg, Germany, [13]Internal Medicine/Nephrology, Weißwasser, Germany.

Through a collaborative effort of several centers in Europe, we have recently demonstrated digenic inheritance in Alport syndrome identifying combined mutations in collagen IV genes (Mencarelli et al J Med Genet 2015). This result was achieved using an NGS panel covering COL4A3, COL4A4, and COL4A5 genes. Here, we further expand the evidence for digenic inheritance using an exome sequencing approach. Alport syndrome is characterized by extreme intrafamilial phenotypic variability including the degree of proteinuria. The phenotype of heterozygotes for a single mutation in collagen IV ranges from asymptomatic to overt disease. We selected patients with clinical evidence of Alport syndrome and typical ultrastructural lesions such as thinning, thickening and splitting of the glomerular basement membrane. We demonstrated that symptomatic cases with a single mutation in a collagen IV gene are compound heterozygous at either NPHS1 or NPHS2 locus, with at least one allele being hypomorphic. This combination is not present in male Alport patients hemizygous for one pathogenic mutation in COL4A5. According to the strength of NPHS1/NPHS2 mutations, patients manifest variable grade of proteinuria. In order to prove the pathogenic role of identified mutations we are currently using a method recently described (Lazzeri et al. JASN 2015) which allows isolation and long-term culture of renal progenitors from fresh urine samples. Overall, on the basis of these results, we can further extend the concept of digenic disease for Alport syndrome which can thus be due to either mutations in two collagen IV genes or mutations in one collagen IV gene and one slit diaphragm gene in the framework of triallelic inheritance.

PS03.05

A novel knockin mouse model for Alport Syndrome

I. Savva[1], *C. Stefanou[1], M. Pieri[1,2], C. Stylianou[3], G. Lapathitis[4], C. Karaiskos[4], G. Papagregoriou[1], C. Deltas[1];*
[1]Molecular Medicine Research Center, University of Cyprus, Nicosia, Cyprus, [2]Department of Life and Health Sciences, University of Nicosia, Nicosia, Cyprus, [3]Department of Nephrology, Heraclion University Hospital, Heraclion, Crete, Greece, [4]The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

Alport Syndrome represents an inherited nephropathy leading to end-stage renal disease by the 2nd-3rd decade of life. It is characterized by alterations of the glomerular basement membrane (GBM) and is caused by mutations in collagen IV genes. Although most of the responsible mutations are missense substitutions, a full phenotypic analysis of a knockin mouse model is absent from the literature to date.
We herein present preliminary results from the phenotypic analysis of a mouse model carrying the Col4α3-p.G1332E mutation, which is homologous to the human COL4A3-p.G1334E mutation representing a frequent founder mutation among Cypriots with thin basement membrane nephropathy (TBMN).
Mutant mice on the 129SvJ background do not develop hematuria but appear to develop proteinuria around 17-wk-old. Homozygous mutant mice on mixed genetic background exhibit the characteristic Alport GBM ultrastructural features, namely irregular thickening, lamellation and podocyte foot process effacement. Furthermore, heterozygous mice demonstrate diffusely thin GBM, which is the main ultrastructural finding in patients with TBMN. Interestingly, kidney immunofluorescence studies using antibodies specific for the Col4α3 and Col4α5 chains, demonstrate increased expression of both collagen chains in mutant GBM as compared to age/sex matched controls. This may explain why these knockin mice live much longer compared to the existing knockout model. The mean survival of the mutant, heterozygous and wild type mice is 17, 22 and 31 months respectively. The complete phenotypic analysis will enable further clarification of the pathophysiologic mechanisms of Alport syndrome and TBMN and allow the testing of novel therapeutic interventions.
Project was co-funded by the ERDF and the Republic of Cyprus through the RPF (NEWINFRASTRUCTURE/STRATEGIC/0308/24).

PM03.06

Dysregulation of FOXF1 gene and Pulmonary capillary hemangiomatosis (PCH) manifestations.

P. Dello Russo, C. Pittini, E. Demori, N. Passon, D. Romagno, G. De Maglio, S. Pizzolitto, **G. Damante***;*
Az. Ospedaliero Universitaria S.Maria della Misericordia, Udine, Italy.

Pulmonary capillary hemangiomatosis (PCH) is a rare disorder that was first reported in 1978, with only seven nonrelated cases having been reported by 1998 and a little more than 100 by 2011.
PCH is characterized by numerous blood vessels that proliferate throughout pulmonary interstitial tissue, blood vessels and airways. PCH is pulmonary hypertension associated.
Congenital PCH has been very rarely described.
We report a newborn died after three days of life with severe neonatal pulmonary hypertension, due to diffuse capillary hemangiomatosis diagnosed post mortem.
He had no additional anomalies or malformations, and no familial occurrence.
High resolution conventional karyotype gave normal results (46,XY).
aCGH discovered a chromosome 16q23.3q24.1 deletion that disrupted the distant *FOXF1* trascriptional enhancer *LINC1081*, mapping 0.3 Mb upstream on 16q24.1.
The deletion was *de novo* and sized about 2.6 Mb.
Recently similar deletions of distant *FOXF1* enhacer associated with Alveolar Capillary Dysplasia with Misalignment of Pulmonary Veins (ACDMPV) have been described.
*FOXF1*gene is known to have a crucial role in human lung and intrinsic pulmonary vascular development.
Here we suggest that dysregulation of *FOXF1* expression due to decrease *LINC01081* expression can contribute to histologically proven pulmonary capillary hemangiomatosis, strengthening the hypothesis of a genetic background of PCH.

PS03.07

Characterization of PKD1/PKD2 mutation negative autosomal dominant polycystic kidney disease family

K. Claes[1], *W. Steyaert[1], M. Van Heetvelde[1], E. Meireson[1], K. De Leeneer[1], E. Fransen[2], K. Vanderstraeten[3], B. Callewaert[1];*
[1]Center for Medical Genetics Ghent, Ghent University, Ghent, Belgium, [2]StatUa Center for Statistics, University of Antwerp, Antwerp, Belgium, [3]Department of Medical Genetics, University of Antwerp, Antwerp, Belgium.

Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common (frequency 1: 1000), adult onset nephropathy accounting for 4-10% of patients requiring dialysis or renal transplant worldwide. Most frequently germline mutations in either PKD1 or PKD2 cause ADPKD. However, not only the identification of large ADPKD families unlinked to either gene, but also the lack of PKD1 or PKD2 mutations detected in ~8% of ADPKD families, suggests further genetic heterogeneity. Until now no additional gene has been identified.
We identified a large three generation family with a classical presentation of ADPKD. DNA was available from eight affected and three unaffected relatives. Mutation analysis of PKD1 and PKD2 ruled out a deleterious mutation in these genes; furthermore, linkage analysis ruled out an association with these loci. Genome-wide SNP analysis suggested linkage with a locus of 5 Mb on chromosome 19 (LOD score= 2.3994). Exome sequencing did not reveal a clear deleterious mutation in this family in this region. Since the coverage of several top candidate genes was not sufficient, we are currently screening the coding regions of these genes by next generation sequencing. Further molecular exploration of this family may lead to the identification of a novel gene associated with ADPKD.

PM03.08

PKD2-related Autosomal-dominant Polycystic Kidney Disease (ADPKD): mutation spectrum, phenotype and prognosis

E. Cornec-Le Gall[1], *M. Audrézet[2], E. Renaudineau[3], E. Michez[4], M. Hourmant[5], C. Vigneau[6], C. Charasse[7], Genkyst Study Group, S. Maestri[2], J. Chen[8], P. Saliou[9], Y. Le Meur[10], C. Férec[11];*
[1]Service de Néphrologie Laboratoire de Génétique INSERM 1078CHRU BREST, BREST, France, [2]Laboratoire de Génétique Moléculaire CHRU BREST, BREST, France, [3]Service de Néphrologie CH Saint Malo, SAINT MALO, France, [4]Service de Néphrologie CH Vannes, Vannes, France, [5]Service de Néphrologie CHU Nantes, Nantes, France, [6]Service de Néphrologie CHU Rennes, Rennes, France, [7]Service de Néphrologie CH Saint Brieuc, Saint Brieuc, France, [8]Etablissements français du sang, BREST, France, [9]Service de santé publique et hygiène hospitalière- Unité INSERM 1078 CHU BREST, BREST, France, [10]Service de Néphrologie CHRU BREST, BREST, France, [11]Laboratoire de Génétique Moléculaire CHRU BREST, unité INSERM 1078, Etablissements français du sang, BREST, France.

PKD1 and PKD2 mutations are identified in ~85% and ~15% of the Autoso-

mal-dominant Polycystic Kidney Disease (ADPKD) pedigrees. As targeted therapies are emerging, accurate description of ADPKD phenotype is crucial to delineate which patients should, or should not, receive these new treatments. PKD2 phenotype has been described as milder but population-based studies, enabling to depict the exact burden of the disease, are currently lacking. We aimed to describe PKD2 mutation spectrum and related phenotype. Between 2010 and 2015, a mutation of PKD2 was identified in 241 patients from the cross-sectional Genkyst study (166 pedigrees).
The 68 different mutations identified included 23 newly described mutations. They spanned on the entire coding region of PKD2 gene and were mainly truncating mutations (84%). A 28-kb deletion involving exons 10-15 was identified in 23 pedigrees confined in an area of ~3500 km^2, which represents the first case of founder mutation in ADPKD. At inclusion, 50 patients had reached end-stage renal disease (ESRD), and median age at ESRD (obtained by Kaplan-Meier model) was 77.8 yrs [ranges=41.5-84.6]. Although there was no gender influence on renal survival, multiple linear regression demonstrated that men had significantly lower kidney function than women. Considerable disease variability was observed amongst patients harbouring the same mutation, suggesting that additional genetic or environmental factors may modulate the disease severity in PKD2 patients. Consistent with this point, in 3 PKD2 pedigrees with cases of early-onset ESRD, disease severity was linked to the co-inheritance of hypomorphic alleles of PKD1. (funded by PHRC inter-regional 2010)

PS03.09
Genomic analysis of biliary atresia by GWAS and whole exome sequencing

Y. Chen[1,2], R. Rajagopalan[2], C. Grochowski[2], A. Falsey[2], K. Loomes[1,2], N. Spinner[1,2], **M. Devoto**[1,2];
[1]University of Pennsylvania, Philadelphia, PA, United States, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, United States.

Biliary atresia (BA) is a rare liver disease presenting within the first months of life characterized by obliteration of the extrahepatic biliary tree in a progressive, necroinflammatory manner, leading to cholestasis, fibrosis, cirrhosis and chronic liver damage, and accounting for 50% of pediatric liver transplantations in the US. The etiology of BA is not well understood, and environmental, inflammatory, and genetic causes have been proposed. A GWAS in Chinese patients previously identified a signal on chromosome 10q upstream of the ADD3 and XPNPEP1 genes. We performed a GWAS in 450 Caucasian non-syndromic BA patients collected through the Childhood Liver Disease Research Network and 1981 controls, with the Illumina Omni2.5 array. The most significant SNP was rs10865291 (p-value = 2.7x10-7; odds ratio 1.6; 95% CI (1.3 -1.9)), in the sixth intron of EFEMP1. Efemp1 is an extracellular glycoprotein implicated in tissue regeneration and organogenesis. Additionally, we sequenced the exome of 100 patients, and looked for rare variants in 21 genes chosen because of reports of mutations in syndromic BA or animal models with hepatobiliary defects, and BA association from GWAS. Filtering for protein-altering variants present at <1% in public datasets, we found 20 missense variants and 2 in-frame insertions in 13 different genes in 26 patients. We found more than one variant in LGR4, ZEB2, DNMT1, INVS, JAG1, and PRICKLE4, some shared among more than one proband. These findings suggest that BA etiology is likely highly heterogeneous and a single gene does not explain the phenotypic complexity of the disease.

PM03.10
Prioritization of candidate variants using targeted next generation sequencing of 208 candidate genes in congenital anomalies of the kidney and urinary tract

N. Nicolaou[1], S. Pulit[1], I. J. Nijman[1], G. Monroe[2], W. F. J. Feitz[3], M. F. Schreuder[4], A. M. van Eerde[1], J. C. Giltay[1], R. H. Giles[5], E. Cuppen[1], E. M. H. F. Bongers[6], N. V. A. M. Knoers[1], K. Y. Renkema[1], **G. van Haaften**[7];

Introduction: The leading cause of end-stage renal disease in children is attributed to congenital anomalies of the kidney and the urinary tract (CAKUT). Familial clustering implicate genetic factors and monogenic mouse models support the involvement of numerous genes in CAKUT aetiology. However, genetic testing for human CAKUT is currently insufficient and additional efforts are needed to identify causal genes.
Materials and Methods: We designed a gene panel of 208 genes, which consists of known genes identified from studies on familial forms of isolated or syndromic CAKUT and candidate genes suggested by in vitro and in vivo models for CAKUT. Targeted next-generation sequencing was performed in 458 patients with sporadic CAKUT with a depth of coverage of 135x per sample.
Results: Rare (frequency < 0.01), truncating, splice-site variants and non-synonymous variants predicted to be deleterious and conserved were defined as candidates. Based on previous reports on disease-causing mutations, we considered 5 variants in 6 patients to be causal mutations and 15 variants in 20 patients to be likely pathogenic. However, 32 variants found in 69 patients that were previously reported as pathogenic were reclassified here as variants of uncertain significance. Finally, we identified 128 candidate variants in 132 patients that were predicted to be loss-of-function.
Conclusions: This study comprises the largest gene set to be analyzed in a cohort of CAKUT patients to date, it demonstrates the advantages of a disease-targeted gene panel, and prioritizes candidate variants identified in 34% of our patient cohort, some of which are currently being followed up using in vitro functional tests.

PS03.11
Whole exome sequencing and targeted sequence analysis in 73 patients with congenital anomalies of the kidneys and urinary tract (CAKUT)

A. Kosfeld[1], *M. Kreuzer[2], C. Daniel[3], F. Brand[1], A. Schäfer[4], A. Chadt[5], A. Weiss[4], V. Riehmer[1], M. Kirschstein[6], T. Seeman[7], K. Amann[3], A. Bjerre[8], L. Pape[2], H. Al-Hasani[5], A. Kispert[4], D. Haffner[2], R. G. Weber[1];*

Medical Faculty – University Hospital Motol, Charles University, Prague, Czech Republic, [8]Department of Paediatrics, Oslo University Hospital, Oslo, Norway.

CAKUT is a genetically highly heterogeneous disorder. To elucidate the genetic aetiology in unclear cases and identify novel CAKUT genes, we performed whole exome sequencing on peripheral blood from 24 patients (22 sporadic, 2 familial) followed by detailed data analysis. In 12/24 (50%) patients, we found 14 different heterozygous loss-of-function (LOF) variants in two known dominant CAKUT genes (PAX2 und SALL1) and 11 CAKUT candidate genes, whereby two patients carried two distinct LOF mutations. Four of the 14 LOF variants were de novo, one was inherited from an affected parent, seven were inherited from a healthy parent, and in two cases inheritance was undetermined. In four patients, known CAKUT causing missense mutations inherited from a healthy parent were detected in the SIX2 (2/24) and the RET (2/24) gene. In 8 patients without LOF variants, heterozygous missense variants were determined in CAKUT candidate genes that were novel and predicted to be pathogenic, three of which belonged to the GDNF-RET-network. In 49 additional CAKUT patients, targeted sequencing of selected candidate genes was performed. One of these genes, in which we detected four rare or novel heterozygous variants including one de novo LOF and three pathogenic missense variants in CAKUT patients, was further analysed in vitro and in vivo. We characterised its expression pattern in mouse embryos during the development of the kidney and urinary tract by RNA in situ hybridisation. In addition, we examined the kidneys and urinary tract of mice with a knock-out of this gene macroscopically and microscopically.

PM03.12
The first genetic study on congenital choledochal dilatation (CCD) implicates extracellular matrix proteins

M. Garcia-Barcelo[1], *J. K. L. Wong[1], N. Ngo[2], T. Son[2], L. Nguyen[2], P. Sham[1], S. Cherny[1], P. Tam[1];*
[1]The University of Hong Kong, Hong Kong, Hong Kong, [2]National Hospital of Pediatrics, Hanoi, Viet Nam.

Congenital choledochal dilatation (CCD) or paediatric choledochal cyst refers to the congenital dilatation of the choledochs (bile ducts) which leads to the obstruction of the ducts and bile retention. Symptoms include cholestatic jaundice, abdominal pain and liver enlargement complicated with cholangitis and pancreatitis. New-borns undergo surgery otherwise the liver could be permanently damaged. CCD is rare, mostly sporadic with variable population incidence, the highest being in Asia (1/1,000 in Asians; 1/150,000 in Caucasians). Its aetiology implicates congenital structural anomalies reflecting a failure in the hepatobiliary-pancreatic development.
Thirty-one CCD trios were exome sequenced. Gene/pathway-set enrichment

analyses grouped genes with at least one damaging allele into focal adhesion and extracellular matrix-receptor interaction pathways.
Pathogenic mechanisms considered included *de novo* germ-line mutations and/or recessive inherited mutations in homozygosis, compound heterozygosis (CH) or as "di-genic/oligogenic" model of inheritance whereby variants in genes of related pathways coexist in a patient through parental inheritance.
Fifteen gene members of those pathways were recurrently mutated and had variants at different sites (more than one damaging allele per gene). These alleles were in compound heterozygosis or co-existing with a mutated functional gene-partner in the same individual.
Patients' genetic profiling revealed CCD as not only genetically heterogeneous but with di/oligogenic inheritance. Yet, the relevant mutated genes are functionally convergent. Data are consistent with the sporadic presentation of CCD. Incidentally, the cholangiocarcinoma rate in Asians is also the highest world-wide. We
are also aiming at finding possible links between these choledochal disorders and at explaining their high incidence in Asia.

PS03.13
Report of two CTRC intronic mutations associated with acute or chronic pancreatitis and delineation of their pathogenic molecular mechanisms

J. M. Chen[1], *E. Masson*[2], *C. Férec*[3];
[1]*INSERM U1078; Université de Bretagne Occidentale (UBO); EFS-Bretagne, Brest, France,* [2]*INSERM U1078; Centre Hospitalier Régional Universitaire (CHRU) Brest, Hôpital Morvan, Brest, France,* [3]*INSERM U1078; Université de Bretagne Occidentale (UBO); EFS-Bretagne; Centre Hospitalier Régional Universitaire (CHRU) Brest, Hôpital Morvan, Brest, France.*

Chymotrypsin C (CTRC) is highly specific in degrading all human trypsin/trypsinogen isoforms, constituting an important line of defense against prematurely activated trypsin within the pancreas. Since 2008, variants in the CTRC gene have been increasingly reported to be associated with chronic pancreatitis. However, to date, all reported CTRC intronic variants have been classified as "unknown significance" due to the lack of functional analytic data. During our routine mutational analysis of four pancreatitis genes, PRSS1, SPINK1, CTRC and CFTR, in patients with acute or chronic pancreatitis, we identified two intronic mutations in the CTRC gene, c.357-2A>G in intron 4 and c.640-12G>A in intron 6 (Table), both of which were absent in 350 healthy controls. We performed RT-PCR analyses of mRNAs prepared from cultured lymphocytes of patients I and II (Table), respectively: c.357-2A>G activated a cryptic splice acceptor signal that is located 147 bp upstream of the wild-type exon 4 whilst c.640-12G>A created a novel splice acceptor signal 8 bp upstream of the normal one. This is the first report of experimentally confirmed pathogenic CTRC intronic mutations associated with acute or chronic pancreatitis. The identification of a pathogenic CTRC variant in the three children or adolescent patients with acute pancreatitis has important implications for genetic counseling; these patients should be advised to avoid alcohol and smoking because they are at high risk in developing chronic pancreatitis.

Clinical data of pancreatitis patients with CTRC intronic mutations

Patient (sex)	Ethnicity	Diagnosis	Current age (y)	Age of first onset (y)	Family history	Mutation in CTRC	Mutation(s) in other pancreatitis genes
I (female)	French Caucasian	Chronic calcific with diabetes	58	20	Mother with the disease	c.357-2-A>G	CFTR p.F508del and SPINK1 c.27delC
II (male)	Moroccan	Acute	7	4	No	c.640-12G>A	No
III (female)	Cameroonian	Acute recurrent	20	18	No	c.640-12G>A	No
IV (female)	Algerian	Acute recurrent	12	6	No	c.640-12G>A	No

PM03.14
Genetic testing for congenital adrenal hyperplasia: the Canadian experience

R. E. Lamont, *H. Zarsky Johnson, L. Graham, J. S. Parboosingh;*
Alberta Children's Hospital, Calgary, AB, Canada.

Congenital adrenal hyperplasia (CAH) most commonly results from a deficiency of 21-hydroxylase, an enzyme in the biosynthetic pathway that converts cholesterol to cortisol and aldosterone. Mutations in CYP21A2, encoding 21-hydroxylase, are identified in >80% of individuals with CAH. CYP21A2 and its highly homologous pseudogene, CYP21A1P, reside within close proximity on 6p21; as a result >90% of CYP21A2 mutation-containing alleles are caused by gene conversion events from CYP21A1P or CYP21A2 deletions arising from non-allelic homologous recombination. Further, CYP21A2 full gene duplications exist and provide a source of false negative and false positive results as carriers of a CYP21A2 deletion may be masked by a CYP21A2 duplication on the opposite allele (2+0 configuration) or carriers of a point mutation may also carry a second non-mutated CYP21A2 in cis. In our lab current CYP21A2 testing consists of dosage analysis by MLPA and coding region sequencing from full-length gene PCR amplification, which currently will not detect 2+0 CYP21A2 deletion carriers. Here we present the distribution of mutations detected during genetic testing from the only CYP21A2 testing laboratory in Canada and present additional data further supporting the need for dosage analysis in all CYP21A2 analyses. We also present an experimental approach to identify individuals with 2+0 silent deletions and provide preliminary data of the prevalence of the 2+0 configuration in a control population of >900 individuals.

PS03.15
Molecular genetic diagnostics of congenital adrenal hyperplasia in the Czech Republic

P. Silerova, *Z. Hruba, Z. Vrzalova, E. Hrabincova, S. Pouchla, L. Kozak, L. Fajkusova;*
University Hospital Brno, Brno, Czech Republic.

Background: Congenital adrenal hyperplasia (CAH) is a group of inherited autosomal recessive disorders caused by enzymatic deficiency which impairs steroid hormone biosynthesis. About 90 % of all CAH cases are due to 21-hydroxylase deficiency (21-OHD) caused by *CYP21A2* gene aberrations. Most of the *CYP21A2* gene mutations result from recombination events with its pseudogene *CYP21A1P*. Mutations in the *CYP11B1, HSD3B2* and *CYP17A1* genes are genetic causes of 11-β-hydroxylase deficiency (11-βOHD), 3-β-hydroxysteroid dehydrogenase deficiency (3-βHSD) and 17-α-hydroxylase deficiency (17-αOHD), respectively.
Methods: For differential amplification of the genes and their homologs, long-range PCR is used (21-OHD, 11-βOHD). Diagnostics of 21-OHD is followed by restriction analysis, secondary PCR, sequencing and MLPA. Further *CYP11B1* analysis comprises secondary PCR and sequencing. Molecular diagnostics of 3-βHSD and 17-αOHD include PCR and sequencing.
Results: Molecular genetic testing confirmed the diagnosis of 21-OHD in 373 probands (45,8 %). Only one mutant allele was found in 80 (9,8 %) of the probands. The diagnosis of 11-βOHD was confirmed in one patient and 17-αOHD was confirmed in two patients. Analysis of -1888G/T and -1858A/G *CYP11B1* promoter SNPs revealed 23 probands (29,1 %) homozygous for -1888 T and -1858 G alleles. Homozygosity of these alleles is associated with reduced 11-β-hydroxylase efficiency.
Conclusion: Molecular genetic testing in our laboratory allows for the identification of mutations in the *CYP21A2, CYP11B1, HSD3B2* and *CYP17A1* genes in patients suspected of steroid hormone synthesis deficiency.

PM03.16
Whole Exome Sequencing in Congenital Hypogonadotropic Hypogonadism

L. Izatt[1], *P. Carroll*[2], *S. Lillis*[3], *Y. Patel*[3], *L. Brodd*[3], *K. Stone*[3], *K. Ryan*[4], *J. Wook Ahn*[4], *M. Simpson*[5], *M. Yau*[3];
[1]*Clinical Genetics, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom,* [2]*Diabetes and Endocrinology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom,* [3]*Genetics, Viapath, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom,* [4]*Bioinformatics, Viapath, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom,* [5]*Genomic Medicine Group, King's College London, London, United Kingdom.*

Congenital hypogonadotropic hypogonadism (CHH [MIM161110]) due to gonadotropin-releasing hormone deficiency is a rare genetic disorder (affects ~1/30,000) characterised by abnormal pubertal development and infertility. Over 60% cases have anosmia (Kallman syndrome) and some exhibit additional phenotypes. CHH is a genetically heterogeneous developmental disease. Most cases present sporadically, although familial forms (AD, AR and X-linked) with incomplete penetrance and variable expressivity occur. Research suggests it is emerging as a digenic or oligogenic disease, rather than a monogenic trait. Genetic testing for this condition has hitherto been costly, time-consuming and incomplete, with mutations identified in less than 30%.
In this study, we investigated three simplex cases (2M with partial anosmia, 1F) who presented with delayed puberty and hypogonadism due to isolated GnRH deficiency. Whole exome sequencing (WES) was performed on each patient using the Illumina HiSeq2500 platform and the Agilent SureSelect

Human All Exon v5 Kit. Following alignment to the human genome, an in-house pipeline applied a virtual panel to restrict the genes to be analysed based on the clinical presentation (22 CHH genes). Variants were filtered to identity potential pathogenic mutations, which were subsequently confirmed by Sanger sequencing.
Results: Five variants in three CHH genes (FGFR1, GNRHR and HS6ST1) were identified. Variants in these genes are recognised to result in deficient GnRH activity, confirming that a Kallman phenotype can result from mutations in CHH genes other than KAL1.
Conclusion: We demonstrate that WES, with analysis limited to relevant genes, can successfully and efficiently confirm a molecular diagnosis in a genetically and phenotypically complex disease, such as CHH.

PS03.17

Comprehensive genetic analysis of 35 unrelated Spanish patients with congenital adrenal hyperplasia due to 21-hydroxylase deficiency. Report of a novel frameshift mutation in the CYP21A2 gene.

P. Fernández-Álvarez[1], *H. Valbuena*[1], *O. Díez*[1], *A. Plaja*[1], *E. García-Arumi*[1,2], *D. Yeste*[3], *E. Tizzano*[1,2];
[1]*Area of Clinical and Molecular Genetics, University Hospital Vall d'Hebron, Barcelona, Spain,* [2]*Biomedical Network Research Centre on Rare Diseases (CIBERER), Instituto de Salud Carlos III, Madrid, Spain,* [3]*Pediatric Endocrinology, University Hospital Vall d'Hebron, Barcelona, Spain.*

We describe the *CYP21A2* mutation spectrum in a cohort of 35 unrelated North-East Spanish congenital adrenal hyperplasia (CAH) patients; 29 women and 6 men, 25 of them diagnosed in pediatric age. The distribution of the phenotypes was: salt-wasting SW (7 patients), simple virilizing SV (5 patients) and non-classical form NC (23 patients). All *CYP21A2* exons were sequenced to determine mutations and MLPA was performed to detect *CYP21A2* large deletions. A genotype-phenotype correlation was investigated. Two mutated alleles were detected in all SW and SV patients as well as in 19 of the 23 NC patients. In the remaining four only one mutated allele was found. A novel p.Leu343Cysfs*20 mutation was identified in a NC patient.
The following table shows *CYAP21A2* allele mutations by phenotype:

	SW	SV	NC	Total
p.Val282Leu			30(71,4%)	30(45,5%)
Total deletion	7(50%)	2(20%)		9(13,6%)
p.Ile173Asn		6(60%)	2(4,8%)	8(12,1%)
IVS2-13 A/C>G	4(29%)		3(7,1%)	7(10,6%)
p.Pro453Ser		1(10%)	2(4,8%)	3(4,5%)
p.Pro483Ser			2(4,8%)	2(3%)
p.Arg484fs	2(14%)			2(3%)
Gene conversions	1(7%)	1(10%)		2(3%)
p.Arg357Trp			1(2,4%)	1(1,5%)
p.Gln319X			1(2,4%)	1(1,5%)
p.Leu343Cysfs*20			1(2,4%)	1(1,%5)
Total	14	10	42	66

The most prevalent mutation in NC patients was p.Val282Leu, whereas p.Ile173Asn and a complete gene deletion were the most observed mutations in SV and SW patients, respectively. These findings are consistent with previously published data of a northern-Spain cohort. Genotype accurately predicted phenotype in more than an 85% of our patients. The finding of CAH cases with only one mutated allele underlies the importance to implement deep-sequencing tests to identify cryptic mutations in *CYP21A2* or mutations in other candidate genes.

PM03.18

Application of next-generation sequencing in the search of causative genes for Taiwanese patients with disorders of sex development

M. Tsai[1], *H. Yu*[2], *P. Chen*[2];
[1]*Department of Pediatrics, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan,* [2]*Institute of Clinical Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan.*

Objectives
This study aims primarily to establish a rapid and high-throughput genetic test for 46,XY DSD. Meanwhile, the applicability and effectiveness of next-generation sequencing are to be evaluated in searching for the remaining unknown causative genes of this inherited disease.
Methods
A membrane hybridization method was used as the main strategy for target sequence enrichment. In a stepwise manner, the capture filter for target genes were designed and developed under specific conditions so that whole-genome fragment DNA libraries could be set up appropriately. The amplified exomes of target genes were hybridized against the DNA libraries and sequenced subsequently.
Results
We have enrolled 6 46, XY DSD patients in this study. Targeted smplicons have been generated and are currently under investigation of their capture efficiency. Exome sequencing has been performed with genomic DNA from two of the patients. Potential disease-causing variants have been identified. A total of 2 genetic variants were identified and thought as the main cause for DSD. One is a missense mutation F846 on the ATRX gene, while the other one is indel with V176_K177insV on the TSPYL1 gene.
Conclusion
Finding the causative gene of a heterogenetic disease is challenging even with recent development of NGS and bioinformatics. In our study, we have a list of candidate disease-causing variants that need to be carefully studied in the cell model system with biochemical assays. Our results indicate that NGS aids on genetic diagnosis of 46,XY DSD.

Methods: Oral Glucose tolerance test (OGTT) was carried out in non-diabetic young DYRK1BR102C mutation carriers and non-carrier relatives. The skeletal muscle (SM) biopsies of these probands were examined by RNA-Seq and Western blot analysis. In addition, wild type and mutant DYRK1B and empty lentivirus constructs were administrated to C56Bl6 mice and their effects on body weight and plasma glucose and key regulators of insulin signaling were examined.
Results: Pathway-based analysis of the SkM RNA-Seq data revealed preferential expression of genes involved in cytoskeletal remodeling, including ACTN3, SLC16A3, MYH11, Grem2, MYL6B, MSS51, and MYLPF. Consistent with RNA-Seq data, staining of SkM of carriers and non-carriers for slow- and fast-twitch fibers demonstrated higher ratio fast glycolytic fibers in mutation carriers than non-carriers (65% vs. 40%). DYRK1B mutation carriers exhibited higher baseline insulin levels (16.7uIU/mL) and compared to non-carriers (8.4uIU/mL) and had higher plasma glucose levels in response to oral glucose ingestion that is indicative of insulin resistance in carriers of R102C mutation. Mice overexpressing DYRK1BR102C allele were similarly insulin resistant.Western blot analysis and Mass Spectrometry of liver proteins illustrated increased expression of G6Pase, PEPCK, Glucokinase, and Pyruvate carboxylase, in mice overexpressing mutant and wild type DYRK1Bcompared to empty vector.
Conclusions: Our findings suggest that DYRK1B initiates cytoskeletal remodeling and causes insulin resistance, while it triggers hepatic gluconeogenesis by enhancing the expression of key gluconeogenic enzymes.

PM03.20

Genetic and functional interactions between β1 integrins and endothelin-3 during enteric nervous system development

E. Gazquez[1,2], *Y. Watanabe*[2], *F. Bondon-Broders*[1], *P. Paul-Gilloteaux*[3], *V. Baral*[2], *J. Heysch*[1], **N. Bondurand**[2], *S. Dufour*[1,2];
[1]*Institut Curie/CNRS UMR 144, Paris, France,* [2]*IMRB INSERM U955, Creteil, France,* [3]*PICT-IBiSA, Paris, France.*

The enteric nervous system (ENS) results from the colonization of the developing gut by enteric neural crest cells (ENCCs). During their migration, ENCCs proliferate and differentiate into glial and neuronal cells, which aggregate into ganglia and give rise to the intrinsic innervation of the bowel. A proper ENS formation requires many different factors among which are the G-coupled receptor EDNRB, its ligand endothelin-3 (EDN3), and Itgb1 encoding the β1-integrin subunit. Interestingly, the enteric phenotype of conditional Itgb1 mutants resembles the phenotype described for Edn3 or Ednrb mutants, i.e. lack of innervation in the distal part of the colon, reminiscent of Hirschsprung disease in Human. Otherwise, EDN3 was shown to regulate adhesion properties of cancer cells and astrocytes.

Considering these observations, we investigated a putative role of EDN3 on ENCC adhesion properties and its functional interaction with β1-integrins during ENS development. We discovered that EDN3 promotes ENCC adhesion in vitro. It stimulates β1-integrin activation and increases the number of ENCCs focal adhesions. Upon EDN3 treatment, ENCCs rapidly exhibited changes in cell shape and membrane dynamics displaying a sustained growth and persistence of lamellipodia. Morever, in vivo double-mutant studies showed that itgb1-/-; Edn3ls/ls mutants displayed an aggravated enteric phenotype and an altered ENS network organization. Ex-vivo live imaging of embryonic guts allowed us to evidence severe migratory defects of double mutant ENCCs that contribute to the enteric defects observed.
Altogether our results reveal that interplays between EDN3 and β1-integrins are crucial for proper ENS ontogenesis.

PS03.21
The analysis of APOB-100, LRPAP1, ABCG5 and ABCG8 genes polymorphisms in gallstone disease patients and healthy donors from Volga-Ural region of Russia

A. Sagdatova[1], *A. Nurgalieva*[2], *S. Zagidullin*[1], *E. Khusnutdinova*[2,3];
[1]*Bashkir State Medical University, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation,* [3]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation.*

Gallstone disease (GSD) is a metabolic diseases of the hepatobiliary system, characterized by the formation of gallstones in the gallbladder, common bile duct stones in the liver bile ducts. 10% of the population suffers from gall stones, and the number of patients in the world with each passing decade becomes larger. The aim of this study was to exam the association of polymorphisms of APOB-100 (rs693), LRPAP1 (rs11267919), ABCG5 (rs4131229) and ABCG8 (rs11887534) genes with the risk of gallstone disease. The patient group consisted of 205 patients with with cholelithiasis, the control group included 190 unrelated healthy individuals. Genomic DNA was extracted from peripheral blood leucocytes by standard phenol/chloroform method. Genotyping was performed by PCR followed by restriction digestion. The analysis has revealed that heterozygous genotype X+X- of rs693 of APOB-100 gene is a marker of increased risk of gallstone disease in Russian (p = 0.03; OR = 2,1). For those of Tatar ethnicity shows that rs693*X-allele and C allele of rs4131229 of ABCG5 gene are markers of increased risk of developing the disease (p = 0,002; OR = 2,0 and p = 0,02; OR = 1,7, respectively), while rs693*X +, rs4131229*T alleles and of rs4131229*T/T genotype are a markers of reduced risk of gallstone disease (p = 0,002; OR = 0,5; p = 0,02; OR = 0.6 and p = 0,03; OR = 0,5, respectively). Results of the study shows that the polymorphisms of the APOB-100 and ABCG5 genes are associated with the risk of gallstone disease.

PM03.22
The mutational analysis of the INF2 gene in Czech patients with FSGS and MCD

M. Šafaříková[1], *J. Reiterová*[2], *J. Štekrová*[1], *M. Kohoutová*[1], *V. Tesař*[2];
[1]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic,* [2]*General University Hospital, Prague, Czech Republic.*

We started to screen for mutations in the INF2 gene in 136 Czech patients (49.82 ± 17.91) with FSGS/MCD. The INF2 protein plays a key role in the function of the slit diaphragm in podocytes.
We have so far identified one already known missense mutation with the proven damaging effect on the function of podocytes. The substitution Arg218Gln, which was in the heterozygous state, was found in two brothers (thirty-two and thirty-one years old) with a positive family history who suffered from FSGS. The heterozygous state did not correlate with the rapid progression and early development of the ESRD (twenty-seven and thirty-one years, respectively), while their father developed ESRD at fifty-seven years. For that reason, we suppose the collaboration of more factors, such as other substitutions in the INF2 gene or in other genes connected with FSGS or the influence of environment, in the case of these two brothers.
The other interesting findings were the undescribed heterozygous changes p.Pro208Ser (c.622 C>T) in the anonymous patient and p.Pro1057Leu (c.2640 C>T) in forty-three years old man (FSGS, negative family history). However, according to predictive programs (PolyPhen-2 and PON-P2), this substitution is not probably causal. It was also found the already known substitution p.Arg214His (c.641 G>A) with proven damaging effect in fifty-one years old woman (FSGS, positive family history).
The previous mentioned results are first data from the mutational analysis of the INF2 gene in Czech patients with FSGS/MCD. The similar study focused on the INF2 gene has never been performed in the Czech Republic.
Supported by the grant project PRVOUK- P25/LF1/2.

PS03.23
Abernathy malformation: a rare association with Goldenhar syndrome

A. de Burca[1], *J. Collier*[2], *H. Bungay*[2], *E. Blair*[1];
[1]*Oxford Department of Clinical Genetics, Oxford, United Kingdom,* [2]*John Radcliffe Hospital, Oxford, United Kingdom.*

Abernathy malformation is a rare congenital malformation characterised by absence or hypoplasia of the hepatic portal vein, resulting in a congenital portosystemic shunt. Consequences of the malformation include focal nodular hyperplasia of the liver, hepatoblastoma and hepatic encephalopathy.
Our patient is a 27 year old woman who was referred to the genetics clinic for preconception counselling due to a diagnosis of Goldenhar syndrome. She was diagnosed with focal nodular hyperplasia of the liver aged 15. Review of historic imaging and magnetic resonance cholangiopancreatogram revealed a type 1a Abernathy malformation, likely to be the cause of the focal nodular hyperplasia.
Congenital absence of the portal vein has been previously described in one individual with Goldenhar syndrome. In this case focal nodular hyperplasia developed into hepatoblastoma requiring liver transplantation. Abernathy malformation is a rarely reported association of Goldenhar syndrome that can cause serious hepatic complications.

PM03.24
Metallothioneins are downregulated in ileal mucosa of Familial GUCY2C diarrhea syndrome patients susceptible to Crohn´s disease

R. R. Tronstad[1,2], *H. Brattbakk*[2], *C. Stansberg*[2], *K. Hanevik*[2], *K. D. -. Pham*[1], *E. Ellinghaus*[3], *K. M. Ersland*[2], *H. L. von Volkmann*[2,1], *S. F. Jørgensen*[4,5], *O. H. Gilja*[2,1], *N. Hovdenak*[1], *T. Hausken*[2,1], *M. H. Vatn*[5,6], *A. Franke*[3], *P. M. Knappskog*[2,1], *T. H. Karlsen*[5,4], *S. Le Hellard*[2,1], *T. Fiskerstrand*[2,1];
[1]*Haukeland University Hospital, Bergen, Norway,* [2]*University of Bergen, Bergen, Norway,* [3]*Christian Albrechts University of Kiel, Kiel, Germany,* [4]*University of Oslo, Oslo, Norway,* [5]*Oslo University Hospital Rikshospitalet, Oslo, Norway,* [6]*Akershus University Hospital, Oslo, Norway.*

Background: Familial *GUCY2C* diarrhea syndrome (FGDS), first described in a Norwegian family (n=38), is caused by an activating mutation in the gene encoding guanylate cyclase C. Patients with FGDS have early onset mild diarrhea but are also susceptible to ileal Crohn's disease (CD) (7 patients). The aim of the present study was to compare global gene expression in ileal biopsies (non-inflamed mucosa) from FGDS patients (n=11), unrelated CD patients (n=6) and healthy controls (n=16). We also assessed whether CD genetic risk variants segregate with CD in the FGDS patients.
Methods: Global gene expression was examined using Illumina Human HT-12 v4 BeadChip. 140 CD risk variants were genotyped (Immunochip array) and the *NOD2* gene was sequenced in 23 adult FGDS-patients (7 with CD).
Results: Nine metallothioneins were significantly downregulated (1.5-3 fold) in FGDS patients, but not in unrelated CD patients, compared to controls. The polygenic risk score did not differ significantly between FGDS patients with and without CD. However 6 of the 7 FGDS patients with CD carried *NOD2* risk variants, and the two most severely affected patients were homozygous for the rs5743289 risk allele . Three of 16 FGDS patients without CD were heterozygous for *NOD2* risk variants
Conclusion: Metallothioneins were significantly downregulated in non-inflamed terminal ileum of FGDS patients, but not in unrelated CD patients compared to controls. Lower levels of these zinc-binding proteins may cause inflammation due to interference with NOD2-stimulated bacterial clearance and autophagy. Further studies are warranted to investigate guanylate cyclase C-related susceptibility to Crohn´s disease.

PS03.25
Molecular analysis of KAL-1 and GnRHR genes in patients with idiopathic hypogonadotropic hypogonadism

I. Pereira-Caetano[1], *J. Silva*[1], *T. Kay*[2], *A. Mirante*[3], *J. M. Aragüés*[4], *M. R. Mascarenhas*[5], *J. Gonçalves*[1];
[1]*Unidade Genética Molecular, Departamento Genética Humana, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisboa, Portugal,* [2]*Serviço Genética Médica, Hospital D. Estefânia - CHLC-EPE, Lisboa, Portugal,* [3]*Serviço Endocrinologia, Hospital Pediátrico Coimbra - CHC-EPE, Coimbra, Portugal,* [4]*Serviço de Endocrinologia, Diabetes e Metabolismo, Hospital Santa Maria – CHLN-EPE, Lisboa, Portugal,* [5]*Clinica de Endocrinologia, Diabetes e Metabolismo, Lisboa, Portugal.*

Introduction: Idiopathic hypogonadotropic hypogonadism (IHH) comprises delayed/absent puberty, infertility and low serum gonadotropins in the context of normal anterior pituitary anatomy and function. Is due to partial/complete absence of gonadotropin-releasing hormone release/action or gonadotropin secretion and its incidence is low (1/10.000-1/86.000) with a nearly 4:1 male-to-female ratio. Approximately two-thirds of individuals with IHH have anosmia or hyposmia (Kallmann syndrome-KS) and one-third

have normosmic IHH (nIHH). Mutations in *KAL1* gene cause X-linked KS, and in *GnRHR* gene autosomal recessive IHH (almost 2% of nIHH patients).
Material and Methods: 45 patients with IHH (42 males, 3 females), with and without hyposmia/anosmia were studied. Mutation analysis of *KAL1* and/or *GnRHR* was performed by SSCP/DHPLC-PCR or by PCR-direct DNA sequencing.
Results: We found two *KAL1* mutations: c.769C>T (p.Arg257*) in a 15-years-old anosmic male; and a novel one, an extensive deletion encompassing exons 4 to 14 confirmed by MLPA, in a 3-years-old boy (detected also in his mother) with micropenis and maternal family history of HH. Two nIHH male patients were compound heterozygous for *GnRHR*: c.[2T>C];[785G>A], p.[(M1T)];[(R262Q)] (39-years-old, prepubertal testicules, gynecomastia, P1-A0 pilosity) and c.[317A>G];[416G>A], p.[(Q106R);(R139H)] (35-years-old with a brother non-tested with similar phenotype). All four mutations are known to be disease-causative.
Discussion: We were able to find the genetic defects in 4 patients. The low detection rate of mutations (8.8%) is related with the existence of several genes implicated in the IHH' pathogenesis. The NGS analysis in patients with IHH may improve the molecular diagnosis as it allows the screening of different genes simultaneously.

PM03.26

Systematic analysis of chromatin interactions at disease associated loci links novel candidate genes to Inflammatory Bowel Disease

C. A. Meddens[1], *M. Harakalova*[2], *N. van den Dungen*[2], *E. Cuppen*[2,3], *F. Asselbergs*[2], *E. Nieuwenhuis*[1], *M. Mokry*[1];
[1]*Wilhelmina Children's Hospital, Utrecht, Netherlands,* [2]*University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Hubrecht Institute, Utrecht, Netherlands.*

Introduction: Genome wide association studies (GWASs) have revealed numerous genomic loci that are associated with complex genetic diseases. Subsequently, many candidate genes have been defined, mainly based on the functional relationships between genes found in the vicinity of the identified loci. However, many of these loci can be linked to regulatory DNA sequences and it is now widely appreciated that part of the GWAS associations is due to sequence variation in regulatory elements. Therefore, the genes controlled by these regulatory elements should be considered as possible candidate genes. Since regulatory elements can regulate genes via chromatin-chromatin interactions that comprise up to 1 Mb, these genes cannot be identified based on base-pair distance from the regulatory regions. To address this, we used chromatin conformation capture-sequencing (4C-seq) to systematically determine the genes that are physically interacting with regulatory units that overlap the disease associated SNPs in Inflammatory Bowel Disease (IBD).
Results: We assayed chromatin interactions in monocytes, lymphocytes and in DLD-1 cells – major cell types implicated in IBD pathogenesis. We performed 4C-seq for 92 IBD-associated loci that localize to regulatory elements in all three cell types. Our approach links 815 novel genes, including *IL10RA, SMAD5, SMAD6* and *PIAS1*, to IBD.
Conclusion: We have performed a novel candidate gene approach in which chromatin interaction data on GWAS-susceptibility loci are intersected with the information about DNA regulatory elements and gene expression in relevant cell types. This revealed 815 novel candidate genes, consisting of multiple notable genes like *SMAD6, IL10RA, PIAS1* and *SMAD5,* thereby complementing previously reported candidate gene approaches.

PS03.27

Johanson-Blizzard syndrome in an Omani infant with neural tube defect: a coincidental findings or a consequence of UBR1 mutation ?

A. Al-Kindy;
Sultan Qaboos University Hospital, Muscat, Oman.

Johanson-Blizzard syndrome (JBS), #243800 is a rare, autosomal recessive multisystem disorder characterized by exocrine pancreatic insufficiency and aplasia/hypoplasia of alae nasi. Additional common features include ectodermal dysplasia, hypothyroidism, growth hormone deficiency, sensorineural hearing loss, urogenital and anorectal anomalies and cognitive dysfunction of variable degrees. Mutations of *UBR1* (MIM #605981) are known to cause JBS. The UBR1 represents one of at least four E3 ubiquitin ligases of the N-end rule pathway, an evolutionary conserved and ubiquitously expressed intracellular proteolytic pathway involved in ubiquitin-mediated degradation of many proteins. JBS has wide and highly variable clinical manifestation with rare malformations observed in some patients with molecularly confirmed JBS. We report a newborn Omani with JBS and a novel truncating mutation in *UBR1*. The clinical features include a beaked nose, hypoplasia of nasal wings, exocrine pancreatic insufficiency presenting with severe failure to thrive and septicemic shock, severe anemia requiring frequent blood transfusion, anal atresia, sparse hair, scalp defect, lumbosacral meningo-myelocele and hydrocephalus.This is a second report of neural tube defect in association with JBS implying that this association is as a result of *UBRI* mutation rather than coincidental. The phenotypic defects in JBS involve several organ systems in addition to pancreas suggesting that UBR1-mediated protein degradation plays a critical role at certain stages of human development, and in specific cell types.

Targeted panel sequencing of 399 renal genes reclassifies primary disease diagnoses in young end stage renal disease patients

A. M. van Eerde[1], *A. van der Zwaag*[1], *M. H. de Borst*[2], *E. Peters*[1], *K. Renkema*[1], *M. Elferink*[1], *P. van Zon*[1], *M. Lilien*[3], *G. van Haaften*[1], *G. Navis*[4], *N. Knoers*[1];
[1]*Department of Medical Genetics, University Medical Center, Utrecht, the Netherlands, Utrecht, Netherlands,* [2]*Department of Nephrology, UMC Groningen, Groningen, Netherlands,* [3]*Paediatriuc Nephrology, University Medical Center, Utrecht, the Netherlands, Utrecht, Netherlands,* [4]*Department of Nephrology, University Medical Center, Groningen, the Netherlands, Groningen, Netherlands.*

Background: About a quarter of patients with end stage renal disease (ESRD) before age 30 do not have a primary renal disease diagnosis. Previous genetic studies have focused on specific clinical diagnoses. We took an innovative approach by sequencing a panel of 399 renal disease genes in 200 cases with ESRD onset before age 30, regardless of their clinical diagnosis. Data for the first 132 cases are presented.
Methods: We designed the "RENome" using SureSelect/Agilent with 399 genes involved in hereditary renal disease. We used SOLiD™ 5500XL for sequencing and an in-house developed bioinformatics pipeline for mapping, variant calling and QC. Variants were annotated using CARTAGENIA software.
Results: On average >95% of in target bases were genotyped, with >99% sensitivity and specificity. Stringent filtering criteria allowed only for coding variants with percentage variant reads of >15%, novel or with allele frequency of <0.005, that were listed as disease-causing in HGMD Pro, had a SIFT score <0.05 and were not predicted to be benign in PolyPhen2. We also selected samples with likely CNVs. Extended analyses, with less stringent filtering criteria and in depth copy number analyses, are presented at the meeting.
Conclusion: This filtering strategy yielded a molecular diagnosis in 15 patients (11.4%), confirming the registered primary disease in 6, and unexpectedly reclassifying it in 9. Considering the stringency of filtering, these numbers underestimate the diagnostic potential of our innovative approach. Adding early RENome sequencing to the diagnostic work-up in all young ESRD patients, improves etiologic classification and genetic counseling.
AMvE is supported by the Dutch Kidney Foundation and Fonds NutsOhra

PS03.29

Significant association of KIR2DL3/HLA-C1 combination with susceptibility to Crohn´s disease

R. Diaz Pena[1,2], *J. Vidal- Castiñeiras*[1], *M. Moro*[1], *R. Alonso-Arias*[1], *P. Castro- Santos*[2];
[1]*Hospital Universitario Central de Asturias, Oviedo, Spain,* [2]*Universidad Autónoma de Chile, Talca, Chile.*

Introduction: The killer cell immunoglobulin-like receptors (KIRs) form a group of regulatory molecules that specifically recognize HLA class I molecules. The aim of this study was to analyze the possible association of specific KIR genes and KIR/HLA-C genotypes with the susceptibility to Crohn's disease (CD) in a Spanish population.
Materials and Methods: A total of 125 patients with RA and 339 healthy control subjects were selected for this study based on clinical criteria. The commercial KIR-SSO typing kit from Luminex (Tepnel Lifecodes) was used to investigate KIR and HLA-C typing.
Results: The centromeric A/A genotype was more frequent in CD patients ($P<10^{-3}$). When we included HLA-C analysis, we found that the centromeric A/A genotype and HLA-C1 combination was significantly increased in CD patients ($P<10^{-3}$). Moreover, KIR2DL2/2DL3 genotype demonstrated a decreased frequency in CD patients (P<0.0005), whereas the KIR2DL3/2DL3 genotype was significantly increased in CD patients (P<0.0005). Remarkably, we also observed a highly significant increase of the KIR2DL3/KIR2DL3 HLAC1/HLAC1 homozygosis in CD patients (P<0.0005).
Conclusion: Our results confirm the relevance of the KIR2DL2/KIR2DL3 genes and their interaction with HLA-C in CD. The presence of a particular KIR-HLA pair may confer functional competence on NK cells and influences differences in NK cell functional responses among individuals. We show that the contribution of the KIR genes to CD susceptibility extends beyond the association with individual KIRs, with an imbalance between activating and inhibitory KIR genes seeming to influence the susceptibility to CD.

Endocrine neoplasia: translational outcome of the genetic study

S. Birla, *E. Malik, V. P.Jyotsna, R. Singla, S. Aggarwal, A. Sharma;*
All India Institute of Medical Sciences, New Delhi, India.

Multiple endocrine neoplasia (MEN) syndromes are characterized by tumors of endocrine and non endocrine organs. They are autosomal dominant disorders and categorized into MEN1, MEN2, Carney complex (CNC), von Hippel-Lindau disease (VHL) etc. caused by genetic lesions in genes like *RET, MEN1, PRKAR1A* with an involvement in regulation of cell growth, differentiation and death.

Definitive treatment is timely screening and surgical resection of tumors. Information on mutation status facilitates effective prophylactic interventions obligatory for management and survival of the patients and their relatives.

The present study reports on mutation screening of *MEN1*, *RET* and *PRKAR1A* in 113 patients and 100 controls. Majority of the patients had characteristic clinical presentations.Some exhibited rare symptoms of acromegaly and infertility as in Carney complex, and another patient showed cutaneous lichen amyloidosis associated with MEN2A. Molecular analyses revealed *RET* hotspot mutation 'C634R' in 36% cases (Table-1). Novel and reported mutations and polymorphisms were identified in the genes screened. *In silico* analysis using computational algorithms predicted the changes to be pathogenic providing evidence for their role in disease causation. Predictive genetic testing was provided to 'at risk' family members to identify changes followed by extensive clinical evaluation of neoplastic changes if any. Translation of genetic findings was achieved by comprehensive evaluation followed by cost effective surveillance and prophylactic surgeries of asymptomatic family members wherever required.

Table-1 Mutations identified in the present study

S.No	Gene	Phenotype	Genotype	Position	Nature of mutation/SNP
1	*MEN1*	Hyperparathyroidism and gastrinoma	14 bp deletion	Exon8	**Novel**
2		Insulinoma	c.445-44G→A	Intron2	**Novel**
3		Insulinoma	M561K	Exon10	**Novel**
4		Insulinoma	c.913-42G→C	Intron6	**Novel**
5	*RET*	Medullary thyroid carcinoma and cutaneous lichen amyloidosis	C634R	Exon11	Reported
6	*PRKAR1A*	Cardiac myxoma, acromegaly and infertility	22bp insertion	Exon6	**Novel**

PS03.31

Clinical exome sequencing for improved diagnostics and treatment of patients visiting a multidisciplinary nephrogenetic outpatient clinic

D. Lugtenberg, *E. A. M. Cornelissen, I. Rood, J. Schoots, J. K. J. Deegens, J. M. Hofstra, J. van Reeuwijk, J. F. M. Wetzels, H. H. Arts, R. Roepman, C. Gilissen, E. Kamsteeg, E. M. H. F. Bongers;*
RadboudUMC, Nijmegen, Netherlands.

Single gene disorders are estimated to account for ~30% of children and ~10% of adult patients attending renal outpatient services. In the Radboudumc a multidisciplinary nephrogenetic outpatient clinic for children and adult patients with (genetic) kidney diseases has been established by a team of (pediatric) nephrologists and a clinical geneticist. Clinical exome sequencing for a broad spectrum of isolated- and syndromic renal (ciliary) disorders has been developed. The approach consists of a two-tier analysis in which the first step is to screen for pathogenic variants in genes that are known to be mutated in renal diseases (170 genes) or (renal) ciliopathies (125 genes). If causative mutations are not identified in the first step, the complete exome data set can be analysed with informed consent. The first results with the renal disease gene panel in 63 unrelated patients with undiagnosed renal disease led to pathogenic mutations in nine cases (14%), and in 11 other cases (17%) likely pathogenic variants needed follow-up studies. Further analysis of the complete exome data set in 17 patients, revealed novel candidate genes in two cases that are under investigation. In addition, copy number variation analysis of exome data revealed a pathogenic deletion of the *NPHP1* gene in two cases, confirming the clinical diagnosis. We conclude that the combination of the multidisciplinary outpatient clinic with diagnostic exome sequencing provides a powerful tool for detecting causative mutations in up to 23 out of 63 patients (35%) with a renal disease.

Introduction Nephronophthisis is an autosomal recessive renal ciliopathy that constitutes the leading monogenic cause of end-stage renal disease in children. The KOUNCIL consortium is a collaboration between the UMC Utrecht, the Radboudumc Nijmegen and UC London aimed at elucidating the genetic etiology and pathophysiological mechanisms underlying nephronophthisis and identifying drugs that prevent renal failure. Our goal is to improve early genome diagnostics, genetic counseling and therapeutic options for nephronophthisis patients.**Methods** We employ next-generation sequencing to identify novel disease genes in 100 nephronophthisis patients included within the AGORA biobank project. The functional effect of novel mutations is assessed using *in vitro* and *in vivo* models. Genotypic and phenotypic patient characteristics are registered in a nephronophthisis database, facilitating correlation analyses and the identification of early phenotypic markers. Newly identified genes are incorporated into a diagnostic targeted next-generation sequencing panel of ciliary genes. We use a systems-biology approach to identify and functionally characterize nephronophthisis-associated protein modules. Finally, we use high-throughput repurposing screens in zebrafish embryos to discover drugs that halt progression of renal failure.**Results** We expect to uncover the causal mutation in 60-90% of nephronophthisis patients. KOUNCIL members were involved in the identification of three novel genes (*IFT172*, *WDR34* and *WDR60*) for nephronophthisis-related disorders. Clinical guidelines and new diagnostic tools for nephronophthisis are developed and implemented in genome diagnostics. We expect to identify FDA-approved drugs that can lead to novel therapies for nephronophthisis.**Conclusion** The KOUNCIL study is designed to advance understanding of renal ciliopathies and improve clinical care for nephronophthisis patients. KOUNCIL is funded by the Dutch Kidney Foundation (CP11.18).

Diagnostics of autosomal recessive polycystic kidney disease by NGS

J. Štika[1], *G. Nagyová*[2], *S. Peková*[1];
[1]*synlab genetics s.r.o., Prague, Czech Republic,* [2]*2nd Department of Pediatrics, Comenius University Medical School and University Children´s Hospital, Bratislava, Slovakia.*

Introduction: Mutations in the *PKHD1* gene cause autosomal recessive polycystic kidney disease (ARPKD). The *PKHD1* gene is located on chromosome 6 and consists of 68 exons. The incidence of ARPKD is approximately 1:30 000. Some newborns with ARPKD die due to insufficiently developed lungs. In those who survive, the disease is manifested by backbone and limb deformations, unusual facial features and distended abdomen. *Kidney function* deteriorates progressively towards renal failure. Fortunately, dialysis and transplantation can extend patients' lifespan.

Materials and Methods: The analysis of the *PKHD1* gene was carried out by next generation sequencing (GS-Junior, Roche). In-house designed primers were used for amplicon preparation. Amplicons cover all coding exons and exon-intron boundaries. Universal design for library preparation was used.

Results: DNA samples of eleven unrelated patients with symptoms of ARPKD were analysed. Thr36Met - a heterozygous mutation causal for ARPKD was identified in five samples. This mutation was accompanied by the second heterozygous mutation in all five cases. Those five mutations have been previously described in literature in patients with ARPKD, namely Arg92Trp, Gly112Arg, Leu2128Ter, Ile2331Lys and Ile2957Thr. In addition, heterozygous mutations - one considered as deleterious Gly1712Arg and one novel Gln1122Ser - were found in one sample. In five samples we did not find any deleterious or suspicious mutations.

Conclusion: Our method allows reliable analysis of the *PKHD1* gene to be achieved in a few days. To assess the clinical significance of novel mutations, it is necessary to analyze the *PKHD1* gene in the individual members of patients' families.

PM03.34

Evidence for a dosage-sensitive mutational network in a cohort of 308 patients with early and severe forms of polycystic kidney disease

S. Neuber[1], *E. Decker*[1], *J. Devane*[2], *C. Kramer*[2], *T. Eisenberger*[1], *M. Hiersche*[1], *C. Decker*[1], *H. J. Bolz*[1], *D. Epting*[2], *E. Ott*[2], **C. Bergmann**[1,2];
[1]*Bioscientia Center for Human Genetics, Ingelheim, Germany,* [2]*Renal Division, Department of Medicine, University Hospital Freiburg, Freiburg, Germany.*

Polycystic kidney disease (PKD) is the most common potentially life-th-

reatening human genetic disorder. In addition to recessive ARPKD, 2-5% of patients with dominant ADPKD show early and severe disease. Genetic testing is cumbersome because of the size and structure of major disease genes and increasing genetic heterogeneity. We established a novel customized sequence capture based NGS panel for PKD that currently targets 95 genes. In total, we analysed a cohort of 308 patients with early and severe PKD. The majority of patients carried mutations in *PKD1, PKD2,* and *PKHD1*, however a subgroup harboured mutations in genes typically related to other ciliopathies such as nephronophthisis, Joubert, Meckel, and Bardet-Biedl syndrome. We demonstrate that *PKD1* is a driver for early and severe manifestations in families with dominant ADPKD. Notably, mutations in both ADPKD genes can also be identified in patients with recessive PKD. A proportion of patients carry aggravating mutations in more than just one single gene/allele in the context of a functionally proven dosage-sensitive network. Zebrafish and Xenopus are used as models for validation of some of our findings. This is the most comprehensive study performed so far by which we propose a dosage-sensitive model for early and severe forms of PKD. Our NGS panel allows the parallel analysis of all disease genes including the pseudogene-variable *PKD1* gene which plays a decisive role in cyst initiation. An accurate genetic diagnosis is crucial for genetic counselling, prenatal diagnostics and the clinical management of patients.

PS03.35

AN ATYPICAL AND RARE FAMILIAL PULMONARY FIBROSIS CASE WITH A PATHOGENIC SFTPC GENE MUTATION: DIAGNOSIS IN THE DETAIL

V. P. McConnell[1], *A. J. Fisher*[2], *T. McManus*[3];
[1]*Northern Ireland Regional Genetics Service, Belfast, United Kingdom,* [2]*Institute of Transplantation, Newcastle Upon Tyne Hospitals NHS FT Trust, Newcastle Upon Tyne, United Kingdom,* [3]*South West Acute Hospital, Western Health & Social Care Trust, Enniskillen, United Kingdom.*

Familial pulmonary fibrosis (FPF) is defined as idiopathic interstitial pneumonia (IIP) in ≥ 2 first-degree relatives with diagnosis based on established clinical criteria. The clinical findings of IIP are bibasal reticular abnormalities, ground glass opacities, or diffuse nodular lesions on high-resolution computed tomography and abnormal pulmonary function tests that demonstrate intrapulmonary restriction. Mutations in TERT, TERC, and SFTPC genes have been identified in about 8%-15% of individuals with FPF and 1%-3% of simplex cases with SFTPC mutations associated with Pulmonary surfactant metabolism dysfunction-2 (SMDP2), inherited in a autosomal dominant manner detected in ≤1% for FPF and simplex cases.
The 26 year old female proband presented after an immigration chest xray demonstrated increased bronchial wall markings in lower zones having had a 2 year history of shortness of breath. Subsequent investigations including HRCT chest and VATS lung biopsy showed appearances in keeping with extensive interstitial fibrosis with a usual interstitial pneumonia type picture. The only deceased sister had reported history of failure to thrive and recurrent pneumothoraces from 17. Subsequent genetic testing detected the proband to be a heterozygous carrier of a pathogenic SFTPC mutation which was maternally inherited.
Further presentation of the familial clinical phenotype and genetic investigation will be presented which illustrates the variable intrafamilial clinical phenotype, adds to the knowledge on SMDP2 gene phenotypic spectrum, the complexity of the diagnostic pathway with rare disease and need for close multidisciplinary liaison, whilst highlighting the importance of clarification of family history and phenotyping.

Integrating genetic analysis with phenotypes of biliary atresia

G. CHENG[1], *P. H. CHUNG*[1], *W. TANG*[1], *E. H. WONG*[1], *E. K. CHAN*[2], *M. SO*[1], *P. SHAM*[1], *S. S. CHERNY*[1], *P. K. TAM*[1], *M. GARCIA-BARCELÓ*[1];
[1]*The University of Hong Kong, Hong Kong, Hong Kong,* [2]*The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

We aim to explore the role of rare copy number variants (CNVs) in non-syndromic BA. We revisited clinical records of 89 non-syndromic type III BA patients with median follow up of 17.20 years, which revealed that 41.57% BAs were affected with chronic extra-hepatic diseases, with high prevalence of autoimmune-allergic diseases (22.47%) and Glucose-6-phosphate dehydrogenase deficiency (14.29% of the males). After genotyping on the genome-wide Affymetrix5.0 array, we shortlisted 29 'BA-CNVs' found in BA patients but not in the general population, and collated 103 BA-associated genes from a gene-based genome-wide association analysis on common variants, for downstream analysis. In BA-CNVs we discovered three categories of genotype-phenotype correlations: i) two de novo BA-CNVs, perturbing genes/chromosome-segments known to BA, correlated with BA; ii) three BA-CNVs encompassing genes known to immunity defects, correlated with comorbidities of those immune disorders in 3 carriers; iii) importantly, genes affected by BA-CNVs (N=102; gene set-1) were enriched with immune genes, correlated with the high prevalence of immunity disorders in BA. Further, we proved significant connectivity between gene set-1 and genes tagged by common variants (N=103; gene set-2) (Empirical p=0.039). As multiple function modules were elucidated in topological analysis of the BA candidate gene network, a 'core' position of cellular signalling pathways, which affect inflammatory and immunity regulation pathways, was highlighted.
Conclusions: BA-CNVs underpin BA phenotypic complexity, and converge with those BA-associated common variants in a molecular network implicated in BA pathogenesis. Integrating clinical/epidemiological data and BA genetic findings is plausible using the BA ‚diseasome' approach.

PS03.37

Steroid resistant nephrotic syndrome (SRNS): NGS panel testing to direct therapy and intervention

P. Dean[1], *M. Gable*[1], *L. Yarram-Smith*[1], *A. Bierzynska*[2], *M. Saleem*[3,2], *M. Williams*[1];
[1]*Bristol Genetics Laboratory, Bristol, United Kingdom,* [2]*Academic Renal Unit, University of Bristol, Bristol, United Kingdom,* [3]*Children's Renal Unit, Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Steroid Resistant Nephrotic syndrome (SRNS) is a disorder of the glomerular filtration barrier. It is characterised by massive proteinuria, hypoalbuminaemia and oedema, and is managed by non-specific heavy immunosuppression. An invasive biopsy is often required and the majority of patients progress to end stage renal failure. Rapid genetic diagnosis is important for therapy and intervention as genetic SRNS is non-responsive to immunosuppression, and has a lower rate of post transplant recurrence. SRNS is associated with over thirty genes expressed at the glomerular filtration barrier.
BGL has received >200 worldwide diagnostic referrals (80% paediatric and 20% adult) for NGS clinical panel testing of 37 SRNS genes (Haloplex; MiSeq; open-source pipeline, including CNV analysis using CONTRA). Likely pathogenic variants have been identified in 27% of referrals, most commonly occurring in NPHS1, NPHS2, WT1, COL4A3 and COL4A4 with a different mutation spectrum in adult and paediatric patients. A further 27% have candidate variants. Heterozygous CNV variants were detected in two patients with NPHS1 and NPHS2 related disease supporting CNV analysis in all patients
Variant stratification is challenging due to the presence of rare variants in under-sequenced populations. A pathogenic LMX1B mutation, c.737G>A, was associated with nail-patella-like renal disease, and a patient with a c.287C>T MYH9 variant presented with thrombocytopaenia and SRNS associated with MYH9-related disease. Several patients have variants in more than one collagen gene. Prenatal diagnosis was performed for a Pierson syndrome family with pathogenic LAMB2 variants, c.[4198_4199delCT];[928T>C].
We present our results illustrated by cases highlighting the clinical benefit of panel testing.

PM03.38

Role of CD2AP mutations in Steroid Resistant Nephrotic Syndrome revisited - new insights from next generation sequencing

K. Soderquest[1], *A. Shaw*[2], *M. Saleem*[3], *A. Bierzynska*[3], *M. A. Simpson*[1], *A. Koziell*[1];
[1]*King's College London, London, United Kingdom,* [2]*Washington University, St Louis, WA, United States,* [3]*University of Bristol, Bristol, United Kingdom.*

To date, mutations in over 50 genes have been published as underlying different cases of Steroid Resistant Nephrotic Syndrome (SRNS). SRNS is a molecularly heterogeneous condition but, in all cases, the underlying insult results in malfunction of the kidney's Glomerular Filtration Barrier (GFB) resulting in protein loss into the urine. CD2AP was first proposed as a site of dominant mutations underlying SRNS in 2003. This was supported by histological features of renal disease in heterozygous loss of function mouse mutants and a heterozygous splice site variant observed in two renal disease patients. Since then, further disease relevant alleles have been reported and the screening of CD2AP has been added to clinical protocols.
The advent of next generation sequencing technologies and the discovery of other causal genes questions whether mutations in CD2AP alone are sufficient to cause SRNS. Here, we present data on CD2AP variants found from whole exome sequencing of over 200 SRNS patients and 1500 controls. We show that several alleles previously described as disease causing are observed in our control population. In addition, whilst we observe rare alleles in CD2AP in two of our cases, in each of these individuals, we observe other rare alleles in other SRNS genes that are predicted to be functionally relevant. These observations demonstrate the challenges in determining the pathogenicity of individual variants in the absence of complete data. Our observations also highlight the potential oligogenic nature of certain forms of SRNS.

This work was funded by a Translational Research Collaboration Grant from the UK National Institute for Health Research.

PS03.39

A study to follow up patients after transient neonatal diabetes mellitus - an International Patient Register

R. James[1], N. N. Zalkapli,[1], L. E. Docherty[1], K. Lokulo-Sodipe[1,2], A. Torokwa[2], D. J. G. Mackay[1], **I. K. Temple**[1,2]*;*
[1]University of Southampton, Faculty of Medicine, Southampton, United Kingdom, [2]University Hospital Southampton NHS Foundation Trust,, Southampton, United Kingdom.

Transient Neonatal Diabetes Mellitus (TNDM 1), caused by overexpression of imprinted genes at 6q24 is characterised by growth restriction and diabetes that presents soon after birth and undergoes spontaneous remission in the first year of life. Individuals have a higher-than-normal risk of developing type-2 diabetes in later life, however the degree of risk is not known. The register includes over 180 cases of 6q24 TNDM and 72 of these families have given consent for follow-up and we have information on 17 individuals over the age of 5 years.
Results: 6/17 (35%) had experienced a recurrence of diabetes between 5 and 14 years (mean age 12y 8m). Permanent recurrence was reported in 4 cases which were treated with insulin. One recurrence was transient and concomitant with an episode of gastric flu at 5y. The remaining case was managed with metformin and diet at the follow up.
11/17 (65%) experienced no recurrence of diabetes at the time of follow up. Ages at follow up ranged between 5 years and 13 years 6 months (mean age at follow-up = 8y 2m)
In total, 7/17 (41%) were reported as having learning difficulties. Of these, 1 attended special school and had a diagnosis of autism and 1 suffered brain damage at birth and requires help with mobility and fine motor skills. The remaining 5/17 (29%) reported some developmental delay, notably in speech and language.
A survey is underway to expand these findings and gather further follow-up data. Additional results will be presented at ESHG.

PM03.40

Urinary system and renal malformations in girls with Turner syndrome

S. Turyk, *M. Sakurai, M. Ciaccio, S. Predier, H. Trimarchi, A. Nolasco, M. Notaris, S. Bonsergent;*
Hospital Britanico de Buenos Aires, Buenos Aires, Argentina.

Turner Syndrome (TS), in which there is a loss of all or part of one X chromosome, occurs in 1 in 2500 to 1 in 3000 born females and is associated with characteristic findings. Renal and urinary system malformations with their posterior complications such as urinary tract infections or proteinuria have been recognized to increase in patients with TS. In this retrospective study we report a detailed clinical history and analyzed renal and urinary system pathology in 34 girls with TS. All TS patents were evaluated by renal and collecting system ultrasonography and if structural renal or urinary system malformations were found, cystourethrography and centellography (DMSA or DTPA) was used.
Patients mean age at renal and urological studies was 9,7 years (2-18 years). The cytogenetic findings in 34 patients with TS were classic in 20 patients (58,82%), mosaic and structural aberration of X chromosome: in 14 patients (41,18%). The prevalence of renal and urinary system pathology was 44,11% (15 patients). The most frequent findings were urinary system malformations 20,58% (7 patients), associated with renal malformations 8,82% (3 patients), while 5 patients (14,7%) had renal malformations alone. Horseshoe kidney, malrotation or other position abnormalities, duplication of the collecting system and different ureterovesicular obstruction were found.
Conclusion: The early diagnosis of renal and urinary system malformation in TS and their follow- up is crucial to reduce the morbility in these patients. There appears to be no correlation between karyotype and the presence or type of renal or urinary system malformation

PS03.41

Whole exome sequencing identifies two pathogenic variants in *NPHS2* and confirms the diagnosis of nephrotic syndrome type 2 in two siblings with atypical Alport syndrome

M. J. N. Sá[1,2]*, R. Kamps[3], S. Sampaio[4], J. Vanoevelen[3], D. Merckx[3], G. Soares[1], A. M. Fortuna[1], H. Smeets[3,5];*
[1]Department of Medical Genetics, Centro de Genética Médica Dr. Jacinto de Magalhães/ Centro Hospitalar do Porto, Porto, Portugal, [2]Unit for Multidisciplinary Research in Biomedicine, Instituto de Ciências Biomédicas Abel Salazar/Universidade do Porto, Porto, Portugal, [3]Department of Clinical Genetics, Unit Clinical Genomics, Maastricht University Medical Centre, Maastricht, Netherlands, [4]Department of Nephrology, Hospital de São João, Porto, Portugal, [5]Research school GROW, Maastricht University, Maastricht, Netherlands.

The authors report a case of two affected sisters, born to non-consanguineous healthy parents, who were diagnosed with Alport syndrome, based on a family history of microscopic hematuria, steroid-resistant proteinuria, end-stage renal disease and sensorineural hearing loss.
Ultrastructural examination of the renal biopsy showed glomerular basement membrane (GBM) thinning and thickening with atypical electron-dense bodies. Detachment of GBM from podocytes was compatible with focal segmental glomerulosclerosis (FSGS). Pathogenic mutations in the *COL4A5*, *COL4A4* and *COL4A3* genes were excluded by direct sequencing of all exons and by MLPA of *COL4A5*. Subsequently, whole exome sequencing was performed in the proband, using the Illumina HiSeq2000 platform and filtering the variants on genes encoding podocyte products. Two substitutions, c.686G>A (p.(Arg229Gln)) and c.928G>A (p.(Glu310Lys)), were detected in the *NPHS2* gene, in compound heterozygosity in the affected sisters, confirming the diagnosis of autosomal recessive nephrotic syndrome type 2 and supporting genetic counselling in this family. FSGS is a glomerular lesion that results from podocyte detachment or death, clinically presenting with proteinuria and progressing to renal failure. It can have multiple primary or secondary causes, including monogenic disorders. Although typical ultrastructural GBM changes are seen in Alport syndrome (as alternating thinning and thikkening, lamellation and the presence of electron-dense bodies), FSGS may be observed in later stages of the disease. This work highlights the relevance of next-generation sequence in determining the molecular genetics diagnosis in suspected cases of Alport syndrome without *COL4A3*, *COL4A4* or *COL4A5* pathogenic mutations.

Mutations in PDE4D and molecular pathology of acrodysostosis without hormone resistance

T. KANAME[1]*, C. Ki[2], K. Yanagi[1], K. Naritomi[1], N. Niikawa[3], G. S. Baillie[4], J. P. Day[5], G. Nishimura[6], N. Mastuura[7], M. D. Houslay[8], S. Cho[2], D. Jin[2];*
[1]University of the Ryukyus, Nishihara-cho, Japan, [2]Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [3]Health Sciences University of Hokkaido, Hokkaido, Japan, [4]University of Glasgow, Glasgow, United Kingdom, [5]University of Cambridge, Cambridge, United Kingdom, [6]Tokyo Metropolitan Children's Medical Center, Tokyo, Japan, [7]Seitoku University, Chiba, Japan, [8]King's College London, London, United Kingdom.

Acrodysostosis without hormone resistance is a rare skeletal disorder characterized by
brachydactyly, nasal hypoplasia, mental retardation and occasionally developmental delay. Mutations in the gene encoding cAMP-hydrolyzing phosphodiesterase-4D (PDE4D) have been reported to cause this rare condition but the pathomechanism has not been fully elucidated.
To understand the pathogenetic mechanism of PDE4D mutations, we conducted 3D modeling studies to predict changes in the binding efficacy of cAMP to the catalytic pocket in PDE4D mutants. Our results indicated diminished enzyme activity in the two mutants. Ectopic expression of PDE4D mutants in HEK293 cells demonstrated this reduction in activity, which was identified by increased cAMP levels. However, cells from an acrodysostosis patient showed low cAMP accumulation, which resulted in a decrease in the phosphorylated cAMP Response Element-Binding Protein (pCREB)/CREB ratio. The reason for this discrepancy was due to a compensatory increase in expression levels of PDE4A and PDE4B isoforms, which accounted for the paradoxical decrease in cAMP levels in the patient cells expressing mutant isoforms with lowered PDE4D activity. We propose that specific inhibitory PDE4D mutations can lead to the molecular pathology of acrodysostosis without hormone resistance but that the pathological phenotype may be dependent on an over-compensatory induction of other PDE4 isoforms that can be expected to be targeted to different signaling complexes and exert distinct effects on compartmentalised cAMP signaling.

Investigation of angiogenesis-associated genes with risk of acute musculoskeletal injuries in two South African populations

M. Rahim[1]*, A. Gibbon[1], H. Hobbs[2], W. van der Merwe[2], M. Posthumus[1], M. Collins[1], A. V. September[1];*
[1]University of Cape Town, Cape Town, South Africa, [2]Sports Science Orthopaedic Clinic, Cape Town, South Africa.

Introduction: Genetic factors have been implicated with risk of anterior

cruciate ligament ruptures and Achilles tendon ruptures. The angiogenesis signalling pathway plays a key role in extracellular matrix remodelling following mechanical loading. Increased levels of angiogenic cytokines have been reported in injured tendons and ligaments.
Aim: To investigate if angiogenesis genes are associated with risk of acute musculoskeletal injuries in two South African populations.
Methods: *Anterior cruciate ligament rupture group*: 227 controls (CON) and 227 participants with ACL ruptures (ACL), of which 126 had non-contact mechanism of injury (NON). *Achilles tendon rupture group*: 125 controls (CON) and 45 participants with ruptures of the Achilles tendon (RUP). All participants were genotyped for the functional *VEGFA* rs699947, *VEGFA* rs1570360, *VEGFA* rs2010963, *KDR* rs2071559 and *KDR* rs1870377 polymorphisms. Haplotypes were also inferred for *VEGFA* and *KDR*.
Results: In the ACL study, the *VEGFA* rs699947 CC genotype (p=0.010, OR: 1.92, 95% CI: 1.17-3.17) was significantly over-represented within participants with non-contact ACL ruptures. The *VEGFA* rs1570360 GA genotype was significantly over-represented (p=0.007, OR: 1.70, 95% CI: 1.16-2.50) in the CON group (48%) compared to the ACL group (35%). Inferred haplotype analyses also implicated genomic regions spanning *VEGFA* and *KDR*. No independent significant differences were observed in the genotype frequency distributions between the Achilles tendon CON and RUP groups.
Conclusion: These novel findings provide preliminary evidence highlighting the potential biological significance of the angiogenesis signalling pathway in the aetiology of acute musculoskeletal injuries.
Grants: Supported by NRF, URC & MRC. MR funded by NRF & UCT, MP funded by Thembakazi Trust.

PS04.03
Genetic Investigation of Anencephaly in Old Order Amish

H. F. Jones, *B. A. Chioza, M. Ahmed, A. H. Crosby;*
University of Exeter Medical School, Exeter, United Kingdom.

Neural tube defects (NTDs) are the second most common type of birth defect after congenital heart defects, affecting over 300,000 births globally each year. They encompass a group of complex congenital malformations of the central nervous system characterised by failure of the neural tube close correctly resulting in an opening in the spinal cord or brain during early embryonic development. Anencephaly is a severe form of NTD, resulting in the absence of a major portion of the brain, skull, and scalp and is a lethal defect. We investigated an extensive eight-generation pedigree from the Amish community with 4 interlinking families with anencephalic births indicative of an autosomal recessively-acting mutation. Assuming that a founder mutation was responsible, we used genome-wide SNP mapping to identify regions of autozygosity in a single affected case likely to harbour the disease gene. This identified three candidate regions located on chromosomes 14q, 3p and 1p. This data was then cross-referenced with exome sequencing data of the affected case to identify the putative causative mutation.
Supported by MRC grant G1002279.

PM04.04
Association of IL1B and IL6 gene polymorphisms with higher disease activity and clinical pattern of psoriasic arthritis.

E. Bueno Martínez[1,2], *N. Cubillo*[3,2], *R. Usategui*[1,2], *C. Quintas Faria*[1,4], *C. Cieza-Borrella*[1,2], *I. Calero*[3,2], *J. Pino-Montes*[3,2], *C. Montilla*[3,2], *R. González-Sarmiento*[1,2];
[1]*Universidad de Salamanca, Salamanca, Spain,* [2]*Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain,* [3]*Department of Rheumatology, University Hospital of Salamanca., Salamanca, Spain,* [4]*Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain, Salamanca, Spain.*

Objective: Psoriatic Arthritis (PsA) is a chronic inflammatory disease associated to psoriasis that affects peripheral joints, the spine and enthesis. As result of the therapeutic success of antagonists of TNF and the IL-23/IL-17 cytokines axis, we know these cytokines play an important role in its pathogenesis. IL-23 is necessary for the differentiation and survival of IL-17 producing helper lymphocytes (Th17) IL-1B and IL-6 also is needed for the differentiation of Th17 cells. Here, we have analyzed whether IL1B (rs16944) and IL6 (rs1800795) polymorphisms are associates with inflammatory activity, radiographic damage or clinical pattern of Psoriatic Arthritis (PsA).
Patients and Methods: 125 patients suffering from PsA were included in the study. Genomic DNA was extracted from peripheral blood using phenol/chloroform procedure and genotyped using TaqMan 5'-exonuclease allelic discrimination assays (Applied Biosystems). Statistical analysis was performed using SPSS software.
Results: The G allele of IL1B rs16944 was associated with higher peripheral joint disease activity (OR: 3,13; P<0,0004; CI95%: 1,43-6,82 p<0,008 (corrected), while the G allele of the IL6 rs1800795 presented a strong trend to be associated with peripheral forms (70,86%) (OR: 1,89; p<0,03; CI95% 1,06-3,39, p: 0,05 (corrected). In addition, this allele showed a lower association with HLA-B27 (15,78%) compared with C allele (28,57%) (OR: 0,469; p=0,02; CI95% 0,238-0,923, corrected P: 0,03). None of the polymorphisms were associated to radiological damage.
Conclusions: IL1B rs16944 and IL6 rs1800795 could modulate the expression of IL-1[[Unsupported Character - Symbol Font ]] and IL-6, having clinical implications in PsA.

PS04.05
Molecular characterization and transcriptome-wide expression profiling of two patients affected with spondyloepimetaphyseal dysplasia with joint laxity type 1

M. Ritelli[1], *N. Chiarelli*[1], *N. Zoppi*[1], *C. Dordoni*[1], *S. Quinzani*[1], *M. Traversa*[1], *M. Venturini*[2], *P. Calzavara-Pinton*[2], *M. Colombi*[1];
[1]*University of Brescia, Department of Molecular and Translational Medicine, Brescia, Italy,* [2]*University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy.*

Mutations in *B3GALT6*, encoding the galactosyltransferase II (GalT-II) involved in the synthesis of the glycosaminoglycan (GAG) linkage region of proteoglycans (PGs), have recently been associated with a spectrum of connective tissue disorders, including spondyloepimetaphyseal dysplasia with joint laxity type 1 (SEMDJL1) and Ehlers-Danlos-like syndrome. Here, we report on two sisters compound heterozygous for two novel *B3GALT6* mutations that presented with severe short stature and progressive kyphoscoliosis, joint hypermobility, hyperextensible skin, platyspondyly, short ilia, and elbow malalignment. Microarray-based transcriptome analysis revealed the differential expression of several genes encoding extracellular matrix (ECM) structural components, including *COMP*, *SPP1*, *COL5A1*, and *COL15A1*, enzymes involved in GAG synthesis and in ECM remodeling, such as *CSGALNACT1*, *CHPF*, *LOXL3*, and *STEAP4*, signaling transduction molecules of the TGFβ/BMP pathway, i.e., *GDF6*, *GDF15*, and *BMPER*, and transcription factors of the *HOX* and *LIM* families implicated in skeletal and limb development. Immunofluorescence analyses confirmed the down-regulated expression of some of these genes, in particular of the cartilage oligomeric matrix protein and osteopontin, encoded by *COMP* and *SPP1*, respectively, and showed the predominant reduction and disassembly of the heparan sulfate specific GAGs, as well as of the PG perlecan and type III and V collagens. The key role of GalT-II in GAG synthesis and the crucial biological functions of PGs are consistent with the perturbation of many physiological functions that are critical for the correct architecture and homeostasis of various connective tissues, including skin, bone, cartilage, tendons, and ligaments, and generates the wide phenotypic spectrum of GalT-II-deficient patients.

PM04.06
Variants in the RANK gene are associated with bone mineral density and fracture risk in Maltese postmenopausal women

M. M. Formosa, *A. Xuereb Anastasi;*
Department of Applied Biomedical Science, Faculty of Health Sciences, University of Malta, Msida, Malta.

Introduction: Osteoporosis is a progressive multifactorial skeletal disease characterised by low bone mass thereby increasing fracture susceptibility. The Receptor activator of nuclear factor Kappa B (RANK) is involved in the regulation of osteoclastogenesis via the RANK-RANK ligand-Osteoprotegerin pathway. The influence of two polymorphisms rs3018362 (A>G) and rs884205 (G>T) in the 3' untranslated region of this gene were analysed in relation to bone mineral density (BMD) and different low trauma fractures in Maltese postmenopausal women.
Materials and Methods: 1045 women were recruited and subdivided in three BMD control groups if without a fracture history: normal, osteopenic or osteoporotic. Cases were women who suffered any type of low trauma fracture. Genotyping of the rs3018362 polymorphism was performed by polymerase chain reaction and restriction enzyme digest, whereas real-time PCR was used for the rs884205 variant. Odds ratios were computed using logistic regression analysis adjusted for age and clinical risk factors.
Results: Homozygosity for the rs3018362 G allele was associated with a low femoral neck BMD (Adjusted OR=2.2 [95% confidence interval 1.1-5.1], p=0.02), and to a lower extent reduced lumbar spine BMD (OR=1.9 [1.1-3.4], p=0.04) relative to research subjects with a normal BMD. Cases carrying two copies of the minor allele T for the rs884205 variant had an increased fracture risk (OR=2.6 [1.1-7.1], p=0.04), especially that of the hip (OR=3.2 [1.2-8.0], p=0.02) and humerus (OR=2.9 [1.1-7.9], p=0.04). Haplotype-based analysis revealed that the alleles were not in linkage disequilibrium.
Conclusion: *RANK* gene polymorphisms predispose to reduced BMD or increased fracture susceptibility in Maltese postmenopausal women.

PS04.07

An unusual type of brachydactyly with delayed ossification and symphalangism

C. L. M. Marcelis[1], *M. Ottink*[2], *W. Klein*[1];
[1]*Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Medisch Spectrum Twente, Enschede, Netherlands.*

We present the case of a now two year old boy. The second child of healthy nonconsanguineous Dutch parents. This boy has normal growth and development and is otherwise healthy. He presented at birth with abnormal positioning of both hands and feet, with abnormal implantation of fingers and toes. The fingers show absent flexion and extension creases over the proximal interphalangeal joints. There is no limitation of movement. Radiological examination at birth showed absent ossification of the preaxial metacarpals and metatarsals. In addition abnormal or absent ossification of the proximal and middle phalanges of the 3rd-5th fingers and absent ossification of the proximal and middle phalanges of the 2nd-5th toe was seen. Ultrasound investigation showed the presence of cartilage at the site of the metacarpals/tarsals and phalanges with the impression of symphalangism between the proximal and middle phalanges of the hands. At age 16m there is irregular ossification of the previously unossified metacarpals, metatarsals and phalanges with symphalangism of the proximal interphalangeal joints in the hands.
X-ray investigation of the spine, pelvis and long bones did not show additional abnormalities. DNA analysis of the NOG gene was normal and Cytoscan HD array analysis showed a normal male profile. We'll discuss overlap with previously described syndromes and suggest this is a new type of brachydactyly.

PM04.08

Report of two novel mutations in PTHLH as a cause of brachydactyly type E

A. Pereda[1], *C. Thomas-Teinturier*[2], *C. Silve*[3,4], *I. Garin*[1], *P. Bougnères*[2], *I. Diez*[5], *A. Linglart*[4,6,7], **G. Pérez de Nanclares**[1];

Introduction: Autosomal-dominant brachydactyly type E (BDE) is a congenital limb malformation characterized by small hands and feet as a result of shortened metacarpals and metatarsals. BDE can be isolated or associated with a syndrome, and in most cases, the genetic cause of BDE remains unknown. One of the genes associated to syndromic BDE is PTHLH, the gene coding for parathyroid hormone related protein (PTHrP), implicated in the regulation of the balance between chondrocyte proliferation and the onset of hypertrophic differentiation during endochondral bone development. Haploinsufficiency of PTHLH has been reported as the cause of BDE, mostly associated to short stature in 6 families.
Subjects and Methods: We report a family case with BDE, short stature and apparently breast hypoplasia in the daughter; and an isolated case, presenting with isolated BDE. PTHLH gene coding exons and coding exon intron-joints of all transcripts were analysed by direct sequencing.
Results: The sequencing of PTHLH gene revealed two intragenic deletions affecting the splicing (47_101+73del128 and c.101+3AAGT) as the cause of the syndrome. Both mutations are predicted to cause a mistake in the splicing, resulting in an aberrant mRNA, which will be degraded by nonsense-mediated decay and produce haploinsufficiency of the PTHrP in both patients.
Conclusion: This is the third report on PTHLH mutations leading to BDE revealing that the spectrum of symptoms is wider than previously described.

PS04.09

The cell signalling pathway and risk of anterior cruciate ligament (ACL) ruptures.

M. Rahim[1], *S. Mannion*[1], *B. Klug*[1], *H. Hobbs*[2], *W. van der Merwe*[2], *M. Posthumus*[1], *M. Collins*[1], **A. V. September**[1];
[1]*Department of Human Biology, University of Cape Town, Cape Town, South Africa,* [2]*Sports Science Orthopaedic Clinic, Newlands, Cape Town, South Africa.*

Polymorphisms within genes encoding signalling molecules have previously been implicated in risk of chronic Achilles tendinopathy. This study aimed to determine if these genetic variants are associated with ACL injury risk.
Methods: In total, 232 control (CON) and 234 ACL rupture participants (ACL), of which 135 had a non-contact mechanism of injury (NON) were genotyped for functional polymorphisms: IL1B rs16944, IL6 rs1800795, IL6R rs2228145, CASP8 rs3834129, CASP8 rs1045485, PTGER4 rs4495224, TGFB2 rs7550232, TNF rs1800629, TNF rs1799964 and TNFRSF1B rs1061622. Haplotypes were inferred for CASP8 and TNF. Statistical analyses were conducted ($p<0.05$) between the groups (CON vs. ACL and CON vs. NON). Sex-specific interactions were investigated.
Results: No significant differences were observed in the genotype and allele frequency distributions when all participants were analysed. The CASP8 rs3834129 del allele was significantly under-represented in the male CON group (41%) compared to the male NON subgroup (51%) ($p=0.047$, OR: 1.46, 95%CI: 1.01-2.12). The IL1B rs16944 TT genotype was significantly under-represented in the female CON group (10%) compared to the female NON subgroup (26%) ($p=0.029$, OR: 3.06, 95%CI: 1.09-8.64). The ins-G CASP8 haplotype was significantly over-represented in the CON group (55%) compared to the ACL (48%, $p=0.017$) and NON subgroup (48%, $p=0.031$). Similar results were observed in the male participants [ins-G: CON (56%) vs NON (43%), $p=0.040$].
Conclusions: This study implicated variants within CASP8 and IL1B with ACL ruptures, highlighting the biological significance of the cell signalling pathway in the etiology of ACL ruptures.

PM04.10

Aquagenic palmoplantar keratoderma as a CFTR-related disorder: confirmation of a separate entity

C. Cabrol[1], *T. Bienvenu*[2], *L. Ruaud*[1], *E. Girodon*[2], *G. Noacco*[3], **L. Van Maldergem**[1], *F. Aubin*[4];
[1]*Centre de génétique Humaine, CHU, Université de Franche-Comté, Besançon, France,* [2]*Laboratory of Biochemistry and Molecular Genetics, Cochin University Hospital, AP-HP, Université Paris-Descartes, Paris, France,* [3]*Dermatology, private practice, Joncherey, France,* [4]*Department of Dermatology, EA3181, CHU, Université de Franche-Comté, Besançon, France.*

A 27 year-old caucasian female was referred to the dermatology clinics for swelling and discoloration of palms and soles a few minutes after bathing or swimming since one year, alongside with hypohidrosis. A single episode of pneumonia at 3 y was reported. On examination, *tinea manuum* and, a few minutes after water exposure, a rapid onset of a papillomatous medio-palmar swelling was observed. Her growth parameters were normal without any chest deformity. Her sinus X-rays indicates absence of nasal polyps. A diagnosis of aquagenic palmoplantar keratoderma (APK) was made. A sweat test indicated chloride concentrations of 64 mmol/l and 51 mmol/l (N<60). Since APK has been already reported in association with clinical cystic fibrosis and/or *CFTR* mutations, next generation sequencing of *CFTR* was undertaken and identified a combination of apparent homozygosity for a missense *CFTR-RD* mutation c.2855T>C (p.Met952Thr), already described in congenital bilateral absence of *vas deferens,* and a large heterozygous deletion encompassing *CFTR* exons 16 to 20, described as c.2620-674_3367+198del9855 known as CF pathogenic mutation. Based on these results, we confirm the existence of a link between isolated APK and *CFTR* mutations and suggest to include this phenotype (APK only) at the mild end of CFTR clinical spectrum. Owing to the small number of CFTR-related APK cases reported sofar, we are unable to conclude on the importance of *CFTR* mutation-negative APK. This observation also suggests that screening for rare *CFTR* mutations should be systematically proposed in case of isolated APK in order to provide appropriate genetic counseling.

PS04.11

FAM110B on 8q12.1 as a new candidate gene for CL±P in a high-prevalence area in South America

F. M. de Carvalho[1], *F. A. Poletta*[2], *R. F. Fonseca*[3], *P. Lapunzina*[4], *A. R. Vieira*[5], *E. E. Castilla*[1,2], *I. M. Orioli*[3];

Background: In South America a cleft lip with or without cleft palate (CL±P) high prevalence region were detected in Patagonia (Argentina). Amerindian ancestry was identified as a risk factor. We aimed the identification of autosomal genomic regions that may contribute to CL±P in this probably more homogeneous population.
Method: The study sample included 30 families with isolated CL±P (31 affected and 113 total individuals). They were genotyped on the Affymetrix Genome-Wide 6.0 array. We calculated linkage disequilibrium (LD) between each pair of SNPs into a window of 50 SNPs, shifting the window 5 SNPs forward and repeating the procedure to scan all autosomes. Then we pruned the data removing one SNP of each pair that was in strong LD (r >0.8). We performed a segmentation analysis to obtain genomic regions significantly associated with CL±P. We identified genomic segments of a maximum length of 250Kb with more than one SNP with p-value less than 0.001.
Results: A total of 14 genomic segments with two or more independent SNPs significantly associated with CL±P were identified. A segment of 61.3Kb on 8q12.1 containing FAM110B gene showed the most significant association with CL±P (p= 0.00007). Other segment of 25.5Kb on 3q29 significantly associated with CL±P (p=0.0002) was close to the FGF12 gene that was previously associated with oral cleft phenotype in other populations.
Conclusion: Our results suggest FAM110B on 8q12.1 as a new candidate gene to CL±P. The region on 3q29 near FGF12 gene should be more investigated because previous associations with CL±P.

PM04.12
Report of a Saudi Family with Kniest dysplasia (KD) showing an Autosomal Recessive Inheritance

N. A. Al-Sanna'a[1], *K. P. Hoornaert*[2], *H. Y. Al-Abdulwahed*[1], *G. Mortier*[3];
[1]*Jonhs Hopkins Aramco Healthcare, Dhahran, Saudi Arabia,* [2]*University Hospital Ghent, Ghent, Belgium,* [3]*University of Antwerp and Antwerp University Hospital, Antwerp, Belgium.*

Kniest Dysplasia (KD) is a rare autosomal dominant spondylo-epiphyseal dysplasia (OMIM # 156550) characterized by a disproportionate short stature, midfacial hypoplasia, progressive myopia, bell-shaped chest, kyphoscoliosis, stiffness and enlargement of the joints, premature osteoarhritis, and contractures of fingers.
Often, it is associated with cleft palate, Pierre-Robin sequence and deafness. KD is caused by a mutation in the COL2A1 gene encoding type II collagen. Here we describe two affected siblings born to a phenotypically normal Saudi Arab first cousins couple. They were born with prominent eyes, cleft soft palate, micrognathia, midfacial hypoplasia, knee joint contracture, and short lower limbs (birth length was 43 cm). Both developed severe myopia which progressed to left-sided retinal detachment in the younger affected sister at 4 years of age, hearing impairment, disproportionate short stature, barrel-shaped chest, thoracolumbar kyphoscoliosis, knee and hip joint flexion contractures, and bowed legs. Radiographic study showed dumbbell shaped femurs and humeri, hypoplastic pelvic bones, platyspondyly, flared metaphyses, and large epiphyses.
Molecular analysis revealed the presence of a "de novo" homozygous splice site mutation in the COL2A1 gene (c.2904+2T>C) in both of the affected siblings.
The parents were found to be heterozygous for the same mutation. Both had an appropriate height, and their radiographic study, hearing test and ophthalmological evaluation were normal). To our knowledge, this is the first reported family in whom two siblings with KD are found to have an identical biallelic splice site mutation in the COL2A1 gene.

PS04.13
Report on a patient with extremely fragile skin, dermatosparaxis, joint hypermobility, short stature, skeletal deformities, and lipomas: a new syndrome?

M. Colombi[1], *C. Dordoni*[1], *N. Chiarelli*[1], *M. Traversa*[1], *N. Zoppi*[1], *E. Giacopuzzi*[1], *M. Venturini*[2], *F. Facchetti*[1], *P. Calzavara-Pinton*[2], *M. Ritelli*[1];
[1]*University of Brescia, Department of Molecular and Translational Medicine, Brescia, Italy,* [2]*University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy.*

We report on a patient who came to our attention with a suspicion of Ehlers-Danlos syndrome (EDS). The proposita, a 56-year-old Italian woman, was born in a geographically isolated valley from healthy and referred non-consanguineous parents, and had two healthy sons. Redundant, sagging, fragile skin with atrophic scars was present since infancy. In adulthood the cutaneous involvement was worsening leading to generalized dermatosparaxis. At examination, generalized photoageing and capillary fragility, deep facial wrinkles and palmar creases, blue sclerae, palpebral ptosis, short stature (150 cm, lower than the 3rd centile), brachydactyly with low-set thumbs, barrel chest, deforming osteoarthritis, bilateral hallux valgus, joint hypermobility according to Beighton score (7/9), varicose veins, and frontal alopecia with thin hair, were observed. Chronic pain, recurrent bursitis, several excisions for lipomas, multiple muscle ruptures, and spontaneously solved subarachnoid hemorrhage, were referred. Immunohistological examination of a skin biopsy revealed epidermal thinning with reduced keratinocytes' layer and increased and morphologically altered elastic fibers resembling solar elastosis, without calcium deposits, and reduced collagen fibers. Cutis laxa and the dermatosparaxis and classic EDS types were excluded for the peculiar clinical presentation of the patient, not yet described to our knowledge. Furthermore, mutational screening of the *ADAMTS2*, *COL5A1* and *COL5A2* genes did not reveal causal mutations. The plausible hypothesis of a recessive inheritance prompted us to perform SNP array analysis that showed the presence of several large chromosomal regions with loss of heterozygosity. We expect that in these candidate regions whole exome sequencing will reveal the causal mutation involved in this disorder.

PM04.14
Craniofrontonasal syndrome with central polydactyly: Case report

F. Hazan[1], *A. K. Yılmaz*[2];
[1]*Department of Medical Genetics, Dr. Behcet Uz Children's Hospital, Izmir, Turkey., izmir, Turkey,* [2]*Department of Neurosurgery , Dr. Behcet Uz Children's Hospital, Izmir, Turkey., izmir, Turkey.*

Craniofrontonasal syndrome (CFNS), also known as craniofrontonasal dysplasia, is an X-linked developmental disorder, caused by mutations in the EFNB1 gene. EFNB1 located at Xq13.1, and encoding a ligand of the Ephrin family of receptor protein tyrosine kinases. This syndrome is characterized by craniofrontonasal bridge and bifid nasal tip, frontal bossing, coronal suture synostosis (unilateral or bilateral), hypertelorism, frizzy and curly hair, corpus callosum agenesis, and cleft lip or palate. Skeletal features include Sprengel shoulder, dysplastic clavicles, partial cutaneous syndactyly of the hands and feet, duplication of the thumbs or halluces and characteristic longitudinal ridging and splitting of nails. Herein we present a girl CFNS patient with a heterozygote c.196 C>T (p.R66*) mutation in EFNB1. The patient also had central polydactyly of the right hand which has not previously been described in this syndrome.

PS04.15
In vitro functional characterization of the Bardet Biedl syndrome-9 gene in nonsyndromic craniosynostosis.

M. Barba[1], *L. Massimi*[2], *M. C. Geloso*[1], *M. Caldarelli*[2], *F. Michetti*[1,3], *C. Di Rocco*[2], *G. Tamburrini*[2], *C. Bernardini*[1], **W. Lattanzi**[1,3];
[1]*Inst. Anatomy and Cell Biology, Università Cattolica S. Cuore, Rome, Italy,* [2]*Inst. Neurosurgery, Università Cattolica del Sacro Cuore, Rome, Italy,* [3]*Latium Musculoskeletal Tissue Bank, Rome, Italy.*

Introduction: The molecular mechanisms underlying nonsyndromic craniosynostosis (NSC) are still largely unknown. Recent evidence obtained thorugh GWAS on a large cohort of patients indicated the significant association of sagittal NSC to the Bardet Biedl Syndrome-associated gene 9 (BBS9). BBS9 is involved in the formation of the primary cilium. Preliminary data demonstrated that cells isolated from prematurely fused sutures of midline NSC patients display aberrant BBS9 expression and reduced number of primary cilia, affecting the cell osteogenic potential. This study was aimed at characterizing the BBS9 gene as associated to midline NSC.
Methods: Calvarial-derived mesenchymal cells (CMSC) were isolated from fused and patent sutures of NSC patients. The expression of BBS9 was analyzed through qPCR, both in fused and patent samples. The BBS9 gene was silenced by siRNA in fused-CMSC, the effect of gene modulation on ciliogenesis was analyzed by immunofluorescence.
Results: BBS9 level was higher in fused-CMSC compared to controls. Confocal microscopy showed that fused-CMSC display a predisposition to produce differently shaped and developed primary cilia. 48 hours of siRNA treatment efficiently reduced the BBS9 level and affected the ciliogenesis, restoring a phenotype like patent-CMSC.
Conclusions: These data confirmed the association between BBS9 expression and aberrant ciliogenesis, suggesting that the dysregulation of primary cilium and its related signaling could underlie the alterated osteogenic process occurring at the site of premature synostosis in NSC.

PM04.16

Non-coding variant in the BMP2 locus associated with sagittal non-syndromic craniosynostosis causes differential GFP expression in zebrafish.

C. Justice[1], J. Kim[2], S. Kim[2], G. Yagnik[2], B. Carrington[3], R. Sood[4], A. Wilson[5], A. Wilson[1], **S. A. Boyadjiev**[2];

[1]Genometrics Section, Computational and Statistical Genomics Branch, National Human Genome Research Institute, National Institutes of Health,, Baltimore, MD, United States, [2]University of California Davis, Sacramento, CA, United States, [3]Zebrafish Core, Translational and Functional Genomics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, United States, [4]Zebrafish Core, Translational and Functional Genomics Branch, National Human Genome Research Institute, National Institutes of Health, Baltimore, MD, United States, [5]1Genometrics Section, Computational and Statistical Genomics Branch, National Human Genome Research Institute, National Institutes of Health,, Baltimore, MD, United States.

Craniosynostosis is a common congenital malformation in which one or more of the cranial sutures of an infant skull fuse prematurely. Sagittal non-syndromic craniosynostosis (sNCS) has an estimated prevalence of ~2 per 10,000 live births. Our recent GWAS study identified robust associations to locus on chromosome 20 that is 345kb 3' of *BMP2*. We did not identify any coding *BMP2* variant, suggesting that variants in the associated region near BMP2 may harbor regulatory elements responsible for the phenotype. To test this we monitored the expression of *BMP2* in primary calvarial osteoblasts from sNCS patients. We observed overexpression of *BMP2* and heightened BMP2-signaling in 2 out of 8 osteoblast cell lines. In order to determine if rs1884302 variation causes functional changes, a 716 bp fragment was cloned into a zebrafish enhancer detector (ZED) vector with the wild-type allele (T) or the risk allele (C). Zebrafish transgenesis carried out with both fragments resulted in a strong expression of green fluorescent protein (GFP) in the head of the transgenic fish with a C, but not with the T alllele of rs1884302. Our *in vitro* results suggest that overexpression of *BMP2* by altered regulatory activity near this gene contributes to the etiology of sNSC, while *in vivo* results indicate that the differences in regulatory activity are dependent on the C or the T allele.

PS04.17

Modeling Craniosynostosis in zebrafish: How to investigate genetic-linked human skull deformations in fish

D. Liedtke, *R. Blümel, E. König, I. Köblitz, E. Klopocki;*
Institute for Human Genetics, Universität Würzburg, Würzburg, Germany.

Craniosynostosis is a human disease condition, in which premature fusion of cranial sutures results in prominent skull deformations. Genetic triggers for these disorders are numerous and are mostly linked to mutations in well-described developmental genes, like *FGFR3* and *TWIST1*. To investigate the function of novel or so far ill-described genes causing craniosynostosis, a reliable animal model is needed, allowing *in vivo* investigations of skull development over time and genetic engineering. Besides mouse, the zebrafish (*Danio rerio*) has become a good choice to study such complex developmental processes in a vertebrate model system.

We performed initial investigations of normal cranial suture development in zebrafish with different techniques and found promising similarities to human cranial development. Especially non-invasive techniques open up the possibility to repeatedly investigate cranial structures over time in single individuals. Conservation of gene expression patterns of craniosynostosis-associated genes in zebrafish hint to the notion that a similar genetic network is established in both species to form sutures. To decipher this network in more detail, we used gene expression analyses and different transgenic reporter lines for visualization of cellular processes. To furthermore conduct functional studies, we introduced site specific genomic alterations in the homologue of *TCF12* via CRIPSR/Cas9. The zebrafish carrying deletions in *tcf12* develop cranial deformations resembling the patients´ phenotypes. Our findings demonstrate that zebrafish is a potent animal model for investigating craniosynostosis and that it is possible to elucidate the functions of causative human mutations in fish.

PS04.19

Whole-exome sequencing approach revealed Carvajal syndrome as a differential diagnosis for Acrodermatitis enteropathica

S. KÜRY[1], *M. Sedghi[2], T. Besnard[1], C. Bossard[1], M. Hosseinzadeh[2], C. Acquaviva[3], E. Blouin[4], S. Bézieau[1];*
[1]CHU de Nantes, Nantes, France, [2]Medical Genetics Laboratory, Alzahra University Hospital, Isfahan, Iran, Islamic Republic of, [3]Centre de Biologie et Pathologie Est, Bron, France, [4]Laboratoire LABCATAL, Montrouge, France.

Background: Acrodermatitis enteropathica (AE; MIM #201100) is a rare and severe autosomal recessive zinc deficiency disorder caused by a biallelic anomaly of zinc transporter gene SLC39A4. It is characterized chiefly by acral and periorificial dermatitis occurring either in the perinatal period, or at weaning in breast-fed children. Its clinical diagnosis has to be necessarily confirmed by a genetic testing, as it may be misdiagnosed as various skin diseases ranging from relatively common ones to rare ones. Our present study is based on an Iranian inbred family with four living members having clinical symptoms suggestive of AE, albeit exhibiting no mutations either in SLC39A4 or in nearly 50 genes directly involved in zinc homeostasis.

Purpose: Our goal was to determine the genetic cause of the AE-like genodermatosis observed in this multiplex family.

Method: Whole-exome sequencing was performed in nine of the family members, including three affected and six unaffected ones.

Results: An exceedingly rare variant was found in the promoter of DSP (desmoplakin gene), which creates an alternative initiation codon. The deleterious effect of this variant was assessed by immunohistochemical and functional studies using luciferase-based assays. This result allowed us to diagnose Carvajal syndrome (MIM #605676), that is a rare autosomal recessive form of palmoplantar keratoderma associated with wooly hair, and with dilated cardiomyopathy, which last symptom was not observed in our patients.

Conclusions: This case not only illustrates the difficulty to recognize AE basing on clinical symptoms and pathology only, but it also emphasizes the usefulness of whole-exome sequencing in its differential diagnosis from other syndromes with overlapping features.

PM04.20

Pure hair and nail ectodermal dysplasia in a consanguineous Turkish family with a novel mutation in HOXC13 gene

E. Kirat[1], *E. Karaca[2], M. Seven[1], H. Ulucan[1], E. Fenercioğlu[1], M. Ozen[1,3], Y. Bayram[2], D. Pehlivan[2], A. Koparir[1], S. Jhangiani[4], A. Yuksel[3], R. Gibbs[4], J. Lupski[2,4,5];*
[1]Department of Medical Genetics, Cerrahpasa Medical School of Istanbul University, Istanbul, Turkey, [2]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, [3]Biruni University, Istanbul, Turkey, [4]Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, United States, [5]Department of Pediatrics, Baylor College of Medicine, Houston, TX, United States.

INTRODUCTION: Pure hair and nail ectodermal dysplasia (PHNED) is a rare disorder which characterized by hypotrichosis/ complete alopecia and nail dystrophy. Recent studies reported recessive families with PHNED having mutations in KRT85 and HOXC13 genes.

MATERIALS AND METHODS: We performed whole exome sequencing (WES) in a patient of PHNED phenotype from a consanguineous family. WES analysis revealed a novel homozygous frameshift mutation (c.353delC; p.T118fs) in HOXC13 gene.

CONCLUSION: To best of our knowledge this is the first Turkish family reported PHNED with novel HOXC13 mutation. In this report we will discuss this novel mutation with the review of the literature.

PS04.21

Refining palmoplantar keratodermal-congenital alopecia syndrome, Wallis type in two unrelated Italian patients

M. Castori[1], S. Morlino[1], M. Malacarne[2], M. Lamp[3], E. Pisaneschi[4], A. Angioni[4], M. Iascone[5], P. Grammatico[1], G. Tadini[6], **F. Forzano**[3];
[1]Division of Medical Genetics, San Camillo-Forlanini Hospital, Rome, Italy, [2]Laboratory of Human Genetics, Galliera Hospital, Genova, Italy, [3]Medical Genetics Unit, Galliera Hospital, Genova, Italy, [4]Cytogenetics and Molecular Genetics Unit, IRCCS-Ospedale Pediatrico Bambino Gesù, Rome, Italy, [5]Laboratory of Medical Genetics, Papa Giovanni XXIII Hospital, Bergamo, Italy, [6]Pediatric Dermatology Unit, Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Milano, Italy.

In 2010, a classification of palmoplantar keratoderma-congenital alopecia syndrome (PPKCA) was proposed with two distinct phenotypes: a benign form with occasional dominant transmission (Stevanovic type; ten patients from four families) and a more severe variant with pseudoainhum, sclerodactyly and recurrence in sibs (Wallis type - PPKCA-WT; seven patients from two families). In the same report, a 10-year-old, sporadic Italian girl was reported as a further case of PPKCA-WT. Here, we describe PPKCA-WT in an additional 18-year-old Italian woman with widespread keratosis pilaris, ulerythema ophryogenes, marked hypotrichosis, and palmoplantar keratoderma progressively causing contractures, pseudoainhum and sclerodactyly. Due to the non-congenital nature of palmoplantar involvement, this patient was previously considered affected by IFAP syndrome. We also present the 5-year follow-up of the patient published in 2010, who demonstrates progression of the disease with worsening of sclerodactyly and pseudoainhum. Sanger sequencing of *GJB2*, *GJB6*, *LOR* and *MBTPS2*, as well as array-CGH (mean resolution: 200 Kb) excluded any pathogenic change in at least one subject. These patients represent two unrelated examples of an extremely rare genodermatosis clinically distinguishable from partially overlapping conditions, including Clouston, Lelis Olmested, KID and HOPP syndromes,

KFSD/IFAP syndrome, and odonto-onycho-dermal dysplasia. Although literature indicates autosomal recessive as the most likely inheritance, we cannot exclude a dominant or X-linked *de novo* mutation in these patients. A next-generation sequencing project is ongoing aimed at identifying the causative gene(s).

PM04.22
Mutational spectrum of hypohidrotic ectodermal dysplasia in Mexican mestizo patients

J. Abad Flores[1,2,3], *N. Monroy[2], C. García[1], A. Villaseñor[1], C. Mena[1], M. Toledo[1], A. Valencia[1], A. Sánchez[1], Y. Akaki[1], B. Del Río[1], J. Aguirre[1], M. López[4], A. Cervantes[5], M. Cerbón[3], V. Morán[1];*
[1]Hospital Infantil de México FG, Mexico, Mexico, [2]Instituto Nacional de Neurología y Neurocirugía MVS, Mexico, Mexico, [3]Facultad de química UNAM, Mexico, Mexico, [4]Sistemas Biológicos UAM-X, Mexico, Mexico, [5]Hospital General de México DEL, Mexico, Mexico.

Hypohidrotic ectodermal dysplasia (HED) is characterized by hypotrichosis, oligo/anodontia and hypohidrosis. HED generally has an X-linked pattern of inheritance, autosomic dominant and recessive cases have been described. The affected genes are *EDA* (Xq12-q13.1); *EDAR* (2q11); *EDARADD* (1q42.2-q43) and *WNT10A* (2q35). Objective: to describe a cohort of Mexican mestizo patients with HED, their mutational analysis and phenotype-genotype correlation. Material and methods: fifteen patients with HED belonging to fourteen different families were included. MLPA for the four genes was performed for dosage alteration in all patients; *EDA* sequencing was carried out in nine patients. Results: Index cases were males (6 months to 24 years of age), eight of them showed an X-linked pattern of inheritance. The following mutations were characterized: Case 1: deletion of exon 1. Cases 2 and 3, two affected brothers (case 3 also suffers from Down syndrome): novel mutation c.1037G>C, p.C346W in exon 8. Case 4: previously reported variant c.467G>A; p.R156H in exon 2. Case 5: the described mutation c.1311C>T; p.R357W in exon 8. Case 6 presented the variant c.466C>T, p.R156C in exon 2. Cases 7, 8 and 9 exhibited a recurrent mutation c.463C>T, p.R155C in exon 2. Maternal samples of cases 2, 3 and 6 were unavailable for molecular study but the clinical data suggested a heterozygous genotype. Carrier state was molecularly confirmed on the remaining mothers; all but one had clinical data. Conclusion: our results confirmed the low frequency of related genes dosage alterations and the high prevalence of X linked HED in Mexican population.

PS04.23
Genetic heterogeneity and clinical variability in musculocontractural Ehlers-Danlos syndrome caused by impaired dermatan sulfate biosynthesis

D. M. Syx[1], *T. Van Damme[1], S. Symoens[1], M. C. Maiburg[2], I. van de Laar[3], J. Morton[4], M. Suri[5], M. Del Campo[6], I. Hausser[7], T. Hermanns-Lê[8], A. De Paepe[1], F. Malfait[1];*

Hospital Vall d'Hebron, Barcelona, Spain, [7]Institute of Pathology, University Clinic Heidelberg, Heidelberg, Germany, [8]Department of Dermatopathology, Liège University Hospital, Liège, Belgium.

Bi-allelic mutations in *CHST14*, encoding dermatan-4-*O*-sulfotransferase-1 (D4ST1), cause musculocontractural EDS (MC-EDS), a recessive disorder characterized by connective tissue fragility, craniofacial abnormalities, congenital contractures and developmental anomalies. More recently, a bi-allelic mutation was also identified in the *DSE* gene, encoding dermatan sulfate epimerase-1 (DS-epi1), in a child with MC-EDS features, thereby suggesting locus heterogeneity for this condition. DS-epi1 and D4ST1 are crucial for biosynthesis of dermatan sulfate (DS) moieties in the hybrid chondroitin sulfate (CS)/DS glycosaminoglycan (GAG) chains of proteoglycans. We report four novel families with severe MC-EDS caused by unique homozygous *CHST14* mutations and the second family with a homozygous *DSE* missense mutation, presenting a somewhat milder MC-EDS phenotype. The glycanation of the dermal DS proteoglycan decorin is impaired in fibroblasts from D4ST1- as well as DS-epi1-deficient patients. However, in D4ST1-deficieny the decorin GAG is completely replaced by CS, whereas in DS-epi1-deficiency still some DS moieties are present. The multisystemic abnormalities observed in our patients support a tight spatiotemporal control of the balance between CS and DS, which is crucial for multiple processes including cell differentiation, organ development, cell migration, coagulation and connective tissue integrity.

PM04.24
The Ehlers-Danlos syndrome type VI spectrum: a genetically heterogeneous group of clinically overlapping conditions

T. Van Damme, *D. Syx, S. Symoens, A. De Paepe, F. Malfait;*
Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium.

The Ehlers-Danlos syndrome kyphoscoliosis type (EDS VIA) is an autosomal recessive disorder characterized by severe kyphoscoliosis and neonatal muscular hypotonia, in addition to the classical signs of EDS, such as joint hypermobility and a hyperextensible and fragile skin. EDS VIA was the first inborn error of collagen metabolism to be solved at the biochemical and molecular level. It is caused by mutations in *PLOD1* leading to deficient activity of lysylhydoxylase 1 (LH1), a collagen-modifying enzyme. Patients with a phenotype resembling EDS VI but with normal LH1 activity were originally classified as EDS VIB. Several studies have now shown that EDS VIB comprises a genetically heterogeneous spectrum that includes defects in dermatan sulfate biosynthesis (musculocontractural EDS, MC-EDS) and defects in the transcriptional regulation of collagen and other extracellular matrix genes (brittle cornea syndrome, BCS). This study reports on the natural history of 31 EDS VI patients (EDS VIA n=12; MC-EDS n=10; BCS n=9). In addition, we critically reviewed the clinical features of 135 molecularly proven EDS VI patients (EDS VIA n=68; BCS n=48; MC-EDS n=19). We provide a comprehensive overview of the clinical characteristics of these three disorders and highlight the disorder-specific features. Our results show that despite the unmistakable clinical overlap, EDS VIA, MC-EDS and BCS are three distinct disorders. Based on this we propose to refine the outdated criteria for EDS VI, which should facilitate early and accurate clinical diagnosis of these rare, but often severe, syndromes.

PS04.25
Two cases of patients with Ehlers-Danlos Syndrome Type VIII and hoarseness

S. George[1], **A. M. Vandersteen**[2], *E. Nigar[3], D. J. P. Ferguson[4], E. J. Topham[5], F. M. Pope[6];*
[1]East Sussex Hospitals NHS Trust, Eastbourne, United Kingdom, [2]Maritime Medical Genetics Service, IWK Health Centre, Halifax, NS, Canada, [3]North West London Hospitals NHS Trust, Harrow, United Kingdom, [4]Nuffield Department of Clinical Laboratory Science, John Radcliffe Hospital, Oxford, United Kingdom, [5]Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom, [6]Ehlers-Danlos Syndrome, National Diagnostic Service, North West London Hospitals NHS Trust, Harrow, United Kingdom.

Ehlers-Danlos syndrome (EDS) encompasses a genetically and clinically heterogeneous group of connective tissue disorders, characterised by joint hypermobility, skin hyperextensibility and tissue fragility. Type VIII EDS is very rare. Clinical features include severe, early-onset periodontitis, skin fragility and abnormal scarring. We report two cases of patients with EDS type VIII and hoarseness. The first patient is a 24 year old male from Bangladesh, the only child of unrelated parents. No other family members are affected. He has marked skin fragility, with easy bruising and splitting on his shins and elbows, early onset periodontitis and chronic hoarseness, the latter due to bilateral vocal cord sulci. The second patient is a 33 year old white Caucasian woman with premature loss of her primary teeth and adult teeth, pretibial bruising and a hoarse voice since her twenties. Her father also had early onset periodontitis. She has two-year-old twin boys who are also likely to be affected. She had an abnormality of her cricoarytenoid and underwent surgical correction. MRI scan revealed subglottic stenosis. While EDS VIII is clinically indistinguishable from vascular EDS, both patients had normal collagen protein analysis and COL3A1 sequencing, ruling out vascular EDS. Voice abnormalities have been described with other EDS subtypes and may result from defects in the collagen of the vocal ligament. Twenty-seven percent of patients with EDS subtypes I, II, III, IV and VI have self-reported dysphonia. Our cases demonstrate rarely reported laryngeal abnormalities and dysphonia, which is not a recognised feature of EDS VIII.

PM04.26
Molecular genetic diagnostics of epidermolysis bullosa in the Czech Republic

L. Kopeckova[1], *P. Silerova[1], H. Buckova[2], B. Pinkova[2], R. Gaillyova[3], J. Nemeckova[3], L. Fajkusova[1,4];*
[1]Centre of Molecular Biology and Gene Therapy, University Hospital Brno, Brno, Czech Republic, [2]Pediatric Clinic, University Hospital Brno, Brno, Czech Republic, [3]Department of Medical Genetics, University Hospital Brno, Brno, Czech Republic, [4]Central European Institute of Technology, Masaryk University, Brno, Czech Republic.

Introduction:
Epidermolysis bullosa (EB) is a clinically and genetically heterogeneous group of disorders. There are four major types of inherited EB: EB simplex,

junctional EB, dystrophic EB, and Kindler syndrome. A characteristic feature of all EB types and subtypes is the presence of skin blistering and erosions.
Methods: EB families presenting at our laboratory over a period of 10 years were assessed using PCR-direct sequencing (KRT5, KRT14, TGM5, COL7A1) and/or sequence capture and targeted resequencing (COL7A1, KRT5, KRT14, DSP, DST, JUP, PKP1, EXPH5, TGM5, PLEC, COL17A1, LAMA3, LAMB3, LAMC2, ITGA6, ITGB4, ITGA3, FERMT1).
Results: Mutations associated with EB were identified in 139 probands: 22 and 42 patients had dominant and recessive mutations in COL7A1, respectively; 16 patients in KRT14; 10 patients in KRT5; 1 patient in PLEC; 36 patients in TGM5; and 1 patient in COL17A1. Eleven patients are without causal mutations despite that all known genes up to now associated with EB were analysed. Totally, mutations were identified in 128 probands (92%).
Conclusion: Besides identification of the spectra of mutations in Czech EB patients, the study present new method implemented into genetic diagnostics of genodermatoses in the Czech Republic - sequence capture and targeted resequencing - that provides more complete diagnosis than a classical gene-by-gene approach. Parallel analysis of known genes in a patient (or in multiple patients) enables fast and cost-effective identification of gene mutations. Currently, we are able to perform analysis of 81 genes associated with different inherited skin disorders.
Supported by IGA MZČR NT14585-3 and TAČR TE02000058.

PS04.27
Molecular genetic testing of FGFR3 gene mutation in the differential diagnosis of achondroplasia and hypochondroplasia in Ukraine

I. Dmytruk, *H. Makukh, M. Turkys, N. Markevych, V. Shuvarska, H. Akopyan;*
Institute of Hereditary Pathology of the Ukrainian National Academy of Medical Sciences, Lviv, Ukraine.

Introduction: The differential diagnosis of achondroplasia and hypochondroplasia in Ukraine is based on the typical clinical and radiologic features that limits accurate diagnosis and leads to many false-positive diagnoses when checked against a complete mutation search of the FGFR3 gene. Thereby, we outline the necessity of implementation molecular-genetic test of FGFR3 gene mutations. The implementation is necessary to carry out differential and prenatal diagnostic of achondroplasia and hypochondroplasia among Ukrainian population.
Materias and Methods: The study included 61 patients with clinical things of achondroplasia or hypochondroplasia and 94 relatives including sibs and parents. The molecular-genetic analysis was performed by PCR (Polymerase Chain Reaction) and RFLP (Restriction Fragment Length Polymorphism) analysis. We optimized the time and temperature conditions and chose specific primers for revealing the c.1138G>A, c.1138G>C and p.Asn540Lys mutations of FGFR3 gene.
Results: Mutation c.1138G>A was found at 22 (36%) individuals aged from 5 months to 40 years old with obvious phenotypical features of achondroplasia of which 20 cases was sporadic. Additionally the mutation c.1138G>C was detected at 3 (5%) probands. Major p.Asn540Lys mutation of the FGFR3 receptor was identified at 3 (5%) probands which causes hypochondroplasia.
Conclusions: We concluded that 98% of mutations were sporadic because no mutations were found at relatives; meanwhile we found one (1.6%) inheritable c.1138G>A mutation at both mother and son. Due to conducting of molecular-genetic diagnostics of FGFR3 mutations c.1138G>A, c.1138G>C and p.Asn540L diagnosis achondroplasia and hypochondroplasia were confirmed at 26 (43%) observed patients and extensive gene analysis are required for the other patients to search for rare FGFR3 rearrangements.

PM04.28
Inhibition of TGFβ signalling inhibits progression of fibrodysplasia ossificans progressiva in an in vitro model of the disease

D. Micha, *E. Voermans, H. W. van Essen, J. Drukker, C. Netelenbos, M. E. W. Eekhoff, G. Pals, N. Bravenboer;*
Vrije Universiteit medisch centrum, Amsterdam, Netherlands.

Fibrodysplasia ossificans progressiva (FOP) is a rare congenital disorder characterized by progressive heterotopic ossification. During the disease course FOP patients present soft tissue lumps as a result of inflammation-induced flare-ups preceding the irreversible replacement of skeletal muscle tissue with bone tissue. Classical FOP patients possess a mutation (c.617G>A; R206H) in the activin receptor IA (ACVR1)-encoding gene. Nonetheless, disease progression in FOP patients with this mutation varies which indicates a strong contribution by environmental factors. Our objective was to study the process of osteogenic differentiation in primary dermal fibroblasts from five FOP patients based on a novel method of growth factor-induced osteogenic transdifferentiation. In all patients the classical FOP mutation was confirmed. The osteogenic properties of the cells were evaluated by the mRNA expression of Runt-related transcription factor 2 (Runx2), alkaline phosphatase (Alp), osteocalcin (OC) and the presence of mineralization by alizarin red staining. Given the pro-inflammatory role of TGFβ, we performed pharmacological inhibition of TGFβ signaling by the TGFβ type I receptor inhibitor GW788388. During osteogenic transdifferentiation the expression of Runx2 and Alp over time was higher in FOP cell lines compared to heathy controls (Runx2:p=0.001; Alp:p>0.05). All cell lines exhibited increase in mineralization. Addition of the inhibitor to the osteogenic media resulted in the attenuation of osteogenic differentiation shown by the decrease in expression of osteogenic markers in patients vs untreated cells (Runx2:p=0.045) and mineralisation. We suggest that TGFβ is involved in the molecular pathway of flare-up-induced ossification. Inhibition of this pathway may limit ectopic ossification in FOP.

PS04.29
A rare association of congenital aplasia of the fibula, cleft palate and skeletal abnormalities: a case report

M. I. S. Crapanzano, *M. C. Cutrupi, C. Pidone, E. Moschella, S. Meduri, M. R. Pizzino, I. Loddo, S. Briuglia;*
UOC Genetics and Pediatric Immunology, University of Messina, Messina, Italy.

We report the case of a 35-years old man, referred for genetic counseling because of cleft palate and limb malformations. The family history was unremarkable. He was son of healthy non-consanguineous parents, born at 40 weeks of gestation. Pregnancy was complicated by threatened miscarriage. At birth, clinical evaluation showed cleft palate and presence of multiple malformations of limbs. Hands and foots showed agenesis of some fingers, with syndactyly and complex brachydactyly. Upper limbs were normal. Right femur was hypoplastic with agenesis of the right fibula, brevity and deformation of the proximal epiphysis of the tibia. Other associated anomalies were scoliosis and hypoplasia of the pelvis. Growth and psychomotor development were normal. Complementary investigations including eye fundus, abdominal, renal and cardiac ultrasound examinations and auditory evoked potentials were normal. This syndrome is apparently distinct from other previously described conditions exhibiting fibular agenesis/hypoplasia, because of the association of fibula aplasia/hypoplasia, cleft palate and oligo-brachy-syndactyly of hands and foots is extremely rare. Figuera et al. (1993) reported a girl with fibular agenesis, together with radial shortening and coalescence of the tarsal bones, telecanthus, flat nasal bridge, retrognatia, cleft palate and oligo-polydactyly. This syndrome has been described as "Oral-facial-digital syndrome with fibular aplasia". Some defects are in common with our case, such as the occurrence of cleft palate and fibular aplasia, but in OFD syndrome polydactyly is present, that is absent in our patient. Since this combination has not been described previously, we suggest a distinct new variant of this syndrome.

PM04.30
Genome-wide association identifies a new susceptibility locus at 2q13 associated with clinical vertebral fractures in post-menopausal women

N. Alonso, *S. H. Ralston, The Clinical Vertebral Fracture Consortium;*
Rheumatic Disease Unit, CGEM-IGMM, University of Edinburgh, Edinburgh, United Kingdom.

Clinical vertebral fractures (CVF) are a serious complication of osteoporosis. They are associated with back pain, kyphosis, height loss, cardiorespiratory compromise and increased mortality. Genetic factors play an important role in regulating bone mineral density (BMD) and susceptibility to non-vertebral fractures, but there is little information on the genetic determinants of CVF. Here we report the results of a genome wide association study to identify loci that predispose to CVF, involving 1634 postmenopausal female CVF cases (from 11 centres in Europe and Australia) and 4662 controls, matched for region and gender. Genotyping was performed using the Illumina OmniX array and standard quality control measures were applied. Each cohort was analysed separately and results were combined using inverse-variance meta-analysis. Replication was sought in 634 CVF cases and 2150 controls. We identified seven loci suggestively associated with CVF (p-values=2.02x10-5 - 3.35x10-7) and one locus on chromosome 2q13 significantly associated with CVF (p=2.42x10-8, OR=1.7 [95%CI 1.42-2.09]). The loci are distinct from those previously identified as genetic risk factors for osteoporosis. We went on to study mRNA expression of candidate genes in the 2q13 locus in transiliac bone biopsies from normal and osteoporotic women. Four genes showed reduced levels of expression in osteoporotic patients (ANAPC1, SLC20A1, TMEM87B, ZC3H6) and two showed increased expression (MERTK, ZC3H8). This study has cast new light on the genetic architecture of CVF and identified a novel variant has one of the largest effect sizes ever detected for

fracture risk. Further studies are in progress to identify the causal variants.
Grant: European Commission(HEALTH-F2-2008-201865-GEFOS) for the Genetic Factors for Osteoporosis Consortium.

PS04.31

Hemihyperplasia and embryonal tumor- presentation of two cases

R. Zordania[1], *H. Põder*[2], *M. Uritam*[2], *I. Rebane*[2], *K. Lepik*[2], *K. Joost*[1];
[1]*Tartu University Hospital United Laboratories Dept Genetics, Tallinn, Estonia,* [2]*Tallinn Children`s Hospital, Tallinn, Estonia.*

Hemihyperplasia (HH) is an asymmetric body overgrowth due to an unregulated cell proliferation. The frequency of HH might be 1:13500 - 1:86000 newborns. HH may involve one side of the body or single limb or half of the face. Some cases are isolated , inherited dominantly or may be a symptom with variety malformation syndroms- Beckwith-Wiedemann (BWS), Sotos, Silver-Russell (SRS), Proteus. It is well documented that children with HH and/or BWS have an increased risk up to 10% of developing embryonal neoplasms, including nephroblastoma, hepatoblastoma, etc.
Aim. To present two unrelated paediatric patients with typical features of asymmetric body overgrowth, diagnosed HH and embryonal neoplasms.
Case descriptions. The first patient - a girl, body asymmetry was detected at the age of 3 months and as her mother had also HH, autosomal dominant HH was diagnosed and the regular surveillance focusing to embryonal tumors was recommended. Systemic abdominal ultrasound (USD) revealed an adrenal tumor at the age of 22 months, which was successfully operated.
The second patient -a boy, whose HH was diagnosed at the age of 2 months. Abdominal USD was performed at the age of 15 months nephroblastoma was diagnosed and treatment started.
Clinical and pedigree data of the patients are presented, literature data and follow up discussed.
Conclusion. Regular surveillance focusing to embryonal tumors is indicated for children with isolated HH-they have higher risk for embryonal tumor and must be systematically investigated by USD up to six years.

PM04.32

Hereditary Heterotopic Ossification Syndromes: Effect of GNAS inactivation in progressive osseous heteroplasia: A case report

P. Ata[1], *A. Turkyilmaz*[1], *K. Delil*[1], *I. Yagci*[2], *K. Gencer*[2], *E. Ozturk*[2], *G. Akyuz*[2];
[1]*Marmara University Faculty of Medicine, Dept. of Medical Genetics, Istanbul, Turkey,*
[2]*Marmara University Faculty of Medicine, Dept. of Physical Medicine, Istanbul, Turkey.*

Bone formation initiates within subcutaneous fat before progressing to deeper tissues in progressive osseous heteroplasia (POH),suggesting that osteogenesis may involve abnormal differentiation of mesenchymal precursors present in adipose tissues. GNAS is a gene encoding two stimulatory G proteins and is a key regulator of fate decisions in adipose-derived mesenchymal progenitor cells that are involved in bone formation. Herein we had detected a patient with GNAS mutation previously not reported.
Case: A 6-year-old boy admitted to our clinic with complaint of left wrist stiffness and limitation in May 2014. His prenatal history revealed oligohydramnious, gestational age as 34 week at birth, delivered with sectio, had 1750 gr birth weight and 45 cm in lenght. At postnatal period he had recurrent infections and apnea . His parents noticed a hard mass on his left wrist when he was 3 months old. The mass progressively became bigger through his first year of life. The biopsy revealed findings as osteoma cutis and could not prove whether it was FOP or POH. In physical examination; he had left wrist and hand deformity, pain with palpation of palmar area. Extension and flexion of left wrist was completely limited, while the range of both supination and pronation were at 30°. He had normal serum PTH, Ca, P, TSH levels. Serial radiographic examinations were reviewed and the progressive HO was noted. The genetic analysis demonstrated GNAS exon 6 mutation as p.Asn167Glnfs*7 (c.498-499insC) heterozygosity and the diagnosis was confirmed as POH certainly. With this case we disscussed the effect of this particular, previously unreported mutation on disease pathogenesis.

PM04.34

EXOME-SEQUENCING APPROACH TO IDENTIFY CANDIDATE GENES FOR INCONTINENTIA PIGMENTI SEVERITY PHENOTYPE

F. Fusco[1], *M. I. Conte*[1], *M. Paciolla*[1], *A. Pescatore*[1], *M. F. Branda*[1], *M. C. Girone*[1], *M. B. Lioi*[2], *M. V. Ursini*[1];
[1]*Institute of Genetics and Biophysics, Naples, Italy,* [2]*University of Basilicata, Potenza, Italy.*

Incontinentia pigmenti (IP, MIM308300) is a rare X-linked neuroectodermal disorder, caused by mutations in the IKBKG/NEMO gene, regulatory protein of the IKK complex, required for the activation of the NF-kB pathway.
In IP patients the skin defects are hallmarks of the disease, while the extra cutaneous defects (ocular, dental, hair, nail and central nervous system-CNS) are present at variable frequency. In 30% of IP patients CNS defects are observed, and the phenotype severity is variable. Moreover, it does not correlate with the genetic alteration in IP locus. Indeed, even when the common deletion is present (NEMOdel4_10 deletion) a wide range of CNS symptoms can occur, from neonatal seizures to severe mental retardation.
To evaluate the contribution of modifier genes on the variability of the IP intellectual disabilities we investigated the genomic background in three selected IP cases carrying the NEMOdel4_10 deletion and severe mental retardation: one was a familial case and two were sporadic cases. Whole exome-sequencing of trios samples was performed. From sequencing of an exome-enriched library a list of single nucleotide/indels variants was produced. By applying combined filtering method with the information related to the inheritance of the variants, we identified candidate genes by selecting those variants fitting to recessive model of inheritance and damaging by bioinformatics analysis.
Candidate genes were associated to cobalamin and folate pathways suggesting that a masked metabolic defect underlines the IP clinical phenotype. We will present the evaluation of candidate genes acting as modifiers and contributing to the severity of phenotype in IP.

PS04.35

Congenital infiltrating lipomatosis of the face caused by a somatic *PIK3CA* mutation

J. J. van den Ende[1], *E. Legius*[2], *H. Brems*[2];
[1]*Department of Medical Genetics, University Hospital Antwerp, Antwerp, Belgium,*
[2]*Center for Human Genetics, University Hospital Leuven, Leuven, Belgium.*

Congenital infiltrating lipomatosis of the face is a rare disorder, occuring in infancy or early childhood, in which mature lipocytes invade adjacent tissues of the face. It is characterized by rapid growth, associated osseous hyperplasia and high recurrence rate after surgical intervention. Also premature dental eruption and regional macrodontia have been described. In 2014 Maclellan et al. identified causal missense mutations in *PIK3CA* in affected tissue samples of patients with this disorder.
The phosphatidylinositol-3-kinase (PI3K)/AKT signaling pathway is critical for cellular growth and metabolism and activating mutations in *AKT1, AKT2, or AKT3* have been found in distinct disorders featuring overgrowth. *PIK3CA* encodes the p110α catalytic subunit of PI3K.
Several *PIK3CA* related syndromes with segmental overgrowth have been described before, like MCAP syndrome (Megalencephaly-Capillary Malformations), Hemimegalencephaly, CLOVES syndrome (Congenital Lipomatous asymmetric Overgrowth of the trunk, Vascular malformations, Epidermal nevi, Skeletal and Spinal anomalies) and FH (fibroadipose hyperplasia). Because even more clinical entities were shown to be caused by *PIK3CA* mutations, the name „*PIK3CA*-Related Overgrowth Spectrum (PROS)“ was suggested. Almost all cases are caused by postzygotic (mosaic) mutations in one allele of the *PIK3CA* gene.
We report a patient who presented with asymmetry of the face, with hypertrophy of the right cheek and hemihypertrophy of the tongue. Segmental neurofibromatosis was suspected, but after a biopsy no Schwann cells were found, but only fat cells and fibroblasts, leading to the diagnosis of Congenital infiltrating lipomatosis of the face. DNA analysis of the affected tissue showed a c.1625A>T mutation in the *PIK3CA* gene.

PM04.36

Development of a comprehensive workflow for the analysis of *RYR1* and *CACNA1S* genes associated with malignant hyperthermia; hybridization-based capture and next generation sequencing (NGS) implemented into a routine genetic diagnostics set-up.

I. Valaskova[1,2,3], *S. Dudova*[1,2], *E. Ostadalova*[1], *R. Spesna*[1], *Z. Svestkova*[1], *R. Gaillyova*[1,2];
[1]*University Hospital Brno, Medical Genetics Dpt., Brno, Czech Republic,* [2]*Masaryk University, Faculty of Medicine, Department of Biology, Brno, Czech Republic,* [3]*Masaryk University, Faculty of Science, Department of Experimental Biology, Brno, Czech Republic.*

Malignant hyperthermia (MH) is potentially fatal pharmacogenetic disorder in which intracellular calcium homeostasis in the skeletal muscle of susceptible individuals is disrupted upon exposure to halogenated anaesthetics, suxamethonium, or both. MH is linked to the ryanodine receptor (RYR1) on chromosome 19 and the α1S subunit of the voltage dependent L-type calcium channel (CACNA1S) on chromosome 1. Molecular diagnosis of MH is essential for provision of genetic counseling and to establish cascade screening in MH families. We have performed a systematic molecular genetic screening program for MH probands. Many techniques has been implemented and optimized such as DNA/cDNA "*RYR1 hot spot*" sequencing,

melting analysis on Real-Time PCR, MLPA or QF PCR to the routine diagnostics screening algorithm in MH patients. 385 patients from 105 different families underwent molecular genetic testing. In about half of the patients included in our cohort, we identified candidate mutation. There was a need for a more powerful screening tool. A NGS-based workflow was designed using capture library to target the coding and splice site sequences of *RYR1* and *CACNA1S* genes followed by GS Junior pyrosequencing. The developed workflow permitted the identification of MH candidate mutations in 10 of 12 patients examined so far. The workflow meets the sensitivity and specifity requirements for the genetic diagnosis of MH and improves on the cost-effectiveness of current approach. This strategy has been implemented into a routine genetic diagnostics set-up as a first screening approach, potentially before the need of more invasive and specific clinical investigations.

PS04.37

Failure of ossification of the occipital bone : a radiologic handle for diagnosis of mandibuloacral dysplasia type B.

D. HAYE[1], *H. DRIDI*[1], *V. LAMBERT*[2], *F. ADJIMI*[2], *J. KOHLHASE*[3], *A. VERLOES*[1];
[1]*Robert Debré University Hospital, Paris, France,* [2]*Regional Hospital, Saint Laurent Du Maroni, Guyana,* [3]*Center for Human Genetics, Freiburg, Germany.*

Mandibuloacral dysplasia type B (MADB) is a rare autosomal recessively inherited disease charectirized by atrophic skin, lipodystrophy and skeletal features. It is caused by mutations in ZMPSTE24 gene encoding a zinc metalloproteinase important in the post-translational modification of lamin. Eleven different mutations in this gene have been identified in 11 patients with MADB from 9 independant families until now.
We report a description of a 12 year-old boy with MADB resulting from a novel missense homozygous mutation in ZMPSTE24 (c.1196A>G ; p.Y399C). The patient had typical skin, sparse hair and skeletal features of MADB, short stature, mild microcephaly, facial dysmorphism and a striking failure of ossification of the interparietal region of the occipital, up to the position where transverse occipital suture can be observed.
Skeletal anomalies such as acrosteolysis, long bone osteolysis, clavicular hypoplasia, spontaneous fractures, delayed closure of cranial sutures, mandibular hypoplasia and skull anomalies are commonly reported in MADB. Wormian bones have described in five cases, but failure of ossification of the occipital bone, reported previously in a single case, appears to be almost pathognomonic for this entity. Occipital bone counts several parts (squama, basio-, exo-, and supraoccipal) and its ossification is multicentric. This observation illustrates that ZMPSTE24 mutations could play a specific role in intramembranouseous ossification of the interparietal part of the squama (Inca bone) but not in the intracartilaginous ossification the supraoccipital. The failure of ossification in the squama appears to be a good handle for radiological diagnosis of mandibuloacral dysplasia type B.

PM04.38

PREDICTIVE PRENATAL TESTING FOR KNOWN FAMILIAL MUTATIONS IN FAMILIES WITH MARFAN SYNDROM

R. Krenkova, *J. Indrakova, M. Dvorakova, P. Cibulkova;*
Laboratore AGEL a.s., Novy Jicin, Czech Republic.

Objectives:
Marfan syndrome (MFS) is an autosomal dominant connective tissue disorder caused by mutations in the FBN1 gene, resulting in defective glycoprotein fibrillin-1. The major features of MFS involve the cardiovascular, ocular and skeletal systems. Each child of an affected parent has a priori 50% chance of inheriting the mutation. We describe three families with FBN1 mutations which caused classic type of MFS and one family with neonatal form of MFS as a result of maternal germline mosaicism.
Methods:
In the first step a clinically affected future parent was tested. DNA was isolated from peripheral blood and the molecular analysis of FBN1 gene was performed by MLPA and NGS. If the causal mutation was found, fetal samples were taken in the first or second trimester of pregnancy. DNA was isolated from chorionic villus samples or uncultured amniotic fluid. The potential contamination of fetal samples with maternal cells was excluded by characterization of alleles using STR.
Results:
We tested 15 fetal samples whose one parent is a carrier of the causal mutation of the FBN1 gene for classical type of MFS, and 2 fetal samples whose mother is a carrier of the germline mosaicism mutation of the FBN1 gene for MFS neonatal form.
Conclusion:
We have confirmed 9 fetuses with a classic type of MFS and all results were confirmed after their birth. Knowledge of diagnosis is important for their immediate and future health care too. No pregnancy had been terminated following the detection of mutation.

PS04.39

Severe fetal phenotype of a dominant mesomelic dysplasia, associated with a 790 kb microduplication of HOXD gene cluster at 2q31.1

S. M. M. ODENT[1,2], *C. Jeanne-Pasquier*[3], *P. Balouet*[4], *A. Molin*[3], *N. Leporrier*[3], *S. Jaillard*[5], *V. Jauffret*[5], *E. Cherot*[1], *M. Fradin*[1], *C. Quélin*[1], *L. Pasquier*[1], *V. David*[6,2], *C. Dubourg*[6,2];
[1]*CHU de Rennes. Hôpital Sud. Service de Génétique clinique, Rennes, France,* [2]*CNRS UMR 6290, IGDR, Université Rennes1, Rennes, France,* [3]*CHU de Caen, Caen, France,* [4]*Centre Hospitalier Mémorial, Saint-Lo, France,* [5]*CHU de Rennes. Laboratoire de cytogénétique, Rennes, France,* [6]*CHU de Rennes. Service de genetique moleculaire et genomique, Rennes, France.*

Objective: The aim of this study was to elucidate the genetic etiology of a very early fetal phenotype of mesomelic dysplasia inherited from the father, and to compare with other phenotypes of mesomelic dysplasia.
Methods: We performed molecular cytogenetic analysis using array CGH and the molecular results were confirmed using QMPSF and FISH.
Results: At 11 weeks of gestation ultrasound showed a cystic hygroma of 4.5 mm, a punctate appearance of the forearm's bones, shortening of the lower limbs, clubfeet, and an unilateral pleural effusion. A TOP was performed at 13 weeks of gestation. Mesomelic dysplasia was confirmed by fetal autopsy, X-rays, and a particular histological appearance(organization of chondrocytes in shortened columns, triangular densification at diaphyseal angulations). The father was followed since childhood for a growth retardation (-2.5 SD) with macrocephaly (+4 SD), ulnar deviation of hands and club feet, a significant shortening of ulna and fibula, bowed forearms and legs, difficulties with flexion / extension of the fingers. Fetal DNA analysis by array-CGH revealed a microduplication of a 790 Kb involving genes *HOXD*13, *HOXD*12, *HOXD*11, *HOXD*10, *HOXD*8, *HOXD*4, *HOXD*3, *MTX*2. This microduplication was also identified in the father.
Conclusions: The different phenotypes of mesomelic dysplasia with early prenatal expression are close, sometimes more severe than the phenotype of an affected parent; research of a genomic microrearrangement is indicated since it can reveal notably a deletion of the *SHOX* region in Xp22.33, or 2q31.1 microduplication encompassing the *HOXD* cluster.

PM04.40

Severe phenotype of metaphyseal dysplasia due to a novel homozygous frameshift mutation in the MMP13 gene

S. Verheyen[1], *P. M. Kroisel*[1], *H. M. Pfingstl*[1], *U. Gruber-Sedlmayr*[2], *M. Sperl*[3], *M. R. Speicher*[1], *C. Windpassinger*[1];
[1]*Department of Human Genetics, Medical University of Graz, Graz, Austria,* [2]*Department of Pediatrics, Medical University of Graz, Graz, Austria,* [3]*Department of Pediatric Orthopaedics, Medical University of Graz, Graz, Austria.*

Introduction: Two sisters of a consanguineous family with Turkish background presenting with short stature and bowlegs were introduced for genetic assessment. The older sister showed more pronounced bowing of the femur and the tibia. Leg pain when walking lead to first surgical correction of both legs at the age of five years. Radiological examination showed genua and coxa vara and metaphyseal and epiphyseal dysplasia of the lower limbs. Additional metaphyseal dysplasia of the radius and the ulna and incomplete closure of the sacral vertebral arch were found concerning the younger sister. Due to suspected recessive inheritance, exploratory genetic testing for shared homozygous alleles was employed.
Material and Methods: Homozygosity mapping was conducted via whole genome SNP analysis using a CytoScan® 750K Array. Subsequent Sanger sequencing of MMP13 gene was performed.
Results: Only one homozygous region (11q22.1-q23.3; HG19:101,897,234-116,462,585) was identified, surprisingly containing the MMP13 gene which is associated with different subtypes of metaphyseal dysplasia. Sequencing of the MMP13 gene revealed a homozygous frameshift mutation (c.381delT) presumably leading to a premature stop codon in the catalytic region of the MMP13 protein.
Conclusion: We describe a novel frameshift mutation in MMP13 gene (c.381delT). Inconsistent with previous reports of inherited metaphyseal dysplasia due to homozygous mutations in MMP13 gene, the associated phenotype of bone dysplasia is severe and requires surgical correction.

PS04.41

Deletion of the miR-17-92 cluster in association with digital anomalies and growth delay

S. E. Anderson[1], *S. F. Jose*[1], *E. McCann*[2], *S. M. Morgan*[1];

[1]Laboratory Genetics Service for Wales, Cardiff, United Kingdom, [2]All Wales Medical Genetics Service, Cardiff, United Kingdom.

MicroRNA's (miRNAs) play a key role in the regulation of gene expression. Hemizygous deletions of the MIR17HG gene, encoding the miR-17-92 polycistronic miRNA cluster, are extremely rare. L. de Pontual et al., 2012, reported the first two cases of a germ-line deletion of the miR-17-92 cluster in association with a distinct phenotype consisting of microcephaly, short stature and digital anomalies (Feingold syndrome Type 2, OMIM #614326). We report one further patient with a hemizygous deletion of the miR-17-92 cluster. The patient was referred to our laboratory because of failure to thrive and clinodactyly. Array CGH analysis showed a 648kb deletion of the long arm of chromosome 13 at q31.3 that includes the MIR17HG gene, encoding the miRNA cluster, and one other OMIM gene, GPC5. Real-time quantitative PCR analysis confirmed the result. To date, the mechanism by which the miR-17-92 cluster modulates skeletal development remains uncertain. This case, however, provides further evidence that miR-17-92 plays an important role in normal growth and skeletal development. A full clinical assessment and parental studies will be presented.

PM04.42

Executive function and adaptive behavior in Muenke syndrome

D. W. Hadley, *Y. A. Addissie, C. M. P. Yarnell, M. Guillen, N. B. Agochukwu, R. A. Hart, E. Wiggs, P. Kruszka, M. Muenke;*
National Institutes of Health, Bethesda, MD, United States.

Objectives: The study investigated executive function and adaptive behavior in persons with Muenke syndrome, the most common craniosynostosis syndrome, using validated instruments with a normative population and unaffected siblings as controls. Additionally, an analysis of modifying factors including absence of craniosynostosis, history of surgery for craniosynostosis, seizures, and hearing loss was done.
Methods: Participants in a cross sectional study included individuals with Muenke syndrome (P250R mutation in FGFR3) and their mutation negative siblings. Participants completed validated assessments of executive functioning (Behavior Rating Inventory of Executive Function; BRIEF) and adaptive behavior skills (Adaptive Behavior Assessment System; ABAS-II).
Results: Forty-four FGFR3 mutation positive individuals, median age 9, range 6 months to 52 years were evaluated with the BRIEF and ABAS-II. Additionally, 10 unaffected siblings were used as controls. For the General Executive Composite scale of the BRIEF, 32.1% of the cohort had scores greater than +1.5 SD, signifying "Potential Clinical Significance." For the General Adaptive Composite of the ABAS-II, 28.2% of affected individuals scored in the "Extremely Low" category" (3rd -8th percentile of normative population) and 53.9% were below the "Average" category (less than the 25th percentile). Multiple regression analysis showed that the presence of craniosynostosis was not a predictor (P = 0.7) of BRIEF and ABAS-II scores.
Conclusion: Individuals with Muenke syndrome are at an increased risk for exhibiting differences in adaptive and executive functioning when compared to a normative population and unaffected siblings. These differences were observed regardless of whether craniosynostosis was present.

PS04.43

Missense substitutions in NF1 and a lack of cutaneous neurofibromas

E. M. M. Burkitt Wright, *M. Pereira, M. Bulman, S. M. Huson, G. Evans;*
Manchester Center for Genomic Medicine, St Mary's Hospital, Manchester, United Kingdom.

Background
Café-au-lait macules (CAL) are the commonest presenting feature of neurofibromatosis type I (NF1), and hence indicators of risk for future NF1-related pathology. Few genotype-phenotype correlations in NF1 are known. Predictors of mild, 'CAL only' phenotypes allow for better prognostication and patient care; p.(992del Met) is the only longstanding example. p.(Arg1809Cys) has recently been reported in association with a similar phenotype (Messiaen, unpublished; Pinna et al, 2014).
Method
We examined genotypes of a cohort of patients with NF1 for evidence of variants predicting a mild phenotype.
Results
Cutaneous neurofibromas (NFs) are less common in patients with missense variants than in those with truncating, frameshift or splice variants ($p<0.05$). p.(Arg1809Cys) is a recurrent substitution (7 individuals from 4 families) in patients without NFs. This mutation has recently been suggested by other groups to be associated with a CAL only phenotype, indicating that this is a robust association. Further substitutions seen in pedigrees without NFs include p.(Arg1276Gln), in 10 individuals from 2 unrelated families, and others clustered around the Ras-binding domain.
Discussion
Missense substitutions in *NF1* predict a lower cutaneous NF burden. It is likely that further specific genotype-phenotype correlations will emerge with testing of more patients. Exclusion of rare complications will require collaborative approaches and long term follow up data.
Conclusion
Certain substitutions in *NF1* segregate with very mild disease. Molecular diagnosis can inform prognosis and management of these patients.

Epidermolysis Bullosa (EB) is caused by mutations in genes encoding for proteins of the epidermal–dermal junction assembly. Due to the extreme clinical/genetic heterogeneity of the disease, current methods in EB diagnostics comprise immunohistochemistry on bioptic samples and transmission electron microscopy followed by single candidate gene Sanger Sequencing (SS) that therefore represents the final phase of a labour intensive and expensive clinical pathway.
According to the recently published recommendations for diagnosis and treatment in EB, the assessment of mutational landscape is instead a fundamental step to a comprehensive diagnosis path; Next Generation Sequencing (NGS), throughout parallel ultra-deep sequencing of many genes, would represent a proper method for reducing timing and costs in EB diagnostics.
We developed an EB disease-comprehensive amplicon panel (AmpliSeq panel), to accomplish NGS onto Ion Torrent PGM platform. The panel was dealt on ten patients with known genetic diagnosis, and then employed in eight family trios with unknown molecular footprinting.
The AmpliSeq panel, obtaining a proof of concept of the sensitivity, specificity, and accuracy of this kind of procedure, showed successful in finding the causative mutations in all the ten patients with known mutations, fully confirming SS data. Besides, showing consistent with the clinical diagnosis, it was effective in trios, identifying all the variants, even the ones SS missed or in case of de novo mutations. NGS and AmpliSeq therefore demonstrated to be an effective approach in the diagnosis of EB, resulting in a cost and time-effective 72 hours procedure.

PS04.45

Targeted NGS for analysis of craniosynostosis identifies a novel mutation in MEGF8

E. König[1], *S. Spranger*[2], *T. Schweitzer*[3], *W. Kress*[1], *E. Klopocki*[1];
[1]*Institute of Human Genetics, University of Wuerzburg, Wuerzburg, Germany,* [2]*Praxis fuer Humangenetik, Bremen, Germany,* [3]*Department of Pediatric Neurosurgery, University of Wuerzburg, Wuerzburg, Germany.*

Craniosynostosis is a frequent craniofacial malformation affecting 1 in 2500 newborns and is defined as the premature fusion of one or more cranial sutures. Premature fusion of the cranial sutures can occur either as isolated malformation in non-syndromic craniosynostoses or as part of a syndrome. So far genetic causes have been identified mainly for syndromic craniosynostoses, i.e. mutations in FGFR2, FGFR3, TWIST1, and EFNB1. However, in more than 50% of cases the underlying genetic cause remains unknown.
We compiled a next generation sequencing (NGS) gene panel comprising 68 genes. In addition to known and candidate craniosynostosis genes of the syndromic and isolated type, the panel includes downstream targets of participating signaling pathways and genes associated with bone development. Target enrichment was performed by the Nextera Rapid Capture Enrichment kit of Illumina and sequencing was done on the Illumina MiSeq

platform. Sequencing data were analysed with the NextGENe software. Performance of the NGS gene panel was validated by sequencing 5 control patients with known mutations. All of these mutations were detected correctly. Subsequently, we sequenced DNA of 13 patients with syndromic as well as isolated craniosynostosis. Two patients are siblings and children of consanguineous parents. Both patients show an a-typical Carpenter phenotype with sagittal craniosynostosis. We identified in both a novel homozygous splice site mutation (c.828G>A) in MEGF8 leading to a predicted loss of the splice donor of exon 5. The mutation was confirmed by Sanger sequencing. Mutations in MEGF8 were shown to be associated with Carpenter syndrome 2 (MIM 614976).

PM04.46

Successful identification of causative single-gene defects using NGS disease-associated genome sequencing approach in a patient affected by perinatal type of hypophosphatasia

A. Jamsheer[1,2], *E. M. Olech*[1], *T. Zemojtel*[3,4,5], *A. Sowinska-Seidler*[1], *P. N. Robinson*[3,6,7], *S. Mundlos*[3,6,7];

Lethal skeletal dysplasias are highly heterogeneous and phenotypically variable group of genetic condition, often unrecognizable based on the clinical symptoms. Here we report on a foetus affected by severe skeletal dysplasia that resulted in stillbirth at weeks 22 of gestation. The patient presented with generalized limb shortening and intrauterine fractures of the lower leg bones revealed by prenatal ultrasound and autopsy examination. Since no clinical diagnosis could be established, we performed NGS panel encompassing all 2741 genes known to be associated with Mendelian disorders (i.e. disease-associated genome; DAG). With this approach, we were able to demonstrate the diagnosis at a molecular level, which turned out to be perinatal lethal hypophosphatasia (HPP). This severe form of HPP, characterized by an inborn defect of ossification, results either in stillbirth or early postnatal death. NGS panel detected compound heterozygous ALPL missense mutations: c.1283G>C (p.R428P) and c.1363G>A (p.G455S), next confirmed by Sanger sequencing. Mutations demonstrated in our proband, although previously described in other HPP cases, have not been reported to coincide in a single individual. Our study therefore extends the knowledge on HPP and helps in genetic counseling of other patients harboring identical mutations. Importantly, the diagnosis in our index was established by means of NGS-based DAG panel sequencing and would be extremely difficult to reach by any other diagnostic approach. Thus, our report highlights the efficiency and important role of NGS strategies in the diagnosis of prenatally manifesting skeletal dysplasias, especially if the clinical data is insufficient to allow for clinical diagnosis

PS04.47

PRINS, the psoriasis susceptibility related non-coding RNA is involved in stress response of cells, but not in inflammation

J. Danis[1], *A. Göblös*[1], *Z. Bata-Csörgő*[1], *L. Kemény*[1,2], **M. Széll**[3,2];

[1]*Department of Dermatology and Allergology, University of Szeged, Szeged, Hungary,* [2]*MTA SZTE Dermatological Research Group, University of Szeged, Szeged, Hungary,* [3]*University of Szeged, Dept of Medical Genetics, Szeged, Hungary.*

We have previously identified a non-coding RNA, PRINS, as a differentially expressed transcript in psoriatic uninvolved and healthy epidermis. Our in vitro experiment showed that PRINS expression is altered after exposure to various stressors i. e. UVB, translation inhibition and microbial agents. A potential stress signal in psoriatic involved skin may be the extracellular DNA, which activates the AIM2 inflammasome. The activated inflammasome cleaves the precursor proIL-1β form into mature, functioning IL-1β which plays a well-known role in the pathogenesis of psoriasis.

The aim of our study was to investigate whether PRINS affects the expression and activation of IL-1β in normal human epidermal keratinocytes (NHEK) and the elevated expression of PRINS in psoriatic uninvolved epidermis contributes to the inflammatory aspect of the disease.

The highest level of IL-1β secretion could be induced by priming the NHEKs with TNF-α and IFN-γ and a subsequent treatment with the synthetic DNA analogue poly(dA:dT). This treatment resulted in a 2-fold PRINS expression and a significantly elevated (p=0.02) IL-1β secretion. Next we silenced and overexpressed PRINS in NHEKs and performed the above IL-1β inducing treatments. Neither the silencing nor the overexpression of PRINS had any effect on the IL-1β secretion of NHEKs suggesting that this non-coding RNA does not have any regulatory role in the AIM2 inflammasome signaling.

PM04.48

Olmsted syndrome: a novel homozygous TRPV3 mutation with severe phenotype

A. Gezdirici[1], *Y. Bayram*[2], *B. Engin*[3], *U. Celik*[3], *T. Gambin*[2], *C. Demirkesen*[4], *E. Karaca*[2], *S. N. Jhangiani*[5], *T. Baris*[6], *Baylor-Hopkins Center for Mendelian Genomics, R. A. Gibbs*[5], *J. R. Lupski*[2,7,8];

[1]*Department of Medical Genetics, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey,* [2]*Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States,* [3]*Department of Dermatology and Venereology, Cerrahpasa Medical Faculty at Istanbul University, Istanbul, Turkey,* [4]*Department of Pathology, Cerrahpasa Medical Faculty at Istanbul University, Istanbul, Turkey,* [5]*Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, United States,* [6]*Burc Genetic Diagnostic Center, Istanbul, Turkey,* [7]*Department of Pediatrics, Baylor College of Medicine, Houston, TX, United States,* [8]*Texas Children's Hospital, Houston, TX, United States.*

Olmsted syndrome (OLMS) (MIM#614594) is a rare, severe keratinization disorder characterized by bilateral mutilating palmoplantar keratoderma and periorificial keratotic plaques. Other associated features include corneal lesions, diffuse alopecia or sparse hair, digital constriction, nail dystrophy, autoamputation of fingers and/or toes. Infections and squamous cell carcinomas can arise on the keratotic areas. OLMS should be differentiated from several genodermatoses, such as Vohwinkel syndrome and Acrodermatitis enteropathica. Although most cases are sporadic, both autosomal dominant and X-linked inheritance have also been reported. The heterozygous mutations in TRPV3 were identified as a cause of autosomal dominant type, while the X-linked recessive inheritance was associated with the mutations in MBTPS2. Recently, the homozygous TRPV3 mutations have also been reported in a few recessive cases.

We report a 16-year-old male patient who has referred to our clinic with severe palmoplantar keratoderma, autoamputation of fifth toes, mild periorificial, perianal and genital keratotic plaques, and mild intellectual disability with prediagnosis of OLMS. His parents had consanguinity and his brother, who has died at the age of 8 due to complication of infections, had similar phenotype. We performed whole exome sequencing (WES) for the index case and a novel homozygous TRPV3 mutation (NM_145068;c.1247G>T;p.Arg416Leu) was identified in our patient. Additionally, we confirmed this mutation by using Sanger sequencing and the parents were found to be heterozygous carriers for this mutation. To our knowledge, this is the third reported autosomal recessive OLMS case in the literature. We conclude that the homozygous TRPV3 mutations result in a more severe OLMS phenotype.

Nonsyndromic cleft lip with or without cleft palate: Genome-wide imputation identifies four novel risk loci and an enrichment of association signals in enhancer datasets relevant to craniofacial development

K. U. Ludwig[1,2], *A. C. Boehmer*[1,2], *H. Schuenke*[1,2], *J. Klamt*[1,2], *J. Hecker*[3], *S. Barth*[1,2], *K. Aldhorae*[4], *A. Rojas-Martinez*[5], *L. Goelz*[6], *A. Rada-Iglesias*[7], *H. Fier*[3], *M. M. Noethen*[1,2], *M. Knapp*[8], *E. Mangold*[2];

[1]*Department of Genomics, Life&Brain Center, Bonn, Germany,* [2]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [3]*Institute for Genomic Mathematics, Bonn, Germany,* [4]*Othodontic Department, College of Dentistry, Thamar University, Thamar, Yemen,* [5]*Department of Biochemistry and Molecular Medicine, School of Medicine, Universidad Autonoma de Nuevo Leon, Monterrey, Mexico,* [6]*Department of Orthodontics, University of Bonn, Bonn, Germany,* [7]*Center for Molecular Medicine, University of Cologne, Cologne, Germany,* [8]*Institute of Medical Biometry and Informatics and Epidemiology, University of Bonn, Bonn, Germany.*

Nonsyndromic cleft lip with or without cleft palate (nsCL/P) is a common congenital malformation and has a multifactorial etiology. Currently, 15 nsCL/P susceptibility loci have been established. Some of the yet unidentified genetic risk factors might be detected by increasing the marker density in genome-wide datasets. We used data from a genome-wide meta-analysis of European individuals (Ludwig et al. 2012, Nature Genetics). Based on ~500.000 genotyped markers, imputation was performed using 2184 alleles (1kGP data). After quality control, a high-density dataset of ~8.26 million variants was statistically analyzed.

One previously unreported SNP was identified with genome-wide significance (rs6740960 at 2p21, P=1.6x10-08). Interestingly, this variant maps 5bp adjacent to a predicted Myc binding site upstream of the PKDCC gene. Pkdcc is downregulated in mice carrying a deletion of the region homologous to the 8q24 nsCL/P major risk locus (Uslu et al. 2014). Additionally,

SNPs at 64 loci showed suggestive evidence of association. Replication at 29 loci in an independent nsCL/P sample (609 cases, 1.745 controls) was performed. After combined analysis, three additional loci reached genome-wide significance: 2p24.2, 14q22.1 and 15q13.3. At genome-wide level, we observed a significant overrepresentation of association signals in functional datasets relevant to craniofacial development such as enhancer datasets from human neural crest cells (Rada-Iglesias et al. 2012) and murine embryonic craniofacial tissue (Attanasio et al. 2013).
Our study identified four novel risk loci for nsCL/P and revealed an over-representation of association signals in functionally relevant datasets. Ongoing analyses include assessment of heritability estimates, and ingenuity pathway analyses.

PM04.50
Antenatal detection of intracranial calcification in a baby with osteocraniostenosis

A. Smith, *J. Campbell, A. Dobbie;*
Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

Osteocraniostenosis (OCS) is a rare, perinatally lethal skeletal dysplasia characterised by gracile bones, premature closure of basal cranial sutures and microphthalmia. Recently, heterozygous mutations in the gene *FAM111A* have been shown to cause OCS.
OCS is allelic to Kenny-Caffey syndrome (KCS), which has a less severe phenotype of small, dense bones, short stature and primary hypoparathyroidism with hypocalcaemia. *FAM111A* mutations have been identified in both disorders. Recent publications suggest that *FAM111A* plays an important role in a pathway controlling calcium homeostasis.
We present a case of an infant who was found antenatally to have a cloverleaf skull, reduced bone density and intracranial calcification (presenting as intracranial echogenicity on ultrasound scanning). The presence of intracranial calcification led to a relatively long list of differential diagnoses. The baby was born at term but died within a few hours of birth. On post mortem examination features of OCS were identified and there was confirmation of foci of calcification in the basal ganglia. A *de novo* heterozygous mutation in *FAM111A* was subsequently detected, confirming the diagnosis.
Intracranial calcification is a recognised feature of OCS, but only on postnatal imaging. Antenatal detection of intracranial abnormalities has not previously been reported. We report the clinical and radiological findings of this rare skeletal dysplasia, review the literature and suggest that OCS should be in the differential diagnosis of antenatal intracranial calcification.

Osteogenesis imperfecta (OI) is a heritable bone fragility disorder that is most often caused by mutations in *COL1A1* (MIM 120150) or *COL1A2* (MIM 120160). Defects in sixteen other genes have been identified in association with dominantly and recessively inherited forms of OI. These genes play a role in the processing of collagen type I or in the control of osteoblast differentiation or function. Despite these advances, a small proportion of individuals that present with a phenotype of severe OI do not have mutations in any of the genes that are known to be associated with OI. We performed whole-exome sequencing to identify the molecular defect in two unrelated girls with severe bone fragility and a clinical diagnosis of osteogenesis imperfecta type IV, and identified two homozygous variants that affect very conserved and interacting residues in a novel protein that interacts with collagen type I and other matrix proteins. The residues substituted by these mutations are essential for the binding of this protein to collagen type I. Skin fibroblasts from our patients express the protein at apparently normal levels but secretion of collagen type I was delayed. Binding of the mutated protein to collagen type I was decreased. Analysis of an iliac bone sample from one affected individual showed that the trabecular bone was hypermineralized on the material level. Herein we present a detailed clinical, radiological and molecular description of this novel form of autosomal recessive OI.

PM04.52
Osteoblasts from Type V OI patients demonstrate gain-of-function for mineralization despite decreased COL1A1 expression

A. Reich[1], *A. Bae*[1], *A. Barnes*[1], *W. Cabral*[1], *A. Hinek*[2], *J. Stimec*[3], *S. Hill*[4], *D. Chitayat*[5], **J. Marini**[1];

Osteogenesis imperfecta (OI) is a genetically heterogeneous disorder characterized by bone fragility. OI is now understood to be a collagen-related disorder, with mutations in type I collagen structure causing dominant OI, while deficiency of collagen-related proteins cause rare recessive OI forms. Type V OI is the only rare OI type to also have dominant inheritance. It is caused by a heterozygous mutation (c.-14C>T) in IFITM5, which encodes BRIL, a transmembrane protein expressed in osteoblasts. The mutation generates a start codon, adding five residues to the BRIL N-terminus. However, the mechanism of type V OI and its relationship with type I collagen is unknown. We identified 8 patients with type V OI. Using cultured patient osteoblasts, we verified normal expression and stability of mutant IFITM5 transcripts and BRIL protein level. Both early (ALPL and IBSP) and late (osteopontin and osteocalcin) markers of osteoblast differentiation are increased in type V OI osteoblasts. Mineralization, assayed by alizarin red staining, was increased in type V OI osteoblasts vs control. In contrast, type V OI osteoblasts have one-third the level of COL1A1 transcripts in control in mid to late differentiation, with concomitantly decreased collagen protein secretion, crosslinked collagen in matrix, and altered appearance of fibrils deposited in culture. The increased mineralization and advanced differentiation of type V OI osteoblasts demonstrate a gain-of-function mutation leading to the overactive tissue calcification and hypertrophic callus formation seen in type V patients. Decreased type I collagen expression, secretion and matrix incorporation establish type V OI as a collagen-related defect.

Osteogenesis imperfecta (OI) is a clinically and genetically heterogeneous brittle bone disorder. The aim of our study was to identify mutations in COL1A1, COL1A2, CRTAP, LEPRE1, PPIB and SERPINF1 genes in Russian OI patients.
We examined 78 patients with OI and 100 healthy controls corresponding by age, gender, ethnicity and place of residence. We sequenced the coding and exon-flanking regions of COL1A1, COL1A2, CRTAP, LEPRE1, PPIB and SERPINF1 genes.
We identified 7 distinct mutations, undescribed before.
For the first time previously unreported nonsense mutation c.967G>T (p.Gly323X), 2 novel frameshift mutations c.3541insC (p.Gly1181ArgfsX38) and c.1098_1099insA (p.Gln367ThrfsX5) and one splicing mutation c.3208+1G>C in COL1A1 gene was observed in 7 patients,
The splicing mutation c.1724+4G>A in LEPRE1 gene was identified in two patients. And novel compound heterozygous mutations (c.913C>G (p.Leu305Val) of SERPINF1 gene and c.641T>C (p.Val214Ala) of CRTAP gene) was observed in three patients.
We also detected three previously described nonsense mutations in seven Russian patients: c.1081C>T (p.Arg361X), c.1243C>T (p.Arg415X) and c.2869C>T (p.Gln957X), two frameshift mutations in two patients: c.579delT (p.Gly194ValfsX71) and c.2444delG (p.Gly815AlafsX293) and two splicing mutations in three patients: c.4005+1G>T and c.697-2A>G.
In conclusion, the present study revealed 11 mutations in COL1A1 gene, 1 mutation in SERPINF1 gene, 1 mutation in LEPRE1, 1 mutation in CRTAP gene, 7 of them was not observed before and no mutations in COL1A2 and PPIB genes in Russian patients with OI. Future research will focus on other genes responsible for OI development in Russian patients

Targeted sequencing of the Paget's disease associated 14q32 locus identifies several missense coding variants in RIN3 that predispose to Paget's disease of bone

M. Vallet[1], *D. C. Soares*[2], *S. Wani*[1], *A. Sophocleous*[1], *J. Warner*[3], *D. M. Salter*[1], *S. H. Ralston*[1], *O. M. E. Albagha*[1];

Background: Paget's disease of Bone (PDB) is a common skeletal disorder with a strong genetic component. We identified a susceptibility locus for PDB on chromosome 14q32 by GWAS, tagged by rs1049863 within the RIN3 gene. Here we investigate the candidacy of RIN3 as a predisposing gene for PDB.
Methods: We conducted re-sequencing of the 14q32 locus in PDB cases and controls and studied expression of RIN3 in bone tissue and bone cells by quantitative PCR, western blotting and immunohistochemistry.
Results: We detected 16 missense variants in RIN3, including 12 rare potentially damaging variants, 7 of which were detected only in PDB. A common coding variant (p.R279C) in LD with the GWAS hit (r2=0.96) was strongly associated with PDB (OR=0.64, P=1.4x10-9). The rare variants were also strongly associated when combined (OR=3.72; P=8.9x10-10). mRNA for RIN3 was strongly expressed in lung, bone and liver with increased expression in osteoclasts as compared with bone marrow (p=0.02). Expression of RIN3 increased at the mRNA and protein level during osteoclast differentiation in vitro.
Conclusions: These findings indicate that RIN3 is the causal gene for PDB on 14q32 and suggest that its susceptibility is mediated by a combination of common and rare coding variants. While the function of RIN3 in bone biology is incompletely understood the data are consistent with a model whereby RIN3 acts to inhibit osteoclast formation and that the predisposing variants damage its ability to do so, resulting in the osteoclast activation characteristic of PDB.

University Hospital of Salamanca- Institute of Biomedical Research of Salamanca (IBSAL)., Salamanca, Spain.*

Paget's disease of bone (PDB) is a focal disorder of bone that affects segmentally the skeleton, presenting an increase in osteoclast number, size and activity that results in a variegated and anarchic bone structure that alters the mechanical properties.
The existence of genetic factors is one of the etiopathogenic hypothesis that attempts to explain the origin of PDB. The most plausible candidate gene is sequestosoma1 gene (SQSTM1), encoding the p62 protein, which plays an important role in cellular signal crossroads related with osteoclastogenesis
Only 3% of patients in a historical cohort of 288 patients were carriers of a mutation in SQSTM1 gene. Five patients were carriers of the c.1000G>C (p.E273D) mutation, not described to date in the literature.
The aim of our study was to try to evaluate the putative role c.1000G>C (p.E273D) mutation in the development of PDB.
"In silico" study categorizes c.1000G>C mutation as pathogenic. A population study in 100 healthy individuals alleles by dHPLC failed to detect mutation.
Then, the cDNA of SQSTM1 gene was cloned in the expression vector pCEFL-FLAG. After site directed mutagenesis the c.1000G>C mutation was incorporated into the construction. Finally COS1 cells were transfected with our construct to perform western blotting and immunofluorescence assays.
By immunofluorescence and western blot assays we did not find differences between the transfected cells with the wt construct and transfected cells with the c.1000G>C construct (Fig1-2).
In conclusion, our results suggest that c.1000G>C (p. E273D) mutation should be considered as a neutral mutation, a polymorphism that increases risk to suffer PDB.

Chronic periodontitis is an inflammation disorder affecting 30-50% of the adult population, leading to teeth attachment loss and degradation of the alveolar bone. Aggressive periodontitis (AP) is a rare form of the disease with a prevalence of approximately 0,1%. It is characterized by an early age of onset, rapid rate of progression and high inflammation activity leading to loss of teeth before the age of 35, if untreated.
Here we report on a Tyrolean four-generation family indicating an autosomal dominant inheritance pattern for AP. The result of our genome-wide linkage analysis revealed one large co-segregating chromosomal region in affected individuals. The interval is 12 Mb in length and contains approximately 300 genes. In addition, we performed whole exome sequencing in four affected family members to identify possible common variants in the linkage region. Assuming a monogenic cause for the disease we have been looking for an unknown, heterozygous mutation in the coding sequence and exon/intron boundaries. Identified variants were filtered with common parameters including alignment against various mutation databases and prioritized based on their translational and predicted functional effects.
In our functional studies we have already shown a significant reduction of chemotactic and phagocytic activity of neutrophils in affected individuals. In regard to
these preliminary results we propose a mutation contributing to an immunological dysfunction. Signs of Ehlers-Danlos-syndrome (EDS) present in some family members may also suggest a mutation resulting in disturbed connective tissue deposition.

Bruck syndrome, a disorder caused by recessive mutations in either *PLOD2* or *FKBP10*, is characterized by contractures and bone fractures and shows strong clinical overlap with Osteogenesis Imperfecta (OI). Animal models for OI are indispensable for unraveling molecular mechanisms in OI pathogenesis. The zebrafish was recently shown to be a useful vertebrate organism to model OI both at the phenotypic and molecular level. Zebrafish mutants that model OI display generalized reduced bone density and misshapen bones with evidence of fractures. Although the molecular role of *PLOD2* has been documented, no animal models for Bruck syndrome, caused by *PLOD2* mutations, have been reported. To elucidate the function of *PLOD2* in vertebrate skeletal development, zebrafish harbouring a homozygous *plod2* nonsense mutation were phenotyped using µCT scanning, alizarin red staining for bone, toluidine blue staining and ultra-thin sectioning. Mutants presented with a shortened body axis and malformed craniofacial structures. The skeleton was severely affected with evidence of bone fragility and fractures, bowing and kinking of the ribs and fin bones. The vertebral column was scoliotic with compressed vertebrae and excessive periosteal bone formation at the vertebral end plates. The observed phenotype is concordant with the clinical findings detected in Bruck Syndrome patients. Therefore, the *plod2* zebrafish mutant is a promising model for elucidation of the underlying pathogenetic mechanisms leading to Bruck Syndrome.

Physiology and Sports Medicine, Angers University, Angers, France.

Pseudoxanthoma elasticum (PXE), an autosomal recessive ectopic mineralization disorder caused by ABCC6 and ENPP1 mutations, is characterized by skin, ocular and cardiovascular (CV) symptoms. PXE shows distinct clinical variability, with growing importance of modifier genes. Modifiers have previously been studied using a candidate gene approach, which only yielded VEGFA as a modifier of the PXE retinopathy.
We introduced Whole Exome Sequencing (WES), capable of analyzing multiple genes in a single reaction, to identify potential modifiers by comparing patients with extreme phenotypes. WES was performed in 13 molecularly and histologically confirmed PXE patients with an extreme (absent or severe) CV phenotype (based on clinical presentation and vascular calcium scoring).
Comprehensive functional analysis of variants unique to the severe cohort led to 9 modifier candidates, which were subsequently validated using Sanger sequencing and screened in an independent cohort of 50 PXE patients. Genotype/allele frequency analysis and multiple logistic regression confirmed significant association of 3 SNPs with severe CV disease: rs2228570 (VDR gene), rs13006529 (CASP10 gene) and rs1042714 (ADRB2 gene). All were previously linked to CV disease and functional data mining yielded links to the PXE pathophysiology. Particularly for rs2228570, reported to increase VDR transcriptional activity, upregulation of several VDR transcriptional targets was demonstrated in PXE.
In conclusion, WES enables to characterize candidate modifier genes through a targeted analysis approach in patients with extreme phenotypes. Our results suggest a role for VDR, CASP10 and ADRB2 in determining the severity of CV complications in PXE, providing valuable assets for management of PXE families. FWO14/ASP/084

PS04.59
Co-inherited ENPP1 mutations can intensify the cardiovascular phenotype of pseudoxanthoma elasticum

M. J. Hosen[1], *I. Vermeulen*[1], *D. G. Devos*[2], *J. De Backer*[3], *S. Fisher*[3], *P. Coucke*[1], *A. De Paepe*[1], *O. M. Vanakker*[1];
[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Department of Radiology, Ghent University Hospital, Ghent, Belgium,* [3]*Department of Cardiology, Ghent University Hospital, Ghent, Belgium.*

Pseudoxanthoma elasticum (PXE) is characterized by aberrant mineralization and fragmentation of elastic fibers, leading to skin, ocular and cardiovascular symptoms with a significant variability in severity. The molecular etiology of PXE has become increasingly challenging as mutations in both ABCC6 and ENPP1 were shown to cause overlapping phenotypes and modifier genes are beginning to be identified. We evaluated the causal role of ENPP1 mutations in PXE patients with an incomplete ABCC6 genotype in both an autosomal recessive or digenic inheritance model. Further, we assessed whether ENPP1 variants, which also cause a severe cardiovascular disease called Generalized Arterial Calcification of Infancy (GACI), could have a disease modifying effect in PXE patients with an exceptionally severe and rapidly progressive (cardio)vascular phenotype. ABCC6 and ENPP1 genotyping of 40 clinically and histologically confirmed PXE patients was performed by Sanger sequencing and MLPA. A vascular calcium score was obtained through whole body CT scanning. In a cohort of 40 PXE patients (13 with an unidentified and 17 with an incomplete ABCC6 genotype; 10 with severe cardiovascular disease), no additional ENPP1 mutations could be found. In one patient of the cardiovascular cohort, an additional ENPP1 mutation co-inherited with biallelic ABCC6 mutations was identified. The vascular calcification score of this patient was exceptionally high (Agatston score of 3600 compared to an average of 422 in PXE patients), resembling the findings in GACI patients. We demonstrate that the co-inheritance of ENPP1 mutations together with ABCC6 mutations has an intensifying effect on the cardiovascular phenotype of PXE.

PM04.60
Development of a Genetically-Modified Human Dermal Fibroblast for the Treatment of Recessive Dystrophic Epidermolysis Bullosa (RDEB)

V. K. Dailey[1], *M. Chakiath*[1], *A. Elayadi*[1], *S. Krishnan*[1], **J. Maslowski**[2], *M. P. Marinkovich*[3];
[1]*Intrexon Corporation, Germantown, MD, United States,* [2]*Fibrocell Science, Exton, PA, United States,* [3]*Stanford University School of Medicine, Stanford, CA, United States.*

Recessive dystrophic epidermolysis bullosa (RDEB) is an autosomal recessive, inherited skin disease caused by null mutations within the type VII collagen gene (*COL7A1*). The mutations cause an absence or reduction of functional collagen VII, which make up anchoring fibrils that maintain binding of the epidermis to the dermis. The disease is characterized by a mechanical fragility and repeated blister formation in the sub-lamina densa, at the level of the structurally defective anchoring fibrils. Currently, there is no effective therapy for this disease, and death is usually the result of aggressive squamous cell carcinoma, sepsis, or malnutrition.
We are developing an autologous, genetically-modified fibroblast cell therapy that is anticipated to improve skin function in RDEB patients through restoration of collagen levels. A patient's fibroblasts will be harvested, genetically modified *ex-vivo* with a functional *COL7A1* gene, and expanded in culture (GM-HDF-COL7). *Ex vivo* transduction will occur through the use of a replication-defective, self-inactivating (SIN) lentiviral vector. After expansion, the fibroblasts are administered back to the patient as a local intradermal injection into target wound margins. The resulting increase in anchoring fibrils is anticipated to stabilize the connection between skin layers and reduce blistering tendency.
In vitro product development data indicates that cGMP scale GM-HDF-COL7 cells express full-length type VII collagen exhibiting the proper trimeric structure, size, and binding functionality. A hybrid *in vitro/in vivo* pharmacology/toxicology study using an organ culture/SCID mouse model is underway at Stanford University to confirm type VII collagen persistence, distribution, localization and toxicology.

PS04.61
Patients with isolated oligo/hypodontia caused by *RUNX2* duplication

A. Molin[1], *S. Lopez-Cazaux*[2], *O. Pichon*[3], *M. Vincent*[3], *B. Isidor*[3], **C. Le Caignec**[3];
[1]*CHU, Caen, France,* [2]*Departement d'odontologie pédiatrique, faculté de chirurgie dentaire, Nantes, France,* [3]*CHU, Nantes, France.*

Loss-of-function mutations of *RUNX2* are responsible for cleidocranial dysplasia, an autosomal dominant disorder characterized by delayed closure of cranial sutures, aplastic or hypoplastic clavicles, moderate short stature and supernumerary teeth. In contrast, an increased gene dosage is expected for duplication of the entire sequence of *RUNX2* and, thus, a different phenotype as cleidocranial dysplasia. To date, two cousins with a duplication including the entire sequence of *RUNX2* in addition to *MIR586*, *CLIC5* and the 5' half of the *SUPT3H* gene have been reported. The patients presented with the association of metopic craniosynostosis and hypodontia.

We report here a family with four patients carrying a 285 kb duplication including the entire sequence of *RUNX2* and the 5' half of the *SUPT3H* gene. Two patients presented with the association of metopic craniosynostosis and oligo/hypodontia previously described, confirming the phenotype caused by a duplication of the entire sequence of *RUNX2*. Interestingly, the two other patients had isolated hypodontia without any craniosynostosis, enlarging the phenotype observed in patients with such duplications.

PM04.62
Childhood osteoporosis and enamel dysplasia: expanding the spectrum of duplication in RUNX2

G. Baujat, *V. Querol, S. Bacrot, F. Poulain, M. Biosse-Duplan, M. Polak, V. Malan, M. Veckemans, A. Munnich, V. Cormier-Daire, S. Romana;*
Hôpital Necker-Enfants Malades, Paris, France.

RUNX2 gene encodes CBFA1, a master transcription factor, regulating both osteoblasts and terminal chondrocytes differentiation, is essential for bone development and mineralization.
A 105-kb duplication containing exons 3-5 of the RUNX2 gene was recently found in affected members from a family with Metaphyseal Dysplasia and Maxillary Hypoplasia with or without Brachydactyly (MDMHB, OMIM 156510). Transfection studies with murine dup3-5 Runx2 cDNA showed a higher transactivation activity suggesting of gain of function of the gene in patients with MDMHB, contrary to the RUNX2 haploinsufficiency, which is associated with Cleidocranial Dysplasia (CCD, OMIM 119600), defined by persistent open skull sutures, clavicles hypoplasia and dental anomalies.
MDMHB is described in only 3 families (2 Canadian and 1 Finnish), and is characterized by metaphyseal flaring, wormian bones, mild osteoporosis, enlargement of the proximal portion of the clavicles, and yellowish teeth. We have identified 3 children from 2 unrelated families (Cambodia and Algeria), presenting with clinical features resembling to MDMHB. They were all referred for Osteogenesis Imperfecta. CGH array and Q-PCR detected a RUNX2 duplication spanning exon 2 to exon 6, resulting, as in the MDMHB Canadian family, to the duplication of the functional CBFA1 QA and RUN domain. In both families, RT-PCR detected interestingly that the fathers were mosaic for this RUNX2 duplication. We highlight the main features of this recognizable phenotype of childhood osteoporosis with abnormal teeth. Finally, we discuss the RUNX2 threshold for consequences on the formati-

on of endochondral and intramembranous bone tissue and odontogenesis process.

PS04.63

Variants of the matrix metalloproteinase-3 gene are not associated with anterior cruciate ligament ruptures

A. P. Gibbon[1], *H. Hobbs*[1], *W. van der Merwe*[1], *S. Raleigh*[2], *M. Posthumus*[1], *M. Collins*[1], *A. September*[1];
[1]*University of Cape Town, Cape Town, South Africa,* [2]*The University of Northampton, Northampton, United Kingdom.*

Introduction: DNA sequence variants have been associated with the risk of musculoskeletal soft-tissue injuries, including several mapping to the matrix metalloproteinase-3 gene (*MMP-3*). This gene encodes an endopeptidase, which by function, degrades extracellular matrix components. Three *MMP-3* variants namely; rs679620, rs591058 and rs650108 have previously been associated with Achilles tendinopathy. Moreover, variants; rs679620 and rs3025058, have been studied for their association with anterior cruciate ligament ruptures (ACL) in two studies. Therefore, the aim of this research was to explore all four variants within *MMP-3* with the risk of ACL injuries.
Material and Methods: A case-control genetic-association study was employed. In total, 232 control participants (CON) and 234 participants with ACL ruptures (ACL) were genotyped for all four *MMP-3* variants. Within the ACL group, 120 participants reported a non-contact mechanism of injury (NON subgroup). Investigated polymorphisms included; rs3025058 (5A/6A), rs679620 (G/A), rs591058 (C/T) and rs650108 (G/A) respectively. Statistical analysis involved investigating the allele and genotype frequency distributions in addition to conducting inferred haplotype analysis between the cases and control participants. Significance was accepted when $P<0.05$.
Results: After adjusting for age, sex and weight, no independent associations were noted for all genotype frequencies ($>P=0.350$). Furthermore, no differences in the inferred haplotypes amongst the cases and controls were observed. All variants were in Hardy-Weinberg Equilibrium ($P>0.05$).
Conclusion: These preliminary observations are in contrast to the previous findings and therefore this genomic region requires further interrogation.
Grants: Research supported by NRF and UCT. Andrea Gibbon funded by NRF and UCT. Michael Posthumus funded by the Thembakazi Trust.

Analyses of the molecular pathways involved in the sarcopenic process in functional and non-functional elderly population.

G. Queipo[1], *M. Fonseca*[2], *Y. Trujillo*[1], *J. Rivera*[1], *I. Palma*[3], *G. Ariti*[1];
[1]*Hospital General de Mexico Eduardo Liceaga-Facultad de Medicina UNAM, Mexico City, Mexico,* [2]*Hospital General de Mexico Eduardo Liceaga, Mexico City, Mexico,* [3]*Molecular and Cellular Morphology Laboratory, Escuela Superior de Medicina, Instituto Politécnico Nacional, Mexico City, Mexico.*

Abstract
Sarcopenia is one of the most deleterious effects of aging. The involuntary loss of muscle mass, strength, and muscular function have a major impact on quality of life in the elderly population. The etiology of the sarcopenia is not clearly established, although, a multifactorial process that develops from the fourth decade of life is proposed. In a previous clinical report we found that evaluation of the muscular contractility is a *per se* and independent factor in the sarcopenia development not related with the muscle volume. In order to understand this phenomenon, we analyzed the molecular pathways involved in the muscle performance and the sarcopenic process. Genetic expression patterns in functional and non-functional elderly groups were studied in 15 muscle biopsies from both groups, using a QRTPCR array (RT2Profiler, Qiagen). We studied critical signaling pathways involved in the sarcopenic process (apoptosis, autophagy, WNT, TGF-Beta, TNF-Alpha and interleukins). Immunohistochemestry and confocal analysis were also performed in order to explore differences in the distribution of the muscular proteins involved in the contractile process (actin, myosin, myopalladin and SERCA). Preliminary results showed an overexpression of genes involved in apoptosis, autophagy and interleukins in the non functional group. Confocal analysis showed a different protein distribution in a qualitative a quantitative fashion in both groups. Our data suggests that inflammatory and apoptotic process in the muscular fiber impacts the proteins involved in contractility and muscular functionality, observed in the clinic as less contractility, strength and muscular performance in the sarcopenic and non functional population.

JmjC demethylase mutation and Split Hand/Foot Malformation with Long Bone Deficiency.

C. Fusco[1], *P. De Nittis*[1], *A. Alfaiz*[2], *L. Micale*[1], *M. Pellico*[1], *B. Augello*[1], *N. Malerba*[1], *L. Zelante*[1], *B. Mandriani*[1], *A. Reymond*[2], *G. Merla*[1];
[1]*IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy,* [2]*Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland.*

We studied an Italian nuclear family with three individuals (mother and two of the siblings) presenting Split Hand/Foot Malformation with Long Bone Deficiency (SHFLD). The duplication at 17p13.3, encompassing bHLHA9 gene and commonly associated with this disease, segregated within the family. The duplication was detected in a set of healthy subjects originating from Southern Italy, suggesting that it could be merely a susceptibility factor. Consistent with this hypothesis, the bHLHA9 duplication was found associated with a range of other limb malformations.
To possibly identify the causative genetic lesion we exome sequenced all members of the family. We filtered, consistently with the expected autosomal dominant inheritance, a heterozygous nonsense mutation (c.4000C>T/p.R1334X) in the KDM5B gene that co-segregates with SHFLD and targets transcripts to nonsense-mediated mRNA-decay, contributing to protein haploinsufficiency. KDM5B encodes a JmjC demethylase, which regulates genes with a role in bone metabolism. The expression of two of its targets, SMAD7 and TCF3, is modified in KDM5B haploinsufficient cells. We similarly showed through luciferase assays that wild-type KDM5B, conversely to the truncated form, controls the promoter of RUNX2, a key transcription factor involved in osteoblastic differentiation. Moreover the expression levels of RUNX2 and OPG are altered in a model of osteoblast-like cells, established from patient's skin fibroblasts. Overall these results suggest that haploinsufficiency of KDM5B could cause transcriptional alteration of genes linked to bone development.
Therefore, considering the variable expressivity and reduced penetrance of SHFLD, we propose KDM5B as a likely second genetic event participating in the index family.

PS04.67

Silver-Russell syndrome phenotype in a patient with a methylation abnormality associated with Beckwith-Wiedemann syndrome

F. Ryan[1], *C. Wenman*[1], *J. Short*[1], *H. Gosrani*[1], *F. Byrne*[1], *H. A. Spoudeas*[2], *R. Taylor*[1];
[1]*South West Thames Regional Genetics Laboratory, St George's University Hospitals NHS Foundation Trust, London, United Kingdom,* [2]*Endocrinology, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom.*

Introduction: Beckwith-Wiedemann syndrome (BWS), an overgrowth disorder, and Silver-Russell syndrome (SRS), a growth retardation disorder, are imprinting disorders associated with abnormalities of the 11p15 region. The majority of BWS cases result from loss of methylation at the KvDMR imprinting control centre whilst ~40% of SRS cases arise from loss of methylation at the H19 DMR imprinting control centre.
Materials and methods: 11p15 MS-MLPA was performed to detect dosage and methylation abnormalities of the 11p15 region in a patient with a suspected diagnosis of SRS.
Results: The patient was found to have loss of methylation at KvDMR at all probes tested and no 11p15 dosage abnormalities. Loss of methylation at KvDMR is a known cause of BWS but not SRS.
Conclusion: This is the first report, to our knowledge, of a patient with loss of methylation at KvDMR only presenting with a SRS phenotype. There have been previous reports of rare patients with loss of methylation at both KvDMR and H19 DMR that present with SRS. It has been hypothesised that the region with greater demethylation gives the dominant phenotype and that, in cases where multiple regions have a similar degree of methylation, one region might have a dominant effect. Also ~45% of SRS cases have an unknown etiology. Therefore, a possible reason that this patient is presenting with a SRS phenotype despite having loss of methylation at KvDMR only, could be that another, as yet unknown, locus with a dominant effect is also affected.

PM04.68

High success of a next generation sequencing panel in the genetic analysis of rare skeletal dysplasias

J. Barraza[1,2,3], *C. I. Rivera-Pedroza*[1,3], *L. Sentchordi-Montané*[4,1,3], *E. Vallespin*[1,2], *V. E. Montaño*[1], *E. Mansilla*[1,2,3], *A. Belinchón*[1,2,3], *S. Benito-Sanz*[1,2,3], *A. Del Pozo*[1,2], *K. Ibañez*[1], *I. González-Casado*[5,3], *E. Guillén-Navarro*[6,2], *P. Prieto*[7], *J. Sánchez del Pozo*[8], *E. Galan*[9], *J. Cruz*[8], *P. Lapunzina*[1,2,3], *S. García-Miñaur*[1,2,3], *F. Santos-Simarro*[1,2,3], **K. E. Heath**[1,2,3];

[5]Dept. of Pediatric Endocrinology, Hospital Universitario La Paz, UAM, Madrid, Spain, [6]Dept. of Genetics, Hospital Virgen de la Arrixaca, Murcia, Spain, [7]Dept. of Pediatric Endocrinology, Hospital Universitario de Salamanca, Salamanca, Spain, [8]Dept. of Pediatric Endocrinology & Dysmorphology, Hospital Universitario 12 de Octubre, Madrid, Spain, [9]Dept. of Clinical Genetics, Hospital Materno Infantil de Badajoz, Badajoz, Spain.

In 2010, 456 skeletal dysplasias (SD) were classified by molecular, biochemical and/or radiological criteria, into 40 groups. The precise, final diagnosis is often difficult due to the high phenotypic and genotypic variability. Aim: To improve SD molecular diagnosis using a custom-designed Next-generation sequencing (NGS) panel, including a total of 315 genes or regulatory regions (967Mb).
A total of 60 SD probands without known mutations were clinically and radiologically evaluated. All probands and in some cases family members, were analyzed using the SKELETALSEQ.V3 panel and sequenced (16 patients/run) on a MiSeq (mean coverage 100X). All variants were confirmed by Sanger sequencing or aCGH.
The molecular defect was identified in 24 probands (40%): 23 mutations (missense, stop or small deletions) and one GLI3 deletion. Interesting cases include the identification of the first FGF9 mutation in a family with craniosynostosis, a second case of spondylometaphyseal dysplasia due to POP1 mutations and the detection of POCA1 mutations in two families with primordial dwarfism/SOFT syndrome.
In conclusion: 1) The SD-NGS panel has permitted a high mutation detection rate, 40%, higher than in other pathologies (average 26%). 2) We have demonstrated that FGF9 mutations can cause not only multiple synostosis but also sagital/coronal craniosynostosis in humans, as observed in the spontaneous mouse model. 3) The advancement in genetic diagnosis of these disorders will improve the management, monitoring and treatment of the patients and allow prenatal and preimplantational studies. 4) Exome sequencing may be helpful in those cases in which no mutation was identified.

PS04.69

An interstitial deletion of chromosome 7q35q36.1 in a 3-year-old boy with clinical features of Weaver syndrome

L. Roht[1], *K. Reinson*[1], *I. Talvik*[2,3], *R. Zordania*[4], *K. Kuuse*[1], *O. Zilina*[1,5], *K. Õunap*[1,3];
[1]Tartu University Hospital, United Laboratories, Department of Genetics, Tartu, Estonia, [2]Children's Clinic, Tartu University Hospital, Tartu, Estonia, [3]Department of Paediatrics, University of Tartu, Tartu, Estonia, [4]Tartu University Hospital, United Laboratories, Department of Genetics, Tallinn, Estonia, [5]Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.

The phenotype of EZH2-related overgrowth known as Weaver syndrome usually incorporates tall stature, variable intelligence, advanced bone age (100%), poor coordination, soft doughy skin, camptodactyly, umbilical hernia, a hoarse low cry in infancy. Facial characteristics may contain macrocephaly, broad forehead, round face, large, fleshy ears, hypertelorism, almond-shaped eyes and retrognathia. Most cases of Weaver syndrome are sporadic and caused by a heterozygous mutation in the EZH2 gene on chromosome 7q36.
The aim is to present a case report of a 3-year-old boy first investigated because of speech delay. His birth weight was 5080 g (> + 2 SD), length 53 cm (0 SD) and head circumference 39 cm (> + 2 SD). In early neonatal period he had an episode of hypoglycemia. At the age of 3 years his head circumference was rather large (+2 SD) but his height was normal (102 cm, +0.5 SD). He had mild dysmorphic features - round face, large, fleshy ears with speech delay, which could be the statement of intellectual disability. Chromosomal microarray analysis (Human CytoSNP-12 BeadChip, Illumina Inc.) revealed a 3Mb de novo interstitial deletion on paternal chromosome 7 in bands 7q35q36.1. The region contained 2 disease-related genes: CNTNAP2 and EZH2.
Conclusion: In this case we present the patient who has some clinical features of Weaver syndrome caused by 7q35q36.1 microdeletion. This is a very rare microdeletion and at the moment its prevalence is unknown.

PM04.70

Prenatal detection of likely causal 4q28.3q31.21 microdeletion in a foetus with skeletal dysplasia.

M. Trková[1], *A. Baxová*[2], *M. Hejtmánková*[1], *V. Bečvářová*[1], *E. Kulovaný*[1], *M. Doležal*[1], *J. Horáček*[1], *D. Stejskal*[1];
[1]Gennet, Prague, Czech Republic, [2]General University Hospital, Prague, Czech Republic.

We report a newborn boy (37th WG, Caesarean section) prenatally monitored for multiple ultrasound anomalies. 37 year old woman underwent first prenatal ultrasound examination at her first pregnancy at 13th WG. Considerable shortening of the lower limbs and spine kyphosis were found and chorionic villi sampling with a subsequent SNP array (300K, Illumina) and FGFR (OMIM*146000) gene mutation screening (negative) were done.
SNP array revealed 4.8 Mb long heterozygous microdeletion at 4q28.3q31.21 that spanned 14 OMIM genes. SNP array examination of the parents showed 0, 87 Mb long microdeletion at 4q28.3 in the phenotypically normal father. Father's microdeletion was shorter and compared to the foetus microdeletion did not span 13 OMIM genes. One of the genes deleted only in the foetus was the RAB33B gene (OMIM*605950), in which the recessive mutations were recently identified in individuals with skeletal Smith-McCort Dysplasia 2 (SMC2, OMIM#615222). Although the phenotypic signs in the foetus were not typical for SMC2, microdeletion was considered to be likely pathogenic for the foetus. Results were discussed with the couple and the parents decided to continue pregnancy. Repeated ultrasound examination at 16th WG confirmed significant femurs shortening, thoracic kyphosis and mild shortening of the upper limbs. Ultrasound at 27th WG showed apart from the skeletal dysplasia ventricular septal defect, clinodactyly and IUGR. Postnatal examinations of the boy were in a concordance with prenatal findings.
Even though the skeletal phenotype does not precisely match the SMC2, we believe the extension of the microdeletion during the parental transmission is likely causal.

PS04.71

Molecular analysis of 94 Short-Rib Polydactyly (SRP) individuals using targeted Next Generation Sequencing (NGS)

C. Huber[1], *G. Baujat*[1], *K. H. Le Quan Sang*[1], *M. Zarhrate*[2], *C. Bole*[2], *C. Masson*[3], *P. Nitschké*[3], *S. Saunier*[4], *the SRP consortium*, *V. Cormier-Daire*[1];
[1]Department of Genetics, INSERM UMR 1163, Université Paris Descartes- Sorbonne Paris Cité, Institut Imagine, Hôpital Necker Enfants Malades (AP-HP), PARIS, France, [2]Plateforme de Génomique, Fondation IMAGINE, PARIS, France, [3]Plateforme de Bioinformatique, Université Paris Descartes, PARIS, France, [4]INSERM, UMR 1163, Laboratory of Inherited Kidney Diseases, Université Paris Descartes- Sorbonne Paris Cité, Institut Imagine, Hôpital Necker Enfants Malades (AP-HP),, PARIS, France.

Objective: The SRP group includes 4 lethal disorders (type I Saldino-Noonan, type II Majewski, type III Verma-Naumoff, type IV Beemer-Langer) 2 disorders compatible with life, asphyxiating thoracic dysplasia (ATD) and Ellis-van Creveld (EVC) syndrome and 2 related conditions, Sensenbrenner and Saldino-Mainzer syndromes. To date, 14 genes encoding primary cilia proteins have been involved in the SRP group. Here, we report the molecular screening of 94 SRP individuals by targeted NGS.
Methods: We performed targeted NGS of a customized ciliopathy gene panel, called ciliome, on a cohort of 94 individuals including 50 ATD, 23 EVC, 13 SPRIII, 2 SRPII, 1 SRPIV, and 5 Sensenbrenner.
Results: We identified 93 variations in 56/94 individuals. Among the 50 ATD cases, 30 were found to harbor variations in DYNC2H1 (21), IFT140 (2), IFT144 (2), WDR34 (1), WDR35 (1), WDR60 (1) or IFT43 (1), whereas and one heterozygote variation in DYNC2H1 and in IFT140 was identified in another case. DYNC2H1 variations were also identified in 9/13 SRPIII cases. WDR34 or IFT122 variations were identified in 2/5 Sensenbrenner cases. Finally, among the 23 EVC cases, EVC (9) or EVC2 (6) variations were identified in 15. Interestingly, a maternal deletion of EVC (4) or EVC2 (3) was present in 7 cases.
Conclusion: By ciliome analysis, we identified variations in ~60% of individuals. DYNC2H1 is responsible for ~48% of ATD-SRPIII spectrum, while EVC/EVC2 account for 65 % of EVC cases, with the presence of a maternal deletion in half cases. Exome sequencing is in progress for the remaining cases.

PM04.72

Bi-allelic TBX6 variations in a patient with spondylocostal dysostosis

N. Jean-Marçais[1], *G. Pierquin*[2], *J. St-Onge*[3], *P. Callier*[4], *Y. Duffourd*[1], **C. Thauvin-Robinet**[1,3], *B. Aral*[4], *J. Rivière*[1,3], *L. Faivre*[1,3], *J. Thevenon*[1,3];
[1]Fédération Hospitalo-Universitaire Médecine Translationnelle et Anomalies du Développement (TRANSLAD), Centre Hospitalier Universitaire Dijon, Dijon, France, [2]Centre de Génétique, Centre Hospitalier Régional de Liège, Liège, Belgium, [3]Equipe d'Accueil 4271, Génétique des Anomalies du Développement, Université de Bourgogne, Dijon, France, [4]Laboratoire de génétique chromosomique et moléculaire, Plateau Technique de Biologie, CHU de Dijon, Dijon, France.

Background: Recurrent 16p11.2 microdeletions encompassing *TBX6* are associated with a wide-spectrum of symptoms including developmental delay, intellectual disability, autism spectrum disorder or obesity. Approximately 15% of patients with the recurrent deletion present abnormal segmentation of vertebrae (ASV). Recently, it was demonstrated that congenital scoliosis in 16p11.2 patients was associated with a specific *TBX6* haplotype in trans. Conversely, a unique family with autosomal dominant spondylo-costal dysostosis (SCD) secondary to a heterozygous *TBX6* stop-loss mutation. These observations suggest the existence of a continuous spectrum of ASV secondary to *TBX6* haploinsufficiency.

Methods: The CHU de Dijon is the french referring centre for SCD molecular diagnosis. The genes implicated in SCD, namely *DLL3, MESP2, LFNG, HES7* and *TBX6* were sequenced on a MiSeq instrument using Nextera XT protocol (Illumina). Array-CGH was performed by each genetic centre before molecular testing.
Results: A case with an inherited 16p11.2 microdeletion encompassing *TBX6* was referred because of a classical SCD. X-ray showed more than 10 contiguous ASV, associated with costal anomalies. Global examination was normal, with a normal psychomotor development, no visceral malformation. The deletion was inherited from an asymptomatic mother. The sequencing of the 5 genes identified a single *TBX6* missense (chr16:30100121G>T, CCDS10670.1:p.His221Asn) inherited from the healthy father. This genomic variation was absent from public databases, affected a conserved position (GERP: 6,02) and residue (PhastCons : 0,982).
Conclusion: Together with the literature data, this observation highlights the hypothesises of a continuous spectrum of ASV secondary to bi-allelic *TBX6* variations.

PS04.73
TGFB3-related connective tissue disorder : a third report with evidence of autosomal dominant inheritance

J. Piard[1], *C. Altuzarra*[1], *E. Puzenat*[1], *Y. Bernard*[1], *P. Coucke*[2], *A. De Paepe*[2], *J. De Backer*[2], *L. Van Maldergem*[1];
[1]CHU Besançon, Besançon, France, [2]University Hospital Ghent, Ghent, Belgium.

Several new connective tissue disorders (CTD) recently came to attention. Among these, TGFB3 mutations were reported in two sporadic patients. We describe here a mother and her son with a heterozygous c.797G>A (p.Arg266His) missense variant in TGFB3. The index patient was evaluated for hypotonia and gross motor delay. When examined at 3 ½ y, epicanthic folds, anteverted nares, a long philtrum with full cheeks, a high-arched palate, a large uvula, joint hyperlaxity, scoliosis and marked pectus excavatum were noted. His mother had a history of recurrent joint dislocation. At 34 y, she presented with joint hyperlaxity, scoliosis, pectus carinatum, high-arched palate, a large uvula and a similar facial gestalt. Slit lamp examinations were normal. Maximal diameter of tubular aorta was 19 mm in the index case and 37 mm in his mother. This is the third report describing patients with a mutation in TGFB3. In 2013, Rienhoff et al identified a de novo missense mutation (c. 1226G>A; p.C409Y) in a young girl with hypotonia, low muscle mass, distal arthrogryposis, bifid uvula, hypertelorism, and hyperextensible large joints but no evidence of vascular disease. Matyas et al reported in 2014 a de novo missense mutation (c.899G>A; p.Arg300Gln) in a hypotonic girl with cleft soft palate, bifid uvula, hypertelorism, pectus excavatum, kyphoscoliosis, generalized hyperextensibility, aortic root diameter at the upper normal limit and mild mitral valve prolapse.
This new familial observation gives further support to the existence of a new autosomal dominant CTD comprising hypotonia, joint hyperlaxity, pectus carinatum/excavatum and a distinctive facial dysmorphism.

PS04.75
FLG gene mutations in urticaria development

G. F. Gimalova[1], *A. S. Karunas*[1,2], *E. F. Khantimerova*[3], *S. Z. Zagidullin*[3], *E. K. Khusnutdinova*[1,2];
[1]Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation, [2]Bashkir State University, Ufa, Russian Federation, [3]Bashkir State Medical University, Ufa, Russian Federation.

Urticaria is a kind of a skin rash that usually starts as an itchy patch and turns into swollen red welts. It is frequently caused by allergic reactions. Filaggrin is the major component of the stratum corneum and is involved in maintaining of skin barrier function. FLG gene loss-of-function mutations lead to epidermal barrier abnormality and are one of the main genetic risk factors for the allergic diseases development. Nevertheless, FLG gene mutations were not studied in urticaria before.
The aim of our study is the analysis of two FLG gene loss-of-function mutations (p.R501X and c.2282del4) in patients with urticaria and healthy individuals from Volga-Ural region of Russia. The patients group include 103 individuals of different ethnic origin (36 Russians, 30 Tatars, 32 Bashkirs and 5 individuals of mixed origin). The control group consists of 106 healthy donor without atopic diseases (24 Russians, 18 Tatars, 4 Bashkirs and 60 individuals of mixed origin). Mutations were genotyped by PCR-RFLP.
There are two individuals (1.9%) with urticaria in patients group who have c.2282del4 mutation. One of them has acute urticaria and another one has chronic from of the disease. The allelic frequency of the deletion is 0.96%. The allelic frequency of the c.2282del4 in healthy donors is 2.12%. Three patients (2.9%) with urticaria are heterozygous for the p.R501X mutation. Two of them have acute from of urticaria and one of them has chronic urticaria. The allelic frequency of the mutation in patients is 1.4% while in controls it is 0.53%. However all shown differences are not of statistical significance.

PM04.76
Type III collagen is important for collagen fibrillogenesis and for dermal and cardiovascular development

S. D'hondt[1], *B. Guillemyn*[1], *S. Symoens*[1], *W. Toussaint*[2], *L. Vanhoutte*[2], *R. De Rycke*[2], *P. Coucke*[1], *B. Lambrecht*[2], *P. Segers*[3], *A. De Paepe*[1], *S. Janssens*[2], *M. Bertrand*[2], *F. Malfait*[1];
[1]Center for Medical Genetics, UGent, Ghent, Belgium, [2]Inflammation Research Center, UGent, Ghent, Belgium, [3]Institute Biomedical Technology, UGent, Ghent, Belgium.

Vascular Ehlers-Danlos Syndrome (vEDS) is a severe, life-threatening heritable connective tissue disorder, characterized by translucent skin, easy bruising, and propensity to rupture of arteries and hollow organs. The molecular basis of vEDS has been well-studied, showing a wide range of mutations in *COL3A1*, encoding type III procollagen. Most mutations lead to glycine substitutions in the helical domain of procollagen. Despite the identification of numerous *COL3A1* mutations, the mechanisms by which mutant type III collagen cause dermal and vascular fragility are not well understood, but factors, other than mechanical failure, are believed to contribute to the phenotype.
To study the role of type III collagen in development and disease, we generated a transgenic mouse model, which expresses *Col3a1* harbouring a typical glycine substitution (p.(Gly183Ser)) within the α1(III)-procollagen helical domain. *Col3a1*^{MUT} animals display clinical features reminiscent of human vEDS patients including thin translucent skin and wound healing problems leading to the development of severe transdermal skin wounds. Biomechanical testing revealed substantial fragility of the skin and aorta of *Col3a1*^{MUT} animals. Collagen fibrils in the skin and aorta were loosely packed, displayed a highly variable diameter, and secretion to the ECM was severely disturbed. The adventitia was significantly thinner and, smooth muscle cells made less connection with elastic fibers, and showed more intracellular space.
Together, our findings underscore a key role for type III collagen in collagen fibrillogenesis in skin and arterial tissue. This novel animal model provides opportunities for in-depth analyses of the role of abnormal type III collagen in vEDS, and for investigation of possible therapeutic interventions for this devastating disease.

PS04.77
Autosomal recessively inherited auto-inflammatory disorder (Weber Christian disease) responsive to tumour necrosis factor alpha inhibition

H. L. Titheradge[1,2], *N. Morgan*[1], *J. Ainsworth*[3], *E. R. Maher*[4];
[1]University of Birmingham, Birmingham, United Kingdom, [2]Birmingham Women's Hospital, Birmingham, United Kingdom, [3]Birmingham Children's Hospital, Birmingham, United Kingdom, [4]Academic Department of Medical Genetics, Addenbrooke's Treatment Centre, Cambridge, United Kingdom.

Introduction: Weber Christian disease (also known as relapsing febrile nodular nonsuppurative panniculitis) is an eponymous condition characterised by idiopathic recurrent inflammation in the subcutaneous fat layer of the skin. The inflammation results in recurrent erythematous subcutaneous nodules with systemic symptoms including fever, myalgia, arthralgia, vomiting, and weight loss. The cause of this rare sporadic condition is unknown. Very rarely severe recurrent panniculitis has been reported in families with the PiZZ genotype of alpha 1-antitrypsin deficiency.
Clinical Summary: We describe a multiply consanguineous family in whom two siblings and a cousin have relapsing nodular panniculitis. This presented in the newborn period and continued as frequent flare-ups involving widespread painful lumps in the skin associated with fever, a raised CRP and white cell count. Additional features in this family include cataract, micronodular cirhosis, developmental delay and growth delay.
Initial treatment with systemic steroids and Anakinra partly ameliorated the condition. The cousin responded well to treatment with a monoclonal antibody against tumour necrosis factor alpha (TNF-α).
This family were recruited into the Molecular Pathology of Human Genetic disease study. Whole exome sequencing studies are in progress. We are looking for other similar families to join this study.
Conclusions: We report this very interesting family and ask for other families with a similar phenotype.
Grant and fellowships: Genetic Approaches to Novel Pathway Target Discovery in Human Genetic Disease with UCB Celltech.

PM04.78

A homozygous deletion of exon 1 in WISP3 causes progressive pseudorheumatoid dysplasia in 2 siblings

B. Neerinckx[1,2], C. Wouters[3], R. Westhovens[2,1], **H. Van Esch**[4]*;*
[1]Rheumatology, University Hospitals Leuven, Leuven, Belgium, [2]Skeletal Biology and Engineering Research Center, Department of Development and Regeneration KU Leuven, Leuven, Belgium, [3]Pediatric Rheumatology University Hospitals Leuven, Leuven, Belgium, [4]Center for Human Genetics, Leuven, Belgium.

Progressive pseudorheumatoid dysplasia (PPD) is a rare autosomal recessive disease, causing progressive joint stiffness, pain and typical radiographic abnormalities in young children. Classically, the disease presents with decreased joint mobility, in particular reduced hip movements, and a progressive involvement of metacarpophalangeal joints (MCPs), interphalangeal joints, wrists, elbows, knees, shoulders and ankles. The first symptoms mostly manifest in childhood, between three and eight years of age. There are no extra-skeletal manifestations. Stature of patients with PPD is normal in infancy but deviates generally to lower than the third percentile in adulthood. It is a progressive disease although the rate of progression is variable between patients.
Most patients are initially misdiagnosed because of the rarity of the disease and the unawareness of most clinicians. Presentation of PPD can mimic juvenile idiopathic arthritis as osseous joint swelling can be mistaken for synovitis. Although, there are no arguments for inflammation in PPD as inflammatory markers are always within the normal range. Radiographs can also help to distinguish, as destructive or erosive bone changes are never seen on radiographs from PPD patients.
PDD arthropathy is associated with loss of function mutations in the WISP3 gene, firstly described in 1999. Here, we describe the clinical case of two sisters suffering from PPD in whom molecular genetic analysis showed a homozygous deletion of exon 1 and the 5'UTR of the WISP3 gene. This is the first time that a gross deletion is described as the causal mutation in PPD.

PS05.01

Genetic variants in familial abdominal aortic aneurysms

D. Heijsman[1]*, A. IJpma[2], M. Oomen[1], H. Brüggenwirth[1], I. van den Boogert[1], D. Majoor-Krakauer[1];*
[1]Department of Clinical Genetics, ErasmusMC, Rotterdam, Netherlands, [2]Department of Clinical Genetics, ErasmusMC, Department of Bioinformatics, ErasmusMC, Rotterdam, Netherlands.

Introduction: Abdominal aortic aneurysm (AAA) is a frequent disorder with a prevalence of approximately 5% in the elderly population. In 20% of the patients AAA is familial. No genetic causes for AAA have been identified so far. The goal of this study is to identify genes that play a role in the formation of abdominal aneurysms.
Methods: The study includes approximately 950 AAA patients, 250 patients with- and 700 patients without a family history of AAA. So far we sequenced the DNA of 92 patients with a family history of abdominal aortic aneurysm. Whole genome sequencing (WGS) was performed in three families (15 individuals) and whole exome sequencing (WES) was performed in eleven families (29 individuals) and 48 single AAA patients with familial disease. Prioritization of resulting variants was performed according to the following gene sets:
1. Genes in diagnostics panel as applied in the Erasmus MC in thoracic or syndromic aneurysms (n=23)
2. A broad selection of genes involved in vascular function or disease (n=4209)
3. All genes in the genome
Results: We present the detailed workflow of the analysis of the genomics data, including the results so far. In six families a variant in one of the set 1 genes was found. Further analysis of the set 2 and 3 genes so far led to the identification of one candidate gene that shows variants in four AAA families and eight single familial AAA patients, and has not been linked to AAA before.
Supported by Stichting Lijf en Leven.

PM05.02

Plasma miRNA-208b and miRNA-499 as biomarkers of acute myocardial infarction

K. Agianitopoulos[1], P. Pavlopoulou[1], K. Tsamis[2], K. Bampali[1], D. Babalis[2], **K. Lamnissou**[1]*;*
[1]Dept of Genetics & Biotechnology, Faculty of Biology, University of Athens, Athens, Greece, [2]Dept of Cardiology, „KAT" General Hospital, Athens, Greece.

Introduction: Acute myocardial infarction (AMI) is a leading cause of morbidity and mortality worldwide. Early and correct diagnosis might afford great benefits in treatment for AMI, thus the exploration of new biomarkers with high sensitivity and specificity in diagnosis of AMI is today a major goal. Recently, several studies indicated that microRNAs (miRNAs) circulating in serum or in plasma are attractive biomarkers for several human diseases. The objective of the present study was to examine the expression of the miRNAs miR-208b and miR-499 in plasma of AMI patients and to investigate whether these miRNAs could be useful biomarkers for AMI.
Materials and Methods: 20 AMI patients and 20 healthy controls were retrospectively recruited for a comparison of their plasma miR-208b and miR-499 expression. The levels of miRNAs in plasma were determined using TaqMan-based miRNA quantitative real-time polymerase chain reaction (qRT-PCR).
Results: Our data indicated that both miR-208b and miR-499 were significantly over expressed in plasma of AMI patients. We have found that the levels of miR-208b and miR-499 were increased by 16-fold and 128-fold, respectively, in plasma of AMI patients compared to healthy controls.
Conclusion: We conclude that plasma levels of miR-499 and miR-208b could be used as potential diagnostic biomarkers for AMI.

PS05.03

RNA expression profiling of Abdominal Aortic Aneurysmal disease

A. IJpma[1,2]*, I. van der Pluijm[3,4], L. te Riet[5], K. van de Luijtgaarden[4], P. van Heijningen[3], R. Kanaar[3], E. Rouwet[4], J. Essers[3,4,6];*
[1]Bioinformatics, Erasmus MC, Rotterdam, Netherlands, [2]Clinical Genetics, Erasmus MC, Rotterdam, Netherlands, [3]Genetics, Erasmus MC, Rotterdam, Netherlands, [4]Vascular Surgery, Erasmus MC, Rotterdam, Netherlands, [5]Pharmacology, Erasmus MC, Rotterdam, Netherlands, [6]Radiation Oncology, Erasmus MC, Rotterdam, Netherlands.

Introduction: An abdominal aortic aneurysm (AAA) is a widening of the aorta below the renal arteries, usually asymptomatic until rupture causes fatal bleeding. AAA risk increases after the age of 65 years. Genetic susceptibility, smoking, hypertension, and atherosclerosis are established risk factors. Targeted ultrasound screening of high risk cases allows reduction of AAA related mortality, thus a better risk prediction model based on clinical characteristics and biomarkers is needed to earlier identify persons at risk. We aim to identify molecular markers for AAA disease by identifying genes involved in aortic vascular wall remodeling in AAA patients.
Methods: Microarray based genome wide expression analysis in affected aortic tissue of AAA patients was performed.
Results: In our gene expression studies in affected aortic tissues, we found genes which have been associated with AAA before: COL11A1, AdipoQ and LPL. Using Ingenuity IPA we identified immunity related pathways. Interestingly, expression levels of genes involved in the TGFβ signaling were significantly changed. We designed a flow chart to select genes as possible markers based on their level of expression, potential as blood marker and possible relevance for aneurysmal disease. We will validate these markers in experimental models for aneurysmal disease and study them further in blood of AAA patients.
Conclusions: Our analysis not only identifies genes and pathways previously associated with AAA genes, but also reveals novel genes and key regulators that will shed light on the processes involved in AAA formation and progression.

Family screening for abdominal aorta aneurysm: don't forget the women

K. M. van den Luijtgaarden, M. W. Oomen, E. Rouwet, H. J. M. Verhagen, **D. Majoor-Krakauer***;*
Erasmus University Medical Center, Rotterdam, Netherlands.

Introduction: Abdominal aortic aneurysm (AAA) occurs in 6% of male and 1% of female population. Recommendations for family screening, allowing timely diagnosis and treatment, depend on estimates of risk for relatives. This study investigated risk for relatives and clinical risk profiles for familial AAA. Methods: Family histories of 568 AAA patients were classified as familial AAA when at least one first-degree relative was reported with an aortic aneurysm. Multivariable regression analysis was performed to identify clinical characteristics discriminating familial from sporadic AAA. Results: Familial AAA was reported in 23% of patients: 27% of female and 22% of male AAA patients. Female AAA patients had more affected relatives than male AAA patients (9.0% versus 5.9%, p = .022). Risk was increased 2 to 4 fold for relatives of male and female patients respectively. In familial AAA risk for relatives was increased 6 to 15 fold. Familial AAA was more frequent in young patients, without diabetes and hypertension.
Conclusions: Risk for relatives is much higher in familial
AAA than in the general population. When family history is not taken into account, an increase in risk remains and family screening is still recom-

mended. It is important that families of female AAA patients have similar access to screening as families of male patients, and that female relatives are screened.
The new insights in familial risk and family screening for AAA are important in counseling to inform AAA patients and allow their relatives to benefit from screening.

PS05.05
Aortic dissection in a male with 1q21.1-q21.2 and 9p22.2 microduplications.

N. S. Karp[1,2], *S. Shickh*[1], *P. Yang*[1,2];
[1]*London Health Science Centre, London, ON, Canada,* [2]*University of Western Ontario, London, ON, Canada.*

We report a male patient who developed an aortic dissection at the age of 47. He is tall with the height of 191cm and weight of 83.5 kg, macrocephalic and normoteloric. He had mild joint hyperflexibility and a high arched palate. He did not meet diagnostic criteria for Marfan syndrome. He reported having developmental delay growing up and learning difficulties at school. He tested negative for an aortic aneurysm panel of 16 genes including *ACTA2, CBS, COL3A1, COL5A1, COL5A2, FBN1, FBN2, FLNA, MED12, MYH11, SKI, SLC2A10, SMAD3, TGFB2, TGFBR1* and *TGFBR2*.
An Affymetrix CytoScan HD microarray analysis showed an 1.935 Mb microduplication 1q21.1- q21.2 {arr[hg19] 1q21.1q21.2(145,895,746-147-,830,830)x3}, and another 0.951 Mb microduplication in 9p22.2 region {arr[hg19] 9p22.2(17,494,208-18,444,711)x3}. The 1q21.1-q21.2 microduplication was maternal in origin. The brother and the niece also had 1q21.1-q21.2 microduplication. The father was not available for genetic testing.
1q21.1 microduplication is associated with increased risk for developmental delay, autism spectrum disorder, schizophrenia, congenital heart disease, macrocephaly, tall stature and obesity. A recent study suggested that 1q21.1 duplication may cause abnormalities of connective tissue origin, such as cysts, varicose veins, carpal tunnel syndrome and congenital hip dysplasia. Significance of 9p22.2 duplication remains unknown.
To date aortic dissection has not been reported in patients with 1q21.1microduplication. We suggest that aortic dissection might be a possible complication of 1q21.1-q21.2 duplication and that patients carrying the duplication may need to undergo regular cardiac surveillance.

PM05.06
Absence of connective tissue remodeling in Smad3 mutant mice leads to aggressive and accelerated aneurysmal growth through disturbed downstream TGFβ signaling

I. van der Pluijm, N. van Vliet, J. Robertus, R. Yanto, P. van Heijningen, B. van Thiel, M. Vermeij, L. Buijs-Offerman, R. Kanaar, A. Bertoli-Avella, **J. Essers**;
Erasmus MC, Rotterdam, Netherlands.

Aneurysm-osteoarthritis syndrome (AOS) is an autosomal dominant condition characterized by aortic aneurysms and early-onset osteoarthritis, caused by mutations in the SMAD3 gene. Smad3 is a part of the
key transcription factor complex Smad2/3/4, essential for TGFβ-activated downstream transcription of CTGF, MMPs, SMAD7 and others. $Smad3^{-/-}$ mice show aneurysmal development at young age, but the underlying mechanism is unknown.
Echocardiograms of cross-sectional studies in $Smad3^{-/-}$ mice showed a significant increase in diameter of root and ascending aorta (18-20%), and a significant increase in length (16-20%) already at age 6 weeks, but no difference in aortic distensibility. Importantly, 50% of $Smad3^{-/-}$ mice died suddenly between 6 and 24 weeks of age. Successive macroscopic analysis showed up to a 5-fold increase in ascending aortic diameter. We next performed longitudinal studies, showing a steep increase of aneurysmal growth within only 6 weeks. Since the aneurysmatic aortic wall remained translucent, this was indicative for the absence of large scale extracellular matrix remodeling or collagen deposition. Indeed, immunohistochemical analysis of $Smad3^{-/-}$ aortic walls showed
no increase in extracellular matrix accumulation, no excessive collagen or CTGF staining, nor loss of vascular smooth muscle cells (VSMCs).
$Smad3^{-/-}$ animals recapitulate the aortic phenotype observed in patients with SMAD3 mutations. Smad3 deficiency leads to imbalanced activation of downstream genes such as Smad6/7 and no activation of CTGF and MMPs in VSMCs. Initial minor dissections in the medial layers of the aortic wall trigger an extensive immune response and sudden acceleration of aneurysm formation, leading to rupture of
the aortic wall.

PS05.07
Lamin A/C gene mutations underlie Arrhythmogenic Cardiomyopathy with atrio-ventricular block

E. Lazzarini, *I. Rigato, M. Cason, B. Bauce, E. Carturan, G. Thiene, C. Basso, K. Pilichou; University of Padua, Padua, Italy.*

Background: Arrhythmogenic Cardiomyopathy (AC) is an inherited heart muscle disease associated with mutations in genes mainly encoding desmosomal components, however mutations in extra-desmosomal genes can cause cardiomyopathies with overlapping AC features.
Case Presentation and Methods: A 76 years-old man diagnosed with biventricular AC died on the waiting list for cardiac transplantation. He had frequent syncopal episodes since young age, left bundle branch block and inverted T waves in V1-V3. He was implanted with pacemaker and then with cardioverter with frequent ventricular fibrillation shocks. Echocardiography exhibited a severe dilatation and hypokinesia in the right ventricle while the left ventricle was apparently normal. Genetic screening was performed by direct sequencing for all major desmosomal encoding genes on a Applied Biosystems ABI310 genetic sequencer and subsequently whole exome sequencing (WES) using TruSeq technology on a Illumina HiSeq2000 was carried out.
Results: Genetic screening was unable to detect genetic variations in desmosomal genes associated with the disease. WES identified a heterozygous point mutation c.949G>A, p.E317K in the lamin A/C gene (LMNA). This genetic variant, absent in the 1000 Genomes and Exome Variant Server datasets, has been previously associated with autosomal dominant Dilated Cardiomyopathy and atrio-ventricular block. The mutation was also detected in the proband`s daughter and son, who exhibited a AC-like pattern.
Conclusion: This study highlights that LMNA gene mutations can mimic the AC phenotype but always accompanied with atrio-ventricular block. A comprehensive genetic test enables a clear differential diagnosis in cardiomyopathies.

Co-inheritance of mutations associated with Arrhythmogenic and Hypertrophic Cardiomyopathy: how does it affect the phenotype?

M. De Bortoli[1], *B. Bauce*[2], *C. Calore*[2], *A. Lorenzon*[1], *M. Calore*[1], *G. Poloni*[1], *E. Mazzotti*[2], *I. Rigato*[2], *L. Daliento*[2], *C. Basso*[2], *G. Thiene*[2], *P. Melacini*[2], *D. Corrado*[2], *A. Rampazzo*[1];
[1]*Department of Biology, Padua, Italy,* [2]*Department of Cardiac, Thoracic and Vascular Sciences, Padua, Italy.*

Background: Arrhythmogenic (ACM) and Hypertrophic cardiomyopathy (HCM) are genetically and phenotypically distinct diseases of the myocardium, showing an autosomal-dominant inheritance with incomplete penetrance and variable expressivity. They are the most common causes of sudden cardiac death in the young and athletes. Here we report 2 families with digenic inheritance of ACM and HCM mutations.
Methods and Results: The ACM probands of two families (A+B) were screened for mutations in 5 ACM genes (PKP2, DSP,DSG2, DSC2, JUP and CTNNA3). Moreover genetic analysis of the 2 major HCM genes (MYH7 and MYBPC3) was performed in 2 HCM patients, one for each family. In family A, 5 patients resulted to be double heterozygotes for a missense mutation (p.Met1601Ile) in DSP gene and a frameshift mutation (p.F305PfsX27) in MYBPC3 gene. The genetic analysis in Family B has identified the presence in 1 patient of an in frame deletion (p.del765L) in CTTNA3 gene and a missense mutation (p.Met877Ile) in MYH7 gene. Five single ACM and 7 single HCM mutation carriers were also found. Clinical evaluation of the 6 double heterozygotes has revealed a phenotypic heterogeneity with 1 asymptomatic case, 3 patients affected with ACM, 1 with HCM and 1 showing both phenotypes.
Conclusions: This is the first time that patients showing co-inheritance of ACM and HCM mutations are reported. The genotype-phenotype correlation in these rare patients indicates that such digenic inheritance is associated with heterogeneous phenotypes, probably due to the incomplete penetrance and variable expressivity of both mutations.

PS05.09
A founder PKP2 gene deletion in arrhythmogenic cardiomyopathy

G. Occhi[1], *B. Bauce*[2], *D. Regazzo*[3], *M. De Bortoli*[1], *M. Calore*[1], *G. Poloni*[1], *E. Lazzarini*[2], *E. Hoorntje*[4], *I. Rigato*[2], *E. Mazzotti*[2], *L. Daliento*[2], *G. Thiene*[2], *C. Basso*[2], *J. van Tintelen*[4], *D. Corrado*[2], **A. Rampazzo**[1], *A. Lorenzon*[1];
[1]*Department of Biology, Padua, Italy,* [2]*Department of Cardiac, Thoracic, and Vascular Sciences, Padua, Italy,* [3]*Endocrinology Unit, Department of Medicine DIMED, Padua, Italy,* [4]*Department of Genetics, Groningen, Netherlands.*

Background - Arrhythmogenic Cardiomyopathy (ACM) is an inherited heart muscle disease characterized clinically by ventricular arrhythmias and increased risk of sudden death, and pathologically by fibro-fatty replacement

of the myocardium. Conventional genetic testing of genes encoding desmosomal components results in a diagnostic yield of about 50% of ACM probands.
Aim - To search for large deletions/duplications in desmosomal genes in a large cohort of ACM index cases.
Methods and Results - Genetic screening for large deletions/duplications in 5 desmosomal genes was carried out in 68 unrelated index patients diagnosed affected with ACM according to revised 2010 Task Force criteria, and resulting negative for pathogenic point mutations in the same genes. Quantitative real-time PCR (qPCR) experiments were performed on an ABI PRISM 7900HT Sequence Detector by using at least three different sets of primer pairs located within exons from the proximal to the distal part of each gene. In 3 patients (4.4%) we identified a plakophilin-2 (PKP2) copy number reduction when compared to control samples thus suggesting a large heterozygous gene deletion. The PKP2 gene deletion was confirmed by Multiplex ligation-dependent probe amplification with the SALSA MLPA kit P168 (MRC-Holland). Haplotype analysis revealed a conserved haplotype among the PKP2 mutation carriers, strongly indicating a common founder.
Conclusions - Among desmosomal genes, only PKP2 shows large deletions of the entire coding region. These findings support the importance of expanding genetic testing in ACM patients with inclusion of PKP2 large deletion analysis when the results of conventional sequencing are negative.

PM05.10
A novel locus on chromosome 19p13.3 linked to arrhythmogenic cardiomyopathy

G. Poloni[1], *I. Li Mura*[1], *B. Bauce*[2], *M. Calore*[1], *E. Mazzotti*[2], *I. Rigato*[2], *A. Lorenzon*[1], *M. De Bortoli*[1], *L. Daliento*[2], *C. Basso*[2], *D. Corrado*[2], *G. Thiene*[2], *A. Rampazzo*[1];
[1]*Department of Biology, Padua, Italy,* [2]*Department of Cardiac, Thoracic, and Vascular Sciences, Padua, Italy.*

BACKGROUND:
Arrhythmogenic cardiomyopathy (ACM) is an autosomal dominant myocardial disorder at risk of sudden death in the young and athletes. Thirteen causative genes have been found, with a central role of the desmosomal genes. Since causative mutations in ACM genes have been detected in about 50% of probands, additional disease genes remain to be identified.
METHODS and RESULTS:
In a large ACM family, where the proband resulted negative for mutation screening of desmosomal genes, genome-wide linkage analysis highlighted a shared region of 2 Mb on chromosome 19p13.3 (multipoint LOD score=3.85). CNV analysis was carried out in order to exclude the presence of structural variations. Whole exome sequencing was performed in 4 affected patients, through two different platforms (HiSeq2000 Illumina, Ion Torrent) at a mean coverage of 80X. Sequencing data didn't reveal the presence of any novel variant shared by the 4 subjects, neither into the linkage region nor in the rest of the exome. Exons with insufficient reads (≤15 depth) of the 13 ACM genes and of the genes inside the critical region were further evaluated by Sanger sequencing but no additional coding mutations were found. Only a novel intronic variant (c.766+8C>A) in TMEM43 gene was identified. The segregation of this variant among all the available family members excludes an association with the disease phenotype.
CONCLUSION:
In this ACM family showing no mutations in known ACM genes segregating with the disease phenotype, a novel locus was mapped on chromosome 19p13.3 and a critical region of 2 Mb was defined.

PS05.11
Inducible pluripotent stem cell technology as a tool to study Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) in a Maritime family

P. CHEN[1], *D. Gaston*[1], *A. Orr*[2], *S. Dyack*[3,4,5], *C. M. McMaster*[6], *M. Gardner*[4], *K. Bedard*[1];
[1]*Department of Pathology, Dalhousie University, Halifax, NS, Canada,* [2]*Department of Ophthalmology, Dalhousie University, Halifax, NS, Canada,* [3]*Department of Pediatrics, Dalhousie University, Halifax, NS, Canada,* [4]*Department of Medicine, Dalhousie University, Halifax, NS, Canada,* [5]*Maritime Medical Genetics Service, IWK Health Centre, Halifax, NS, Canada,* [6]*Department of Pharmacology, Dalhousie University, Halifax, NS, Canada.*

ARVC is an inheritable disease featuring potentially lethal arrhymias and heart failure characterized pathologically by fibrofatty replacement of cardiaomyocytes (CMs). We have ascertained a large Maritime family segregating a form of ARVC that is mutation-negative for all genes currently known to cause ARVC, suggesting that a novel variant must be responsible. Using DNA derived from formalin fixed, paraffin embedded tissue, as well as from blood or saliva of known carriers and relatives, we have performed extensive genetic investigation to identify the novel mutation responsible for the disease in this family (i.e. SNP genotyping, haplotype analysis, whole-exome and whole-genome sequencing). We have identified candidate genomic regions shared among affected individuals, however the precise causative mutation remains elusive. To assist in identifying the causative factor and to study the underlying disease mechanisms, we have used a novel inducible pluripotent stem cell (iPSC) technique to generate disease specific CMs that were derived from B-lymphocytes of ARVC patients. Human iPSC lines were successfully developed by using episomal plasmid vectors to over express reprogramming factors. CMs were then differentiated from iPSC by modulating Wnt/β-catenin signaling. Currently, gene expression analyses with RNAseq from RNA isolated from iPSC derived CMs that were generated from affected and healthy control samples are underway. The iPSC technique used in this project may help identify the specific mutation that causes this specific form of ARVC, enabling life-saving intervention in at-risk individuals. Additionally, this technique offers a potential pathway for identifying causal variation in diseases in which coding-sequence changes are not obvious.

PM05.12
Bioinformatics analysis of the genomic candidate markers for diagnostic panel of atherosclerosis

E. Derevyanchuk, *E. Butenko, D. Potemkin, D. Romanov, T. Shkurat;*
Southern Federal University, Rostov-on-Don, Russian Federation.

Despite the significant achievements in the field of medicine and biology, morbidity and mortality from atherosclerotic lesions remain at a high level, and the range of adequate antiatherosclerotic therapy goals is still limited due to the lack of validated biomarkers. Therefore, the main goal of our research is the development of a new reliable genomic indicators panel for early, pre-clinical diagnostics of possible future disease.
We performed a bioinformatics analysis of potential candidate genes directly or indirectly involved in the pathogenesis of atherosclerosis. The analyzed genes list included lipid metabolism, matrix metalloproteinases, folate cycle, oxidative stress genes and some others. The motifs search was implemented using bioinformatics package MEME Suite.
In the investigated genes vicinity we detected 670 motifs, homologous pre-mi-RNA, and 4300 motifs, homologous mature mi-RNA. The average mi-RNA distribution density in genomic sites ranged from 0 to 2.2 pre-mi-RNA per 1000 p.n. and mature mi-RNA - from 0 to 6.9 per 1000 p.n. Inside the investigated genes we identified 433 motifs, homologous pre-mi-RNA, and 2780 motifs, homologous mature mi-RNA. The average motifs distribution density amounted to 0.4 per 1000 p.n. for pre-mi-RNA and 3.3 per 1000 p.n. for mature mi-RNA. The most frequently encountered were motifs, homologous mmu-mir-466i, hsa-mir-5096, hsa-mir-1273g, ppy-mir-1268 and hsa-mir-619. According to the MirTarBase data we established that hsa-miR-138-5p is the multigene regulator for the studied genes groups.
The obtained results could be used to develop atherosclerosis diagnostic panel.
This research was supported by the Ministry of Education and Science of Russia project N6.703.2014/K. Analytical work was carried out on the equipment of Center for collective use of Southern Federal University „High Technology", grant RFMEFI59414X0002.

PS05.13
Whole exome sequencing identifies a novel germline mutation in calcium ion channel; associated with atrial fibrillation.

G. Ahlberg[1], *I. E. Christophersen*[1], *L. Refsgaard*[1], *J. B. Nielsen*[1], *S. Haunso*[1], *A. Holst*[1], *J. Hastrup-Svendsen*[2], *M. S. Olesen*[1];
[1]*Danish Arrhythmia Research Centre, Copenhagen, Denmark,* [2]*Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark.*

Introduction - AF is the most prevalent sustained cardiac arrhythmia, responsible for considerable morbidity and mortality. Due to the complex pathophysiology of AF the underlying mechanisms are incompletely understood. In the few cases of familiar form of AF, where the causative mutation has been found, it has been identified in genes encoding ion-channels involved in sodium or potassium handling. Nevertheless in the majority of cases with familiar forms of AF the cause is still unknown.
Methods and Results - Whole exome sequencing was performed on seven individuals from a Danish family, presumably with a highly penetrable monogenetic form of AF. Quality control showed that the whole exome could be investigated sufficiently.
Analysis, following Broad institute current best practices, revealed 2 novel variants (not found in over 60,000 controls, of which 2000 Danish). Interestingly one of the novel mutations was found in a calcium ion channel. In silico predictions supported the pathogenic potential of this variant, predicted damaging in 7/8 prediction tools.
Discussion - In this study a calcium ion channel variant that co-segregated

fully with AF in a large family was identified as the potential monogenetic cause of AF. This study suggests a previously undescribed pathophysiological pathway for AF.

PM05.14

Next-generation sequencing of AVNRT patients identifies high prevalence of mutations in genes involved in sodium and calcium handling

L. Andreasen, *P. Weeke, M. S. Olesen;*
University Hospital of Copenhagen, Rigshospitalet, Department of Cardiology, Laboratory of Molecular, Copenhagen O, Denmark.

Atrioventricular nodal re-entry tachycardia (AVNRT) is the most common paroxysmal supraventricular tachycardia, affecting women twice as frequently as men, often before turning 40 years. Familial clustering, early onset of symptoms, and lack of structural anomaly indicate involvement of genetic factors in the development of AVNRT. However, the field is poorly investigated, and a great amount of work is to be done, in order to reveal the plausible genetic causes.
We hypothesized that AVNRT patients have a high prevalence of mutations in 38 genes potentially involved in arrhythmic diseases and highly expressed in the heart.
Next-generation sequencing of 38 genes previously associated with cardiac arrhythmia and highly expressed in the atrioventricular conduction axis was applied to the DNA profile of 99 AVNRT patients using Haloplex target enrichment system and the results were verified using an Illumina next-generation sequencing amplicon-based platform, the TruSeq Custom Amplicon Kit.
In total, we found 28 mutations in 11 genes; 25 missense mutations, two synonymous, and one in-frame mutation. Twelve of these were novel. The main part of these mutations are in genes responsible for sodium and calcium handling, such as SCN5A, SCN10A, the CACNA genes, ATP2A2 encoding the SERCA pump, and RYR2, indicating that AVNRT might be a sodium- and calcium-channel disease like Brugada Syndrome as opposed to atrial fibrillation which in addition has a potassium channel affection. This is, to our knowledge, the first study to report a genetic component in AVNRT.

PS05.15

The first SCN5A founder mutation in a Belgian cohort of Brugada syndrome patients

D. Proost[1], *C. Claes*[1], *T. Robyns*[2], *P. Koopman*[3], *R. Willems*[2], *G. Mortier*[1], *C. Vrints*[4], *B. Loeys*[1], *L. Van Laer*[1], *J. Saenen*[4];
[1]*Center of Medical Genetics, Faculty of Medicine and Health Sciences, University of Antwerp and Antwerp University Hospital, Antwerp, Belgium,* [2]*Department of Cardiovascular Sciences, Faculty of Medicine, KU Leuven and Leuven University Hospital, Leuven, Belgium,* [3]*Heart Center Hasselt, Jessa Hospital, Hasselt, Belgium,* [4]*Department of Cardiology, Faculty of Medicine and Health Sciences, University of Antwerp and Antwerp University Hospital, Antwerp, Belgium.*

Brugada syndrome (BrS) is a heritable primary electrical disorder with typical ECG alterations accounting for up to 20% of sudden cardiac death in young patients (<45 years) without apparent structural cardiac abnormalities. BrS is genetically heterogeneous and so far a dozen causative genes have been identified, of which SCN5A is the predominant gene. At present a causal mutation is identified in about 20-30% of BrS patients. SCN5A encodes a sodium channel and loss of function mutations will lead to a decreased sodium inward current. In the Netherlands, an SCN5A founder mutation (p.1795insAsp) was previously described, which gives rise to an overlap syndrome between BrS, Long QT syndrome and cardiac conduction defects (Postema et al., 2009).
Here, we present 23 BrS patients of 17 different Belgian families carrying the identical c.4813+6_4813+7insGGGT mutation in SCN5A. This mutation, previously described in two families of Western European descent, creates a cryptic splice site in exon 27 leading to complete loss of function of the sodium channel (Hong et al., 2005; Rossenbacker et al., 2005). We identified a shared haplotype consisting of seven genetic markers spanning a region of 5.2 Mb. Based on the haplotype size, we estimate that the common ancestor of these families lived approximately 300 years ago. The clinical spectrum of mutation carrying individuals ranges from asymptomatic to full blown BrS. In this cohort, a relatively low number of sudden cardiac death has been observed.
As such, we have identified the first Belgian BrS founder mutation. These families will be instrumental for the future identification of BrS phenotype modifying genes.

PM05.16

Molecular autopsy of sudden cardiac death with structurally normal heart: the circumstances of death and ECG tracings can address the final diagnosis

M. Cason, *F. Migliore, S. Rizzo, E. Carturan, E. Bertaglia, K. Pilichou, G. Thiene, C. Basso;*
Department of Cardiac, Thoracic and Vascular Sciences, University of Padua, Padova, Italy.

Background. Sudden cardiac death with normal heart can occur in the setting of inherited ion channel diseases. Among these, Brugada syndrome (BrS) is characterized by non-ischemic ST segment elevation associated with PR prolongation and right bundle branch block, whereas Lenégre disease is characterized by atrio-ventricular block with progressive structural changes of the conduction system. In these arrhythmic syndromes, more than 1300 nucleotide variations has been identified in SCN5A gene.
Methods & Results. A 35-years old asymptomatic male died suddenly during sleep. Post-mortem examination excluded extracardiac causes of sudden death as well as the absence of structural abnormalities in the working myocardium. Personal clinical history re-assessment revealed a 'coved-type' ST segment elevation on right precordial leads with PQ prolongation (220 msec) in a patient's ECG performed during blood donation, compatible with BrS. Detailed conduction system investigation by serial section technique showed severe fibrosis of the bifurcating His and proximal bundles with sclerotic interruption of the left bundle branch. Genetic screening of SCN5A (NM. 198056.2) gene identified a mutation in exon 22 (c.3673 G>A , E1225K), defined as "likely to be pathogenic" by in silico tools, and previously linked to BrS phenotype with atrio-ventricular block. Cascade genetic screening detected 5 additional family mutation carriers, and provoked electrical stimulation unmasked ECG abnormalities in 2 of them.
Conclusion. Lenégre disease and BrS are overlapping clinical entities, «bookends» in a continuum of sodium current deficiency, accounting for a structural cardiomyopathy of the specialized conducting tissue occurring in the setting of an otherwise normal heart.

PS05.17

Functional analysis of a coding variant in ZC3HC1 at 7q32.3 associated with protection against coronary artery disease

T. Linseman, *S. Soubeyrand, M. Nikpay, P. Lau, A. Turner, A. Martinuk, R. McPherson;*
University of Ottawa Heart Institute, Ottawa, ON, Canada.

Genetic and environmental factors are believed to contribute equally to the risk of coronary artery disease (CAD). The CARDIoGRAM Consortium first identified a coding variant, rs11556924, (MAF, 0.38) in the *ZC3HC1* gene associated with protection against CAD ($p= 9.8x10^{-18}$; OR= 0.90). The amino acid change (Arg363His) is in a conserved region of the gene and is predicted to have functional effects (Polyphen-2). The gene product of *ZC3HC1*, Nuclear Interaction Partner of ALK (NIPA), is a regulator of cellular proliferation and is an essential component of an SCF-type E3 ligase complex. This complex catalyses the ubiquitination of proteins (such as cyclin B1) targeting them for proteasomal degradation. We have investigated the functional effects of this amino acid change in *ZC3HC1*. Here we demonstrate a) allele specific differences in mRNA expression in whole blood, b) differential ERK dependent phosphorylation of Arg363 vs His363, c) a small but reproducible decrease in mobility of the risk variant, Arg363 by Fluorescence Recovery After Photobleaching (FRAP), that may reflect differences in their steady state interaction with nuclear partners. Additional studies are underway to further characterize effects on NIPA structure and activity, relevant to cardioprotection.
Heart and Stroke Foundation of Canada Grant (T7268)

PM05.18

Is lipoma-preferred partner (LPP) a cause of cardiac malformations with reduced penetrance?

D. A. Mordaunt[1], *L. Fitzgerald*[1], *B. Coppin*[2], *J. Nicholl*[1], **C. P. Barnett**[1];
[1]*Women's and Children's Hospital/SA Pathology, North Adelaide, Australia,* [2]*Flinders Medical Centre, Bedford Park, Australia.*

There are two published reports of variants in LPP (OMIM #600700) in association with isolated conotruncal defects and congenital heart disease in VACTERL association. Variants have included deletions and missense mutations. Here we report a child with transposition of the great arteries (TGA) and coarctation of the aorta (CoA) with a deletion of multiple exons of LPP. We discuss the evidence for the role of LPP in the causation of cardiac malformations.
The 2 ½-year-old patient was born at 37 weeks gestation. TGA and CoA were diagnosed on day 1 and surgically corrected shortly after. Developmental milestones were normal and the child and her mother have no dysmorphic

features. Array CGH (BlueGnome Cytochip oligo ISCA 4080-5 8x60k array) identified a 205kb interstitial deletion involving exons 2-4 of LPP (#600700) in the child. The deletion was inherited from her unaffected mother.
LPP has been linked to cell-cell adhesion, cell motility and transcriptional regulation however a mechanistic link between LPP function and cardiac embryogenesis has not yet been established. We have performed a comprehensive review of mutation databases (DECIPHER, ISCA and DGV) for other LPP deletions and identified 21 patients and 9 controls with deletions varying from large (12.6 Mb) deletions to small exonic and intronic (5.2 Kb) deletions. Three of these individuals were reported to have cardiac malformations.
Our case provides an additional case of LPP deletion associated with congenital heart disease raising the possibility that rare loss-of-function variants of LPP may be associated with cardiac, in particular, conotruncal malformations, with reduced penetrance.

PS05.19

A microRNA target site in *SHOX2* associates with cardiac arrhythmia

Cardiac arrhythmias contribute significantly to cardiovascular morbidity and mortality. Developing approaches towards disease prediction and treatment of heart rhythm disorders is therefore an important topic in healthy aging. Although environmental factors play an important role in the pathogenesis of cardiac arrhythmias, multiple studies have demonstrated that there is also a strong genetic component. Molecular pathways involving the homeodomain transcription factor Shox2 control the development and function of the primary cardiac pacemaker. Genotyping untranslated regions of the *SHOX2* gene in 378 arrhythmia patients and 1870 control individuals demonstrated a significant association between a 3'UTR variant and the disease (p=0.00515, OR=2.373). Patients with the 3´UTR variant clinically presented significantly longer PR intervals. Mechanistically, this variant creates a novel functional microRNA binding site. Circulating microRNA levels in plasma were found to be significantly altered in all testable patients carrying the 3'UTR variant, compared to patients with the wild type allele (p=0.0095).
These results provide direct evidence that a genetic variant in the *SHOX2* gene is associated with cardiac arrhythmias and point to a microRNA as potential biomarker and therapeutic target in this disease.

Genetic Analysis of Cardiac Arrhythmias in Patients from Saudi Arabia

J. Al-Aama[1,2], *A. Bdeir*[1], *S. Alghamdi*[3], *K. Dagriri*[4], *A. Al-Qarawi*[1];
[1]*1Princess Al Jawhara Albrahim Center of Excellence in Research of Hereditary Disorders, King Abdulaz, Jeddah, Saudi Arabia,* [2]*Department of Genetic Medicine, Faculty of Medicine , King Abdulaziz University, Jeddah, Saudi Arabia,* [3]*Department of Cardiology, NGH, Riyadh, Saudi Arabia,* [4]*Prince Sultan Cardiac Center, Riyadh, Saudi Arabia.*

Hereditary arrhythmias are hereditary due to mutations in genes responsible for normal cardiac rhythm generation and propagation. These genes include KCNQ1, KCNH2, SCN5A, RYR2, CASQ2. Mutation detection leads to proper clinical diagnosis, therapy, behavioral management, and family screening. This may decrease the incidence of sudden cardiac death.
Our center took a pioneering initiative to set up a comprehensive cardiac arrhythmia genetic research and diagnostic laboratory to provide specialized cardiogenetic clinical services in Saudi Arabia and neighboring countries and to create a database of local mutations to develop a "genomic chip" to be used in routine screening for cardiac arrhythmia patients in these countries. Our ultimate goal is to discover new genes in arrhythmia pathology, which will lead to development of novel gene targeted pharmacotherapy for cardiac arrhythmia. Presently, we receive referrals from all over the Kingdom and neighboring countries.
Over 3 years, 46 families were assessed, and genetic analysis was performed in our lab. Arrhythmogenic mutations were found in 29 index patients (63%). Cascade screening of family members identified 176 relatives with mutations, 80% which were founder mutations. Some were more common in specific geographic regions. All mutation carriers had variability in clinical presentation of the arrhythmias (no symptoms to sudden death). In 6 families, index patients presented with arrhythmias and deafness, (Jervell Lange and Nielsen syndrome JLNs), with mutations in both alleles of the KCNQ1 gene. The proportion of JLNS among LQTs was higher than most population studies. We identified novel, recurrent and also founder mutations in the genes involved in cardiac function.

Introduction: Sudden cardiac death (SCD) is responsible for a large proportion of sudden, unexpected deaths in young individuals (<50 years). In forensics, one-third of the cases remain unexplained after autopsy. In the remaining two-thirds, structural cardiac abnormalities are found, although often unspecific and without a clear cause of death. Sudden deaths are frequently suspected to be caused by inherited cardiac diseases. Implementation of genetic investigations in forensic medicine may increase the diagnostic rate in cases of sudden death in the young. The purpose of the study was to explore the utility of genetic testing using next-generation sequencing (NGS) by investigating the frequency of pathogenic variants in 100 genes associated with cardiac diseases in a cohort of suspected SCD victims. Methods: Genetic investigation of 133 unrelated, young SCD victims with (1) sudden unexplained death (SUD), or (2) non-diagnostic structural cardiac abnormalities without cause of death, or (3) structural cardiac abnormalities diagnosed as cardiomyopathy, was performed. Using NGS, all exons and UTR regions of 100 genes associated with inherited cardiomyopathies and cardiac channelopathies were investigated. Results: The results show that 45% of SUD cases, 35% of cases with non-diagnostic structural cardiac abnormalities and 48% of cases with cardiomyopathy had likely pathogenic variants in one or more disease-related genes. Conclusion: Screening by NGS of these 100 genes revealed that between one-third and half of the suspected SCD victims had likely pathogenic genetic variants. Large-scale genetic testing seems a powerful supplementary tool in forensic investigations in sudden death cases and increases the diagnostic efficiency.

Study of the consequences of *BAG3* molecular variants associated with human dilated cardiomyopathy

A. Korniat[1], *T. Hery*[1], *S. Westphal*[2], *E. Villard*[1];
[1]*INSERM/UPMC UMRS 1166, Hôpital Pitié-Salpêtrière, Paris, France,* [2]*Department of Internal Medicine 2, University Hospital Ulm, Ulm, Germany.*

Introduction: Dilated cardiomyopathy (DCM) is a rare pathology defined by left ventricular dilatation and reduced ejection fraction, leading to heart failure and often heart transplantation. We identified DCM-causing dominant heterozygous mutations in *BAG3* (*BCL2-associated athanogene 3*). BAG3 is a cytoprotective co-chaperone involved in protein homeostasis, and plays a role in clearance of proteotoxic misfolded, aggregated, or altered proteins. Deleterious *BAG3* mutations are located in the BAG domain, which interacts with the chaperone Hsp70 family (heat shock protein 70). We hypothesized that *BAG3* mutations induce cardiomyocyte dysfunction due to impaired cellular proteostasis.
Methods/Results: We studied biochemical and cellular effects of BAG domain mutations in heterologous cell models with transient overexpression of GFP-BAG3 chimeric proteins, or in the zebrafish model organism. Rat neonatal cardiomyocytes overexpressing $BAG3^{mut}$ displayed disorganized sarcomeres, BAG3-positive cytoplasmic aggregates, and atrophy, resulting in cell death. Using GST pull-down and co-immunoprecipitation, we demonstrated a loss of $BAG3^{mut}$-Hsp70 interaction, indicating strong structural

effects of *BAG3* mutations and potential impairment of HSP70-dependent proteostasis. Accordingly, using heat-shock induced transient denaturation of luciferase reporter mimicking proteotoxic stress, we showed decreased protein refolding in HEK cells transfected with $BAG3^{mut}$ compared to $BAG3^{wt}$. Finally, zebrafish microinjected with mutant cDNA developed pericardial edema mimicking cardiac dysfunction.
Conclusion: Our results strongly suggest that *BAG3* mutants fail to bind to HSP70, blunting HSP70-dependent response to proteotoxic stress. Such functional alteration leads to protein aggregation, cardiomyocyte loss and probably cardiac insufficiency. It reveals a new putative DCM pathological mechanism.

PS05.23
TTN truncating mutations are a major cause of dilated and noncompaction cardiomyopathy

H. Bruggenwirth[1], *J. van Waning*[1], *M. van Tienhoven*[1], *I. de Graaf - van de Laar*[1], *K. Caliskan*[2], *D. Majoor - Krakauer*[1], *M. van Slegtenhorst*[1];
[1]*Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, Netherlands,* [2]*Department of Cardiology, Erasmus Medical Center, Rotterdam, Netherlands.*

Cardiomyopathies are characterized by extreme genetic and clinical heterogeneity, with >50 causative genes known to date. With Sanger sequencing, in about 45% of the hypertrophic cardiomyopathy (HCM) patients a pathogenic mutation was identified, whereas only 15-20% of the dilated cardiomyopathy (DCM) and noncompaction cardiomyopathy (NCCM) cases were solved. Nowadays we make use of a targeted NGS panel (48 genes) including the Titin gene (*TTN*), the largest known human protein that plays a central role in sarcomere organization. *TTN* truncating mutations have been found to be a major cause of DCM, but these type of mutations have not frequently been reported in NCCM or HCM.
Sixty-seven NCCM patients, 84 DCM patients and 150 HCM patients were tested with a NGS targeted sequencing approach, including the largest isoform of TTN (NM_001267550.1).Twelve DCM patients (~14%) and 9 NCCM patients (~13%) showed a truncating mutation in exons encoding the A-band of TTN (exons 259-359), whereas no mutations were detected in HCM patients in this region. This A-band of Titin was recently reported to contain the majority of truncating mutations in DCM patients (Roberts *et al.* Sci Transl Med. 2015,14;7; 270).
In conclusion, targeted NGS is an effective approach for cardiomyopathy diagnostics, resulting in increased diagnostic yield for all types of cardiomyopathies. For DCM patients, the majority of mutations are caused by truncating mutations in *TTN*. We now report that truncating mutations in *TTN* also are a major cause of NCCM.

PM05.24
Whole exome sequencing (WES) in 41 Czech families with inherited cardiovascular diseases

N. Ptakova[1], *L. Piherová*[2], *A. Krebsová*[3], *M. Kubánek*[3], *V. Stránecký*[2], *V. Melenovský*[3], *J. Kautzner*[3], *S. Kmoch*[2], **M. Macek Jr**[1], *M. Macek Sr*[1];

WES facilitates genetic diagnostics of inherited cardiovascular diseases, enables genetic stratification and may eventually foster individualized therapies. Due to integrated cardio-genetic care, altogether 96 families with ≥ 2 affected individuals were characterized and WES was carried out in a total of 41/96 families (TruSight Exome, Illumina, USA). 23/41 families suffered from dilated cardiomyopathy (DCM), 1/41 - non-compaction cardiomyopathy (LVNC), 14/41 - hypertrophic cardiomyopathy (HCM), 1/41 -arythmogenic cardiomyopathy (ACM) and 2/41 had unexplained cardiac arrest (UCA). Detected variants were confirmed by Sanger DNA sequencing and by segregation analysis. WES revealed a putative molecular genetic mechanism in 22/41 (64%) families. The pathogenic mutations were identified in 12/22 (54 %) DCM, 1/1 LVNC, 13/14 (92%) HCM, 1/1 ACM and in 1/2 familes with UCA. The most frequently mutated gene in DCM was TTN (23%) and in HCM the MYH 7 (29%). In case of LVNC, the likely pathogenic variant was identified in the OBSC, for ACM in PKP2 and in the family with UAC in SCN5A genes, respectively. Although disease genes were already identified, most mutations were novel. Our results and mutation distribution are in accordance with other studies. Our model of integrated genetic care of patients with inherited cardiovascular diseases is the first one in Czech Republic. Functional analysis of the 9p21 coronary artery disease-associated locus using isogenic cell lines generated by genome editing

D. G. McVey[1], *V. Codd*[1], *D. Lodwick*[1], *N. Samani*[1,2], *T. R. Webb*[1];
[1]*Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom,* [2]*National Institute for Health Research Leicester Cardiovascular Biomedical Research Unit, Glenfield Hospital, Leicester, United Kingdom.*

Introduction: Genome-wide association studies (GWAS) have identified multiple loci associated with coronary artery disease, the most significant of which is located on chromosome 9p21.
Harismendy et al (Nature, 2011) suggest that the causal variants at this locus are two SNPs that disrupt STAT1 transcription factor binding to an enhancer element. This may therefore result in altered gene expression of nearby protein and RNA genes. Here, we investigated this hypothesis by utilising genome editing to produce isogenic cell lines that differ at only the two SNPs of interest. This allows any functional effects of these variants, in response to inflammatory signalling, to be determined.
Methods: Genome editing by recombinant adeno-associated virus (rAAV) was used to specifically alter the genotype of the two SNPs in HeLa-S3 cells, with all other variants remaining constant. Heterozygous lines were derived from the homozygous-protective parental line.
Genotype-specific variation in STAT1 binding was assessed following interferon-γ treatment using chromatin immunoprecipitation and quantitative PCR (ChIP-qPCR). Local gene expression of treated cells was also investigated using qPCR.
Results: ChIP-qPCR revealed a reduction in STAT1 binding by approximately 50% in cells heterozygous for the risk alleles compared to the homozygous non-risk control. However, no difference in gene expression of CDKN2A, CDKN2B and several ANRIL transcripts was observed. Analysis of additional local genes is on-going.
Discussion: The observed reduction in STAT1 binding suggests that these SNPs are functional, but the absence of a gene expression difference indicates that other functional variants in the region may be required to contribute to disease.

PM05.26
A novel de novo TFAP2B mutation in a sporadic patient with Char syndrome

M. Y. Alp, *A. Yeşilyurt, F. Alpaslan Pınarlı;*
Dışkapı Yıldırım Beyazıt Research and Training Hospital Genetic Diagnostic Center, Ankara, Turkey.

Char syndrome first described by Florence Char in 1978, is a rare autosomal dominant disorder characterized by patent ductus arteriosus (PDA), facial dysmorphism, and anomalies of the fifth finger. Char syndrome is caused by mutations in TFAP2B gene encoding a neural crest-derived transcription factorthat play an important role in development, apoptosis, cell-cycle control, and complex morphogenic processes. Also it is suggested that TFAP2B mutations may be associated with isolated nonsydromic PDA. Here we described a 4 year-old male patient associated with PDA, clinodactyly of the fifth fingers, facial dysmorphism and developmental delay. Sequence analysis of TFAP2B gene revealed a single-base heterozygousc.698T>A (cDNA.867T>A, V233D) mutation in exon 4 which results in the replacement of valine by aspartic acid at codon 233. Parental mutation screening detected wild type genotype. To the best of our knowledge, this is the first report of V233D mutation in TFAP2B gene associated with Char syndrome.

PS05.27
High yield of copy number variations in individuals with complex congenital heart disease in Saudi Arabs

N. Dzimiri, *S. M. Wakil, N. P. Muiya, E. Andres, S. Hagos, H. Aldusery, M. Dasouki;*
King Faisal Spec. Hospital and Research Centre, Riyadh, Saudi Arabia.

Introduction
Congenital heart diseases (CHDs) are complex cardiac disorders that manifest in different forms, such as tetralogy of Fallot (TOF), ventricular septal defects (VSDs), atrial septal defects (ASDs), coarctation, and may occur in combination with other defects. Copy number variations (CNVs) have been implicated in many complex disorders, including cardiovascular and cancer. However, the impact of such variants on congenital heart disease (CHD) manifestation is not fully explained yet.
Methods
In the present study, we selected and performed Copy Number Analysis on 50 Saudi (Arab) cases of complex CHDs, including TOFs, bicuspid aortic val-

ve (BCV), tricuspid atresia (TCA) and subaortic membrane (SAM) disorders, to determine the possible link of the disease to changes in copy numbers.

Results

Among the 50 individuals, 22 exhibited CNVs on four chromosomal regions. Out of these were 16 TOFs exhibiting duplications, three of which were linked to chromosome 17q21.31, two to 16p11.2, and one each to 2q13,, 19p13.3 and 20p12.3. Furthermore, one TOF together with three complex cases involving BAV, and SAM, Kartagener's syndrome, exhibited deletions at 16p11.2 and 15q11.2. Interestingly, an individual case with TCA showed copy number gain at 2q13, while another with Kartagener syndrome showed a copy number loss at the same locus. These duplications/deletions involved sequences of 420-1200 kbp. The qPCR verification assays on five of the studied individuals confirmed the duplications and deletions found by cytoscanning.

Conclusion

Our study reveals a high yield of CNVs in CHD, mostly in the regions of chromosomes 16p11.2 and 17q21.31, which could be used clinically to identify such patients routinely.

PM05.28

Sporadic congenital heart disease and copy number gains on chromosome 21

D. L. Brown[1], *I. Wilson*[1], *L. Sutcliffe*[1], *J. O'Sullivan*[2,1], *B. Keavney*[3], *J. Goodship*[1];
[1]Institute of Genetic Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Department of Paediatric Cardiology, Freeman Hospital, Newcastle upon Tyne, United Kingdom, [3]Institute of Cardiovascular Sciences, Manchester University, Manchester, United Kingdom.

Congenital heart disease (CHD) is 1000 times more common in people with Down syndrome (DS) than the general population. Complete atrioventricular septal defects have the strongest association with DS, and the combination of AVSDs and tetralogy of Fallot is almost unique to people with DS. To evaluate the hypothesis that copy number (CN) gains on chromosome 21 are associated with sporadic CHD we analysed more than 2000 non-DS case samples and 800 controls using the Illumina 660W quad array. After an extended quality control pipeline, CN gains larger than 10kb called by both QuantiSNP and Penn CNV algorithms were included. Cases were enriched for copy number gains in DSCAM and COL6A1 which have been previously identified as candidates for DS-related CHD. These results suggest they may also have a role in sporadic, non-DS CHD.

PS05.29

Polygenic risk for coronary artery disease is associated with cognitive ability in older adults

S. P. Hagenaars, *S. E. Harris, T. Clarke, L. Hall, M. Luciano, A. Fernandez-Pujals, G. Davies, C. Hayward, G. Scotland, J. M. Star, D. J. Porteous, A. M. McIntosh, I. J. Deary; University of Edinburgh, Edinburgh, United Kingdom.*

Introduction: Coronary artery disease (CAD) is associated with cognitive decrements and risk of later dementia, but it is not known if shared genetic factors underlie this association. We tested whether polygenic risk for CAD was associated with cognitive ability in community-dwelling cohorts of middle-aged and older adults.

Materials and Methods: Individuals from Generation Scotland: Scottish Family Health Study (GS:SFHS, N=9865) and from the Lothian Birth Cohorts of 1921 (LBC1921, N=517) and 1936 (LBC1936, N=1005) provided cognitive data and genome-wide genotype data. Polygenic risk profile scores for CAD were calculated for all of the cohorts using the largest available GWAS data set, the CARDIoGRAM consortium (22,233 cases and 64,762 controls). Polygenic risk profile scores for CAD were then tested for their association with cognitive abilities in the presence and absence of manifest cardiovascular disease.

Results: A meta-analysis of all three cohorts supported a negative association between CAD polygenic risk and fluid cognitive ability, verbal intelligence and memory. Whereas these findings were not statistically significant in the Lothian Birth Cohorts, in GS:SFHS polygenic risk for CAD was negatively and significantly associated with fluid cognitive ability (β = -0.02, p = 0.03), Mill Hill Vocabulary test (β = -0.03, p = 0.006) and Logical Memory (β = -0.02, p = 0.042).

Conclusions: Increased polygenic risk for CAD is associated with lower cognitive ability in older adults. Common genetic variants may underlie some of the association between age-related cognitive decrements and the risk for CAD.

PM05.30

A loss-of-function mutation in the haptoglobin gene is associated with a decrease in serum haptoglobin and an increase in non-HDL cholesterol and cardiovascular risk

E. Bjornsson[1,2], *P. Sulem*[1], *H. Holm*[1,3], *A. Helgadottir*[1,2], *H. Helgason*[1,2], *S. Gretarsdottir*[1], *A. Oddsson*[1], *R. P. Kristjansson*[1], *I. Olafsson*[3], *D. F. Gudbjartsson*[1,2], *G. Thorgeirsson*[2,3], *U. Thorsteinsdottir*[1,2], *K. Stefansson*[1,2];
[1]DeCODE Genetics, Reykjavik, Iceland, [2]University of Iceland, Reykjavik, Iceland, [3]Landspitali University Hospital, Reykjavik, Iceland.

Human haptoglobin is a plasma protein which binds free hemoglobin released by the destruction of red blood cells, thereby protecting against oxidation. Whether serum levels of haptoglobin contribute to cardiovascular disease remains controversial. Here, through whole-genome sequencing of 2,230 Icelanders followed by imputation into 5,411 Icelanders with serum haptoglobin measurements, we found a rare (minor allele frequency = 0.57%) loss-of-function mutation associated with a decrease in serum haptoglobin levels (effect = -1.28 SD per minor allele, $P = 7.4x10^{-25}$). In addition, this variant associated with an increase in non-HDL cholesterol (effect = 0.18 SD per minor allele, corresponding to 0.18 mmol/l, $P = 1.2x10^{-5}$) and increased risk of coronary artery disease (OR = 1.26, $P = 0.011$). This mutation is a splice donor variant in the haptoglobin gene (*HP*) on chromosome 16q22 and represents a founder mutation in the Icelandic population. This signal was independent of a common copy-number variation in the *HP* gene and a previously reported common SNP (rs2000999) at that locus, previously shown to associate with haptoglobin levels. In addition to haptoglobin, these common variants were also associated with non-HDL cholesterol, demonstrating an inverse relationship between their effects on the two traits.

In summary, we report a loss-of-function mutation in the *HP* gene, present in about 1 out of 90 Icelanders, which is associated with a decrease in serum haptoglobin levels and an increase in non-HDL cholesterol and cardiovascular risk. Our genetic results point to a role of haptoglobin in cholesterol metabolism.

PS05.31

Identification of rare potential CAD-causing variants in GWAS loci

M. Kleinecke[1], *I. Brænne*[1], *B. Reiz*[1], *T. Strom*[2], *H. Schunkert*[3], *J. Erdmann*[1];
[1]Institute for Integrative and Experimental Genomics, Luebeck, Germany, [2]Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany, [3]Deutsches Herzzentrum München, Technische Universität München, Munich, Germany.

The identification of genes causing coronary artery disease (CAD) is one of the most important tasks to understand the disease and to develop potential new treatments. Genome-wide association studies (GWAS) have identified more than 50 loci associated with CAD. If common variants increases the risk of CAD, it is likely that rare variants within the same locus also increase the risk. Indeed, the presence of such variants may even point the GWAS locus to the causal gene. Further, as rare variants are expected to have stronger effects, unraveling the disease mechanism might be easier. Hence, this study aims to identify rare variants in known CAD risk genes and to find potential causal genes in CAD GWAS loci.

We screened for variants in a total of 82 genes close to or harboring CAD associated SNPs ($p<5x10^{-8}$). For these candidate genes, we screened for rare (<1%) truncating variants in a pool of 255 exome sequenced early onset MI patients with a positive family history. Each variant was validated by Sanger sequencing and tested for co-segregation with CAD in respective family members.

We only identified a small number of rare variants in a subset of the candidate CAD genes. Exemplary, LDLR and ABCG8 are known to harbor rare variants increasing CAD risk and we confirm these findings. In addition, we also report rare variants in genes where only common risk variants are reported so far. For instance, to our knowledge, we are the first to report rare loss-of-function variants in *NBEAL1*.

PM05.32

A Mesenchymal Stem Cell-Based Approach for Investigating Cardiovascular Disease-Related Genetic Variants

S. K. Rai[1], *T. R. Webb*[1], *N. J. Samani*[1,2], *D. Lodwick*[1];
[1]Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom, [2]National Institute for Health Research Leicester Cardiovascular Biomedical Research Unit, Glenfield Hospital, Leicester, United Kingdom.

Introduction: Large-scale genetic studies have identified many loci that contribute to complex disease. We have explored the use of Mesenchymal Stem Cells (MSCs) as a system for creating genotype-specific cell models to investigate the biological mechanisms of complex disease-related genetic variants in vitro. Here we describe the differentiation of MSCs down a vascular

smooth muscle (VSMC) lineage in order to investigate a coronary artery disease (CAD)-associated genetic variant.
Materials and Methods: MSCs were isolated from umbilical cords using an explant method. Flow cytometry and StemPro® Differentiation Kits were used to characterise MSCs. MSCs were differentiated to VSMCs using TGF-β1, and characterised by qPCR, immunofluorescence and calcium imaging.
Results: A bank of 114 umbilical cord-derived MSCs was created, and characterised by cell surface markers (99.7% positive for CD105, CD90 and CD73, and 0.2% positive for the negative markers CD45, CD34, CD11b, CD19 and HLA-DR) and differentiation into adipocytes, chondrocytes and osteoblasts. MSCs were differentiated towards a VSMC lineage, demonstrated by an upregulation of VSMC markers; ACTA2, TAGLN2 and CNN1 ($p<0.001$). As a proof of concept, we investigated the functional CAD-associated coding variant, rs3825807, located in the protease ADAMTS7 in MSCs carrying either the risk or non-risk allele. A trend showed MSCs with the risk allele had increased migratory ability, consistent with findings reported by Pu et al., (2013). We are currently undergoing studies with differentiated VSMCs.
Conclusion: Our findings show that our MSC bank can be used to study genetic variants associated with complex disease including CAD-related phenotypes.

PS05.33

Mypn knock-in mutant mice develop dilated cardiomyopathy

R. A. Peat[1], *S. Alcoléa*[2], *T. Héry*[1], *L. Duboscq-Bidot*[1], *N. Mougenot*[1], *A. Jacquet*[1], *G. Dilanian*[1], *M. Komajda*[1,3], *E. Villard*[1];
[1]*INSERM UMRS 1166, Paris, France,* [2]*Université de Nantes, Nantes, France,* [3]*AP-HP CHU Pitié-Salpêtrière, Paris, France.*

Dilated cardiomyopathy (DCM) causes severe heart failure, but even with over 30 causative genes identified, DCM pathophysiology is poorly understood. In addition, current treatments only ameliorate symptoms without treating underlying causes, therefore developing genetic therapies is essential. We identified human DCM mutations in *MYPN* (myopalladin), and created a knock-in mouse model carrying one such mutation. We also introduced two synonymous variations into the murine recombination vector, creating an experimentally validated shRNA target sequence permitting specific extinction of mutant allele expression. Introduced variations did not interfere with normal allelic splicing, nor allelic expression ratios in either skeletal or cardiac muscles when assessed via allele-specific qPCR. Mice were fertile, with normal growth rates and long-term survival. Mutant heart gross morphology appeared normal, but electron micrographs demonstrated thickened sarcomeric Z-lines. Echocardiography until 18 months demonstrated that both heterozygote and homozygote mutant mice displayed cardiac insufficiency from the age of three months. In mutant mice, systolic ventricular diameter and volume were increased, and ejection fractions and fractional shortening reduced, confirming systolic dysfunction. In contrast to most published murine models of dominant human DCM which display recessive phenotypes, we generated a knock-in mouse model of persistent mild dominant DCM, highlighting its particular utility for potential allele-specific genetic therapy. Future analysis of mutant cardiomyocyte contractile properties and calcium handling will provide further insights into dominant *Mypn* DCM genotype/phenotype pathophysiological relationships.

Next generation sequencing for the molecular genetic characterization of patients with dilated cardiomyopathy

J. Bernasovska[1], *I. Boronova*[1], *J. Kmec*[2], *V. Szabadosova*[1], *P. Ferenc*[1], *I. Bernasovsky*[3];
[1]*Department of Biology, University of Presov, Presov, Slovakia,* [2]*Cardiocentre, Faculty Hospital of J.A. Reyman, Presov, Slovakia,* [3]*Institute of Romany Studies, University of Presov, Presov, Slovakia.*

Dilated cardiomyopathy (DCM) is an important cause of heart failure and the leading indication for cardiac transplantation worldwide. Genetic etiology plays an important role in disease pathogenesis. The aim of our study was genetic testing of 49 patients with diagnosed DCM using next generation sequencing technologies (SOLiD 5500xl). All probands underwent a clinical examination. High blood pressure, coronary disease, chronic excess of alcohol consumption and systemic disease were excluded prior to genetic analysis. Genomic DNA was extracted from peripheral blood leukocytes or buccal swab sampling according to standard protocols. Molecular-genetic analyses included 50 different genes implicated in causing DCM. In the survey of selected Slovak patients with dilated cardiomyopathy missense mutations in GM2A, DHX57, NDUFV2, COL12A1, EXD1, IBA57, LAD1, MORN2, KRT15 genes were detected. In 33% of cases missense mutation - pathogenic mutation rs1805124 T/C in the gene SCN5A channel (responsible for the reduction of PR and QRS intervals) including mutations in the intron regions: rs7428779 C/T and rs41312433, G/T were identified. In five patients was found the rare variant rs11408120, -/G in TCEAL6 gene. The variant was confirmed by Sanger sequence analysis using ABi 3500 xl DNA Sequencer (Applied Biosystems). In recent years the progress in identifying the genetic causes of cardiomyopathies. Introduction of screening methods forms potential benefits of gene based diagnosis to identify individuals at risk for developing heart failure.
This study is the result of implementation of the projects APVV-0644-12 and ITMS 26220120241.

Dilated cardiomyopathy (DCM) is a disease of the myocardium caracterized by left ventricular dilatation, systolic dysfunction and myocardial fibrosis. It is a major cause of morbility and mortality and the first indication for cardiac transplantation. Clinical manifestations are variable and include heart failure, thromboembolism and sudden cardiac death. The etiology may be genetic for up to 50% of cases either sporadic or familial (F-DCM). Most F-DCM cases have an autosomal dominant form of inheritance (90%). More than 40 genes have been associated with the disease, and the frequency of mutations varies from one population to another. The purpose of our study is to describe the mutations producing DCM in Mexican patients. Coding exons and intron flanks of 31 well characterized genes responsible for DCM, were sequenced by NGS with the Ion Torrent technology looking for pathogenic genetic variants in Mexican patients diagnosed as having idiopathic or F-DCM. Preliminary results in 22 index cases show mutations in the *TNNT2, RBM20* and *CSRP3* genes, and two different mutations already detected in patients with Brugada Syndrome, in the *SCN5A* gene. In one index case we found a mutation in the *MYSH7* gene associated to Hypertrophic cardiomyopathy (HCM). Also, two new SNVs causing a stop gain, one in TTN, the other in LMNA were found in different patients. At present, we detected a known mutation in six patients and a new variant in two. We are confirming by capillary sequenciation and completing the study including the available relatives.

Background
Truncating mutations in Titin (TTN) occur in 25% of dilated cardiomyopathy (DCM) cases, but also in 3% of healthy controls. We studied whether truncating TTN mutations cause a clinically distinguishable form of DCM .
Methods
We compared clinical data of probands and their relatives with either a truncating TTN mutation or a pathogenic mutation in Lamin A/C (LMNA), to probands with DCM who tested negative for both.
Results
We studied 240 subjects: TTN probands (n=47) and their relatives (n=73), LMNA probands (n=31) and their relatives (n=29), and probands negative for both (TTN/LMNAneg DCM; n=60). Median follow-up was at least 2.5 years in each group. TTN mutation carriers presented at a significantly higher age with DCM than LMNA mutation carriers (48.6 vs 41.5 years, $p=0.045$ for probands; 59.7 vs 47.0 years, Log-Rank $p=0.01$ for relatives). TTN mutation carriers less often developed left ventricular ejection fraction (LVEF) below 35% (HR=0.50, $p=0.02$ for probands), and had better outcome (less composite endpoints (HR=0.10, $p<0.001$ for probands; HR=0.21, $p=0.02$ for relatives) compared to LMNA mutation carriers, and compared to TTN/LMNAneg DCM patients (HR=0.33, $p=0.05$)). Strikingly, after initiation of standard heart failure treatment an LVEF increase of at least 10% occurred in 50.0% of the TTN subjects, while this only occurred in 6.3% of LMNA subjects ($p<0.001$) and 22.2% of TTN/LMNAneg DCM subjects ($p=0.03$).
Conclusions

This study shows that truncating mutations in TTN induce a DCM that is less severe at presentation and more amenable to standard therapy than either LMNA mutation induced DCM or TTN/LMNAneg DCM.

PS05.37

Assessment of the mechanical stability of the aorta in a mouse model of Ehlers-Danlos syndrome vascular type (EDS IV)

J. Münger[1], J. Meienberg[1], J. Crabb[2], A. Mauri[2], C. Kaiser[3], G. Barmettler[3], C. Giunta[4], U. Ziegler[3], S. Zeisberger[5], E. Mazza[2], **G. Matyas**[1,6]*;*
[1]Center for Cardiovascular Genetics and Gene Diagnostics, c/o Foundation for People with Rare Diseases, Schlieren-Zurich, Switzerland, [2]Institute of Mechanical Systems, Swiss Federal Institute of Technology Zurich, Zurich, Switzerland, [3]Center for Microscopy and Image Analysis, University of Zurich, Zurich, Switzerland, [4]Division of Metabolism, University Children's Hospital, Zurich, Switzerland, [5]Swiss Centre for Regenerative Medicine, University of Zurich, Zurich, Switzerland, [6]Zurich Center of Integrative Human Physiology, University of Zurich, Zurich, Switzerland.

Introduction: EDS IV is an autosomal dominant connective tissue disorder caused by mutations in the COL3A1 gene and associated with an increased risk for aortic rupture. So far, only disease management and treatment of symptoms are available. Haploinsufficient mice of a recently described novel mouse model of Col3a1 show reduced mechanical stability of the aorta and spontaneous death (~28% of cases) due to aortic rupture similar to the human EDS IV phenotype. Our goal was to characterize the mechanical stability of the aorta in this mouse model compared to wild-type mice.
Methods: 1.5-mm-long sections of aortic arch as well as ascending and descending aorta from Col3a1 mice were mounted on two 200-µm diameter stainless steel wires on a TissuePuller (Danish Myo Technology) and stretched radially until tissue damage, thereby continuously recording the stretching force (in mN).
Results: Maximum force at tissue damage was significantly lower in heterozygous Col3a1 mice compared to age- and gender-matched wild-type animals in both the ascending and descending parts of the aorta. For both genotypes, the mechanical stability of the aorta was decreasing, with increasing distance from the heart.
Conclusions: We developed a protocol for the assessment of the mechanical stability of mice aorta, which is suitable to detect significant differences between heterozygous and wild-type Col3a1 mice. Our results open the way to test pharmacological substances for their potential to increase the mechanical stability of the aorta with the goal to find a targeted therapy for patients with EDS IV and related aortic disorders.

PM05.38

The type of variants at the COL3A1 gene associates with the phenotype and severity of vascular Ehlers-Danlos syndrome

BOUTOUYRIE*[8,2,3]*, J. FIESSINGER*[1,3]*, J. EMMERICH*[1,3]*, E. MESSAS*[1,3]*, X. JEUNEMAITRE*[1,2,3]*;*
[1]AP-HP, Hôpital Européen Georges Pompidou, Département de Génétique, Service de Médecine Vasculaire et Centre de Référence des Maladies Vasculaires Rares, PARIS, France, [2]INSERM, U970, Paris centre de Recherche Cardiovasculaire – PARCC, Paris, France, [3]Université Paris Descartes, Sorbonne Paris Cité, Faculté de Médecine, Paris, France, [4]AP-HP, Hôpital Européen Georges Pompidou, Service de Médecine Interne, PARIS, France, [5]Université Paris Descartes, Sorbonne Paris Cité, Faculté de Médecine, P, Austria, [6]AP-HM, Service de Médecine Vasculaire, Hôpital de la Timone, MARSEILLE, France, [7]AP-HP, Hôpital Européen Georges Pompidou, Service de Radiologie Cardiovasculaire, PARIS, France, [8]AP-HP, Hôpital Européen Georges Pompidou, Service de Pharmacologie, PARIS, France.

Vascular Ehlers-Danlos syndrome (vEDS) is a rare and severe autosomal dominant disorder caused by COL3A1 gene variants, with little evidence of genotype-phenotype correlation. Clinical characteristics and course of disease of 215 molecularly-proven patients (146 index-cases and 69 relatives), were analysed. We found 126 distincts variants that were divided into five groups : 1) Glycine substitutions (71 variants in 127 patients), 2) splice-site and in-frame insertions-deletions (36 variants in 55 patients), 3) variants leading to haploinsufficiency (7 variants in 14 patients), 4) non glycine missense variants within the triple helix (4 variants in 7 patients), 5) non glycine missense variants or in-frame insertions-deletions, in the N- or C-terminal part of the protein (8 variants in 12 patients). Overall, our cohort confirmed the severity of the disease with a median age at first complication of 29 years [IQR 22 to 39], the most frequent being arterial (48%) and digestive (24%) ruptures. Groups 2 and 1 were significantly more severe than groups 3-5 with extreme median ages at first major complication of 23 to 47 years. Patients of groups 3-5 had a less typical phenotype and remarkably absence of digestive events. The glycine-replacing amino-acids were frequently destabilizing residues of the collagen assembly. Thus, the natural course of vEDS and the clinical phenotype of patients are influenced by the type of COL3A1 variant. This study also confirms that patients with variants located in the C- and N-termini or leading to haploinsufficiency have milder course of the disease, and less prevalent diagnostic criteria. These findings may help refine diagnostic strategy, genetic counselling and clinical care.

PS05.39

Differential DNA methylation in individuals with a history of cardiovascular diseases

D. Martinsson, M. Ahsan, U. Gyllensten, A. Lind-Thomsen, W. Ek, S. Enroth, **Å. Johansson***; Uppsala university, Uppsala, Sweden.*

Cardiovascular disease (CVD) is among the leading causes of death worldwide. There are several known genetic and lifestyle risk factors, but association between epigenetics and CVD is poorly understood. In this study, we investigate the link between DNA methylation and CVD. We performed an epigenome-wide association study in a population-based cohort (N=730). Participants were not ascertained upon disease background, but some had a history of CVD (Table). DNA methylation was measured at 470789 autosomal CpG-sites. Differentially methylated sites were identified for a subset of diseases (Table). Some sites were located in genes previously associated to CVD, e.g. BNIP3 and GDF15. Enrichment analysis identified a number of molecular functions and biological processes, which are overrepresented among the differentially methylated genes. For example, participants with a history of myocardial infarction had an enrichment (FDR q-value=0.00142, Enrichment = 4.69) of differential methylation in genes associated with cardiac muscle tissue growth. The identified genes are good candidates for additional studies to further understand the genesis and progression of CVD, as well as for the development of therapies and treatments.

Table

CVD	No. affected individuals (%males)	No. significant CpG (FDR q-value < 0.05)
Cardiac Arrhythmia	5 (60%)	1
High Blood Pressure	147 (40%)	0
Myocardial Infarction	48 (58%)	211
Stroke	27 (56%)	0
Thrombosis	22 (59%)	0

Exome sequencing reveals novel functional mutation in APOB causing Familial Hypercholesterolaemia

A. C. Alves[1,2]*, A. M. Medeiros*[1,2]*, A. Extebarria*[3]*, C. Martin*[3]*, M. Bourbon*[1,2]*;*
[1]Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisboa, Portugal, [2]BioISI – Biosystems & Integrative Sciences Institute, Faculdade de Ciências, Universidade de Lisboa, Lisboa, Portugal, [3]Unidad de Biofísica (Centro Mixto CSIC, UPV/EHU) and Departamento de Bioquímica, Universidad del País Vasco, Bilbao, Spain.

Introduction: APOB mutations are a rare cause of Familial Hypercholesterolaemia (FH) and routine genetic diagnosis only includes the study of two small APOB fragments (exon 26 and 29). Recently functional mutations have been described in APOB fragments not routinely studied and our group characterized 2/5 as causing FH.
The main aim of this project was to identify and characterize novel alterations in APOB in order to identify the genetic cause of the hypercholesterolemia in these patients.
Methods: we performed whole-exome sequencing of 5 Portuguese clinical FH patients apparently mutation negative. All results found in APOB were analysed. For functional studies LDL from index patients and relatives was separated and marked with FITC-LDL for studies by flow cytometry in HepG2 and U937 growth assays.
Results: We identified 2 alterations in exons 19 and 26 in 2 patients. In vitro analysis of exon 26 alteration (p.Thr3826Met) carrier showed a decrease in binding and internalization of LDL and in U937 growth assays, showing a similar effect as APO3527. As reported before, also in this family the penetrance is also reduced. Alteration in exon 19 had a neutral effect.
Conclusions: The spectrum of functional alterations in APOB outside the fragments routinely screened is growing. Screening of all 29 exons of APOB should be performed in routine diagnosis, now possible by NGS. It is expected that a further 10% of clinical FH patients can have FH due to a novel APOB mutation. On this basis we are currently sequencing a panel of 95 negative patients.

PM05.42

LDLR functional in vitro assays: a step forward for the correct genetic diagnosis of familial hypercholesterolaemia

S. Azevedo[1]*, A. C. Alves*[1,2]*, A. M. Medeiros*[1]*, P. Barros*[1]*, C. Martín*[2]*, M. Bourbon*[1]*;*
[1]Unidade de I&D Grupo de Investigação Cardiovascular Departamento de Promoção da Saúde e Prevenção de Doenças Não Transmissíveis Instituto Nacional de Saúde Dr. Ricardo Jorge and BioISI – Biosystems & Integrative Sciences Institute, Faculdade de

Ciências, Lisboa, Portugal, [2]Unidad de Biofísica (CSIC, UPV/EHU) and Departamento de Bioquímica y Biología Molecular, Universidad del País Vasco, Bilbao, Spain.

Aim: Familial hypercholesterolaemia (FH) is an autosomal dominant disorder that confers an increased cardiovascular risk, due to high levels of cholesterol in blood since birth. FH has a prevalence of 1:500, being estimated that >90% of these patients have mutations in the *LDLR*. Although more than 1600 alterations have been identified, the majority of them remain without functional studies.
The aim of this work is to construct vectors for the *in vitro* study of common alterations in Portuguese FH patients, contributing for phenotype/genotype clarification.
Methods: The 14 most common *LDLR* alterations to date without functional assessment were selected. *In silico* assessment was performed using described tools. Site-directed mutagenesis was performed in a pcDNA3_LDLR plasmid and functional assessment is being performed in CHO-ldlA7 cells by flow cytometry. Complementarily, protein expression and immunofluorescence studies will be performed.
Results: *In silico* prediction classified 7/14 alterations as benign (p.Met1Leu, p.Gly20Arg, p.Gln92Glu, p.Asp221Tyr, p.Ile473Val, Ala606Ser and p.Ile764Thr) and 7 as probably pathogenic (p.Cys184Tyr, p.Gly207_Ser213del, p.His211Asp, p.Glu626Lys, p.Glu288Lys, p.Asp601Val, p.His656Asn). 9/14 alterations were also reported in several other countries as mutation causing disease. Among these constructs, 11 of the mutagenesis occurred successfully and the functional assessment is underway. The remaining are being performed.
Conclusions: Although more than 1600 variants have been described in the *LDLR*, there are still novel variants being found, proving its heterogeneity. It is imperative to functionally characterize these alterations to contribute for the elucidation of the molecular basis of FH worldwide. An accurate diagnosis and early personalized counseling/treatment, will improve FH patients prognosis.

Familial Hypercholesterolaemia - An efficient genetic testing laboratory service for multiple lipid centres using Next Generation Sequencing and PASS

A. Hills[1], J. Honeychurch[1], P. Dean[1], L. Yarram-Smith[1], G. Dennis[1], G. Woodward[1], M. Greenslade[1], G. Bayly[2], K. Haralambos[3], M. Williams[1], **E. Watson**[1];
[1]Bristol Genetics Laboratory, Bristol, United Kingdom, [2]Bristol Royal Infirmary, Bristol, United Kingdom, [3]University Hospital of Wales, Cardiff, United Kingdom.

NICE recommends comprehensive genetic testing in all patients clinically diagnosed with FH, and genetic cascade testing of at-risk relatives. The Cardiovascular Disease Outcomes Strategy (2013) has improving case ascertainment for FH (12 to 50%) as a key target. British Heart Foundation are supporting implementation of a cascade testing programme for England through start-up funding bids, however, the cost of FH genetic testing can still remain a barrier to commissioning.
High throughput automated NGS genetic testing processes large numbers of samples at reduced cost using a unique patient sequence barcode identifier. The custom-designed targeted capture assay (HaloPlex, Agilent) sequences 4 FH genes; *LDLR*, *PCSK9*, *APOB* and *LDLRAP1* and the *SLCO1B1* variants (*rs2306283* and *rs4149056*) associated with statin-induced myopathy. Data analysis uses an open-source pipeline; alignment (bwa), variant calling (GATK), variant annotation (Geneticist Assistant, SoftGenetics), and copy number analysis (CONTRA/bespoke CNV tool).
Bristol Genetics Laboratory (BGL) has tested >600 FH index cases by NGS from >15 referral centres with a 35% positive detection rate, the most common mutations being *APOB* c.10580G>A and *LDLR* c.313+1G>A. CNV analysis has detected 12 *LDLR* deletions and 1 duplication. 7% of patients have variants of uncertain significance (VUS) with the majority of these found in *APOB*. 116 relatives have undergone cascade testing.
BGL is trialing the online PASS database to link the genetic testing process directly to lipid clinics using workflow management tools. We report the genetic test results on our cohort, and our service developments, highlighting the efficiencies of using an NGS testing approach and PASS.

PM05.44

Identification of familial hypercholesterolemia in patients with early onset MI by systematic molecular genetic analysis

I. Brænne[1], *M. Kleinecke[1], B. Reiz[1], E. Graf[2], T. Strom[2], T. Wieland[2], M. Fischer[3], C. Hengstenberg[4], T. Keßler[4], T. Meitinger[5], J. Erdmann[1], H. Schunkert[4];*
[1]Institute for Integrative and Experimental Genomics, University of Luebeck, Luebeck, Germany, [2]Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany, [3]Klinik und Poliklinik für Innere Medizin II, Universitätsklinikum Regensburg, Regensburg, Germany, [4]Deutsches Herzzentrum München, Technische Universität München, Munich, Germany, [5]Institute of Human Genetics, Helmholtz Zentrum München, Munich, Germany.

Familial hypercholesterolemia (FH) is an oligogenic disorder characterized by markedly elevated low-density-lipoprotein (LDL)-cholesterol levels. Despite the knowledge of the FH candidate genes, it is largely under-diagnosed in European countries. Since FH increases the risk for coronary artery disease (CAD) and myocardial infarction (MI), it might be specifically overlooked in the large number of such patients.
Here, we systematically examined the frequency of potential FH-causing variants in LDLR, APOB, PCSK9 and STAP1 by exome sequencing in 255 German patients with premature MI and a positive family history for CAD. We further performed co-segregation analyses in an average of 5.5 family members per MI patient.
In total, we identified eleven potential disease-causing variants that co-segregate within the families. Eight variants were previously reported as disease-causing and three are novel (LDLR.p.V271I, PCSK9.p.D204N and STAP1.p.T47A). However, exome sequencing also revealed that some variants, which have been reported to cause FH, do not co-segregate with the disease in respective families.
The data reveals that 1 out of 20 patients with premature MI carries potential FH-causing mutations. Hence a large proportion of FH patients escapes the diagnosis. Systematic molecular-genetic screening for FH may assist and unravel the diagnosis in a substantial number of cases and thereby allow a timely intensive or preventive treatment of FH. Interestingly, some of the previously reported disease-causing variants could not be validated in this study. Our results highlight the need for careful evaluation of each potential disease-causing variant prior to reporting.
This Study was supported by the Deutsche Forschungsgemeinschaft cluster of excellence ‚Inflammation at Interfaces'.

PS05.45

Anomalous retinal vasculature in MYH11-associated Familial Thoracic Aortic Aneurysms and Dissection (FTAAD)

E. R. A. Thomas[1], *H. Brittain[2], J. W. V. Marshall[3], N. Chung[1], S. Mathur[4], P. Coucke[5], L. Robert[1];*
[1]Guy's and St Thomas' Hospital, London, United Kingdom, [2]Great Ormond Street Hospital, London, United Kingdom, [3]Maidstone and Tunbridge Wells NHS Trust, Maidstone and Tunbridge Wells, United Kingdom, [4]Evelina London Children's Hospital, London, United Kingdom, [5]Ghent University Hospital, Ghent, Belgium.

Background: Familial thoracic aortic aneurysms and dissection (FTAAD) is a heterogeneous autosomal dominant condition which compromises the wall of the thoracic aorta, and in some cases other vessels. MYH11 mutations have been reported in families with FTAAD associated with patent ductus arteriosus (PDA).
Case report: We here report a three-generation family with a splice site mutation in intron 27 of MYH11. The proband was a 29-year-old woman who died 11 days post-partum due to two separate areas of dissection in the thoracic and abdominal aorta. On family screening, her 12-year-old son was found to have a PDA, and her 56-year-old father was found to have dilatation of the proximal ascending aorta (4.1cm), and a subsequent CT angiogram identified tortuosity of the innominate artery. No clinical features suggestive of a wider disorder of connective tissue were found in the proband's father or son, but both shared the MYH11 splice mutation. On ophthalmological examination, the proband's father also had anomalous vascular loops identified in both eyes.
Conclusions: The family reported here exhibits the range of phenotypes associated with FTAAD caused by MYH11. In general, there is little genotype-phenotype correlation in FTAAD, but the presence of PDA directs suspicion towards MYH11. In addition, one family member had retinal vascular tortuosity, possibly resulting from his generalised abnormality of the vasculature. The prevalence of retinal vascular anomalies in FTAAD requires further investigation; if widely prevalent, ophthalmological examination would provide a valuable non-invasive test of extra-cardiac vascular status.

PM05.46

FBN1 gene polymorphysms association with dilatative pathology of the ascending thoracic aorta (DPATA)

Ž. Stanevičiūtė[1], *R. Šepetienė[1], V. Patamsytė[1], G. Zukovas[2], R. Benetis[1,2], V. Lesauskaitė[1];*
[1]Institute of Cardiology of the Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania, [2]Department of Cardiac, Thoracic and Vascular Surgery, Lithuanian University of Health Sciences, Kaunas, Lithuania.

In most cases the causes leading to the aortic wall expansion and/or dissection remains unclear. Certainly, this pathology is caused by aortitis, atherosclerosis or inherited as a single gene mutation. Evidence has shown that FBN1 mutations may predispose DPATA in the absence of phenotypic cha-

racteristics of Marfan syndrome and lately FBN1 polymorphisms drew more attention to cause sporadic DPATA. Based on LeMaire et al study in 2011, we investigated polymorphisms of the FBN1 gene (rs2118181, rs1036477, rs10519177, rs755251, rs4774517) in a case-controlled study for DPATA from Lithuanians.
We studied 312 patients who had undergone aortic reconstructive surgery for DPATA. Patients were subdivided into test groups according to the DPATA phenotypes: ascending aortic aneurysms, dissectionsandpost-stenotic-dilatation. The control group (n=472) was obtained from a random sample screened within epidemiological studies of the Lithuanian population. The FBN1 polymorphisms were investigated by real-time polymerase-chain-reaction amplification. Fisher's exact test, $\chi 2$ test and allelic association odds ratio were used for statistics. The distribution of genotypes was conformable with Hardy-Weinberg equilibrium ($p>0.15$).
We observed that minor alleles of all five FBN1 SNPs were significantly associated with aortic dissection with OR 2.13-2.59, $p<0.001$, and two SNPs: rs2118181 and rs1036477- with an increased risk of ascending aortic aneurysm with OR 1.67, CI 95% 1.61-2.40.There were no significant associations between all studied FBN1 SNPs and post-stenotic aortic dilatation.
Minor alleles of all SNPs investigated might be considered as risk alleles for aortic dissection and two of them (rs2118181, rs1036477) are increasing odds for aortic aneurysm formation.

PM05.48

Upregulation of Antigen Presentation Pathway under the treatment with neuropropeptide Semax in a rat model of brain focal ischemia

S. A. Limborska[1,2], *E. V. Medvedeva*[1], *N. F. Myasoedov*[1], *L. V. Dergunova*[1,2];
[1]*Institute of Molecular Genetics RAS Dept. of Molecular Bases of Human Genetics, Moscow, Russian Federation,* [2]*Institute of Cerebrovascular Pathology and Stroke, Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

Neuroprotective synthetic oligopeptide Semax composed of a fragment of ACTH4-7 and C-terminal tripeptide Pro-Gly-Pro is used for therapy of acute stroke. The molecular mechanisms of its neuroprotective action have been hitherto unknown. The response of the transcriptome of ischemized rat brain cortex tissues to the action of Semax in the male Wistar rat brains was investigated. The intraperitoneal injection of peptide was done at 15 min, 1, 4 and 8h after permanent middle cerebral artery occlusion (pMCAO). mRNA expression change was analyzed in 24h groups versus 3h groups following pMCAO and "pMCAO + Semax". The Illumina RatRef-12 Expression BeadChip was used in our study. The action of Semax enhanced the expression of 17 genes (Ap1, B2m, Cd74, Hla-C, Hla-Dma, Hla-Dmb, Hla-Dqa1, Hla-Dra, Hla-Drb1, Hla-E, Psmb8, Psmb9, Tapbp) belonged to the major histocompatibility complex (MHC). We identified significant overlap between 13 of these genes and the Antigen Presentation Pathway ($p=4.4E-11$). BioRank Ingenuity ranking system assigns to this pathway the high scores that means that this set of changed expression genes hit a critical component of the pathway in the Ingenuity Canonical Signaling Pathway library. Besides we observed changed levels of transcripts of 7 genes (Cd74, Hla-A, Hla-Dra, Psmb8, Psmb9, Tap1, Tapbp) belonged to the MHC in the "ischemia" group during one day after pMCAO. But for the Antigen Presentation Pathway this set of genes was scored lower than in the case of neuropeptide treatment. Our data assume that Semax affects the immune response during the active stage of ischemia.

PS05.47

A human laterality disorder associated with a homozygous WDR16 deletion

A. Ta-Shma[1], **Z. Perles**[1], *B. Yaacov*[2], *M. Werner*[2], *A. Frumkin*[2], *A. J. J. T. Rein*[1], *O. Elpeleg*[2];
[1]*Pediatric cardiology, Hadassah Hebrew University Medical Center, Jerusalem, Israel,* [2]*Monique and Jacques Roboh Department of Genetic Research, Hadassah Hebrew University Medical Center, Jerusalem, Israel.*

Visceral asymmetry is determined through embryonic ciliary motion. A failure to generate the normal left-right (L-R) asymmetry during early stages of embryogenesis may result in severe anatomical abnormalities, including heterotaxy syndrome (HS) which consists of abnormal L-R axis arrangement of the abdominal and thoracic viscera and situs inversus totalis (SIT) which manifests by mirror image asymmetry of the internal viscera. HS is at times accompanied by complex congenital cardiovascular anomalies whereas SIT is frequently associated with Primary Ciliary Dyskinesia (PCD). The genetic etiology of defects not associated with PCD is largely unknown.
In this study we investigated the cause of situs anomalies, including HS and SIT (PCD excluded), in a consanguineous family.
Whole exome analysis including thorough coverage analysis, revealed a homozygous deleterious deletion in the WDR16 gene - chr17. hg19:g.9481617_9489649del8033.
The finding was confirmed both by cDNA analysis and by the results of Multiplex Ligation-dependent Probe Amplification analysis which confirmed segregation of the deletion in the family. Serial PCR reactions using intronic primer sets, resulted in the amplification of a genomic fragment which contained the breakpoint.
WDR16 protein was previously proposed to play a role in cilia-related signal transduction processes; the rat Wdr16 protein was shown to be confined to cilia possessing tissues and severe hydrocephalus was observed in the wdr16 gene knockdown zebrafish.
The phenotype associated with the homozygous deletion in our patients suggests a role for WDR16 in human laterality patterning. Exome analysis is a valuable tool for molecular investigation even in cases of large deletions.

Hereditary hemorrhagic telangiectasia (HHT) is an autosomal dominant disorder characterized by an aberrant vascular development. HHT affects approximately 1 in 5000 people and is caused by pathogenic variants in a number of genes involved in the TGF-β signaling pathway. Endoglin (ENG) and activin receptor-like kinase-1 (ALK1/ACVRL1) encode proteins expressed on vascular endothelial cells. These genes are casually related to HHT. The clinical diagnosis of HHT is based on recurrent epistaxis due to telangiectases and arteriovenous malformations (AVMs) which can occur in the pulmonary, cerebral and hepatic circulation leading to stroke, internal hemorrhage, and severe anaemia. We used classical sequencing approaches to perform molecular characterization in 18 clinically affected unrelated probands with the suspected diagnosis of HHT, and detected a total of 7 different mutations in the two genes. Two mutations were identified in the ENG gene, both deletions, one of which was novel, in exon 8 and exon 11. There were tested also several family members of these probands and we identified 5 and 2 mutation carriers, respectively. Three of five mutations identified in the ALK1/ACVRL1 gene were novel and comprised missense mutation in exon 6, deletion in exon 3 and small indel in exon 8. No mutations were found in ENG/ACVRL1 in 11 probands. Genetic testing can confirm the clinical diagnosis in individuals and identify presymptomatic mutation carriers. Once a famililal mutation is identified, relatives at risk can be tested. Individuals with a mutation are identified for intensive clinical surveillance. We offer genetic counseling for at-risk relatives.

PM05.50

Sarcomeric gene mutations in Turkish families with hypertrophic cardiomyopathy

E. Komurcu-Bayrak[1], *F. Bayrak*[2], *G. Kahveci*[3], *F. Guclu-Geyik*[1], *N. Erginel-Unaltuna*[1];
[1]*Department of Genetics, Institute for Experimental Medical Research, Istanbul University, Istanbul, Turkey,* [2]*Department of Cardiology, Acibadem University, Istanbul, Turkey,* [3]*Department of Cardiology, Kartal Kosuyolu Heart and Research Hospital, Istanbul, Turkey.*

Background: There is little knowledge about familial hypertrophic cardiomyopathy in Turkey. In this study, our aim was to determine a causing mutation in three sarcomeric genes (MYH7, MYBPC3 and TNNT2) in Turkish families with HCM and high-risk for sudden cardiac death (SCD).
Materials and methods: The study included twelve index cases of early onset (<40 years) clinically diagnosed HCM patients with a positive family history for HCM and SCD. All participants were evaluated with a detailed history, physical examination, 12-lead electrocardiography and two-dimensional echocardiography. DNA was extracted from peripheral blood and coding regions and flanking intronic sequences of MYH7, MYBPC3 and TNNT2 genes were screened using array-based re-sequencing. All novel variants and known mutations were confirmed with Sanger sequencing. After the causal mutation in family members was screened.
Results: From 12 index cases, a known missense mutation was found in 6 individuals and also novel missense mutation was found in 2 individuals. Four different causal mutations in the cardiac-beta myosin heavy chain (MYH7) gene, one in the cardiac myosin binding protein C (MYBPC3) gene and one in the cardiac troponin T (TNNT2) were found. In addition, two novel intronic variants in MYH7 and MYBPC3 genes were found in 2 different index cases. Detection of the novel missense mutations and intronic variants within the family members and control population is ongoing.
Conclusion: Our preliminary result provides a general view of the familial

hypertrophic cardiomyopathy with high-risk for SCD and highlights the importance of mutation screening for these three genes in Turkey.

PS05.51
Disease causing variation is differentially distributed in MYH7 but not in MYBPC3 in patients with hypertrophic cardiomyopathy

J. R. Homburger, *C. A. Caleshu, E. A. Ashley;*
Stanford University, Stanford, CA, United States.

Hypertrophic cardiomyopathy (HCM) is an inherited disorder of the heart muscle. HCM has been linked to dominant genetic variants in sarcomere genes, most commonly in *MYH7* and *MYBPC3*. The *MYH7* and *MYBPC3* gene products interact but have distinctly different functions: *MYH7* encodes the myosin head, the molecular motor that binds and pulls actin, while *MYBPC3* is a regulatory protein that binds to both the myosin and actin. Despite these functional differences, variants in both genes lead to a similar presentation of HCM. To investigate the differences between the variant profiles of *MYH7* and *MYBPC3*, we combine published and unpublished data from three centers (Stanford University, the Mayo Clinic, Harvard University). The combined dataset included results from 4349 patients. In *MYH7*, 215 out of 234 (91.9%) unique damaging variants are missense, while only 164 out of 343 (47.8%) are missense in *MYBPC3* (Fisher $p=1.25x10^{-6}$). We compared variant locations in *MYH7* and *MYBPC3* from HCM patients with those from 60,706 individuals in the Exome Aggregation Consortium (ExAC). We find a significant difference in the distribution of HCM and ExAC variant locations in *MYH7* (KS $p=3.95x10^{-13}$), but not in *MYBPC3* (KS p=0.462). The peak of differential variant density in *MYH7* covers the head, the lever arm, and the beginning of the tail of the myosin heavy chain molecule. Our results suggest differing regional biophysical contributions to the pathogenicity of disease for *MYH7* and *MYBPC3*.

PM05.52
Cardiac Ankyrin Repeat Protein (CARP/Ankrd1) gene variants in Hypertrophic Cardiomyopathy

J. Kusic-Tisma[1], A. Divac Rankov[1], L. Rakicevic[1], A. Nestorovic[1], J. Jasnic-Savovic[1], M. Tesic[2,3], N. Antonijevic[2,3], S. Kojic[1], **D. Radojkovic**[1];
[1]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [3]Clinic for Cardiology, Clinical Center of Serbia, Belgrade, Serbia.

CARP/Ankrd1 belongs to the muscle ankyrin repeat protein (MARP) family involved in a mechano-signaling pathway that links myofibrillar stress response to muscle gene expression. Also, CARP/Ankrd1 has an important role in transcriptional regulation, myofibrillar assembly, cardiogenesis and myogenesis. Few studies supported a role of CARP gene variants in the etiology of hypertrophic (HCM) and dilated cardiomyopathy. We have performed screening for mutations/variants in Ankrd1 coding sequences in 50 familiar or idiopathic HCM patients. Two missense heterozygous CARP variants in exon 2 (P52A and R66Q) were identified, each in one patient. Preliminary functional analysis of these variants on protein level were performed in rat neonatal cardiomyocytes by Fluorescent Recovery After Photobleaching (FRAP) assay. The results of the FRAP experiments showed difference in mobility between wt and P52A variant, while R66Q exerted similar behavior as wt protein. Our findings point to possible disruption of the protein-protein interaction and disturbance of the normal cardiac signaling in cardiomyocytes caused by P52A allele variant of CARP/Ankrd1.
This work was supported by grant 173008 from the Ministry of Education, Science and Technological Development of Republic of Serbia.

PS05.53
Investigation of Pathogenic Genes in Chinese Hypertrophic Cardiomyopathy Patients by Whole Exome Sequencing

J. Xu[1], *J. Wu[2], M. Dong[1], X. Shi[1], Y. Zhang[1], X. Ren[3], J. Li[1], W. Xie[1], Z. Sun[4], X. Liu[1], Q. Dai[5];*
[1]Southeast University, Nanjing, China, [2]Wenzhou Medical College, Wenzhou, China, [3]Nanjing General Hospital of Nanjing Military Command, Nanjing, China, [4]Chinese Academy of Sciences, Beijing, China, [5]ZhongDa Hospital, Nanjing, China.

Hypertrophic cardiomyopathy (HCM) is a cardiovascular disease with high heterogeneity. The limited knowledge about ~40% patients suggests that it needs to be investigated to understand the pathogenesis of the disease. A large number of variants were identified by whole exome sequencing in seventy-four HCM patients passing Sanger method sequencing eight HCM causative genes. After filtering against multiple databases and functional filter, 3228 SNPs and 475 InDels in 3046 genes were identified. TADA model was then applied using exome sequencing data of 2000 controls and 74 cases and 99 genes gained priority, with DNAH11, OBSCN ranking the first and second place, respectively. Associated analytical tools as DAVID and IntPath were also adopted to explore the novel mechanism underlying the HCM phenotype. The results showed that various genes and gene sets related to cytoskeleton, ATPase activity, dynein and calcium transport played critical roles in the pathogenesis of HCM, with a lot of other processes as well, implicating many processes involved in the HCM phenotype. We also found two novel OBSCN variants that co-segregated with the HCM patients in two HCM families. Additionally, we described the OBSCN role in HCM. Our study provides a way for exploring the pathogenesis of a less understood HCM cohort.

PM05.54
Mutational spectrum of Filamin C (FLNC) in hypertrophic cardiomyopathy

J. Gómez, *J. R. Reguero, M. Martín, R. Lorca, E. Coto;*
Hospital Universitario Central Asturias (HUCA), Oviedo, Spain.

Exome sequencing identified the Filamin C (*FLNC*) as a hypertrophic cardiomyopathy (HCM) candidate gene.[1] The *FLNC* putative mutations segregated with the disease in several families. We also demonstrated that patients with *FLNC* mutations showed marked sarcomeric abnormalities in cardiac muscle, and functional studies revealed that these *FLNC* variants resulted in the formation of large filamin C aggregates. Our aim was to characterize the mutational spectrum of *FLNC* in a large cohort of HCM patients. We performed a Next-generation sequencing of *FLNC* in 335 HCM patients, including 117 sarcomeric-mutation carriers. We identified a total of 25 HCM index cases who were heterozygous carriers of putative mutations, 21 in the 218 patients without sarcomere-mutation (10%) and 4 in the 117 sarcomere-positive cases (3%; $p<0.05$). Only five of the 25 *FLNC* variants were reported in healthy subjects in the Exome Sequencing Project (ESP) database, but all of them at a frequency <0.001%. Three variants, p.A1247V, p.A1539T, and p.A2340V, were found in two index cases. In nine of the 14 families we had several affected members, and all were mutation carriers. Interestingly, some of the *FLNC* mutations were linked to sudden cardiac death episodes. In conclusion, our work suggested that *FLNC* mutations were a significant cause of HCM.

[1]Valdés-Mas R *et al*. Mutationsin filamin C cause a new form of familial hypertrophic cardiomyopathy. Nature communications. 2014;5:5326).

PS05.55
The Clinical Utility of a Proton-Ion Ampliseq-based Cardiac Gene Panel

M. J. DASOUKI, *N. P. Muiya, E. Andres, O. M. ALBEDAIRY, M. M. ABOUELHODA, N. Dzimiri;*
King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia.

Introduction: Whole exome sequencing (WES) and whole genome sequencing (WGS) are increasingly being used in clinical practice. However, these approaches continue to be expensive, time consuming and difficult to interpret. So far, clinical WES studies have yielded diagnostic results in ~ 25% of cases. Hence, a complementary easier, equally sensitive method needs to be developed.
Method: A 406 cardiac related (cardiomyopathy, congenital heart disease, arrhythmias, vascular aneurysms) gene panel (with 10490 amplicons) based on Ion Torrent AmpliSeq technology was developed. So far, 243 gDNA samples were sequenced using the Proton-Ion sequencing instrument.
Results: In total, 4.13 Gb were mapped with 94% on target and base reads with 370 reads per amplicon and overall average base coverage depth of 325. In the 243 samples, a total of 51 variants (including 2 homozygous CACNA1C and SCN5A homozygous mutations) with an overall clinical sensitivity of 51/242 (21%) was found. Sub-panel diagnosis based clinical sensitivity was 32% for cardiomyopathy, 10% for congenital heart disease, 31% for arrhythmias and 29% for aortic aneurysms/Marfan syndrome.
Conclusion: This custom made, comprehensive cardiac gene panel appears to have a clinical sensitivity comparable to that of the current WES with the advantage of faster turnaround time and far fewer variants to analyse. Only in 6% of the genes on this panel were relevant DNA sequence variants identified. Hence, a tiered approach starting with a custom gene panel followed by WES is probably a more efficient clinical approach.

PM05.56
Homozygous, and compound heterozygous mutation in 3 Turkish family with Jervell and Lange-Nielsen Syndrome

S. G. TEMEL[1,2], *F. UYSAL[3], G. TOKSOY[4], O. M. BOSTAN[3], E. EVKE[5,6], Z. O. UYGUNER[4], H. KAYSERILIOGLU[4], E. Cil[3];*
[1]University of Near East, Faculty of Medicine, Department of Histology & Embryology, Lefkosia, Cyprus, [2]University of Uludag, Faculty of Medicine, Department of Histology

and Embryology, Bursa, Turkey, [3]University of Uludag, Faculty of Medicine, Department of Pediatric Cardiology, BURSA, Turkey, [4]University of Istanbul, Faculty of Medicine, Department of Medical Genetics, ISTANBUL, Turkey, [5]University of Uludag, Faculty of Medicine, Department of Histology & Embryology, BURSA, Turkey, [6]Bursa Genetic Diagnostic Center, Bursa, Turkey.

Long QT syndrome is one of the most common congenital cardiac ion channel disorder that the morbidity and mortality rate can be decreased by an early diagnosis and proper treatment. Cardiac repolarization abnormality that is characterized by prolonged OT interval and propensity for ventricular tachycardia of the torsades de pointes type are characteristics of the disease. This syndrome represents high risk for presyncope, syncope, cardiac arrest and sudden death. Jervell and Lange-Nielsen syndrome (JLNS) is recessive form of long QT syndromes with additional finding of profound sensorineural hearing loss. JLNS has been shown to occur due to homozygous and compound heterozygous mutations in KCNQ1 or KCNE1. Pathogenic mutations in the KCNQ1 gene were detected in all our JLNS cases. Index cases of 3 families were 2 month yr, 3.5 yr old female and 3-yr old male who visited the hospital due to intrauterine bradicardia, recurrent seizures/syncope, cardiac murmur, respectively and had all congenital sensorineural deafness. Their electrocardiograms revealed a markedly prolonged QT interval. The sequence analysis of the probands revealed the presence of compound heterozygous mutation ([(c.477+1G>A) + (c.520C>T, p.R174C)] and homozygous missence mutations (c.728 G>A, p. R243H), (1097G>A, p.R366Q), respectively. Heterozygous mutation in KCNQ1 was identified on the maternal, paternal and sibling sides. Homozygous mutation was identified in 3-yr old male's sister and cousin also. Interestingly even if her QT is long she had intact hearing. β-blocker therapy was initiated to all affected ones. Asymptomatic heterozygous family members were taken to a clinical follow up. Clinical and moleular findings will be discussed to further enlighten the genotype-phenotype association.

PS05.57

A common variant associated with coronary artery disease increases atheroma size within atherosclerotic plaques of patients with carotid stenosis

S. W. van der Laan, *J. van Setten, H. M. den Ruijter, F. W. Asselbergs, P. I. W. de Bakker, G. Pasterkamp;*
UMC Utrecht, Utrecht, Netherlands.

Background
To date, genome-wide association studies have identified 2 susceptibility loci for large artery ischemic stroke and 45 loci for coronary artery disease (CAD). We investigated whether these SNPs affected atherosclerotic plaque characteristics in the Athero-Express Biobank Study (AE, www.atheroexpress.nl) of patients with clinically significant carotid stenosis, from whom plaque specimens have been histologically analyzed.
Methods
We genotyped 1,439 patients from the AE and imputed missing genotypes using HapMap. We tested the 47 SNPs for association to macrophages numbers, smooth muscle cells (SMCs) numbers, neovascularization, intraplaque hemorrhage (IPH), atheroma size, calcification, and collagen content, using linear or logistic regression, correcting for age, sex, year of surgery, array type, and 10 principal components. We considered a significant association at p < 1.5 x 10-4 after Bonferroni correction for the number of variants and phenotypes tested.
Results
The most significant association was found for rs12539895 (coded allele frequency = 0.75, odds ratio = 1.59 per C allele, p = 9.0 x 10-6) with percentage of atheroma. This direction of effect was such that the same allele increases atheroma size and CAD risk. Other variants were nominally significantly associated with macrophages (rs17609940, p = 0.0457), SMCs (rs11203042, p = 0.0478), IPH (rs11203042, p = 0.0020), and atheroma (rs2023938, p = 0.0331; rs445925, p =0.0082), all with effect directions consistent with their reported effect on CAD.
Conclusion
Of 47 previously associated variants, one variant (rs12539895) was significantly associated with atheroma size in patients with carotid atherosclerosis. Further research is warranted to better understand underlying mechanisms.

PM05.58

Role of ceramide synthase 5 gene (*LASS/CERS5*) in molecular pathogenesis of atherosclerosis.

N. Coban, *O. Yildirim, F. Geyik, B. Ozsait, N. Erginel-Unaltuna;*
Institute for Experimental Medical Research, Department of Genetics, Istanbul, Turkey.

Ceramide, the backbone of sphingolipids, is the key component which affects atherosclerotic changes through its important second-messenger role. In previous studies, the protective role of *AMPK* gene with its regulated genes in atherosclerosis and hypertension is shown. *LASS5 (CerS5*) gene takes place in ceramid synthesis and has an indirect effect on *AMPK* gene. In this study, our aim was to identify *LASS5* gene function in athrerosclerosis. Briefly, *LASS5* gene specific siRNA mediated gene silencing was performed in HUVEC and subsequently the differencial expession *AMPK* regulated genes were analyzed. Then, HUVEC cells were treated with *AMPK* inhibitor or activator in order to examine the relation of change in gene expression levels with *AMPK* activity changes. As a result, we have identified a noval physiological function of *LASS5*. The treatment of *AMPK* inhibitor (Compound C) ligand significantly increased *LASS5* mRNA expression in HUVEC. Downregulation of *LASS5* was found to attenuate ceramide production, and increased the expression of *eNOS* and *KLF2*. In addition, we observed that presence of *LASS5* siRNA induced the expression of *KLF2* genes, and that this induction was partially prevented by Compound C. On the contrary, we observed that co-presence of *LASS5* siRNA and *AMPK* activator (AICAR) increased the expressions of *eNOS* and *KLF2*.
In summary, this is the first study demonstrated that *LASS5* was involved in the negative regulation of atherosclerosis related genes, namely *eNOS* and *KLF2*. These findings provide an insight into the molecular mechanism of atherosclerosis and also have importance for the development of potential therapeutic agents in the treatment of atherosclerosis.

PS05.59

Use of gene panels for the diagnosis of cardiac arrhythmia

C. N. S. Sarton, *K. McGuire, A. Seller;*
Oxford Medical Genetics Laboratories, Oxford, United Kingdom.

Cardiac arrhythmia occurs when the electrical impulses of the heart become disrupted. This can lead to a variety of syndromes including Catecholaminergic Polymorphic Ventricular Tachycardia (CPVT), Brugada Syndrome(BS), and Long QT Syndrome(LQTS). These disorders are all genetically and clinically heterogeneous with significant phenotypic and genetic overlap. Incomplete penetrance and variable expressivity adds further complication. In cases of sudden cardiac death where no record of the heart's electrical activity exists, it is extremely difficult to predict the correct molecular diagnosis.
Next Generation Sequencing (NGS) technology allows the provision of clinically relevant and cost effective solutions for molecular diagnosis. We have developed and validated an NGS panel of 43 genes which includes four subpanels for arrhythmic disorders CPVT, BS, LQTS and arrhythmia molecular autopsy. The strategy used is Haloplex enrichment technology (Agilent Technologies) followed by paired end sequencing on the MiSeq (Illumina) and an in-house analysis pipeline, "HAPPy". The pipeline is fully flexible, thus allowing any combination of genes on the panel to be analysed together.
The results of the first six months of this new service will be presented to demonstrate the analytical and clinical sensitivity of our testing strategy. Emphasis will be placed on the interpretation and clinical follow up of unclassified variants in the diagnostic setting e.g. a non-synonymous potentially pathogenic variant in *CALM1* in a patient with young onset severe Brugada syndrome. *CALM1* pathogenic variants have previously only been reported in LQTS and CPVT.

PM05.60

Loss of Y in blood and plaque is associated with atherosclerotic disease in men undergoing carotid endarterectomy

S. Haitjema[1], *D. Kofink[1], J. van Setten[1], S. W. van der Laan[1], S. C. A. de Jager[1], P. I. W. de Bakker[1], G. Pasterkamp[1], F. W. Asselbergs[1,2,3], H. M. den Ruijter[1];*
[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]University College London, London, United Kingdom, [3]ICIN-Netherlands Heart Institute, Utrecht, Netherlands.

Introduction:
The Y chromosome has long been considered genomic wasteland with few genes only implicated in sex determination. However, recent studies found an immunoregulatory role for Y and a relation between loss of Y (LOY) and a higher cancer risk and mortality. Given the involvement of immune cells in atherosclerosis, we hypothesized that LOY is associated with cardiovascular disease (CVD) phenotypes in men undergoing carotid endarterectomy (CEA).
Materials and Methods:
LOY was quantified in blood and plaque from raw intensity genotyping data in a cohort of 582 men in the Athero-Express Study. We tested LOY for association with CVD phenotypes, atherosclerotic plaque phenotypes and outcomes during 3-year follow-up.
Results:
LOY in 228 blood and 135 plaque samples was negatively associated with age in both blood (beta=-0.03/10yr, p=3.34*10-5) and plaque (beta=-0

.02/10yr, p=0.001). Quartiles of LOY were associated with contralateral arterial stenosis in blood (beta=-0.83,p=0.02) and peripheral arterial occlusive disease (beta=0.17,p=0.03) and stroke history (beta=-0.20,p=0.3) in plaque. LOY was not associated with plaque phenotypes. Event-free survival for major cardiovascular disease events was lowest in the quartile with the most Y-loss in blood (log-rank test p-value=0.03). Although LOY was correlated between blood and plaque the variance was higher in blood suggestive for more Y instability in blood as compared to plaque.
Conclusion:
LOY in blood and plaque is associated with hallmarks of atherosclerotic disease, but not with plaque phenotype in men undergoing CEA. Furthermore, men with LOY in blood had more major cardiovascular events during follow-up.

PS05.61
Losartan therapy in Marfan syndrome is only effective in patients with haploinsufficiency of FBN1

R. Franken[1], A. den Hartog[1], T. Radonic[2], D. Micha[2], A. Maugeri[2], F. S. van Dijk[2], H. E. Meijers-Heijboer[2], J. Timmermans[3], A. J. Scholte[4], M. P. van den Berg[5], M. Groenink[1], B. J. M. Mulder[1], A. H. Zwinderman[1], V. de Waard[1], **G. Pals**[2]*;*
[1]Academic Medical Center Amsterdam, Amsterdam, Netherlands, [2]VU University medical center, Amsterdam, Netherlands, [3]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [4]Leiden University Medical Center, Leiden, Netherlands, [5]University medical center Groningen, Groningen, Netherlands.

Introduction: Patients with Marfan syndrome - caused by FBN1 mutations - have an increased risk of life-threatening aortic complications. It has been shown that losartan reduces aortic dilation rate in these patients. The response to losartan treatment, however, was highly variable between individuals. Here we investigate whether there is a difference in Losartan effectiveness in genetically classified subgroups.
Methods: In this predefined sub-study of the COMPARE trial, we classified FBN1 mutations into: 1) Dominant negative mutations leading to a mutated fibrillin-1 protein incorporated in the extracellular matrix, 2) Haploinsufficient mutations leading to decreased amount of normal fibrillin-1 protein. The response to losartan therapy based on aortic root dilatation rate was compared between the two groups.
Results: Baseline characteristics between treatment groups were similar. Overall, losartan significantly reduced aortic root dilatation rate. However, losartan only reduced aortic root dilatation rate in haploinsufficient patients and not in dominant negative patients.
Conclusion: Marfan patients with haploinsufficient FBN1 mutations are more responsive to losartan therapy with respect to inhibition of aortic root dilatation rate compared to dominant negative patients. In order to predict response on losartan therapy, mutation classification should be performed for all Marfan patients. More research for novel treatment strategies is needed in Marfan patients with a dominant negative FBN1 mutation

Aortic root dilatation in Marfan patients

Type of FBN1 mutation	Aortic root dilatation	in mm/3 years	
	No losartan	+ losartan	p-value
total	1.3 ± 1.5 (n=59)	0.8 ± 1.4 (n=58)	0.009
dominant negative	1.2 ± 1.7 (n=38)	0.8 ± 1.3 (n=41)	0.197
haploinsufficient	1.8 ± 1.5 (n=21)	0.5 ± 0.8 (n=17)	0.001

Dissecting metabolic syndrome-related QTLs on rat chromosome 4 via eleven new double congenic rat strains

E. Skolnikova, *F. Liska, L. Sedova, D. Krenova, V. Kren, O. Seda;*
Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University, Prague, Czech Republic.

Rat chromosome 4 comprises several regions frequently associated with metabolic syndrome features. In order to dissect the individual QTLs we derived 11 new double congenic strains by introgressing distinct segments of rat chromosome 4 (RNO4) of spontaneously hypertensive rat (SHR) origin into BN-Lx (Brown Norway) genomic background.
Methods: We defined the spans of respective differential segment using 79 microsatellite markers. 16-week-old male rats (n=6/strain) were fed a standard diet. We assessed comprehensively the morphometric and metabolic profiles of all groups, including glucose tolerance tests, levels of insulin, adiponectin and concentrations of triglycerides and cholesterol in 20 lipoprotein fractions. One-way ANOVA with STRAIN and as major factor was used.
Results: Fasting glucose (ANOVA p = 0.00014) was considerably lower in BN-Lx.SHR4(A2m) (2.3 ± 0.24 mmol/l) and BN-Lx.SHR4(Il6 Lmbr Rat7 (Rat248-Rat150)) (3.66 ± 0.20 mmol/l) compared to BN-Lx (4.8 ± 0.42 mmol/l). Glucose tolerance was improved in BN-Lx.SHR4(A2m) (area under the glycemic curve fell by 42,1% compared to BN-Lx) but deteriorated in BN-Lx.SHR4(Pparg) (area under the glycemic curve rose by 17% compared to BN-Lx). We observed most striking shifts of TG and cholesterol concentrations profile in strains BN-Lx.SHR4(A2m), BN-Lx.SHR4(CD 36) and BN-Lx.SHR4(Pparg). In silico sequence comparison of differential segments in these strains revealed several genes harboring mutations in SHR.
Conclusion: Using derivation of series of double congenic strains, we have validated several metabolic syndrome-related QTLs and identified potential sequence variants underlying these loci.
Supported by MSMT LK11217.

PS05.63
Clinical diversity of MYH7- novel mutations and novel insights into pathogenesis.

T. Hershkovitz[1], *N. Ekhilevitch[1], A. Kurolap[1], E. T. DeChene[2], W. H. Tan[3], H. N. Baris-Feldman[1,4];*
[1]The Genetics Institute, Rambam Health Care Campus, Haifa, Israel, [2]Division of Genomic Diagnostics, Children's Hospital of Philadelphia, Philadelphia, PA, United States, [3]Division of Genetics and Genomics, Boston Children's Hospital; Harvard Medical School, Boston, MA, United States, [4]Rappaport School of Medicine, Technion – Israel Institute of Technology, Haifa, Israel.

Introduction
Mutations in the myosin heavy chain 7, cardiac muscle, beta gene (*MYH7*) are an important cause of both primary cardiomyopathy and skeletal myopathy. Previous data have established interesting correlations between various phenotypical features described in *MYH7* related disease (*MYH*-RD) and the specific site of the mutations within the gene.
Case Series
Three pedigrees with cardiomyopathy were studied. Pedigree 1, a Jewish Yemenite family, had 11 members with echocardiographic evidence of non-compaction cardiomyopathy and varying degrees of Epstein anomaly. This phenotype comprises approximately 4% of *MYH7*-RD. Pedigree 2 had a single member suffering from congenital dilated cardiomyopathy (DCM) and skeletal myopathy consistent with congenital fiber-type disproportion. The presentation of DCM and concomitant skeletal involvement congenitally is relatively uncommon. The third pedigree included 2 deceased siblings with DCM and their deceased first cousin with reported restrictive cardiomyopathy.
Results and Discussion
Direct sequencing of *MYH7* (NM_000257.3) in these pedigrees identified two novel mutations; c.1859T>C (p.Leu620Pro) in pedigree 1 and c.5655+1G>A in pedigree 2, predicted to disrupt the donor splice site of exon 38. These mutations expand the known genotypic spectrum of these relatively rare phenotypes of *MYH*-RD. Mutation analysis of the one available patient from pedigree 3 identified a compound heterozygous mutation c. 427C>T (p.Arg143Trp) and c. 4588C>T (p.Arg1530X). Interestingly, c. 427C>T was previously described as causing hypertrophic cardiomyopathy via a dominant negative effect, yet the proband's healthy mother and aunt carried this mutation. This may alter our view on disease pathogenesis, suggesting the contribution of nonsense mutations in the resulting disease phenotype.

Introduction: Thoracic aortic aneurysm and dissection (TAAD) is a genetically heterogeneous disorder representing a frequent cause of morbidity and mortality in the western world. To date, only two heterozygous loss-of-function mutations have been described in *MYLK* (myosin light chain kinase) causing familial aortic disease with little to no aortic enlargement prior to dissection. Here, we have aimed to expand the phenotypical spectrum associated with *MYLK* mutations.
Methods and results: After the application of a next-generation sequencing based TAAD gene panel in a cohort of 359 syndromic and non-syndromic TAAD patients, we identified two novel heterozygous *MYLK* mutations leading to a premature stop codon. Two female patients, with nonsense mutations at amino acids p.Arg1458 and p.Arg1487, presented with type B aortic dissection at ages 47 and 49 years, respectively. Both patients had a longstanding history of hypertension. Physical exam revealed unilateral iris flocculi in one, whereas the other woman presented with several systemic connective tissue findings. Remarkably, none of the patients had a family

history of aortic aneurysms or dissections.
Conclusions: Two novel heterozygous loss-of-function *MYLK* mutations have been identified. In addition to vascular findings, patients showed variable systemic features. The current report doubles the number of known *MYLK* mutations and significantly informs the further clinical delineation of the *MYLK* phenotypic spectrum.

Coincidence of ANKRD1, TMEM43 and PKP2 mutations in patient with ARVD

J. Kadlecova[1], *D. Nikulenkov Grochova*[1], *L. Durcova*[1], *M. Hiemerova*[1], *I. Grochova*[2,3], *L. Skutkova*[3], *P. Vlašín*[2];
[1]*Cytogenetic laboratory Brno, Brno, Czech Republic,* [2]*Center of prenatal diagnosis, Brno, Czech Republic,* [3]*International Clinical Research Center, St. Anne´s University Hospital Brno, Brno, Czech Republic.*

Background. Cardiomyopathy is characterized by mechanical or electrical dysfunction of cardiac muscle and it is a known risk factor of sudden cardiac death. More than hundreds of variant in 84 genes have been associated with inherited cardiomyopathy. A high number and variability of involved genes complicate diagnosis of cardiomyopathy. New technology of targeted next generation sequencing has a great potential in diagnostic settings of cardiomyopathies. It allows us to analyze several genes in parallel, which entails that several variants of potentially pathological or even unknown clinical significance are detected.
Methods. We applied next generation sequencing of 46 genes which have previously been shown to be associated with different types of cardiomyopathies (TruSight Cardiomyopathy Panel, Illumina) on group of unrelated patients with DCM, ARVC and ventricular fibrillation.
Results. The summary of the results of our analysis of the entire group of patients will be presented. A case report is selected, in which we present a patient with serious symptoms of Arrhythmogenic right ventricular dysplasia (ARVD), including ventricular tachycardia and sudden cardiac arrest, in which we revealed three potentially pathological mutations in three different genes. Two missense mutations in *ANKRD1*and *TMEM43* gene and one mutation in *PKP2*, which causes aberrant splicing were detected.
Conclusions. We hypothesized that the combination of these three pathological mutations could be the reason for the lethal course of the disease. Moreover, we assume that mutations in *ANKRD1* gene, which were previously shown to be responsible for dilated cardiomyopathy and hypertrophic cardiomyopathy, could be associated also with ARVD.

PM05.66
Rare variants residing in the ADAMTS13 von Willebrand factor (VWF) binding domain contribute to pediatric stroke susceptibility

M. Stoll[1], *F. Ruehle*[1], *A. Witten*[1], *A. Barysenka*[1], *A. Arning*[1], *C. Strauss*[1], *U. Nowak-Göttl*[2];
[1]*Institute of Human Genetics, Genetic Epidemiology, Muenster, Germany,* [2]*Institute of Clinical Chemistry, Hemostasiology, Kiel, Germany.*

Recently we reported a gene network of ADAMTS (A Disintegrin-like and Metalloprotease with Thrombospondin motifs) genes as central component of the genetic risk contributing to pediatric stroke. ADAMTS13 is a prime example for such a key component as it cleaves VWF multimers, reduces platelet adhesion and aggregation and down-regulates thrombus formation and inflammation. Here we characterized the genetic architecture of ADAMTS13 through targeted next generation sequencing of 48 affected children and their unaffected siblings. In total, we identified 226 variants in ADAMTS13, 36 of which are rare and resist filtering for unambiguous allele calling. For genotyping in 270 trios, 21 common variants covering the complete ADAMTS13 gene were selected based on significance in the sib-ship disequilibrium test ($p<0.05$) or protein altering properties. Transmission disequilibrium testing was performed for affection status and ADAMTS13 activity levels using PLINK and FBAT, respectively. 10 SNPs were significantly associated with pediatric stroke ($p<0.05$ to <0.001), two of which (rs2285489, rs28793911) were also significantly associated with ADAMTS13 levels ($p=0.0004$ and $p=0.0092$). The C-alpha collapsing test implemented in AssotesteR was used to assess significance across the set of 36 rare variants yielding a significant association ($p=5.73x10-6$). Haplotype association using a sliding window approach assigns this association to the ADAMTS13 VWF-binding domain ($p=1.2$ x10-4). Our data provide a link between the genetic architecture of ADAMTS13, ADAMTS13 levels and stroke risk. Altogether, these studies render ADAMTS13 an attractive candidate for functional studies and a potential diagnostic kit that incorporates genetic variation as predictors for stroke risk.

Molecular screening of NKX2.5 in two Moroccan cohorts with atrial septal defect (ASD) and tetralogy of Fallot (TOF)

I. El Bouchikhi[1,2], *K. Belhassan*[1], *F. Moufid*[1,2], *M. Iraqui Houssaini*[2], *S. Atmani*[3], *L. Bouguenouch*[1], *I. Samri*[1], *K. Ouldim*[1];
[1]*Medical Genetics and Oncogenetics Unit, HASSAN II University Hospital, Fez, Morocco,* [2]*Lab. Microbial Biotechnology, Faculty of Sciences & Technologies, Fez, Morocco,* [3]*Medico-Chirurgical Unit of Cardio-pediatrics, HASSAN II University Hospital, Fez, Morocco.*

Congenital heart disease (CHD) is one of the most frequent disorders observed at birth, affecting more than 1/100 live births. Among all CHDs, Atrial Septal Defect (ASD) and Tetralogy of Fallot (TOF) account for approximately 10% and 7% respectively. The previous studies have shown that mutations in NKX2.5 were associated with these two disorders. The aim of this study was to screen the NKX2.5 mutations in two series of Moroccan patients affected respectively by ASD and TOF.
Thirty four patients were recruited in HASSAN II university hospital of Fez; DNAs were extracted from Blood samples. Then, all samples have undergone amplification by PCR and direct sequencing of NKX2.5 coding regions. The obtained sequences were analysed by Bioinformatic alignment tools.
We have detected 3 mutations in ASD cohort and 2 mutations in TOF cohort which represents respectively 10.5% and 15.3% of the studied cohorts. These prevalences are much higher than those reported in the previous studies, which requires more studies in larger Moroccan cohorts. Moreover, we have found that the polymorphism c.63A>G is quite common in the Moroccan population with prevalence around 75%.
Grant References: Faculty of Medicine and Pharmacy of Fez – Hassan II University Hospital of Fez, Morocco.

PM05.68
Novel desmoplakin splice site and TMEM43 missense variant presenting with noncompaction cardiomyopathy (NCCM)

J. I. van Waning, **R. A. Oldenburg**, *K. Caliskan, M. A. Slegtenhorst, D. F. Majoor-Krakauer; Erasmus MC, Rotterdam, Netherlands.*

Noncompaction cardiomyopathy is a genetic cardiomyopathy associated with defects in sarcomere genes, in particular MYH7 and Titin. NCCM is characterized by distinct morphologic changes with hypertrabeculation and deep intertrabecular recesses of the left ventricular wall. In arrhytmogenic right ventricular cardiomyopathy loss of myocytes and fibro-fatty tissue replacement are caused by mutations in genes affecting the function of the desmosomal complex resulting in comprised cell-to-cell adhesion and differential signaling. Among the ARVC genes the DSP gene has shown to have a strong effect on left ventricular function, in contrary to TMEM43. Mutations in ARVC genes are rarely observed in NCCM. So far only two heterozygous truncating DSP variants (c.5208_5209delAG and c.1339C>T) and no TMEM43 variants have been associated with NCCM.
We found a DSP splice site mutation (c.3084+1G>A) classified as pathogenic, in a women who had 2 children, diagnosed with NCCM at age 33 years. She suffered from palpitations and repeated syncope, the ECG showed sustained ventricle tachycardia with right bundle branch morphology. After cardioversion the resting ECG didn't show inverted T-waves or epsilonwaves as expected in ARVC.
Cardiac echo showed a dilated right ventricle without dyskinesia and a hypertrabeculated left ventricle fulfilling the Jenni criteria for NCCM. The cardiac MRI showed a dilated right ventricle with hypertrabeculation, without dyskinesia. Left ventricle showed a decreased ejection fraction of 40% with noncompacted versus compacted ratio of 4,6. The patient met diagnostic criteria for NCCM, not for ARVC. These observations suggest genetic overlap between ARVC and NCCM and further studies are needed to elucidate the underlying shared pathophysiologic mechanism.

Genetics in noncompaction cardiomyopathy(NCCM)

J. I. van Waning[1], *K. Caliskan*[1], *M. Michels*[1], *A. F. L. Schinkel*[1], *Y. M. Hoedemaekers*[2], *M. Wessels*[1], *I. van de Laar*[1], *M. A. Slegtenhorst*[1], *D. F. Majoor-Krakauer*[1];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*UMCG, Groningen, Netherlands.*

Introduction: Noncompaction cardiomyopathy (NCCM) is a genetic cardiomyopathy, characterized by excessive trabeculations with deep recesses of the left ventricular wall. We present the results of genetic analysis in a large cohort of NCCM patients.
Method: The study included all NCCM index patients diagnosed and tested from 2005 till 2015 in our medical center. Current molecular testing for genetic defects is performed using novel next generation sequencing techniques of a panel of 48 cardiomyopathy related genes. Genetic sequence

variants in the cardiomyopathy genes were classified for pathogenic effect according to the current five category diagnostic criteria.
Results: The study include 128 index NCCM patients. Pathogenic or likely pathogenic variants (class 4 and 5) were identified in 40% (49/128) of the patients, including two or more (likely) variants mutations in 8 % (4/49). MYH7 mutations were the most frequent, affecting 16% (21/128) of the patients. The titin gene appeared to be an important cause of NCCM since we found truncating variants classified as likely pathogenic in 10% (7/67) of the tested patients. In two patients (2/67) the MIB1 gene, known to regulated embryologic compaction of the ventricular wall, was involved. In 30% (38/128) of the patients a variant of unknown clinical significance (class3) was found.
Conclusion: Extensive genetic testing detected a (likely) pathogenic variant in 40% of NCCM patients. The improving molecular diagnostics for cardiomyopathies have a profound impact on counseling and screening of families of NCCM patients. Further studies are needed to understand the contribution of genetic factors to this disease.

PM05.70

Paediatric cardiomyopathy (PC); the utility of a 71 gene NGS diagnostic panel to detect variants in rare cardiac genes.

*M. J. Gable[1], **K. Smith**[1], J. M. Honeychurch[1], H. Sawyer[1], R. Newbury-Ecob[2], C. Steward[3], L. Robert[4], T. Bueser[5], C. Gardiner[6], C. Bowen[7], M. Williams[1];*
[1]Bristol Genetics Laboratory, BRISTOL, United Kingdom, [2]Clinical Genetics, St Michael's Hospital, BRISTOL, United Kingdom, [3]Bristol Royal Infirmary, BRISTOL, United Kingdom, [4]Clinical Genetics, Guy's and Thomas' Hospital, LONDON, United Kingdom, [5]Guy's and St Thomas' Hospital, LONDON, United Kingdom, [6]West of Scotland Regional Genetics Service, Glasgow, United Kingdom, [7]Clinical Genetics and Pathology, Southern General Hospital, Glasgow, United Kingdom.

Paediatric cardiomyopathy (PC) can present in infancy with cardiac failure and sudden death. Considerable clinical and genetic heterogeneity exists within and between cardiomyopathy families hence cost effective gene panel testing aids diagnosis and elucidates complex clinical presentations. A 71 PC gene panel (Agilent SureSelect) has been validated (UKGTN approved) with coverage of 99.9% at 30X, and data analysis using an in-house bioinformatics pipeline based on the Broad Institute and Geneticist Assistant (SoftGenetics).
To date 37 patients have been tested, including paediatric cases; patients negative for other genes and patients who have phenotypic incompatibility with their reported pathogenic variant where digenic inheritance is suspected. 32/37 (86%) patients have at least one potentially pathogenic variant. In one family with HCM, a *MYBPC3* variant c.1505G>A, p.(Arg502Gln) and a previously reported *NEBL* pathogenic variant c.180G>C, p.(Lys60Asn) (nebulette protein) were detected in a severely affected male demonstrating that multiple variants can explain phenotypic severity. The utility of testing rare genes is exemplified by: 1) A teenager with LV dilation and FH of sudden death who was heterozygous for a *RMB20 (*RNA binding protein) variant c.1907G>A, p.(Arg636His), previously reported with severe familial DCM; 2) a patient with congenital heart block, LV dilation and FH was heterozygous for a novel likely pathogenic *MYH6* (alpha heavy chain subunit) variant c.3578C>T, p.(Ala1193Val). Furthermore, a novel heterozygous *TTN* A-band frameshift variant was identified in an infantile DCM patient; recent data suggests *TTN* frameshift variants have not been reported in infantile cardiomyopathy.
An audit of this patient cohort will be presented, illustrated by interesting cases.

Genome-wide analysis of parent-of-origin effects on cardio-metabolic traits

R. Tabassum[1], *S. Söderlund[2], A. Sarin[1], S. K. Service[3], A. Palotie[1,4], N. B. Freimer[3], M. Taskinen[2], S. Ripatti[1,5,6];*
[1]Institute for Molecular Medicine Finland, Helsinki, Finland, [2]University of Helsinki, Diabetes and Obesity Research Program, and Helsinki University Hospital, Heart and Lung Centre, Department of Cardiology, Helsinki, Finland, [3]University of California Los Angeles, Los Angeles, CA, United States, [4]Broad Institute of MIT and Harvard, and Massachusetts General Hospital, Cambridge, MA, United States, [5]Department of Public Health, University of Helsinki, Helsinki, Finland, [6]Wellcome Trust Sanger Institute, Hinxton, United Kingdom.

Parent-of-origin effect (POE) is an epigenetic phenomenon that makes two alleles at a locus functionally non-equivalent and manifested as phenotypic differences between reciprocal heterozygotes. We performed parental origin-specific genome-wide association analyses for cardio-metabolic traits to identify genetic variants exhibiting POE.
The study included 617 individuals with at least one parent genotyped from 150 large Finnish dyslipidemia families, and were genotyped at ~550,000 genetic variants using Illumina CoreExome beadchip array. Parental origins of alleles were determined using long-range phasing and genealogy as implemented in Alphaphase 1.1. POE was assessed using mixed linear models (adjusted for age, sex and relatedness) evaluating (1) phenotypic differences between reciprocal heterozygotes, and (2) effect of maternally and paternally inherited alleles separately.
Analysis revealed potential POEs on cardio-metabolic traits in seven loci (*NTNG1, CELF4, CLDN14, CDKN1A, PMP22-TEKT3, GPR56, EIF4E)* at *P* value $<1.0\times10^{-7}$. The strongest signal for parental origin specific association was obtained at rs531284 near *NTNG1* for fasting glucose levels. The maternally inherited minor allele at rs531284 showed association with reduced fasting glucose level [$_{mat}$=-0.67 s.d. units, $P_{mat}=7.8\times10^{-8}$] whereas paternal allele was not associated. At rs2249508 near *CLDN14*, paternal specific association was observed with LDL particle size [$_{pat}$=-0.55 s.d. units, $P_{pat}=9.8\times10^{-8}$]. These preliminary associations are now being tested for replication on further family studies.
In conclusion, the study indicates POE of genetic variants on glucose and lipid-related traits and suggests that this approach could help to identify new susceptibility genes for complex disorders.

PM05.72

Association of R279Q and C1562T polymorphisms of Matrix metallopeptidase-9 (MM-9) gene and increased risk for myocardial infarction in patients with premature coronary artery disease among Iranian population

M. Sheikhvatan;
Tehran Heart Cneter, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Background: The present study assessed the relationship between these two polymorphisms of the matrix metalloproteinase-9 (MMP9) gene (R279Q A/G polymorphism (rs17576) and C1562T polymorphism (rs3918242)) and occurrence of myocardial infarction in patients with premature coronary artery disease.
Methods: Our prospective study included 1000 patients with the final diagnosis of premature CAD and classified into two groups with history of MI (n = 461) and without of MI (n = 539). The polymorphism variants were determined by PCR-RFLP and High Resolution Melting techniques. Among study samples, 640 were followed with a median follow-up time 59 months for determining association of major adverse cardiac events (MACE) and polymorphisms.
Results: The prevalence of wild, heterozygous and mutant genotypes of R279Q polymorphism in MI group was 14.5%, 57.3%, and 28.2% and in non-MI group was 36.9%, 38.4%, and 24.7%, respectively with a considerable difference ($p < 0.001$). There was a significant difference in the prevalence of wild, heterozygous and mutant genotypes of C1562T polymorphisms in MI group (12.4%, 41.2%, and 46.4%, respectively) and in non-MI group (46.8%, 38.6%, and 14.7%, respectively) ($p < 0.001$). After adjustment for covariates, significant differences were revealed in genotypes of R279Q and C1562T polymorphisms between MI and non-MI groups. No difference was found in total-MACE free survival rate in MI patients and also in non-MI patients with different genotypes of R279Q and C1562T polymorphisms.
Conclusion: C1562T and R279Q polymorphisms of MMP-9 gene can be associated with the susceptibility to MI in premature CAD patients. However, these polymorphisms may not be able to predict long-term cardiac events in these patients.

PS05.73

Pathogenic potential of FOXC2 mutations identified in patients with primary lymphedema

D. Tavian[1], *S. Missaglia[1], S. Michelini[2], M. Ricci[3], M. Bertelli[4];*
[1]Univeristy, Milan, Italy, [2]Hospital, Rome, Italy, [3]Hospital, Ancona, Italy, [4]Onlus, Rovereto, Italy.

Dominant mutations in the FOXC2 gene cause a form of lymphedema that usually develops around puberty. In a large percentage of patients, lymphedema is accompanied by distichiasis and varicose veins. Other clinical abnormalities, such as cardiac defects, epidural cysts, ptosis and cleft palate have also been reported but are less common. FOXC2 is a member of the forkhead/winged-helix family of transcription factors and plays essential role in different developmental pathways and physiological processes. Most of FOXC2 mutations described so far either truncate the protein or are missense mutations in the forkhead domain causing a loss of function. The

haplo-insufficiency is associated with generalized hyperplasia of lymphatic system in mice as well as in humans.
We previously described six unrelated families with primary lymphedema in which patients showed different FOXC2 mutations. Of those, 4 were missense mutations, one a frame-shift mutation and the last one a stop mutation; all of them were located outside of the forkhead domain. To evaluate their pathogenic potential, we now have examined their subcellular localization and performed a transactivation assay using a luciferase construct with FOXC1 response elements. All FOXC2 mutated proteins are able to localize correctly into the nucleus. Alf of them present reduced while the remaining increased transcriptional ability, ranging from a complete loss to a significant gain of function. Our data suggest that the unbalanced FOXC2 activity causes a dramatic perturbation of lymphatic vessel formation leading to lymphedema.

PM05.74
Molecular and functional characterization of BMPR2 gene in Pulmonary Arterial Hypertension

G. Pousada[1,2], *V. Lupo*[3], *S. Cástro-Sánchez*[1,2], *A. Baloira*[4], *C. Espinós*[3], *D. Valverde*[1,2];
[1]*Universidad de Vigo, Vigo, Spain,* [2]*Instituto de Investigación Biomédica de Vigo (IBIV), Vigo, Spain,* [3]*Centro de Investigación Príncipe Felipe (CIPF), Valencia, Spain,* [4]*Complejo Hospitalario de Pontevedra, Pontevedra, Spain.*

Pulmonary Arterial Hypertension (PAH; OMIM 178600, ORPHA 422) is an autosomal dominant disease characterized by pulmonary vascular resistance increase, vascular remodelling and right heart failure. Symptoms of PAH include fatigue, shortness of breath and syncope. Several genes have been related to HAP, the most implicated gene is BMPR2 with more than 300 mutations described, 80% in Familial HAP and 20-40% in Idiopatic HAP. However, some of the functional implications for these mutations are unknown. The aim was to characterize the pathological mechanism of several mutations in BMPR2 and correlate them with the clinical spectrum of the disease.
Variants were selected from an in silico analysis. mRNA expression studies were performed using pSPL3 vector to confirm splicing alterations, studies of subcellular localization were performed using pEGFP-N1 vector and luciferase assay were performed using pGL3-Bassic vector. Correlation genotype-phenotype was performed using Spss v.19 software.
Nine out of 24 analyzed changes affect mRNA processing (p.S52Sfs*2, p.C84F, p.P138A, p.R211R, p.Y218*, p.V278V, p.W298*, p.P327P, p.K467R) and 4 out of 18 variants affects the subcellular localization (p.S52Sfs*2, p.C84F, p.Y218*, W298*). Five changes were identified at 5´UTR region and four of them produced a gene expression decrease of >50%. Patients with these pathogenic mutations showed an early age of diagnosis (p=0.047) and greater sPaP (p=0.042).
Molecular and functional studies have allowed us to check the real implication of the mutation and to correlate the role in the phisiopathological pathway of the disease. Likewise, these mutations predispose individuals to a more severe phenotype and this group shown a early age at diagnosis.

Introduction: Catecholaminergic polymorphic ventricular tachycardia (CPVT) is a rare inherited cardiac disorder characterized by adrenergically-mediated ventricular arrhythmias. The most common autosomal dominant form of CPVT is caused by mutations in the cardiac ryanodine receptor (*RYR2*) gene. Apart from the myocardium, this calcium release channel is highly expressed in the brain. Here we studied the prevalence and characteristics of neuropsychiatric disorders in patients with CPVT.

Methods: We included all CPVT patients with a pathogenic *RYR2* mutation and intellectual disability (ID) from 4 tertiary referral centers in the Netherlands and Japan. ID was defined as significant impairment of cognitive and adaptive functions with onset before the age of 18.

Results: Among 250 CPVT patients carrying a *RYR2* mutation, we identified 18 patients with ID (7.2% compared to 1% of the general population). The *RYR2* mutations (15 missense and 1 splice site) clustered in the known hot-spot regions. Two mutations have been previously described in patients without reported ID. In 9 out of 14 patients studied (64%) the mutation appeared *de novo*. The severity of ID ranged from mild to severe, and was often accompanied by behavioral disorders including autism and attention deficit hyperactivity disorder. Of note, the majority of patients displayed marked supraventricular and ventricular arrhythmias, with a high incidence (39%) of serious arrhythmic events during follow-up including 3 fatal events.

Conclusions: ID is more prevalent among *RYR2* positive CPVT patients than in the general population, and is associated with a malignant cardiac phenotype.

In order to assist the integration of patient data on rare diseases with tools for statistical analysis, we created advanced form of a patient/variation/symptom database for the use on desktop computers and particularly for installation on a web server. The secured web form of the database is controlled via assignment of individual logins and passwords and security of the data is achieved by fine layering of data access/editing permissions and, at the same time, is adjusted to enable sharing of the data which is a crucial function of the database.
Structure of the underlining MySQL database is designed in the way that each gene is represented by a separate table with patients/variations (rows) and their symptoms (columns), and the content of the tables is called by built-in statistical functions to perform inference. Database administrator is able to add new genes (tables) while the users of the database create new records (rows) of patients/variations and fill in their symptoms. We will present current structure of the user interface of the software and details of the included statistical tools which enable to test hypotheses on subsets of patients and subsets of their variations and symptoms. The current version contains tables for genes with structural functions in the cytoskeleton and nucleoskeleton and patient data including symptoms of diseases like dystrophy, cardiomyopathy, lipodystrophy etc. This work is supported by the Czech Ministry of Industry and Trade (MPO FR TI 3 588) and the Czech Ministry of Education (COST MSMT LD12063).

PS05.77
MCEMP1 expression as a biomarkers of stroke diagnosis and prognosis

K. Raman[1], *M. O'Donnel*[1,2], *G. Pare*[1];
[1]*Population Health Research Institute, Hamilton Health Sciences and McMaster University, Hamilton, ON, Canada,* [2]*National University of Ireland, Galway, Ireland.*

Introduction: Stroke is a leading cause of death and functional disability. A limitation in the current evaluation and treatment of patients with suspected stroke is the lack of a rapid diagnostic test. A blood-based biomarker of acute stroke may expedite stroke diagnosis and prognosis. As such we sought to identify genes expressed in peripheral blood that are associated with (1) stroke, (2) primary stroke type, ischemic or hemorrhagic, and (3) stroke prognosis.
Methods: Stroke cases and controls were recruited from a subset of centers involved in the international INTERSTROKE study. Patients were consecutively assigned to the biomarker discovery cohort (N=302) or validation cohort (N=62). In the discovery cohort transcriptome-wide peripheral blood gene expression was assessed using the Illumina HumanRef-8 v4 bead chip. Significant genes were validated using qPCR in the validation cohort.

Results: Expression of a single gene, MCEMP1, was sufficient to distinguish between stroke cases and controls (FC=2.4, P-value = 8.2 x 10-22, AUC=0.812). MCEMP1 expression also differentiated between ischemic and hemorrhagic stroke cases (AUC=0.783). Furthermore, MCEMP1 expression was significantly associated with one-month outcome, measured as Modified Rankin Score (MRS), after adjustment for available risk factors, primary stroke type and baseline MRS (FC=1.29, P-value = 1.09 x 10-5). Finally the associations between MCEMP1 and stroke and one-month MRS were independently confirmed in the validation cohort.
Conclusion: Peripheral blood expression of MCEMP1 may have utility as a diagnostic test for acute stroke, in distinguishing ischemic stroke from intracerebral hemorrhage and a prognostic biomarker of outcome.

PM05.78
NOTCH3 mutations and risk of young stroke in INTERSTROKE

M. Chong[1], *M. O'Donnell*[1,2], *V. Thijs*[3], *S. Yusuf*[1], *G. Paré*[1];
[1]*Population Health Research Institute, Hamilton Health Sciences, and McMaster University, Hamilton, ON, Canada,* [2]*National University of Ireland, Galway, Ireland,* [3]*Leuven University Hospital, Leuven, Belgium.*

Introduction: CADASIL is a rare Mendelian stroke syndrome due to mutations in the NOTCH3 gene. CADASIL syndrome is characterized by ischemic stroke, migraine, and cognitive impairment in young patients with a family history of stroke. Whether mutations in NOTCH3 or other Mendelian stroke genes are risk factors in young patients unselected for syndromic features is unknown.
Methods: Using exome sequencing, 10 Mendelian small-vessel stroke genes were analyzed in young unrelated stroke cases (mean age: 47.6 years), comprising 100 intracerebral hemorrhage (ICH) and 85 small-vessel ischemic stroke (SVIS), and 185 matched controls from INTERSTROKE, a large international case-control study of stroke.
Results: Canonical CADASIL mutations were exclusive to cases and associated with risk of all stroke (P=0.02), explaining 3.2%, 3%, and 3.5% of all stroke, ICH, and SVIS, respectively. We estimated that CADASIL mutation carriers are at high risk of ICH (OR=9.36; P=0.02) and that the population prevalence of CADASIL is 340 per 100,000 individuals. Non-CADASIL NOTCH3 mutations were also associated with risk of ICH (OR=2.66; P=0.03) and were present in 19% of ICH cases and 8% of controls. Secondary features of CADASIL (migraine, depression, psychiatric disturbances, subclinical infarcts, parental history of stroke) were not more frequent in NOTCH3 mutation carriers as compared to non-carriers. No significant associations were observed for the other 9 genes.
Conclusion: NOTCH3 mutations are important risk factors for ICH in young people. CADASIL mutations pose high risk to ICH and their prevalence may be underestimated. Genetic screening of NOTCH3 should be considered in young stroke patients.

PS05.79
Sudden cardiac arrest and rare genetic variants in the community

E. M. Lodder[1], *M. T. Blom*[1], *A. Milano*[1], *D. A. van Hoeijen*[1], *J. Barc*[1], *T. T. Koopmann*[1], *L. Beekman*[1], *E. van der Schoot*[2], *P. Lichtner*[3], *C. R. Bezzina*[1], *H. L. Tan*[1];
[1]*Academic Medical Centre, Amsterdam, Netherlands,* [2]*Sanquin Research, Amsterdam, Netherlands,* [3]*Helmholtz Zentrum, Technische Universität München, München, Germany.*

Sudden cardiac arrest (SCA) ranks among the most common causes of death worldwide. SCA incidence in the community varies between 0.6 and >1.4 per 1,000 individuals. Because SCA mostly occurs in individuals without previously known cardiac disease, the identification of patients at risk for SCA could save many lives. In unselected SCA victims from the community, common genetic variants (which are not disease-causing per se, but may increase susceptibility to VF) have recently also been associated with increased SCA risk. However, whether rare genetic variants contribute to SCA risk in the community is largely unexplored.
We here investigated the involvement of rare genetic variants in SCA risk at the population level, by studying the prevalence of six founder genetic variants present in the Dutch population (PLN-p.Arg14del, MYBPC3-p.Trp792fsX17, MYBPC3-p.Arg943X and MYBPC3-p.Pro955fsX95, PKP2-p.Arg79X and the Chr7q36 IVF risk-haplotype) in a cohort of 1440 unselected Dutch SCA victims included in the AmsteRdam REsuscitation Study (AREST). The six studied founder mutations were found to be more prevalent, 1.1% carried one of the mutations, in our cohort of SCA patients than in a locally matched reference cohort (0.4%, n=1379, p<0.05) and in publicly available reference variant databases (e.g. the Genome of the Netherlands cohort, GoNL, 0%, n= 500 p<0.02). This finding provides proof-of-concept for the notion that rare genetic variants contribute to SCA risk in the community.

Family follow up and genetic testing in sudden cardiac death with a structurally normal heart

R. mcintyre[1], *I. findlay*[2], *C. Brown*[3], *V. Murday*[2];
[1]*University of Dundee, Dundee, United Kingdom,* [2]*NHS Greater Glasgow and Clyde, Glasgow, United Kingdom,* [3]*University of Glasgow, Glasgow, United Kingdom.*

Aims:
To assess the efficiency of the Familial Arrhythmic Network Scotland (FANS) in following up the families, and to assess the effectiveness of genetic testing, in those who died of sudden cardiac death with a structurally normal heart.
Methods:
We performed an audit of those whose post-mortem reported a cause of death 'SADS' or 'unascertained'. Cases of 'SIDS' were excluded in this study.
Results:
In 27 cases of sudden cardiac deaths since the 01/01/11, there were 125 first-degree relatives. Of these 73 (58%) received an ECG and 53 (42%) received an echo. 21/27 tissues were genetically tested using the routine test panel of KCNQ1, KCNH2, KCNE1, KCNE2, SCN5A and RYR2. Pathogenic mutations were found in 2/21 of cases (SCN5A and RYR2 genes). In the majority of families where no gene mutation was identified, no diagnostic findings were found on clinical investigations. In addition, when these findings were combined with an earlier audit, we also found that in 22/56 (39%) cases, there was evidence in the post-mortem report of non-toxic levels of alcohol consumption around the time of death.
Conclusion:
The yield of pathogenic mutation (10%) was lower than reported literature (15-33%). This may be due to restriction of genes tested. Family follow up of those with a sudden cardiac death was adequate, although could be improved. This audit also highlights the prevalence of recent exposure to alcohol/non-toxic levels of alcohol at time of death in this group, and the role of alcohol in sudden death may merit further investigation.

PS05.81
Low yield of genetic testing for cardiac channelopathy in sudden unexplained infant death

P. Constantinou[1], *D. O'Sullivan*[2], *S. Tennant*[2], *J. H. K. Grieve*[3], *P. Brown*[3], *V. Murday*[4], *A. M. Ross*[1], *J. C. S. Dean*[1];
[1]*North of Scotland Regional Genetic Service, Foresterhill, Aberdeen, United Kingdom,* [2]*Molecular Genetics Department, University of Aberdeen, Foresterhill, Aberdeen, United Kingdom,* [3]*Pathology Department, University of Aberdeen, Foresterhill, Aberdeen, United Kingdom,* [4]*West of Scotland Regional Genetics Service, Glasgow, United Kingdom.*

Introduction: Sudden unexplained infant death (SUDI, death under 12 months without cause on autopsy) accounts for 12.8% of infant deaths in Scotland. Cardiac channelopathy (CC) accounts for an estimated 5% of SUDI. Genetic variant identification in SUDI may have implications for recurrence risk and cascade screening. We present our experiences of genetic testing for CC in SUDI.
Methods: Retrospective analysis of gene testing for CC in SUDI at a single centre over 10 years. Six genes (SCN5A, KCNE1, KCNE2, KCNH2, KCNQ1, RYR2) were screened in all cases.
Results: In total, 24 cases of SUDI were referred; 3 were excluded due to alternative causes of death. Variants were detected in 7 (33.3%); none were conclusively pathogenic. Potential pathogenicity was assigned in two cases, though these variants are present in over 0.1% of 6,500 "normal" individuals in the NHLBI Exome Sequencing Project dataset. First-degree relatives were screened in both cases and no cardiac abnormalities were identified.
Discussion: In this small series, genetic testing did not uncover CC as a cause of SUDI. In contrast, 2/17 cases of sudden unexplained death in 1-5 year olds tested at our centre had pathogenic variants. There are clear difficulties interpreting variants due to conflicting literature evidence and minimal phenotypic data in most SUDI cases. CC is likely a rare cause of SUDI. Next generation sequencing panels may further increase interpretation complexity where variants are detected in little-studied genes. Cardiological investigation of first-degree relatives is essential when counselling families, particularly where variants of unknown significance are identified.

PM05.82

Telomere length and coronary heart disease: a bi-directional Mendelian randomization study

Y. Zhan[1], *R. Karlsson*[1], *A. Tillander*[1], *I. Karlsson*[1], *C. A. Reynolds*[2], *N. L. Pedersen*[1], *S. Hägg*[1];
[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*University California Riverside, Riverside, CA, United States.*

Objective: To assess the bi-directional causal relationships between leukocyte telomere length (TL) and coronary heart disease (CHD) using a Mendelian randomization (MR) approach.**Methods:** Using a genetic risk score (GRS) of seven genetic variants associated with TL (Codd *et al*, 2013) as instrumental variable, we tested whether TL may be causally associated with CHD in two Swedish and one US cohort and, moreover, in summarized genome-wide association study (GWAS) data. Likewise, we examined if CHD may be causally associated with TL using a CHD GRS comprising forty-five variants (CARDIoGRAMplusC4D, 2013) as instrumental variable. **Results:** In observational analysis in our cohorts, we found shorter TL associated with higher risk of CHD incidence [hazard ratio (HR):1.20, 95% confidence interval (CI):1.04, 1.37] and a past CHD event associated with shorter TL (β:-0.07, 95% CI:-0.02, -0.12). TL GRS was associated with TL (β:-0.05, 95%CI:-0.02,-0.08), although its association with ever CHD was not significant [odds ratio (OR):1.01, 95% CI: 0.96, 1.06], nor was the MR analysis (OR: 1.29, 95%CI: 0.49, 3.42). However, the MR estimate from summarized GWAS data indicated causality (OR: 1.26, 95%CI: 1.12, 1.42). We further confirmed a causal effect of a past CHD on TL from summarized GWAS data (β:-0.04, 95%CI: -0.003,-0.08), but not in our own cohorts. **Conclusions:** Significant bi-directional associations between TL and CHD were observed in three cohorts of European ancestry. We further provided evidence for a causal effect of shorter TL on higher risk of CHD and for CHD event on shorter TL from summarized GWAS data.

Genetic determinants of the platelet glycoproteins. Results from the GAIT 2 Project.

M. Vázquez-Santiago[1], *A. Ziyatdinov*[2], *N. Pujol-Moix*[1,3], *J. Úbeda*[4], *J. Nomdedéu*[4], *J. Fontcuberta*[1], *J. Soria*[2], *J. Souto*[1];
[1]*Unit of Haemostasis and Thrombosis, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* [2]*Unit of Genomics and Complex Diseases, IIB-Sant Pau, Barcelona, Spain,* [3]*Deparment of Medicine, Universitat Autònoma de Barcelona (UAB), Barcelona, Spain,* [4]*Department of Laboratory Haematology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.*

Introduction: Platelets play a key role in arterial and venous thrombosis. The glycoproteins (GP) on the platelet surface are involved in the adhesion process, by GP Ib-V-IX complex (CD42a and CD42b) and GP IV (CD36). They are also involved in the aggregation process, by GP IIb-IIIa complex (CD41 and CD61). Therefore, their involvement in thrombosis is very important. Previous studies have identified the genetic *loci* that code for the GP, but the phenotypic variance among individuals due to genetic differences have not been defined.
Materials and Methods: 935 individuals were studied from 35 large Spanish families recruited in the second phase of the GAIT (Genetic Analysis of Idiopathic Thrombophilia) Project. The GP were obtained using platelet-specific immunolabelling and flow cytometry. The fluorescence mean (F) and counts of the positive GP events percentatge (CT) were determined for the CD36, CD41, CD61, CD42a and CD42b. A variance component analysis based on maximal likelihood was applied to quantify the covariates effect, shared environment and genetic factors. Genetic effects were defined as heritability (h^2) which estimates the proportion of the total variability due to genetic factors.
Results: All of the GP parameters had high h^2 (range 0.37-0.71) with strong statistical significance (p-value range $4.48{\cdot}10^{-16}$-$7.44{\cdot}10^{-31}$). CD36CT and CD36F had the highest h^2 (0.71 and 0.61 respectively).
Conclusions: The high heritability of these traits means that genes play a pivotal role in determining the GP density on the platelet surface. Thus, it should be possible to identify specific genes that affect these platelet traits.

A common polymorphism in the promoter of the Tumor Necrosis Factor-α (TNFA) gene mediates postprandial triacylglycerol following sequential meal ingestion

Y. LI[1], *A. Minihane*[2], *J. A. LOVEGROVE*[1], *C. M. WILLIAMS*[1], *K. G. JACKSON*[1], *K. S. VIMALESWARAN*[1];
[1]*UNIVERSITY OF READING, LONDON, United Kingdom,* [2]*UNIVERSITY OF EAST ANGLIA, NORWICH, United Kingdom.*

Tumor necrosis factor-alpha (TNFA) is a proinflammatory cytokine produced from activated macrophages and has been shown to be associated with altered lipid metabolism. Dietary fat plays an important role in inflammatory response, with the level of TNFA reported to be increased following the ingestion of a high-fat meal. However, not all studies have found an association between TNFA and postprandial triacylglycerol concentration (TAG), which could be due to the variations in the *TNFA* gene or meal fat composition. The present study investigated the effect of a common promoter polymorphism, -308G→A (rs1800629), on circulating lipid metabolites, glucose and insulin concentrations over 8 h following sequential high-fat meals in 207 participants (BMI: 25.9±0.2 kg/m^2; age: 52±1 years). Biochemical measurements were determined at baseline and hourly interval following the test breakfast. At the baseline, the GG homozygotes were associated with higher fasting glucose concentration than A-allele carriers (P<0.001). Following the mixed breakfast (49 g fat) and lunch (29 g fat), a significant association was observed between genotype and the incremental area under the time response curve (iAUC) for the postprandial TAG (P=0.03) with a 41% higher TAG iAUC in the GG homozygotes (n=139) (69% of this population) than A allele carriers (n=63), where the genotype explained 18% of such variation. However, the impact of genotype on postprandial TAG was evident only in men (P=0.04). Our findings confirm previous associations and suggest that the *TNFA* -308G→A promoter polymorphism could be an important genetic factor predisposing to the increased level of triglyceride.

Next generation sequencing for congenital vascular malformations

A. Bruson[1], *R. E. Mattassi*[2], *A. Porcella*[3], *S. Benedetti*[1], *S. Cecchin*[1], *M. Bertelli*[1];
[1]*Magi's Lab Human Medical Genetics Institute, Rovereto (TN), Italy,* [2]*Center for Vascular Malformations, Castellanza (VA), Italy,* [3]*Laboratory of clinical Analysis; Clinical Institute Humanitas, Castellanza (VA), Italy.*

Next generation sequencing (NGS) is shedding light on the genetic causes of vascular anomalies and making it possible to combine tests for similar but distinct diseases. Vascular malformations (VMs) are a heterogeneous group of congenital circulatory malformations, characterized by morpho-structural and/or functional defects of various nature, severity and extent. They may occur in any part of the body and any type of vessel (arteries, capillaries, veins and lymphatic vessels). Although most VMs are sporadic (simple or combined), syndromic and familial forms also exist with substantial clinical overlap between lesions, and each can mimic the others.
We designed a 25-gene NGS panel for VMs with Mendelian inheritance (autosomal recessive, autosomal dominant or paradominant). Analysing 128 patients with sporadic congenital VMs, we identified 40 variations in 33 patients (25%). To estimate their pathogenicity, we looked up variations in dbSNP137, compared their frequency using data from the Exome Variant Server, evaluated the effect of protein amino acid substitution by in silico analysis, and also investigated the family if possible. Our results show that many genes can cause a wide variety of syndromic and non-syndromic disorders, confirming that genetic testing by NGS is useful and effective even in sporadic cases. Since the etiopathogenesis of many vascular lesions seems similar to that of tumours, we are screening tissue samples for mutations. Identification of causative genes and the possibility of tracing somatic mutations in tissues could provide important information about disease-free areas, useful for planning surgery to reduce the possibility of relapses.

Acyl-Co dehydrogenase family, member 9 (ACAD9) mutations are a frequent, usually fatal cause of early-onset hypertrophic cardiomyopathy and mitochondrial respiratory chain complex I deficiency in early childhood
Here, we report 7 unrelated patients with mutations in ACAD9. Heart failure or cardiovascular collapsus were the consistent presenting symptom in 7/7 probands. Age at onset ranged from the neonatal period to the first few months-years of life and echocardiography consistently revealed severe hypertrophic cardiomyopathy. At the time of diagnosis, one patient presented with neonatal encephalopathy with white matter anomalies on brain MRI, whereas no extra cardiac involvement was clinically present in 6 patients. The variability in the severity of the disorder was wide. Three patients had severe and rapidly progressive evolution and died before 2 years of age. One

patient recovered spontaneously. 3 patients were proposed for heart transplantation as they had no other organ involvement at the time of diagnosis. Among them, two survived. Most importantly, the 3 living patients latter developed delayed-onset neurologic and muscular symptoms, namely cognitive impairment, seizures, muscle weakness and exercise intolerance. Other organ involvement included proximal tubulopathy, renal failure, secondary ovarian failure or optic atrophy. Yet, while 2 patients enjoyed an almost normal personal and professional adult life, one patient experienced some learning difficulties and required special schooling. This is to our knowledge the first example of successful heart transplantation in ACAD9 mutation. Yet, the decision to carry out organ transplantation remains difficult as delayed neurological symptoms may occur and worsen despite their absence before transplantation.

PM06.02

Novel mutations in mitochondrial aminoacyl-tRNA synthetase genes and their phenotypic expression

E. Ciara[1], *D. Piekutowska-Abramczuk[1], E. Jurkiewicz[1], M. Bekiesińska-Figatowska[2], H. Mierzewska[2], D. Rokicki[1], J. Trubicka[1], P. Halat[1], M. Pronicki[1], M. Litwin[1], L. Ziółkowska[1], K. Chrzanowska[1], D. Jurkiewicz[1], M. Krajewska-Walasek[1], R. Płoski[3], E. Pronicka[1];*
[1]The Children's Memorial Health Institute, Warsaw, Poland, [2]Institute of Mother and Child, Warsaw, Poland, [3]Medical University of Warsaw, Warsaw, Poland.

Mitochondrial aminoacyl-tRNA synthetases encoded by nuclear aaRS2 genes are essential enzymes in the translation of genetic information from mitochondrial DNA to the oxidative phosphorylation system complexes. Recently reported pathological mutations identified in 15 of the aaRS2 genes have been associated with diverse clinical presentations, usually characterized by early-onset and autosomal recessive transmission. Encephalopathy is the most common manifestation. Other clinical features include myopathy with anaemia, cardiomyopathy, tubulopathy and hearing loss. A relatively tight genotype-phenotype correlation has been reported for most of these cases. We report 10 patients, from five unrelated families, with infantile-onset mitochondrial disorder (Nijmegen score >4) and two mutant alleles for EARS2 (p.R55H/p.G109R and p.R55H/p.P419L), FARS2 (p.V345A/p.R419C), PARS2 (p.I80T/p.P364R), and RARS2 (p.Q208*/p.M342I) genes identified by whole-exome sequencing. Among the nine various substitutions, only p.R55H was reported previously. Eight novel mutations segregated with the disease within the families. Moreover, their pathogenic role was determined by using five different prediction algorithms. The characteristic "neurological" phenotype, reported previously, was associated with EARS2, PARS2 and RARS2 defects, however, facial dysmorphism, failure to thrive and icterus revealed in one compound heterozygote for EARS2 mutations (p.R55H/p.P419L). In addition, our patient with Alpers syndrome due to PARS2 mutations confirms genotype-phenotype correlation observed so far in only one child. In the family with heterozygous variants in FARS2 a completely new phenotype, including cardiomyopathy and renal hyperkaliemic acidosis was observed.
In conclusion, novel mutations in four aaRS2 genes expand the list of aaRS2-associated diseases, including new phenotypes potentially related to mutations in FARS2 and EARS2 genes.
This work was supported by the projects: CMHI-134/13, -136/13, -216/12.

PS06.03

A Comparative Assessment of Plasma Peptides, GDF-15 and FGF21, as Biomarkers for Mitochondrial Disease Among Two Biobank Cohorts

K. Nickander, W. Highsmith, R. Gavrilova, D. Gavrilov, K. Raymond, P. Rinaldo, S. Tortorelli, D. Matern, **D. Oglesbee***;*
Mayo Clinic, Rochester, MN, United States.

Background: Recent studies have proposed that transforming growth factor-β superfamily member, GDF-15, and fibroblast growth factor 21, FGF21, might be useful biomarkers for mitochondrial disease. We hypothesized that we could verify the sensitivity and specificity of GDF-15 and FGF21 as plasma biomarkers from our Mitochondrial Disease Biobank of over 300 individuals with a clinical diagnosis or suspicion of mitochondrial disease as determined by clinical, molecular, enzymatic, and/or histological findings.
Methods: Thirty-three participants with confirmed primary mitochondrial disease (MELAS, MERRF, NARP, CPEO,and others) provided EDTA plasma specimens. Age-matched, control plasma for reference ranges were obtained from 120 Mayo Clinic Biobank donors, who did not have a clinical history of diabetes, cardiac, renal, or liver disease. Plasma GDF-15 and FGF21 were measured by ELISA and compared across cohorts.
Results: Mitochondrial disease participants demonstrated plasma GDF-15 (median: 1163 pg/mL; 1st-99th%-iles: 491-6817 pg/mL) and FGF21 (median: 486 pg/mL; 1st-99th%-iles: 211-2816 pg/mL) levels that were higher than the control cohort (GDF-15 median: 423 pg/mL; 1st-99th%-iles: 230-1560 pg/mL and FGF21 median: 394 pg/mL;1st-99th%-iles: 88-1658 pg/mL). Receiver operator characteristic curves of GDF-15 and FGF21 demonstrated that GDF-15 specificity was 88% while FGF21 was only 41%. In addition, participants with MELAS showed higher GDF-15 levels (median: 3290 pg/mL) than any other mitochondrial disease diagnosis (GDF-15 median: 921 pg/mL).
Conclusions: Among two promising biomarkers touting utility for mitochondrial disease, GDF-15 demonstrated better specificity and sensitivity than FGF21. Moreover, the elevations of GDF-15 highlights a putative integrative role for this signal transducer in the pathology of mitochondrial disease.

PM06.04

Gene duplication in congenital adrenal hyperplasia (CAH) complicates genetic counselling

S. J. Kenwrick[1], *I. Berry[2], C. Taylor[1], S. Park[1];*
[1]Addenbrooke's Hospital, Cambridge, United Kingdom, [2]Leeds Genetics Laboratory, Leeds, United Kingdom.

Congenital adrenal hyperplasia (CAH) is an autosomal recessive condition with an incidence of about 1 in 12,000 individuals. Over 90% of cases are due to mutations in the gene for 21-hydroxylase (CYP21A2) and ten mutations account for the majority of those known. The presentation of CAH, classical, simple virilising or non-classical, is related to mutation type.
In recent years it has been recognised that carrier detection can be complicated by rare haplotypes that contain duplicated copes of CYP21A2. Our Italian patient was tested as his partner had already been identified as a carrier for a mutation primarily associated with non-classical CAH. His result showed that he is heterozygous for a classical CAH mutation, p.(Gln319Ter) but also that he has at least 3 copies of the CYP21A2 gene. Gln319Ter is a common CAH mutation associated with a classical to non-classical phenotype depending on mutation combination. However, a rare European haplotype has been described with Gln319Ter in the context of a duplication. Individuals who have this haplotype are therefore not carriers as there is a functional gene in cis. This rare haplotype is in linkage disequilibrium with rare variants, in intron 2 and the 3' untranslated region of CYP21A2, as well as HLA-B50-Cw06 subtype, and has been reported in the Italian population. Accurate preconception, and extended family counselling, requires distinguishing between Gln319Ter in the context of a single CYP21A2 gene or the duplication haplotype, using family studies and additional markers, where possible.

PS06.05

A very common inborn error of carnitine biosynthesis about which little is known

A. L. Beaudet, *R. Kochel, M. Ziats, Y. Yang, S. Elsea, Q. Sun, J. Lupski, A. Patel, T. Gambin, C. Shaw, C. Schaaf, P. Stankiewicz;*
Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States.

Introduction: *TMLHE* deficiency is a very common inborn error of carnitine biosynthesis. The gene is X-linked, and about 1 in 350 healthy males of European descent have a deletion of exon 2 resulting in inability to synthesize carnitine. *TMLHE* deficiency likely is a risk factor for autism, but the penetrance for autism is less than 5%, and replication studies are needed.
Materials and Methods: The frequency of exon 2 deletion was determined in 10,678 male samples undergoing array CGH for evaluation of heterogeneous disabilities and in 2124 male samples from the Baylor Mendelian Genome Center exome project. A case evaluation was performed on a *TMLHE* deficient male with autism and two episodes of regression.
Results: Deletion of exon 2 of *TMLHE* was found in 50 of 10,678 males undergoing array CGH (0.46%) compared to 7 in 2245 males undergoing exome sequencing in the Mendelian studies (0.31%). The phenotypic data for the deficient males are being tabulated. Carnitine deficiency in a *TMLHE* case suggests that deficits in carnitine biosynthesis may be responsible for some cases of regression in individuals with autism.
Conclusions: Deletion of exon 2 is confirmed to be very common in various clinical samples. A case study suggests that carnitine supplementation may be useful in treating regressive autism episodes in patients with *TMLHE* deficiency. It is unknown if infant males with *TMLHE* deficiency should receive any dietary modification. It is unknown if there are genetic, dietary, or microbiome factors that influence the development of autism in *TMLHE* deficient males.

PM06.06

A novel nonsense mutation of the ABHD5 gene causes the early onset of Chanarin-Dorfman syndrome

S. Missaglia[1], *N. Gupta*[2], *S. Gothwal*[2], *A. K. Satpathy*[2], *T. Dipsal*[2], *M. Kabra*[2], *D. Tavian*[1];
[1]*Catholic University of the Sacred Heart, Milan, Italy,* [2]*All India Institute of Medical Sciences, New Delhi, India.*

Chanarin-Dorfman Syndrome (CDS), also known as Neutral Lipid Storage Disease with Ichthyosis (NLSD-I), is a rare autosomal recessive lipid storage disease. This syndrome is characterized by non-bullous congenital ichthyosiform eryhthroderma (NCIE), hepatomegaly and liver steatosis. Additional clinical features include muscle weakness, ataxia and sometimes neurosensory hearing loss, subcapsular cataracts, nystagmus, strabismus and mental retardation. Patients are often born as collodion babies. ABHD5 gene mutations have been identified as the cause of CDS. This gene codifies for the α/β-hydrolase domain-containing protein 5 (ABHD5), a co-activator of the patatin-like phospholipase domain-containing protein 2 (PNPLA2). PNPLA2 is a lipase, associated to the lipid droplets surface, that catalyzes the initial step of triacylglycerols lipolysis. Until now, about 40 different mutations of ABHD5 gene are associated with CDS onset and 15 of them result in truncated proteins.
In a 29-month-old Indian girl we have identified a homozygous nonsense mutation (c.297C>A) of ABHD5 gene, causing the production of a short truncated protein (p.C99X). The little CDS patient presented NCIE, hepatomegaly, diffuse hepatic steatosis and splenomegaly. After the molecular confirmation of CDS diagnosis, she was put on a low fat diet.
Our results show that the early onset of CDS (in Indian patient) is probably due to the production of an ABHD5 protein which loses the putative interacting domain required for PNPLA2 activation. Moreover, an early initiation of a diet poor in long chain fatty acids might improve the liver condition and prevent severe systemic damages.

New genetic insights into the spectrum of disorders of glycosylation: a patient with multiple congenital anomalies

M. M. Oud[1], *N. van Vlies*[2,3], *A. M. de Bruin*[2,3], *R. J. A. Wanders*[4], *S. T. Pals*[2,3], *H. G. Brunner*[1], *J. Cobben*[5], *R. Roepman*[1], *H. Arts*[1,6], *T. W. Kuijpers*[5];
[1]*Radboudumc, Nijmegen, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands,* [3]*University of Amsterdam, Amsterdam, Netherlands,* [4]*Academic Medical Centre, Amsterdam, Netherlands,* [5]*Academic Medical Center University Hospital, Amsterdam, Netherlands,* [6]*University of Western Ontario, London, ON, Canada.*

Introduction: Glycosylation is essential for human development. More than 100 clinically diverse inherited disorders are known to result from glycosylation defects. One subtype of the congenital disorders of glycosylation (CDG) is caused by defects in glycosaminoglycan (GAG) synthesis. Here, we describe an infant from a consanguineous family with a GAG-CDG. Phenotypic features include respiratory insufficiency, discrete skeletal anomalies, renal insufficiency, and T-cell depletion.
Methods: We performed whole-exome sequencing (WES) on patient leucocyte DNA to identify the causative mutation. Immunocytochemistry was conducted to characterize the identified mutations functionally in patient-derived and control fibroblasts. Different GAG levels were measured in fibroblasts and urine from the patient and several controls.
Results: Through WES we detected two homozygous missense mutations in highly conserved regions of two glycosylation genes regulating GAG synthesis and modification. It remains unclear whether mutations in one or both of the genes contribute to the clinical phenotype. We found that one of the mutated proteins that normally localizes to the Golgi apparatus was absent in this organelle in patient cells. Immunocytochemical analysis of the other mutated protein failed. Finally, heparan sulphate GAG levels were significantly reduced in patient-derived fibroblasts, though within the normal range in urine.
Conclusion: We describe an infant with multiple congenital anomalies. WES analysis revealed two mutations in two glycosylation genes. One of the mutated proteins mislocalizes in patient-derived fibroblasts. Our data indicate that this patient has a GAG-CDG.

PS06.09

Distribution of nine most common CYP21A2 point mutations in Macedonian patients with congenital adrenal hyperplasia

V. Anastasovska, *M. Kocova;*
Genetic Laboratory, Department of Endocrinology and Genetics,University Children's Clinic, Skopje, Macedonia, The Former Yugoslav Republic of.

Background: Nine pseudogene-derived point mutations account for about 80% of all defects in the CYP21A2 gene coding the 21-hydroxylase enzyme that deficiency is present in 90-95% of all cases with congenital adrenal hyperplasia (CAH). It can present as severe salt wasting (SW) or simple virilizing (SV) form, or the milder late onset form (LO).
Methods: Using the PCR/ACRS method, we have studied nine CYP21A2 point mutations in 66 Macedonian patients with clinical and laboratory signs of CAH evaluated at Department of Endocrinology and Genetics, University Children's Clinic, Skopje, Republic of Macedonia. Of the CAH patients 25 had SW form, 17 the SV and 24 the LO form of the disease.
Results: Six different mutations were detected in 72.7% alleles of the Macedonian patients. The most prevalent mutation was IVS2, present in 44 alleles (33.3%), followed by the P30L in 26 (19.7%), Q318X in 15 (11.4%), I172N in 6 (4.5%), V281L in 5 (3.8%) and R356W in 3 alleles (2.3%). Del 8ntG110, cluster exon 6 and InsT307 were not found. Mutations were detected in 86% of the SW, 85.3% SV and 50% LO alleles. In 60.6% (40/66) of the Macedonian patients complete genotype was revealed (31 homozygous and 9 compound heterozygous) with good correlation with phenotype. The most common genotype was IVS2/IVS2 (33.9%). Sixteen (24.2%) patients were heterozygotes and 10 (15.2%) harboured none of the tested mutations.
Conclusion: We observed high P30L and Q318X frequencies and low I172N frequency in our population compared to the most of the other European countries.

PM06.10

Subjects treated with migalastat demonstrate stable renal function, reduced left ventricular mass and gastrointestinal symptom improvement in Phase 3 and a long-term extension study of Fabry Disease

D. P. Germain[1], *D. G. Bichet*[2], *R. Giugliani*[3], *D. A. Hughes*[4], *R. Schiffmann*[5], *W. Wilcox*[6], *E. R. Benjamin*[7], *J. P. Castelli*[7], *J. Kirk*[7], *N. Skuban*[7], *J. Yu*[7], *J. Barth on behalf of the FACETS study investigators*[7];
[1]*University of Versailles - St Quentin en Yvelines, Dept. of Medical Genetics, 78180 Montigny, France,* [2]*Université de Montréal Hôpital du Sacré-Coeur de, Montréal 5400, boul, QC, Canada,* [3]*Dept. Medical Genetics Service, HCPA/UFRGS, Porto Allegre, Brazil,* [4]*Royal Free Campus, University College London, London, United Kingdom,* [5]*Baylor Research Institute, Dallas, TX, United States,* [6]*Department of Human Genetics, Emory University, Decatur, GA, United States,* [7]*Amicus Therapeutics, Cranbury, NJ, United States.*

Objectives: Migalastat (1-deoxygalactonojirimycin, AT1001) is an orally-administered investigational pharmacological chaperone for Fabry disease that selectively binds and stabilizes α-Gal A, leading to increased lysosomal activity. Study 011 (AT1001-011, NCT00925301) included a 6-month double-blind placebo-controlled period (Stage 1) and an 18 month open-label extension. Sixty-seven subjects were randomized; 48 subjects completed the study and continued in long term extension Study AT1001-041.
Methods: Estimated GFR (eGFR) was assessed every 3-6 months using the CKD-EPI and MDRD equations. Left ventricular mass index (LVMi) was assessed by echocardiography every 6-12 months by a blinded central laboratory. Gastrointestinal symptoms were assessed every 6 months using the Gastrointestinal Symptom Rating Scale (GSRS). p-values are unadjusted for multiple comparisons. Efficacy results are reported for the 50 subjects with amenable *GLA* mutations.
Results: eGFR remained stable in subjects treated up to 48 months, with mean annualized eGFR changes (±SEM) of -0.80±0.60 (CKD-EPI) and +0.70±0.80 (MDRD) mL/min/1.73m^2/yr. LVMi was significantly reduced in subjects treated up to 48 months (-8.0 ±5.5 g/m^2); the largest reductions were observed in subjects with abnormal LVMi at baseline (-17.2±16.5 g/m^2). Improvement was observed in the diarrhea domain of GSRS during the 6-month double-blind period (-0.3 migalastat, +0.2 placebo, p=0.03), and in diarrhea, indigestion and reflux domains during the open-label extension.
Conclusions: Treatment with migalastat for up to 48 months was associated with stable renal function, reduced LVMi and improved gastrointestinal symptoms in patients with Fabry disease who have amenable GLA mutations.

DNA analysis of familial hypercholesterolemia in Slovakia

D. Balaziova[1], *B. Vohnout*[2], *M. Huckova*[1], *D. Stanikova*[1,3], *J. Stanik*[1,3], *I. Klimes*[1], *K. Raslova*[2], *D. Gasperikova*[1];
[1]*Diabgene and Laboratory of Diabetes and Metabolic Disorders, Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*National Reference Center for Familial Hyperlipoproteinemias, Slovak Medical University, Bratislava, Slovakia,* [3]*First Department of Pediatrics, School of Medicine, Comenius University, Bratislava, Slovakia.*

Introduction: The clinical phenotype of familial hypercholesterolemia (FH) is associated with mutations in genes encoding LDL receptor, apolipoprotein B and PCSK9. The general prevalence of FH in most countries is 1:500,

that accounts for approximately 10 000 patients in Slovakia. However, spectrum of mutations in Slovak patients has not been published previously. The aim was to analyze spectrum of mutations in *APOB, LDLR* and *PCSK9* genes in patients with clinical suspicion of FH.
Materials and Methods: The p.Arg3527Gln mutation in *APOB* gene was tested by real-time PCR. The mutations in *LDLR* and *PCSK9* genes were analyzed by Sanger sequencing. The large rearrangements in *LDLR* were assessed by MLPA analysis.
Results: Out of 136 probands and 103 relatives, we have confirmed the presence of *APOB* mutation p.Arg3527Gln in 9 probands and 2 relatives, respectively. In remaining 127 probands and 101 relatives, the presence of pathogenic mutation in *LDLR* was confirmed in 58 probands and 49 relatives. All together, we have identified 41 mutations and 9 new variants in *LDLR* gene. Their potential pathogenicity predicted by *in silico* analysis was confirmed by cosegregation analysis in given families. Direct sequencing of *PCSK9* gene revealed no pathogenic mutation.
Conclusions: By DNA diagnostics, the clinical diagnosis of FH was confirmed in 49.3% probands and 49.5% of relatives. The high incidence of mutations in the genes analysed in our study emphasise the importance of genetic testing for targeted treatment and prevention in families with FH in Slovakia.

PM06.12
Mutation spectrum in German patients with familial hypercholesterolemia

T. Grenkowitz[1], U. Kassner[1], W. März[2,3,4], P. Binner[2], E. Steinhagen-Thiessen[1,5], **I. Demuth**[5,6]*;*
[1]Charité-Universitätsmedizin Berlin, Lipid Clinic, Berlin, Germany, [2]Synlab Center of Laboratory Diagnostics, Heidelberg, Germany, [3]Medical Clinic V (Nephrology, Hypertensiology, Endocrinology, Diabetolgy, and Rheumatology), Mannheim Medical Faculty, University of Heidelberg, Mannheim, Germany, [4]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria, [5]The Berlin Aging Study II; Research Group on Geriatrics; Charité – Universitätsmedizin Berlin, Berlin, Germany, [6]Institute of Medical and Human Genetics, Charité – Universitätsmedizin Berlin, Berlin, Germany.

Autosomal-dominant familial hypercholesterolemia (ADH) is characterized by elevated plasma levels of low-density lipoprotein cholesterol (LDL-C) and a dramatically increased risk to develop cardiovascular disease (CVD). The prevalence of ADH is about 1:500, with a higher frequency because of founder effects in some populations. Mutations in three major genes have been associated with ADH: LDL receptor gene (LDLR), apolipoprotein B gene (APOB) and proproteinconvertase subtilisin/kexin 9 gene (PCSK9).
We investigated the mutation spectrum in 120 patients (51% females) clinically diagnosed with possible or probable ADH. We sequenced the coding region of the LDLR gene followed by sequencing the site of the major disease causing mutation in the APOB gene, c.10580G>A (p.Arg3527Gln) and, finally, sequencing of the PCSK9 coding region,.
Pathogenic mutations were identified in 53 patients (44%) in one of the analysed genes. As expected, most of the mutations were identified within the LDLR gene (about 90%). Heterozygous missense mutations in the APOB gene were detected five patients and no mutation in the PCSK9 gene was found.
In 48 patients we detected a total of 51 LDLR mutations. 33 of the patients showed missense mutations. In addition we identified 6 small deletions (≤20 nucleotides), 5 slice-site mutations and 7 nonsense mutations. Three of the 48 patients were probable compound heterozygous. Six of the mutations identified have not been described before.
The results of the mutation screening will be presented together with phenotypic data and will be discussed with respect to previous data on German ADH mutations and phenotype-genotype correlations.

PS06.13
Acid ceramidase deficiency: clinical implications of an emerging spectrum and potential therapies

A. Solyom[1,2]*, C. Simonaro[3], X. He[3], E. Schuchman[3];*
[1]University of Mainz, Mainz, Germany, [2]University of Pecs, Pecs, Hungary, [3]Icahn School of Medicine at Mt. Sinai, New York, NY, United States.

Mutations in the ASAH1 gene lead to acid ceramidase deficiency, the resultant accumulation of the lipid ceramide, and a distinct variety of disease phenotypes, culminating in two recognized diseases: Farber disease and Spinal Muscular Atrophy with Progressive Myoclonic Epilepsy (SMA-PME). Farber disease represents a broad clinical spectrum presenting from infancy through late childhood, associated with the pro-inflammatory and pro-apoptotic characteristics of ceramide. SMA-PME, a late childhood onset, primarily neurologic disease, has been less well characterized to date, and the pathophysiologic mechanisms underlying the clinical manifestations are the subject of ongoing study. The prevalence of both diseases is currently unknown and awareness of them is limited due to their rarity; both are likely underdiagnosed.
We have collected data on over 20 living Farber patients, the largest cohort to date, including data on biochemical and immunologic phenotypes. Our findings reinforce the validity of the characteristic symptoms of Farber disease: early-onset polyarticular arthritis, subcutaneous nodules and dysphonia. However, it also reveals that there are patients who present with only one or two of these symptoms, and that the spectrum of disease includes remarkably attenuated forms with relatively little associated disability. We feel there is an indication for diligent screening of certain pediatric (and even young adult) polyarticular arthritis patients for Farber disease, and certain therapy-resistant epilepsy patients for SMA-PME. Such screening is being initiated and natural history studies are planned in both diseases.
Recombinant human acid ceramidase enzyme therapy is currently under development and is expected to enter clinical trials in 2016.

PM06.14
Development of a cell-based approach to identify small molecules as regulators of FGF23 signalling

S. Diener[1]*, K. Schorpp[2], B. Lorenz-Depiereux[1], K. Hadian[2], T. M. Strom[1,3];*
[1]Helmholtz Zentrum München, German Research Center for Environmental Health, Institute of Human Genetics, Neuherberg, Germany, [2]Helmholtz Zentrum München, German Research Center for Environmental Health,Institute of Molecular Toxicology and Pharmacology, Neuherberg, Germany, [3]Klinikum Rechts der Isar der Technischen Universität München, Institute of Human Genetics, Munich, Germany.

Fibroblast growth factor 23 (FGF23) is a key regulator of phosphate homeostasis. It plays a critical role in hereditary and acquired hypo- and hyperphosphatemic disorders. Moreover, FGF23 has emerged as a promising biomarker for the prediction of adverse clinical outcomes in patients with chronic kidney disease (CKD), since it might be related to mortality, cardiovascular abnormalities and disease progression. FGF23 is a bone-derived endocrine factor that regulates renal tubular phosphate reabsorption and vitamin D metabolism by activating FGF receptor (FGFR)/Klotho complexes in the kidney. Mitogen-activated protein kinase (MAPK) pathway is employed as a major signalling pathway. To investigate the molecular mechanisms underlying FGF23 actions in more detail, we established a cell model of FGF23-inducible cells stably expressing Klotho (HEK293-KL cells). The FGF23-mediated induction of HEK293-KL cells was shown by detecting the activation of MAPK pathway, which could be reduced by the use of two known small-molecule inhibitors of this pathway: SU5402 and U0126. Based on our established cell model, reporter assays suited for high-throughput screening (HTS) were developed to identify novel small-molecule compounds that modulate FGF23 signalling. In a pilot screen, robustness and appropriateness of the method could be verified. The discovery of candidate hits would provide the basis to manipulate FGF23 signalling and would potentially validate this pathway as druggable in disorders caused by altered actions of FGF23.

PS06.15
Four cases of gangliosidosis GM1 with prenatal onset in a consanguineous family

E. GORDUZA[1]*, C. Rusu[1], L. Butnariu[1], E. Braha[1], M. Stamatin[1], A. Petrariu[2], V. Martiniuc[2], A. Bivoleanu[2];*
[1]UNIVERSITY OF MEDICINE AND PHARMACY IASI, 6600 IASI, Romania, [2]"Cuza Vodă" Maternity Iasi, 6600 IASI, Romania.

We present four cases of gangliosidosis GM1 in a consanguineous family from gipsy minority. The first case is a 6 months girl (born in 2007) with coarse facies, periorbital oedema, broad nasal bridge, bulbous nose, short neck, hepatosplenomegaly, muscular hypotonia, psycho-motor disability. The girl died at 11 months. Second case (I degree cousin with first case) is a 3 weeks girl (born in 2008) with delayed weight and height development, coarse facies, periorbital oedema, broad nasal bridge, bulbous nose, macroglosia, retrognathia, low set years, short neck, sacral dimple, thymus hypertrophy, cardiomegaly, hepatomegaly, splenomegaly, muscular hypotonia and psycho-motor disability. This girl died at 10 months. The last couple have a normal girl and other two affected children a boy born in 2012 and girl born in 2015. Both were diagnosed in neonatal period, after pregnancies with ascites and hepatomegaly. Both presented: coarse facies, generalised oedema, broad nasal bridge, bulbous nose, macroglosia, retrognathia, low set years, short neck, cardiomegaly, hepatosplenomegaly, muscular hypotonia. The boy presented a huge scrotal oedema. In the 4th child of couple were found corpuscles Alder-Reilley and a 0,004 nmol/spot level of -galactasidasis. The baby died at age of 8 months. In all cases the genetic analysis was impossible. We made the genetic counselling, but for religious and low level

of education reasons, the couple don't take in account the risk. We consider that in this family could be useful to identify the mutation in the last affected child and search the same mutation in other risk's individuals.

PM06.16

Delineation of a poorly studied type of bone crisis in patients with type 1 Gaucher disease: bone crises of the small bones of the hands and feet

H. Baris Feldman[1], **M. Weisz Hubshman**[2,3,4];
[1]The Genetics Institute, Rambam Health Care Campus, Haifa, Israel, [2]Schneider Children's Medical Center of Israel, Petah Tikva, Israel, [3]2The Raphael Recanati Genetics Institute, Rabin Medical Centre, Petah Tikva, Israel, [4]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

Background: Type 1 Gaucher disease is the most common form of Gaucher disease, an inherited lysosomal storage disorder affecting around one in every 40,000-60,000 people in the general population and approximately one in every 800 people of Ashkenazi Jewish origin. Bone crises in type 1 Gaucher disease are reported in long bones, in weight bearing bones and other bones, but rarely in the small bones of the hands and feet.
Method: We retrospectively examined the incidence of bone crises, including small bone crises, in patients followed at the Rabin Medical Centre, Petah Tikva, Israel, before and following the initiation of imiglucerase enzyme replacement therapy (ERT).
Results: Of 100 type I Gaucher disease patients, 30% experienced one or more bone crises. Small bone crises represented 31.5% of all bone crises and were preceded by crises in other bones. While the incidence of long bone crises decreased after the initiation of ERT, the incidence of small bone crises increased. Almost 60% of all patients with bone crises were of the N370S/84GG (representing only 30% of the cohort) suggesting a greater susceptibility of N370S/84GG patients to severe bone complications. These patients also underwent the greatest number of splenectomies (70.6% of all splenectomised patients) consistent with a more severe disease phenotype. Patients who underwent splenectomy showed a trend towards increased bone crises after surgery. **Conclusion**: Physicians should be aware of the possibility of bone crises in the hands and feet and should consider imaging studies to investigate unexplained pain in the hands and feet.

PS06.17

Association of PTPN22 gene functional variant C1858T, HLA-DQ alleles and autoantibodies with Type-1 Diabetes Mellitus in Kuwaiti children

M. Z. Haider[1], *M. A. Rasoul[1,2], S. A. Mathews[1], H. Al-Kandari[3], M. Al-Mahdi[4], J. Sukumaran[1], G. S. Dhaunsi[1];*
[1]Kuwait University, Safat, Kuwait, [2]Mubarak Al-Kabeer Hospital, Jabriya, Kuwait, [3]Farwania Hospital, Farwania, Kuwait, [4]Adan Hospital, Adan, Kuwait.

An interplay between susceptibility genes, immune mediators and environmental factors predispose susceptible individuals to T1DM. We have determined the prevalence of PTPN22 gene C1858T functional variant, HLA-DQ alleles and three autoantibodies in Kuwaiti children with T1DM. This study included 191 Kuwaiti children with TIDM and 101 controls (healthy, ethnically matched). The diagnosis of T1DM was based on the ISPAD criteria. The genotypes for PTPN22 gene variant C1858T (R620W) were identified by PCR-RFLP. HLA-DQ alleles were determined by sequence-specific PCR in 178 patients. The presence of autoantibodies (ICA, INS and GAD) were determined by radioimmunoassay. The variant genotype of the PTPN22 gene was detected in homozygous/heterozygous combination in 39% patients compared to 27% in controls. The homozygous TT-genotype was detected in 8% patients compared to 0.99% in controls ($p < 0.001$). Nine different combinations of HLA-DQ alleles were detected in patients. In 55% patients, the genotype was either homozygous for DQ2 or in combination with a DQ8 allele. In 36% patients, the genotype was homozygous DQ8 or with other alleles. Collectively, 91% of the patients had either DQ2 or DQ8 alleles. In patients with TT-genotype of PTPN22 gene, 93% had at least one DQ2 allele and 60% carried either a DQ2 or a DQ8 allele. In T1DM patients with TT-genotype, GAD autoantibody was detected in 83%, INS-Ab in 67% and ICA-Ab in 54% cases respectively. Our data demonstrate that the variant T-allele of PTPN22 gene and HLA-DQ2/DQ8 alleles constitute significant determinants of genetic predisposition to T1DM in Kuwaiti Arabs.

PM06.18

International datasharing of Exome sequencing results for the clinical delineation of extremely rare disorders: example of autosomal recessive mutations in GFER

S. Nambot[1,2], *J. Thevenon[1,3,4], D. Gavrilov[5,6], A. Beaudet[7], M. Bainbridge[8], C. Goizet[9], N. Niu[7], F. Xia[7], A. Bruel[2,4], J. Saint-Onge[2,3,4], Y. Duffourd[3,4], C. Thauvin-Robinet[1,3,4], J. Rivière[2,3,4], L. Faivre[1,3,4];*

Introduction: A family with 2 affected sibs presenting with congenital cataract, progressive muscular hypotonia, hypotrophy, and psychomotor delay followed by severe neurological regression associated with seizures was followed up for several years. The oldest sibling died at age 21 years, and her brother displays severe encephalopathy with cachexia. Along this diagnostic odyssey, a mitochondrial condition was suspected after morphological analysis of a muscle biopsy, exhibiting rare COX-negative fibers. Whole exome sequencing (WES) detected autosomal recessive truncating mutations in *GFER*. This gene has already been assigned in human pathology in three siblings born to healthy consanguineous Moroccan parents (Di Fonzo et al., 2009). The siblings carried a homozygous missense mutation in *GFER*, and presented a very similar phenotype including congenital cataract, progressive muscular hypotonia, sensorineural hearing loss, developmental delay, scattered COX-negative muscle fibres with moderate reduction of complex IV activity.
Material and Methods: Through an international data sharing, another family with two siblings has also been identified, also presenting with bilateral cataracts, global developmental delay, lactic acidosis, and increased mitochondrial DNA copy number. Similarly, the diagnostic approach in this family was WES.
Results: These 7 cases issued from 3 families strongly support the existence of a new recognizable mitochondrial disorder associating progressive encephalo-myopathy with congenital cataract secundary to autosomal recessive mutations in the *GFER* gene.
Conclusions: This report highlights the clinical utility of WES in rare diseases and underlines the importance of a broad data sharing for an accurate interpretation of previously unrecognised clinical entities.

PS06.19

Molecular Investigation of Glutaric Aciduria Type1 in Iran

B. Shokrolah nasab, *M. Houshmand, O. Aryani, Z. Pirzadeh, F. Ghasemi, S. Salehpour; National Research Center forGenetic &Biotechnology, Tehran, Iran, Islamic Republic of.*

Glutaric Acidemia, Type I (GA I), was first described in 1975. The disease is caused by a genetic deficiency of the enzyme, Glutaryl-CoA Dehydrogenase (GCD), which leads to the buildup of Glutaric acid in the tissues and its excretion in the urine of affected patients. GA I is one of the most common organic acidemias and has an estimated incidence of about 1 in 50,000 live births. Because of the initial slow progression of clinical symptoms, GA I is frequently undiagnosed until an acute metabolic crisis occurs A total of 25 unrelated patients suspected to GA1 were investigated in our study. Genomic DNA was extracted from peripheral blood cells of the 25 probands whom were biochemically and/or clinically and/or neuro-radiologically suspected to GA1. 15 of them had elevated glutaric acid in the urine organic acid test. PCR and direct sequencing of all 11 exons and their flanking region of the GCDH gene were examined.Some of them were investigated for known mutation in the other therir family members..Fifteen patients had homozygous mutations and 10 patients were normal for GCDH gene. Our Results Showed:• 60% Known mutation were found in our 15 patients• 80% can be detected by 4 exons sequencing so for molecular investigatins exon 6, 7, 8, 10 are good choice for beginning of analysis• 33% was mutation in exon 7, so because of the cost of genetic diagnosis we suggest that investigation begin with this exon.• Pro 348 Leu was most detected 20%.• 40% are new mutations wich will be investigated for phenotype Genotype Correlations

PM06.20

GENETIC ANALYSIS OF GLYCOGEN STORAGE DISORDERS BY MASSIVE PARALLEL SEQUENCING

C. Medrano, A. Vega, R. Navarrete, F. Leal, L. Desviat, P. Rodríguez-Pombo, M. Ugarte, C. Perez-Cerda, **B. Pérez**;
Centro de Diagnóstico de Enfermedades Moleculares. CIBERER. IdiPAz., Madrid, Spain.

Glycogen storage disease (GSD) is a group of genetic disorders resulting from an abnormal metabolism of glycogen. Currently 22 different types of GSD are known. The nonspecific clinical picture and the lack of specific biomarkers hamper diagnosis being DNA methods the gold standard for successful diagnosis. Nevertheless the cost and time consuming gene by gene Sanger sequencing has made difficult to achieve successful diagnosis and many GSD patients in our country remain without definitive diagnosis. Here, we report the genetic analysis in a cohort of 31 Spanish patients referred to our laboratory. We have diagnosed 12 patients by conventional Sanger sequencing of genes associated with the clinical history and in the last year, 15 by massive parallel sequencing with a customized panel or clinical exome sequencing. Overall GSD type III (AGL gene) and GSD IXa (PHKA2 gene) were the most frequent GSD deficiencies accounting for close to 75% of the GSD patients. The mutational spectrum includes 29 different mutations, 14 novel, most of them loss-of-function mutations. By clinical exome sequencing analysis we have diagnosed four further patient with mutations, ALDOB, LIPA, NKX2-5 and CPT2, not related to GSD but with shared phenotypic characteristics such as liver, muscular and cardiac dysfunction. This study shows that next generation sequencing is an accurate high throughput method for the genetic diagnosis of Glycogen Storage Disease and other related clinical diseases of genetic origin enabling appropriate therapeutic and genetic counselling.

PS06.21
Homozygosity mapping using SNP microarray as a useful diagnostic tool in consanguineous populations

L. Cohen[1], N. Orenstein[2], M. Weisz- Hubshman[2], I. Maya[1], D. Behar[1], S. Kahana[1], T. Tene[1], M. Feingold-Zadok[1,3], M. Shohat[1,4], **L. Basel-Vanagaite**[1,4]*;*
[1]The Raphael Recanati Genetics Institute, Rabin Medical Center, Beilinson Hospital, Petah-Tikva, Israel, [2]Genetics Unit, Schneider Children Medical Center, Petah-Tikva, Israel, [3]Genetics Institute, Assaf Harofeh Medical Cente, Zerifin, Israel, [4]Sackler School of Medicine,Tel Aviv University, Tel Aviv, Israel.

Introduction: Consanguinity increases the coefficient of inbreeding and the likelihood of the presence of pathogenic mutations in homozygotic state. An SNP-based microarray is a useful tool not only for studying copy number variants but also for the detection of uniparental disomy and regions of homozygosity (ROH) throughout the genome. Evaluation of ROH can guide medical geneticists to focus on a single specific gene in order to achieve molecular diagnosis in families with common parental ethnic background or consanguinity. In addition, ROH analysis can eliminate genes as possible candidates in highly heterogeneous recessive conditions.
Methods: We describe six cases in which analysis of SNP-based microarrays (Illumina HumanOmniExpress-24 v1.0 BeadChip) has assisted us reaching molecular diagnosis in consanguineous families by sequencing a single candidate gene that was localized within homozygosity region.
Results: We identified a disease-causing mutation in all the families. All the genes are related to metabolic or neurological disorders and include: CRLF1 (Crisponi syndrome/CISS1 syndrome), PHKG2 (Glycogen storage disease IXc) NPC1 (Niemann-Pick C disease), MPV17 (hepatocerebral mitochondrial DNA depletion), MAN2B1 (Alpha-mannosidosis), and MOCS2 (Molybdenum cofactor deficiency).
Conclusions: These examples demonstrate the great diagnostic value of SNP microarray in deciphering molecular defect in consanguineous families by minimizing the need for massive parallel sequencing and reducing the cost of the molecular work-up.

PM06.22
Impaired mitochondrial RNA processing in HSD10 disease

A. J. Deutschmann[1], *A. Amberger[1], J. A. Mayr[2], S. Oerum[3], W. W. Yue[3], J. Zschocke[1];*
[1]Division of Human Genetics, Innsbruck, Austria, [2]Paracelsus Medical University Salzburg, Salzburg, Austria, [3]University of Oxford, Oxford, United Kingdom.

Introduction: Missense mutations in the 17ß-Hydroxysteroid dehydrogenase type 10 gene (*HSD17B10*) result in HSD10 disease, a rare X-chromosomal childhood disorder mainly characterized by psychomotor regression and cardiomyopathy. HSD10 is part of the mitochondrial RNase P enzyme complex required for 5`-end cleavage of mitochondrial precursor tRNA´s. Here, we analyzed whether *HSD17B10* mutations are linked to RNase P deficiency.
Methods: Expression of RNase P proteins was analyzed by Western blots. Real-time RT-PCR and Northern blot analysis were performed to quantify mt-tRNA processing in HSD10 knock-down cells, patient (R130C and Q165H) and control fibroblasts.
Results: HSD10 protein expression was strongly reduced in fibroblasts with mutation p.R130C which was associated with low expression of MRPP1 protein, an essential component of the RNase P complex. Knock-down experiments further revealed that expression of HSD10 is necessary for normal MRPP1 expression. Mutation p.Q165H shows equal amounts of HSD10 and MRPP1 protein than controls. Transcript analysis demonstrated that reduced HSD10/MRPP1 expression resulted in an accumulation of precursor transcripts of mitochondrial heavy strand RNA. Furthermore, in fibroblasts with mutation p.Q165H mitochondrial RNA processing was equal than in controls. This finding correlates well with the observed phenotype in patients with mutation p.Q165H who exhibit normal development. Interestingly, processing of light strand transcripts was not affected in patient cells.
Conclusion: Our results indicate that HSD10 plays a crucial role in the HSD10/MRPP1 complex formation, and loss of HSD10 results in impaired mitochondrial tRNA processing of heavy strand transcripts. The findings provide a novel explanation for mitochondrial dysfunction observed in HSD10 disease.

PS06.23
Pharmacogenetics in channelopathies causing congenital hyperinsulinism in Slovakia

L. Valentínová[1], *J. Staník[2,1], M. Hučková[1], M. Škopková[1], M. Rosoľanková[3], D. Staníková[2,1], L. Tichá[2], Slovak Congenital Hyperinsulinism Study Group, D. Gašperíková[1], I. Klimeš[1];*
[1]Diabgene & Diabetes Laboratory, Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia, [2]First Department of Pediatrics, Faculty of Medicine, Comenius University, Bratislava, Slovakia, [3]Department of Intensive Care in Neonatology, Faculty of Medicine, Comenius University, Bratislava, Slovakia.

Congenital hyperinsulinism (CHI) is the most common cause of the persistent hypoglycaemia in children. Mutations in KCNJ11 and ABCC8 genes coding potassium channel subunits are major cause of CHI development in newborns. The type of B-cell hyperplasia (focal or diffuse) depends on the type of mutation and determines diagnostics, treatment and further prognosis. This study aimed to evaluate genetic cause of severe hypoglycaemia and recommend an appropriate therapeutic approach in particular cases.
Patients and Methods: For genetic testing 14 unrelated probands with congenital hyperinsulinism were reffered over the ten years (2005 - 2014) throughout Slovakia. For molecular diagnosis of the disease, direct sequencing of ABCC8 and KCNJ11 genes was carried out.
Results: We found mutations in ABCC8 or KCNJ11 in 36% (5/14) of patients. We identified two paternaly inherited ABCC8 mutations (Q444H and c.2694+1G>C) in two diazoxide-unresponsive patients with focal form of CHI. Subsequently, both patients underwent pancreatic surgery to reduce B-cell mass. Another two paternaly inherited mutations were found in two diazoxide sensitive patients, one novel in KCNJ11 (T180N) and another known in ABCC8 gene (V17A). Compound heterozygote KCNJ11 mutations (Q52*, R30G) were identified in a 4-months old boy with severe diazoxide-unresponsive hypoglycaemia. Based on this results treatment with octreotide was started. Finally, the combination of octreotid with frequent feedings through a gastrostomy led to normalization of glycaemia.
Conclusion: Taken together, we have resolved etiology in 36% CHI cases, which helped to choose the most appropriate therapeutic procedure.

Dual genome investigation in Leber Hereditary Optic Neuropathy

C. Ribeiro[1], J. Pratas[1], M. J. Santos[1], M. Simões[1], C. Mendes[1], M. C. Macário[2], L. Diogo[2], P. Garcia[2], P. Fonseca[2], E. Silva[3], L. J. Wong[4], **M. Grazina**[3,1]*;*
[1]CNC - Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal, [2]CHUC - Coimbra Hospital and Universitary Centre, Coimbra, Portugal, [3]Faculty of Medicine, University of Coimbra, Coimbra, Portugal, [4]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States.

Leber hereditary optic neuropathy (LHON) is a maternally inherited mitochondrial disorder characterized by retinal ganglion cell degeneration leading to acute bilateral loss of central vision, particularly affecting young adult males. LHON has a negative detrimental impact for the quality of life and it is by far the most common mitochondrial genetic OXPHOS disease.
According to literature, the majority of LHON patients with mitochondrial DNA (mtDNA) mutations harbor one of three primary point mutations (90-95%): m.3460G>A, m.11778G>A and m.14484T>C.
A sample of 10 patients suspected of LHON, followed at the Ophthalmology and Neurology Departments of CHUC, was studied (2 females and 8 males: age mean±SD: 35±15 years). Total DNA was extracted from peripheral blood and muscle. Analysis of mtDNA and 513 nuclear genes related to mitochondrial disorders was performed by next generation sequencing (NGS).
The typical LHON mtDNA mutations were found in 5 patients: 3 with m.11778G>A, 1 having m.14484T>C and 1 with m.3460G>A.
The nuclear DNA (nDNA) analysis revealed that 8 samples have alterations, all heterozygous, with a predictable functional impact, according to in silico

analysis; the majority of these alterations (9) are novel. All affected genes are related to mitochondria network reinforcing the communication between the two genomes, but this issue must be further investigated.
This study was financed by Foundation for Science and Technology (PTDC/DTP-EPI/0929/2012 and PEst-C/SAU/LA0001/2013-2014).

LHON/MELAS overlap syndrome in a girl with complex I deficiency caused by very rare mtDNA mutation m.13046T>C

H. Kolarova[1], *M. Tesarova[1], H. Hansikova[1], P. Liskova[2], O. Ulmanova[3], M. Forgac[3], J. Zeman[1], T. Honzik[1];*
[1]Department of Paediatrics and Adolescent Medicine, First Faculty of Medicine and General University Hospital at Charles University in Prague, Prague, Czech Republic, [2]Laboratory of the Biology and Pathology of the Eye, Institute of Inherited Metabolic Disorder, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic, [3]Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic.

LHON and MELAS syndrome are mitochondrially-inherited diseases characterized by subacute visual failure and variable multisystemic presentation, respectively. We present a unique case of LHON/MELAS overlap syndrome in a 13-year-old girl with genetic background previously described in one patient with MELAS/Leigh syndrome.
Results: A firstborn girl of healthy, unrelated Caucasian parents was born after uneventful pregnancy and delivery. Patient´s mother and two younger brothers are clinically healthy, but the mother suffered from two misscarriages. The disease manifested at the age of 12 years with an abrupt, painless and simultaneous loss of vision with a subsequent stabilization two months later. The ophtalmologic examination documented visual acuity of 0.6/20 (O.S.) and 4/20 (O.D); the perimetry objectified a bilateral caecocentral scotomas. Over the next months, the girl developed a moderate sensorineural hearing loss, vertigo, headache, anhedonia and thyroiditis. There was no Leigh syndrome or postictal changes on brain MRI. Initial genetic analyses excluded all three LHON prevalent mutations in mtDNA. Extensive metabolic workup documented elevated CSF lactate of 4.25 mmol/l (C in ND5 subunit (urine 71%, muscle 70%, hair follicles 44%, fibroblasts 40%, buccal smear 34% and blood 27%). Surprisingly, the mutation was not detected neither in patient´s mother nor her two younger brothers.
Discussion: We report the second known patient with m.13046T>C mutation. Based on a combination of clinical symptoms, we concluded the condition as LHON/MELAS overlap syndrome. Institutional support was provided by IGA NT 14156/3, IGA NT 13114/4, RVO-VFN 64165/2012, GAUK 38515/2015.

The University of Texas at Austin, Austin, TX, United States, [2]OWL Metabolomics, Derio, Spain, [3]CIC bioGUNE, Derio, Spain, [4]CIBERehd, Barcelona, Spain, [5]Ikerbasque, Basque Foundation for Science, Bilbao, Spain, [6]INSERM, U872, Nutriomique; Université Pierre et Marie Curie-Paris, Centre de Recherche des Cordeliers, Paris, France, [7]ICAN Institut Cardiométabolisme et Nutrition, Paris, Pitié-Salpêtrière Hospital, Paris, France, [8]CRNH-Ile de France, Paris, France, [9]INSERM U895, Team 8 „hepatic complications of obesity", University of Nice, Nice University hospital, Nice, France, [10]Liver Research Unit, Hospital Universitario Santa Cristina, Madrid, Spain, [11]Liver Unit, Hospital Clinic, Barcelona, Spain.

The etiology of nonalcoholic fatty liver disease (NAFLD) remains poorly understood. Several molecular mechanisms have been proposed to explain how steatosis progresses to nonalcoholic steatohepatitis and hepatocellular carcinoma. One of them is altered methionine metabolism, which is coupled to the folate biosynthetic pathway.
Herein, we report a multicenter association study of 756 biopsy-proven NAFLD patients and controls, which together with various functional approaches allowed us to describe the role of the *solute carrier family 19 (folate transporter) member 1* (*SLC19A1*) gene in the development of NAFLD.
Two (one missense) out of the three studied SNPs within *SLC19A1* showed a significant association ($p<10^{-3}$) with NAFLD for the single-marker allelic test. In addition, minor homozygous genotypes were related to NAFLD clinical features such as body-mass-index and serum levels of triacylglycerol (TAG) and transaminases.
The functional role of *SLC19A1* was studied *in vitro* using shRNA-gene-knockdown technologies in THLE2-cells, which caused intracellular folate content 4-fold lower than in the wild type-cells. Furthermore, the lack of functional *SLC19A1* significantly altered the expression of critical genes leading to spontaneous lipid droplet accumulation within cells. Lipidomic analyses showed that the most abundant stocked lipids were TAG and cholesteryl-ester species (the main known components of intracellular lipid droplets) as well as polyunsaturated fatty acids.
We can conclude, for the first time, that genetic variants of *SLC19A1* are associated with NAFLD, and that the failure of this gene dysregulates critical genes for normal liver function, causing low intracellular folate levels and increased lipid accumulation.

PS06.27

Identification and characterisation of novel GLA mutations in Fabry disease

J. Lukas[1], *S. Scalia[2], A. Pockrandt[1], S. Eichler[3], A. Giese[1], G. Duro[4], A. Rolfs[1];*
[1]Albrecht-Kossel-Institute for Neuroregeneration, Rostock, Germany, [2]Institute of Biomedicine and Molecular Immunology "A. Monroy" (IBIM), Palermo, Italy, [3]Centogene AG, Rostock, Germany, [4]Institute of Biomedicine and Molecular Immunology "A. Monroy" (IBIM), Palermo, Germany.

Fabry disease (FD) is a rare, progressive, metabolic disorder of glycosphingolipid storage and is caused by mutations in the gene encoding the lysosomal hydrolase α-galactosidase A (GLA). In males, the disease usually leads to a classic spectrum of symptoms including cardiomyopathy, nephropathy, acroparaesthesia, cornea verticillata and gastrointestinal problems and, eventually, myocardial infarction, renal failure or stroke. Certain circumstances complicate the diagnosis of the disease. (1) The X-linked inheritance mode causes female heterozygotic mutation carriers to develop symptoms that are commonly milder and do not comprise the whole spectrum. (2) Mutations that do not completely abolish α-galactosidase A (AGAL) function usually manifest with milder disease.
In collaboration with Centogene AG/Rostock we frequently detect new variants where the clinical significance is unclear (VUS). We utilize cell culture-based over-expression of the mutant cDNAs in order to objectify the disease potential of the variants by their in vitro enzyme activity.
We introduce outline data for 25 patients harbouring novel GLA mutations (age of diagnosis, symptomatic spectrum) and oppose the data for in vitro enzyme activity and responsiveness to the pharmacological chaperone (PC) 1-Deoxygalactonojirimycine (DGJ), an alternate treatment for misfolding-prone AGAL variants.
We show increased prevalence of patients with GLA gene variants with an enzyme activity of >20%. Since these cases can lead to symptom onset later in life, a close clinical check-up is demanded. The in vitro enzyme activity system supports prediction of the pathologic progress of a given mutation and impacts decision-making on time and type of therapeutic intervention.

PM06.28

Clinical picture in Estonian patients with heteroplasmic m.3243A>G mutation in MT-TL1 gene

E. Kurvinen[1], *R. Zordania[1], S. Ütt[2], P. Rudenko[3], K. Anton[4], K. Joost[1,4];*
[1]Department of Genetics, United Laboratories, Tartu University Hospital, Tallinn, Estonia, [2]Neurology Clinic, West Tallinn Central Hospital, Tallinn, Estonia, [3]Internal Medicine Clinic, North Estonian Medical Centre, Tallinn, Estonia, [4]Asper Biotech Ltd, Tartu, Estonia.

The m.3243A>G mutation is known as the MELAS (mitochondrial myopathy, encephalopathy, lactic acidosis and stroke -like episodes) mutation. However many clinical phenotypes associated with this mutation have been described including maternally inherited diabetes and deafness (MIDD).
The aim of the study was to describe clinical picture of Estonian patients with heteroplasmic m.3243A>G mutation referred to genetic councelling.
Results: the common m.3243A>G point mutation was detected in eight patients from three families. In all of them (8/8) progressive hearing loss was detected, followed by diabetes mellitus (7/8), migraine (6/8), psychiatric disorders (3/8), brain atrophy(3/8) and hypertrofic left cardiomyopathy (2/8). Most of our patients (7/8) had thin build and short stature.
Clinically MELAS syndrome was diagnosed in four patients from two families and MIDD in four patients from one family.
Conclusions: Our results confirm the clinical heterogeneity of the m.3243A>G mutation. Progressive hearing loss is a first and universally presented feature in our small cohort. Therefore m.3243A>G mutation should be considered in patients with (progressive) hearing loss. There are some evidence that m.3243A>G mutation causes similar clinical pictures within the family. But as our cohort is small this conclusion need further wider clinical investigation.

PS06.29

amamutdb.no: A relational database for *MAN2B1* allelic variants which compiles genotypes, clinical phenotypes, and biochemical and structural data of mutant MAN2B1 in α-mannosidosis.

H. F. Riise Stensland[1], *G. Frantzen*[2], *E. Kuokkanen*[3], *E. K. Buvang*[4], *H. B. Klenow*[1], *P. Heikinheimo*[3], *D. Malm*[5], *Ø. Nilssen*[4];
[1]*University Hospital of North Norway, Tromsø, Norway,* [2]*Jupiter System Partner AS, Tromsø, Norway,* [3]*University of Turku, Turku, Finland,* [4]*University of Tromsø The Arctic University of Norway, Tromsø, Norway,* [5]*The Tromsø Internal medicine Specialist center, Tromsø, Norway.*

α-Mannosidosis (MIM# 248500) is an autosomal recessive lysosomal storage disorder caused by mutations in the *MAN2B1* gene, encoding the lysosomal α-mannosidase. The disorder is characterized by a range of clinical phenotypes of which the major manifestations are mental impairment, hearing impairment, skeletal changes and immunodeficiency. Here we report an α-mannosidosis mutation database, amamutdb.no, which has been constructed as a publicly accessible online resource for recording and analyzing *MAN2B1* variants. Our aim has been to offer structured and relational information on *MAN2B1* mutations and genotypes along with associated clinical phenotypes. Classifying missense mutations, as pathogenic or benign, is a challenge. Therefore, they have been given special attention as we have compiled all available data that relate to their biochemical, functional and structural properties. The α-mannosidosis mutation database is comprehensive and relational in the sense that information can be retrieved and compiled across datasets; hence, it will facilitate diagnostics and increase our understanding of the clinical and molecular aspects of α-mannosidosis. We believe that the amamutdb.no structure and architecture will be applicable for the development of databases for any monogenic disorder.

PM06.30

Gut microbiome composition is linked to metabolic improvements induced by dietary changes in Korean adoptees

E. Kim[1], *R. Chae*[1], *G. Jeong*[2], *G. Ko*[3,4], *J. Sung*[1,4], *J. Lee*[5], *S. Jin*[6];
[1]*Complex Disease and Genome Epidemiology Branch, Department of Epidemiology, Graduate School of Public Health, Seoul National University, Seoul, Korea, Republic of,* [2]*Laboratory of Immunology, School of Biological Sciences, Seoul National University, Seoul, Korea, Republic of,* [3]*Department of Environmental Health, Graduate School of Publich Health, Seoul National University, Seoul, Korea, Republic of,* [4]*Institute of Health and Environment, Seoul National University, Seoul, Korea, Seoul, Korea, Republic of,* [5]*Department of Food and Nutrition, Sookmyung Women's University, Seoul, Korea, Republic of,* [6]*Department of Traditional Dietary Life Food, Graduate School, Sookmyung Women's University, Seoul, Korea, Republic of.*

Introduction: A growing body of evidence suggests that healthy diet is one of the major factors associated with metabolic health and changes in gut microbiota. Here we conducted a low-salt, high-fiber diet intervention trial on Korean adoptees, to assess alterations in gut microbiome composition in response to changes in diet and the associations with metabolic improvement.
Materials and methods: We developed a modified version of traditional Korean diet (K-DASH), a high-fiber, low-fat, and low-salt diet with a sufficient supply of fruits and nuts. 19 Korean adoptees (mean age: 29.4 years, male: 44.4 %) whose diets are mainly western style were recruited. 16S ribosomal RNA genes were extracted from stool samples at both pre- and post-intervention trial. The V4 region was amplified by PCR and sequenced using Illumina MiSeq platform. QIIME v.1.9.0 was used to estimate taxa from the sequenced reads.
Results: The metabolic profiles, including weight, waist circumference, systolic blood pressure, high-density lipids, and triglyceride levels, showed an improvement, except for fast blood sugar level. The gut microbiome profiles at the phylum level, Firmicutes were decreased, while Bacteroidetes were increased in abundance. The operational taxonomic unit that showed the most significant increase in abundance belonged to the family Leuconostocaceae, which is known to produce acetate and lactate (FDR-corrected p = 0.0028). The change of triglyceride levels correlated with that of abundance of Actinobacteria (Pearson's correlation coefficient: 0.61, p=0.005).
Conclusions: Our findings suggest that metabolic improvements induced by a short-term changes of diet are mediated through their effects on the gut microbiome.

PS06.31

Role of ACBD3 protein in the mitochondrial energy metabolism

M. Tesařová[1], *H. Kratochvílová*[1], *M. Rodinová*[1], *V. Stránecký*[2], *H. Hartmannová*[2], *A. Vondráčková*[1], *J. Spáčilová*[1], *H. Hansíková*[1], *J. Zeman*[1];
[1]*Department of Pediatrics and Adolescent Medicine, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague 2, Czech Republic,* [2]*Institute of Inherited Metabolic Disorders, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague 2, Czech Republic.*

A homozygous mutation c.460A>G in ACBD3 gene was found by whole-exome sequencing in patient with mitochondrial encephalomyopathy and combined deficiency of respiratory-chain complexes. ACBD3 encodes a 60 kDa acyl-coenzyme A binding domain containing 3 protein (also known as PAP7 or GCP60) localized in the Golgi apparatus, endoplasmic reticulum, and mitochondria. ACBD3 protein plays an important role in many cellular processes (lipid metabolism, membrane transport, neuronal division, embryogenesis, steroidogenesis, keeping the structure of the Golgi apparatus, apoptosis, iron homeostasis).
In mitochondria, ACBD3 protein is a part of the complex (140-200kDa) mediating cholesterol transport into the organelle. An integral part of this complex is VDAC protein (Porin) which forms freely permeable pores in the outer mitochondrial membrane and further associates with ANT protein (adenine nucleotide transporter) in the inner mitochondrial membrane. ANT is an ADP/ATP carrier that controls a pool of mitochondrial adenine nucleotides required for mtDNA maintenance.
The aim of the study is characterize the consequences of stably down-regulated expression of ACBD3 protein on the biogenesis and functions of OXPHOS complexes in HEK293 to elucidate its role in the pathogenesis of the patient´s phenotype. The first results show that deficit of ACBD3 protein leads to the decrease of amount and activity of complex IV and decrease of selected subunits of complex IV. Supported by research projects IGA NT/13114-4, GAČR 14-36804G, RVO-VFN64165/2012, and GAUK 1308214.

Identification of causal mutations in three Czech patients with cytochrome c oxidase deficiency and haematological disturbances

A. Vondráčková[1], *H. Kratochvílová*[1], *V. Dvořáková*[1], *V. Stránecký*[2], *K. Beránková*[1], *E. Rozsypalová*[1], *D. Dočekalová Zajícová*[1], *T. Honzík*[1], *H. Hansíková*[1], *J. Zeman*[1], *M. Tesařová*[1];
[1]*First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague 2, Czech Republic,* [2]*Institute of Inherited Metabolic Disorders in The First Faculty of Medicine at Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic, Prague 2, Czech Republic.*

Introduction: Anaemia represents a heterogeneous group of hematologic diseases, which can be induced by plenty of genetic and risk factors. Although the association of mitochondrial dysfunction and hematologic pathology is generally known, the underlying pathologic factors with regard to evolving anaemias are poorly characterized. In this study, we report on three patients, who manifested profound cytochrome c oxidase deficiency combined with anaemia.
Methods: Genetic causes of patients' defective OXPHOS system were found with the use of sequencing targeted to mitochondrial exome, application of SNP microarray chip and performance of protein studies in affected patient tissues.
Results: The presence of pathologic mutations was excluded in patients' mitochondrial DNA. A rarely occurring pathological 6-kbp homozygous deletion was identified in two unrelated patients affecting the *PUS1* gene, which remarkably leads to different disease-phenotypes in both patients. Two previously characterized deleterious missense sequence variations of *COX10* gene (p.Asn204Lys; p.Pro225Leu) were identified in the third patient, however, their combination has not been reported yet, which may imply the variant patient disease-phenotype.
Conclusions: Based on our results and current knowledge, we suggest the infantile deficiency of *PUS1* and *COX10* to be classified as the early fatal and slow progressive forms. To conclude, mitochondrial disorders manifest poor phenotype-genotype correlation even in the patient with the same causal mutations.
This study was supported by grants RVO-VFN64165/2012, IGA NT13114-4/2012, UNCE 204011 and GAČR 14-36804G.

PS06.33

Evaluation of results from a large NGS nuclear mitochondrial panel supports the use of NGS panels in cases of mitochondrial-like clinical features or non-specific presentations

J. Bevilacqua, D. Patel, **H. Reddi**;
Transgenomic, Inc, New Haven, CT, United States.

Next-generation sequencing (NGS) panels have expanded the number of genes that can be simultaneously investigated and are an attractive option because of their increased efficiency and reduced cost. Design of the 448 gene nuclear mitochondrial NGS panel included genes that are involved in various mitochondrial functions ranging from oxidative phosphorylation, transcription/ translation, mtDNA synthesis/biogenesis, and mitochondrial regulation. These genes also include those associated with conditions that

may mimic mitochondrial disease. We evaluated 43 Nuclear Mitome NGS cases to determine the most commonly reported and phenotypically informative genes. We reported Sanger confirmed variants in 372 of 448 genes. Overall about 65% of variants could be categorized into one of three mitochondrial disease associated subtypes: oxidative phosphorylation subunits, mitochondrial regulatory function, or conditions mimicking mitochondrial disease. About 43% of reported variants were in genes that cause similar clinical phenotypes, 20% were in genes that code for oxidative phosphorylation subunits, and 9.8% were related to regulatory function. The ten most reported genes (*RYR1, WFS1, POLG, SCN1A, MTFMT, TTBK2, ABCD1, MYH7, ATM,* and *ATXN7*) accounted for over 15% of all reported variants. Six of these ten genes are associated with conditions that may mimic mitochondrial disease. They may not be directly related to mitochondrial function but these patients' phenotypes prompted suspicion for mitochondrial disease demonstrating the importance of using NGS testing early in the diagnostic process for economic and efficiency purposes. Our results support the use of NGS panels to identify a potential diagnosis in cases of non-specific clinical features or mitochondrial disease-like symptoms.

PM06.34
Mitochondrial DNA mutation testing: how low can you go?

F. Khawaja[1], *E. L. Blakely*[2], *C. Fratter*[3], *R. W. Taylor*[2], *Z. Deans*[1];
[1]*UK NEQAS for Molecular Genetics, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom,* [2]*Wellcome Trust Centre for Mitochondrial Research and NHS Highly, Specialised Mitochondrial Diagnostic Laboratory, Newcastle upon Tyne, United Kingdom,* [3]*Oxford Medical Genetics Laboratories, Oxford University Hospitals NHS Trust, Oxford, United Kingdom.*

The UK National External Quality Assessment Service (UK NEQAS) for Molecular Genetics has provided external quality assessment (EQA) for genetic testing laboratories since 1991. The Scheme challenged participants of the 2014 mitochondrial DNA (mtDNA) EQA run by distributing a validated sample with a very low level of mtDNA heteroplasmy (3% mutated mtDNA in circulating lymphocytes) of the m.3243A>G *MTTL1* mutation, resulting in a third of all participants reporting a critical genotyping error.
Thirty six percent of laboratories were either unable to identify the m.3243A>G mutation present at this low level or failed to state the sensitivity of their quantitative assay to determine mtDNA heteroplasmy in their report. Various testing methods were used for analysis and erroneous results were even reported by laboratories claiming to have test sensitivity as low as 1%.
The results of the EQA scheme highlighted that when reporting quantitative assessment of mtDNA mutation loads it is crucial that test sensitivity is included on reports to enable the reader to correctly interpret the result. Furthermore, if a diagnostic laboratory is using a test for the heteroplasmic m.3243A>G mutation which cannot reliably detect <10% mutant load then it is recommended that an alternative, more sensitive, testing strategy is employed or that an alternative, non-invasive DNA sample (e.g. urinary sediment) in which this mutation is known to segregate to higher levels, is routinely screened in patients referred for m.3243A>G testing.

PS06.35
Exome sequencing in a patient with suspected mitochondrial disease: the truth unveiled.

S. Ait-El-Mkadem[1], *A. Chaussenot*[1], *C. Rouzier*[1], *K. Fragaki*[1], *S. Bannwarth*[1], *A. Cano*[2], *B. Chabrol*[2], *V. Paquis-Flucklinger*[1];
[1]*Nice Hospital - Medical Genetics - IRCAN, Nice, France,* [2]*Marseille Hospital - La Timone - Pediatric Neurology, Marseille, France.*

As the recognition of mitochondrial diseases has increased, the spectrum of clinical manifestations has expanded to include organ systems such as gastrointestinal tract, kidney and liver. Here, we report our efforts to identify the pathogenetic cause for a patient, born to healthy consanguineous parents, who presented since the neonatal period a constellation of symptoms suggestive of a mitochondrial disorder: chronic diarrhea, failure to thrive, tubulopathy, hepatic cytolysis with a complex IV deficiency of the mitochondrial respiratory chain (MRC) in liver. Mutations in mitochondrial DNA and nuclear candidate genes have been excluded. Whole-Exome Sequencing (WES) of the patient identified a homozygous missense variant c.347G>A (p.Cys116Tyr) in the EPCAM gene, which is known to cause Congenital Tufting Enteropathy (CTE), a rare autosomal recessive diarrheal disorder. Additionally a homozygous missense mutation c.1870A>G (p.Thr624Ala) was identified in the SLC3A1 gene, which causes cystinuria, an autosomal inherited disorder characterized by impaired epithelial cell transport of cystine and dibasic amino acids in the proximal renal tubule and gastrointestinal tract. The two variants are novel, occur in highly conserved amino-acids, are predicted to be damaging and are present in the heterozygous state in the parents and the asymptomatic sister. This patient's complex phenotype reflects a complex genetic etiology in which no single gene explained the complete clinical presentation, but rather more than one mutant locus is involved. This study demonstrates the benefit of WES in providing the molecular diagnosis to patients with complex clinical presentations and in revealing a possible secondary MRC defect.

PM06.36
Unraveling the genetic cause of mitochondrial disorders by whole exome sequencing

D. Hellebrekers[1], *T. Theunissen*[2], *S. Sallevelt*[1], *M. Gerards*[2], *R. Szklarczyk*[2], *B. de Koning*[1], *R. Kamps*[1], *M. Nguyen*[2], *W. Gottschalk*[1], *A. Hendrickx*[1], *T. Slangen*[1], *G. Schoonderwoerd*[3], *J. Vanoevelen*[1], *I. de Coo*[4], *H. Smeets*[2];
[1]*Department of Clinical Genetics, Maastricht University Medical Center, Maastricht, Netherlands,* [2]*Department of Clinical Genetics & Research Institute GROW, Maastricht University Medical Center, Maastricht, Netherlands,* [3]*Department of Clinical Genetics, Erasmus MC, Rotterdam, Netherlands,* [4]*Department of Pediatric Neurology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands.*

Mitochondrial disorders are often fatal multisystem disorders. Due to extreme clinical and genetic heterogeneity of these diseases, establishing a genetic diagnosis is challenging. Mitochondrial disorders can be caused by mitochondrial DNA (mtDNA) mutations, accounting for ~15% of cases, or by nuclear genetic defects. To date, mutations have been found in ~200 nuclear genes in mitochondrial patients but many disease genes still have to be discovered.
Development of whole exome sequencing (WES) has revolutionized our approach to uncover disease-causing mutations in known and novel mitochondrial disease genes. We performed WES analysis on ~50 (consanguinous or non-consanguinous) patients with suspected mitochondrial disease and no mtDNA or POLG1 mutations, filtering the exome data based on the presumed genetic model (mostly autosomal recessive). So far, in ~35% of these patients a clear (~25%) or probable (~10%) genetic cause has been identified; most (~2/3) of these are mutations in known mitochondrial genes while ~1/3 are not previously linked to mitochondrial disease.
Therefore, WES has now been implemented in our laboratory as a diagnostic test for patients with suspected mitochondrial disease, starting with a mitochondrial gene panel of ~450 genes for initial filtering. In case the causal genetic defect is not found, filtering the complete exome data ('Open Exome') based on the presumed genetic model can be performed as a second step. For most novel candidate genes and mutations, however, functional testing is required to prove pathogenicity or, alternatively, identification of similar gene mutations in patients with comparable phenotypes, demonstrating the value of data sharing.

PS06.37
Particularities of mitochondrial DNA connected with manifestation of muscle tissue hypoxia in congenital myopathies.

A. Voronkova, *N. Litvinova, T. Baranich, V. Sukhorukov, D. Kharlamov;*
Moscow Clinical Institute of Pediatrics, Moscow, Russian Federation.

Introduction
The confirmation or exclusion of mitochondrial diseases remains a challenge in clinical practice, especially for pediatric cases, which show enormous variation in clinical presentations. Demonstrative example are infant myopathies. Different manifestations of congenital myopathy may mask mtDNA alterations. Oftimes mitochondrial disorders are not suspected and manifest unexpectedly. In this regard, molecular mtDNA testing is getting increasingly important as a stage of diagnostics.
Materials and methods
We researched unexplained infant myopathy cases with manifestation of muscle hypoxia. First, we analyzed mitochondrial distribution in the tissue. Then, we explored distribution of Hypoxia Inducible Factor 1 alpha (HIF1a) to evaluate hypoxia. For this stage, we used polyclonal rabbit antibodies to HIF1a and secondary antibodies AlexaFluor555 goat anti-rabbit IgG. Thereafter we made complete mtDNA sequence with Sanger method and capillary electrophoresis.
Results
Histological research of muscle tissue revealed ragged red fibers. More interestingly, we found loci with both HIF1a high concentration sites and increased mitochondrial clusters. In the light of these findings, we analyzed complete mtDNA sequence in order to find pathological mutations. We found no confirmed disease-associated mutations. Yet in the full mtDNA sequence we found several novel variants in each patient: A191T, T199C, T961C, T3197C, A4769G, T7080C, G8251A, A8860G, T11770C, A15218G, A15326G, A16080G, T16209C, C16294T, C16256T, T16519C (no connection with haplogroup).

Conclusions
We expect novel individual mtDNA variants to be connected with mitochondrial disorders and local manifestations of muscle tissue hypoxia. We suppose it is crucial not only to check mtDNA "hot points" but also to make complete mtDNA sequencing to evaluate novel genetic variants in cases of unexplained infant myopathies.

Association between seminal protein oxidation and mitochondrial membrane potential of human spermatozoa from infertile men

S. Daoud[1], *J. Auger*[2], *J. P. Wolf*[2], *E. Dulioust*[2];
[1]*Biology of Reproduction Department, Faculty of medicine of Sfax, Sfax, Tunisia,* [2]*Biology of Reproduction Department, Cochin Hospital, Paris Descartes University, Paris, France.*

Introduction: Sperm mitochondria are one of the major sources and targets of reactive oxygen species (ROS). Furthermore, mitochondrial dysfunction is reported to be an early indicator of sperm damage. The aim of this study was to evaluate the influence of oxidative stress, as assessed by seminal oxidation protein level, on mitochondrial membrane potential (MMP) of sperm.
Materials and Methods: Study population included 25 male partners of infertile couples. Were excluded men with known male factor of infertility and/or low ejaculate volume (<1.5 mL) and/or low sperm count (< 15 Million/mL), evaluated according to WHO 2010 recommendations. MMP was determined by flow cytometry using 3,3'-dihexyloxacarbocyanine iodide (DiOC6) as probe. Seminal plasma level of advanced oxidation protein products (AOPP), a marker of oxidative stress, was assessed by spectrophotometry. The relationship between semen parameters, sperm MMP and AOPP levels were analyzed (Spearman's Rank correlation test).
Results: Nearly one-third of the participants (n=8) had normal semen parameters. Among the remaining participants, 70 % had a single parameter below WHO reference values. Sperm progressive motility was significantly correlated with MMP (r=+0.44; p=0.02). We found a negative correlation between AOPP seminal level and sperm concentration (r= -0.40; p=0.04). There was no association between AOPP level and MMP (p=0.9).
Conclusion: In accordance with previous studies, sperm MMP was a sensitive indicator of functional integrity of the spermatozoa. The lack of association between MMP and AOPP level could be related to the relatively good semen quality of the participants in this study. Indeed, semen vulnerability to oxidative damage is strongly linked to semen quality and its antioxidant capacity.

PS06.39
Molecular diagnosis of monogenic diabetes by targeted next-generation sequencing in Slovak MODY patients

M. Škopková[1], *L. Valentínová*[1], *J. Staník*[2,1], *M. Hučková*[1], *D. Daniš*[1], *I. Klimeš*[1], *D. Gašperíková*[1];
[1]*Diabgene & Diabetes Laboratory, Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*First Department of Paediatrics, Faculty of Medicine, Comenius University, Bratislava, Slovakia.*

Maturity Onset Diabetes of the Young (MODY) is genetically heterogeneous disorder. Generally, only few genes with most prevalent mutations are sequenced according to patient phenotype. In this study, we used targeted NGS sequencing of a panel of MODY genes in patients, where no mutation had been found in one or two most probable genes by Sanger sequencing.
Patients and Methods: We designed a custom targeted sequencing panel focusing on 13 known MODY genes (HNF4A, GCK, HNF1A, PDX1, HNF1B, NEUROD1, KLF11, CEL, PAX4, INS, BLK, ABCC8, KCNJ11). The target regions (exons with 50bp padding, UTRs and promoters) were sequenced using PGM IonTorrent platform. Missing and low coverage fragments, as well as candidate variants, were sequenced by Sanger. We have analyzed 21 patients with MODY phenotype negative for most probable genes.
Results: Designed panel covered 93.7% of target sequences and, out of these, 98.1% were covered more than 20x. Analysis of data revealed 3 known mutations: in GCK, ABCC8 and HNF1B genes, and 2 novel likely pathogenic mutations in ABCC8 and HNF4A genes. We have also found additional 3 variants in HNF1B, PAX4 and BLK genes with unknown significance. Co-segregation analysis with diabetes in the families did not support their pathogenicity.
Conclusions: Our first results from targeted NGS data showed an effective usage of this method in the routine DNA diagnostics of MODY in Slovakia. We have solved 5 out of 21 cases (25 %) of patients, who would not be diagnosed by classical approach due to their atypical phenotype.

PM06.40
A new MRM-MS assay for the diagnosis of mucopolycaccharidosis type IVA (Morquio A disease) in dry blood spots

C. Cozma[1], *S. Eichler*[1], *G. Wittmann*[1], *A. Flores Bonet*[1], *G. J. Kramp*[1], *A. Giese*[2], *A. Rolfs*[1];
[1]*Centogene AG, Rostock, Germany,* [2]*Albrecht-Kossel-Intitute for Neuroregeneration AKos, University of Rostock, Rostock, Germany.*

Mucopolysaccharidosis IVA (MPS IVA; Morquio A disease) is an autosomal recessive disease caused and characterized by an impaired activity of galactosamine-(N-acetyl)-6-sulfate-sulfatase (GALNS), resulting in keratan sulfate and chondroitin-6-sulfate accumulation in tissues and secondary organ damage. Enzyme replacement therapy, currently in clinical trials, renders the identification of MPS IVa patients in a rapid and facile manner of outmost importance. We propose a newly developed assay for the stabile and reproducible detection of GALNS deficiency in dry blood spots (DBS). Blood samples were taken from 57 healthy individuals and 18 randomly selected MPS IVA patients. The patients were presenting the MPS IV A phenotype and the genetic test revealed GALNS gene mutations, ten of which previously not described in literature. The material extracted from DBS was incubated with a 4-methylumbelliferyl-β-D-galactopyranoside-6-sulfate as a specific synthetic substrate. Final enzymatic product, 4-methylumbelliferone, obtained after adding exogenous beta-galactosidase, was quantified by LC/MRM-MS (liquid-chromatography/multiple-reaction-monitoring mass-spectrometry). 4-propyl-5-hydroxy-7-methyl-2h-chromen-2-one was used as internal standard, a compound with a very similar molecular structure and fragmentation pattern in negative ion mode as 4-methylumbelliferone (the enzymatic product in the present assay). The cut-off was established at 4.8 µmol/L/h. The enzymatic assay yielded a positive and negative predictive value of 1.0 for genetically confirmed MPS IVa patients (with a GALNS activity of 0.35 ± 0.21 µmol/L/h) compared with controls (normal GALNS activity 23.1 ± 5.3 µmol/L /h). Results show a pathologically reduced GALNS activity in all MPS IVa patients, while the control enzymes show always normal activity.

PS06.41
Mutation analysis of the MRAP2 gene in Prader Willi like patients and obese children and adolescents.

E. Geets[1], *D. Zegers*[1], *S. Beckers*[1], *A. Verrijken*[2], *G. Massa*[3], *K. Van Hoorenbeeck*[4], *S. Verhulst*[4], *L. Van Gaal*[2], *W. Van Hul*[1];
[1]*Department of Medical Genetics, Antwerp, Belgium,* [2]*Department of Endocrinology, Diabetology and Metabolic Diseases, Antwerp, Belgium,* [3]*Department of Pediatrics, Hasselt, Belgium,* [4]*Department of Pediatrics, Antwerp, Belgium.*

Background: In general, there is increasing recognition that accessory proteins can modulate G protein-coupled receptor (GPCR) trafficking, ligand binding and signaling to the cell surface. *In vitro* studies showed that melanocortin receptor 2 accessory protein 2 (MRAP2) can interact with the melanocortin 3 (MC3R) and 4 receptor (MC4R), two GPCRs which play an important role in the leptin-melanocortin signaling. *MRAP2* is located on chromosome 6q14.2, a region which is associated with a Prader Willi like (PWL) phenotype, a syndromic form of obesity. In addition, Asai *et al.* identified four rare heterozygous variants in four unrelated, nonsyndromic, severely obese individuals. Therefore we decided to perform mutation analysis in both a PWL and obese cohort.
Method: We screened 122 PWL patients and 404 obese children and adolescents for mutations in *MRAP2* using high-resolution melting curve analysis. Sanger sequencing was performed for samples with melting patterns deviating from wild-type.
Results and conclusions: Mutation analysis of all coding exons and intron-exon boundaries of *MRAP2* resulted in the identification of one rare non-synonymous heterozygous variant A40S (c.118G>T) in one PWL patient. Screening of the 404 obese individuals didn't lead to any variants in the gene. *In silico* analysis showed a probably damaging effect of the A40S variant on the protein structure of MRAP2. Further functional analysis is necessary to investigate the influence of the variant on the MRAP2 function. This would indicate a possible role of *MRAP2* in the pathogenesis of Prader Willi like phenotype, albeit in a limited number of patients.

PM06.42
'Early treatment with Elaprase: Can it be effective in neuropathic form of MPS II?'

K. Orchel-Szastak, *M. Bik-Multanowski;*
Department of Medical Genetics, Jagiellonian University, Medical College, Krakow, Poland.

Introduction: Enzyme replacement therapy (Elaprase) has been used for treatment of patients with mucopolysaccharidosis type II (MPS II) for the last eight years. During this time only few early-diagnosed infants have been

treated. Therefore, data on treatment effectiveness in this age group is very limited.
Case presentation: We present unexpected therapeutic findings in one of two affected siblings. In the older patient first symptoms of MPS II were noticed at the age of three years and diagnosis was established two years later. At the age of seven years, typical dysmorphism, restriction of joint movements, heart involvement, hepatomegaly and severe intellectual delay could be observed. In the younger patient diagnosis of MPS II was made in the first month of life. Treatment with Elaprase was introduced in the third month of life. At the age of seven years the patient remains clinically symptom-free (including normal intellectual development) despite presence of typical biochemical abnormalities. In both patients activity of iduronate 2-sulfatase in leukocytes was below norm and a missense mutation of the iduronate 2-sulfatase gene (p.Tyr523Cys) was detected.
Conclusion: Although hampering of some symptoms could be explained with beneficial effects of Elaprase, normal intellectual development in the younger patient is unexpected. One possible explanation could be decreased disease penetration. However, similar extent of biochemical abnormalities in both patients suggests similar disease severity. Therefore, in our opinion possibility of significant attenuation of disease course should be considered as a result of early introduction of enzyme replacement therapy.

Hospital Universitario Vall d'Hebron, Barcelona, Spain.

Thymidine kinase 2 (TK2) is a mitochondrial enzyme participating in the salvage of deoxyribonucleotides needed as substrates for mitochondrial DNA (mtDNA) replication. TK2 mutations were typically associated with a severe myopathic form of mtDNA depletion syndrome that manifests during infancy and leads to the early death of most patients. Recently, several patients (n=7) have been diagnosed with a late-onset and milder myopathy with multiple mtDNA deletions. Here we describe seven patients diagnosed in their adulthood (16-55 years old), with different forms of mitochondrial myopathy associated with multiple mtDNA deletions and no depletion in skeletal muscle, in contrast to what is observed in typical infantile patients. Phenotypic presentation varied from mild myopathic signatures, such as ptosis and myalgia, to progressive muscle weakness and respiratory dysfunction. After genetic analysis, previously reported pathogenic mutations in TK2 were identified in all patients (p.K202del and p.T108M that seem particularly frequent in the Spanish population, and p.R192K). Fibroblasts were obtained from two of these patients and TK2 activity was measured showing a drastic reduction that resembled that found in typical paediatric patients (3% and 6% residual activity as compared with age-matched healthy controls). This observation suggests that redundant or complementary biochemical mechanisms can bypass the biochemical defect in some individuals, preventing mtDNA depletion, and ameliorating the course of the disease. Therefore, TK2 mutations should be investigated in patients with myopathy associated with either mtDNA depletion or multiple deletions, independently of their age at onset or clinical severity.

Homozygous mutations in MFN2 are a novel cause of multiple symmetric lipomatosis in patients without a MERFF mutation

S. L. Sawyer[1], *A. C. H. Ng[1], A. M. Innes[2], J. D. Wagner[1], D. A. Dyment[1], M. Tetreault[3,4], Care4Rare Canada Consortium, J. Majewski[3,4], K. M. Boycott[1], R. Screaton[1], G. Nicholson[5];*
[1]Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada, [2]Department of Medical Genetics and Alberta Children's Hospital Research Institute for Child and Maternal Health, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [3]Department of Human Genetics, McGill University, Montreal, QC, Canada, [4]McGill University and Genome, Quebec Innovation Centre, Montréal, Quebec, Canada, Montreal, QC, Canada, [5]University of Sydney, ANZAC Research Institute, Concord Hospital, Sydney, Australia.

Multiple symmetric lipomatosis (MSL) is a mitochondrial disorder with impaired brown fat metabolism that has been associated with MERFF mutations in some, but not all patients. We studied a sibling pair and an unrelated individual who presented with multiple symmetric lipomatosis (MSL) and neuropathy to determine the genetic etiology of this disorder in patients who did not carry the MSL-associated MERFF mutation. The siblings presented with striking cervico-thoracic lipomatosis in their 40's, with tongue hypertrophy and impaired swallowing, diabetes, and a peripheral neuropathy. Whole exome sequencing was performed on the siblings and a rare, shared homozygous mutation in *MFN2* (c.2119C>T: p.R707W) was identified. The mutation was not present in their healthy siblings. In silico programs predict it to be pathogenic and heterozygous carriers of the MFN2 p.R707W substitution are known to have Charcot-Marie-Tooth disease (CMT). A third, unrelated, patient with multiple symmetrical lipomatosis and neuropathy also harbored the same homozygous mutation and had been previously diagnosed with CMT. Functional studies in patient fibroblasts demonstrate that the p.R707W substitution impairs homotypic (MFN2-MFN2) protein interactions required for normal activity, and renders mitochondria prone to perinuclear aggregation. These findings show that homozygous mutations at p.R707W in *MFN2* are a novel cause of multiple symmetrical lipomatosis.

PS06.45

A homozygous p.Trp22Arg *NDUFB3* mutation is a recurrent cause of mitochondrial complex I deficiency associated with Irish ancestry, a characteristic facial appearance and good prognosis

C. L. Alston[1], *L. He[1], R. McFarland[1], J. P. H. Shield[2], P. G. Murray[3], A. A. M. Morris[3], P. E. Clayton[3], E. Crushell[4], J. Hughes[4], R. W. Taylor[1];*
[1]Wellcome Trust Centre for Mitochondrial Research, Newcastle upon Tyne, United Kingdom, [2]University of Bristol and Bristol Royal Hospital for Children, Bristol, United Kingdom, [3]Institute of Human Development, Faculty of Medical & Human Sciences, University of Manchester and Royal Manchester Children's Hospital, Manchester, United Kingdom, [4]National Centre for Inherited Metabolic Disorders, Temple Street Children's University Hospital, Dublin, Ireland.

Isolated complex I deficiency is the most common paediatric mitochondrial disease presentation and the prognosis is often poor with high mortality. Complex I comprises 44 structural subunits with at least 10 ancillary proteins involved in its assembly; mutations in at least 25 of these have been reported as causal. There are limited genotype-phenotype correlations to guide clinicians to the correct genetic diagnosis, although next-generation sequencing strategies including exome sequencing have proven extremely useful in a research setting. In a diagnostic setting, it is crucial to provide a genetic diagnosis in a rapid and cost-effective manner and we apply a validated, targeted next-generation sequencing strategy to sequence the genes encoding all structural subunits and ancillary proteins in clinically- and biochemically-characterised paediatric patients. This strategy has uncovered a clinically-distinctive cohort of children of small stature, with persistent growth retardation and mild dysmorphic facial features (n=7 patients from 6 families) who are all homozygous for a previously reported c.64T>C, p.Trp22Arg *NDUFB3* mutation. Two further children from a seventh family were referred after exome sequencing identified the same homozygous p.Trp22Arg *NDUFB3* mutation; these children presented with primordial short stature without obvious metabolic dysfunction. The p.Trp22Arg mutation has previously been associated with severe metabolic presentations and poor prognosis. Our cohort highlights that the long-term prognosis related to this *NDUFB3* mutation can be very good, and recognition of the distinctive facial features should suggest screening for this specific mutation to provide a genetic diagnosis, circumventing the requirement of muscle biopsy to direct molecular genetic investigations.

PM06.46

Newborn screening for fatty acid oxidation disorders: effects on population frequency and clinical outcome in the Czech Republic

P. Chrastina[1], M. Pavlíková[1], P. Ješina[1], E. Hrubá[1], H. Vlášková[1], T. Honzík[1,2], J. Sokolová[1], A. Hnízda[1], V. Smolka[3], D. Friedecký[4], T. Adam[4], **V. Kožich**[1];
[1]Institute of Inher Metab Dis, Charles Univ-1st Fac Med and General Univ Hospit, Prague, Czech Republic, [2]Dept Pediatrics, Charles Univ-1st Fac Med and General Univ Hospital, Prague, Czech Republic, [3]Dept Pediatrics, University Hospital Olomouc, Olomouc, Czech Republic, [4]Dept Clin Bioch, Faculty Hospital Olomouc, Olomouc, Czech Republic.

Introduction: Newborn screening (NBS) program in the Czech Republic was

expanded from three to 13 disorders in October 2009 and tests also for the medium chain acyl-CoA dehydrogenase (MCADD) and long chain 3-hydroxyacyl-CoA dehydrogenase deficiency (LCHADD). In this study we examined the effect of five years of NBS on detection rate and clinical outcome compared to the pre-NBS period.
Patients and Methods: In the pre-NBS cohort 21 MCADD and 12 LCHADD patients were ascertained on clinical basis and followed for 236 and 73 patient-years, respectively. In the NBS cohort 29 MCADD and 10 LCHADD patients were detected among 661,000 newborns with a follow-up of 74 and 26 patient-years, respectively. A severity scoring index (SSI) was developed to assess the clinical outcome. Statistical analyses were carried out using statistical environment R.
Results: The NBS increased significantly the frequency of ascertained patients with MCADD from 1:211,300 to 1:22,800 and with LCHADD from 1:141,300 to 1:66,100. A total of 12 and 8 variants in the ACADM and HADHA genes were detected and a different spectrum of mutations was observed between the NBS and clinically ascertained cohorts. The age-adjusted clinical SSI in the pre-NBS cohort of MCADD patients (median 0.8 versus 0.0, p=0.009, Wilcoxon test) and LCHADD patients (median 3.5 versus 0.4, p=0.011, Wilcoxon test) were significantly higher compared to the NBS cohort.
Conclusions: Five years of newborn screening for MCADD and LCHADD in the Czech Republic significantly increased detection rate and improved clinical outcome in patients.
Study was supported by project MH-CZ-DRO-VFN64165.

Familial hypercholesterolemia (FH) is one of the most common monogenic disorders mostly inherited as autosomal dominant trait and when untreated results in early coronary heart disease. Identification and early treatment of affected individuals remains a challenge worldwide. Majority of FH cases are caused by mutations in four genes (APOB, LDLR, PCSK9 and LDLRAP1). The spectrum of disease causing mutations is very diverse and mutation panels commonly used in diagnostics cover only a minority of disease causing genetic variants. In FH patients not expressing the physical symptoms and with unknown family history DNA based tests may provide the route to FH diagnosis. Here, we evaluate the use of targeted next generation sequencing (NGS) as a potential method to identify cases of FH in the cohort of coronary artery disease (CAD) patients and individuals with abnormal low density lipoprotein cholesterol (LDL-C) levels.
We used targeted amplification of LDLR, APOB, PCSK9 and LDLRAP1 coding regions followed by NGS in 42 CAD patients (LDL-C 4.1-7.2 mmol/L) and 50 individuals from population based cohort (LDL-C 5.1-9.7 mmol/L). In total 22 synonymous, 31 non-synonymous variants, eight variants in close proximity (10 bp) of intron-exon boundaries and 50 other variants were found. We identified 4 pathogenic mutations (Arg3527Gln in APOB gene, Gly20Arg, Arg350X and IVS11 -10 (G>A) in LDLR gene) in seven patients (7.6 %). In addition 3 possible pathogenic variants were also found in four patients.
This work was supported by European Regional Development Fund „Research and development of novel diagnostic methods for genetic and immunologic testing" no 2013/0042/2DP/2.1.1.1.0/13/APIA/VIAA/002 and State Research Project "BIOMEDICINE".

Niemann-Pick disease type C (NPC) is a rare autosomal recessive lysosomal storage disorder, resulting from abnormal cholesterol trafficking. NPC has a heterogeneous clinical presentation, but is typically characterised by a range of progressive neurological problems.
Traditionally, a biochemical laboratory diagnosis is made by demonstrating impaired cholesterol trafficking via filipin stained fibroblast cultures, requiring an invasive skin biopsy. A more sensitive and specific LC-MS/MS method for quantifying cholesterol oxidation products, shown to be increased in the plasma of NPC patients is now available in Manchester as a new first line test, allowing less invasive, rapid screening of this previously underdiagnosed disease.
Currently, molecular analysis of NPC following abnormal biochemical screening results, involves direct Sanger sequencing of all 30 exons of the *NPC1* and *NPC2* genes combined. However, a more robust efficient approach was required to meet the potential increase in demand for NPC genetic testing.
We have developed a more comprehensive sensitive mutation screening service for both *NPC1* and *NPC2* using a combination of MLPA and Next Generation Sequencing (NGS). The latter is based on enrichment by long-range PCR, amplicon normalisation, equimolar pooling and dilution, fragmentation and tagging using Nextera XT followed by MiSeq NGS, with a minimum coverage of 100x reads. Analysis using a custom bioinformatics pipeline allows a range of point variants and small insertion/deletion mutations to be accurately identified.
In addition, the cholesterol oxidation levels from a number of patients were compared to their genotypes and good concordance between the two tests was revealed.

PS06.49
Lyso-Sphingomyelin-509 as sensitive and specific biomarker for Niemann-Pick Type C Disease

A. Giese[1], *H. Mascher*[2], *J. Lukas*[1], *C. Cozma*[3], *G. Kramp*[3], *G. Wittmann*[3], *U. Grittner*[4], *A. Rolfs*[1];
[1]*Albrecht-Kossel-Institute for Neuroregeneration, Medical University of Rostock, Rostock, Germany,* [2]*Pharm-Analyt GmbH, Baden, Austria,* [3]*Centogene AG, Rostock, Germany,* [4]*Institute for Biostatistics and Clinical Epidemiology, Charite-University Medicine, Berlin, Germany.*

Introduction: Biomarkers are a relevant factor in diagnosing and monitoring many different diseases. The ideal biomarker detects the presence, extent and outcome of a specific disease and is reliably quantifiable in a clinically easily accessible sample. For Niemann-Pick Type C (NP-C), an autosomal-recessive disease caused by mutations in either the NPC1 gene (95% of all patients) or NPC2 gene (5% of all patients) biomarkers have been established in the past, which facilitate either early diagnosis (cholestane-3β,5α,6β-triol; Jiang et al. 2011) or long-term follow-up (Lysotracker Assay measuring relative acidic compartment volume; TeVruchte et al., 2014). However, early diagnosis and monitoring of treatment in patients is still difficult and the existing markers are not really reflecting the disease burden.
Material and Methods: Based on a new LC/MRM-MS (liquid-chromatography/multiple-reaction-monitoring mass-spectrometry) assay we developed and validated a novel biomarker, lyso-Sphingomyelin-509. Primary detection of the biomarker was performed in 10 NP-C patients and 10 controls. Further validation of the biomarker was performed in 242 subjects including NP-C patients, NP-C carriers, healthy controls and patients with other LSDs.
Results: In total, 242 subjects were investigated, including 110 NP-C patients (lyso-Sphingomyelin-509: 6.7ng/ml (IQR: 3.4-10.3ng/ml)), 63 NP-C carriers and 43 healthy controls. With a sensitivity of 100% and specificity of 91% a cut-off of 1.4ng/ml was established. Neither NP-C carriers nor healthy controls displayed elevated measurements of lyso-Sphingomyelin-509.
Conclusion: Lyso-Sphingomyelin-509 has been established as a sensitive and specific biomarker for NP-C. Tracking the disease progression and response to treatment by this surrogate biomarker is currently under investigation.

PM06.50
Recurrence of Niemann-Pick Type C in extended families with no consanguinity

J. Imrie[1], *S. Jones*[2], *P. Gissen*[3];
[1]*NPUK, Bolton, United Kingdom,* [2]*CMFT, Manchester, United Kingdom,* [3]*GOSH, London, United Kingdom.*

Niemann-Pick Disease Type C(NPC) is a rare neurodegenerative lysosomal storage disorder with an incidence of about 1:120,00. Inheritance is autosomal recessive. There are less than 90 cases in the United Kingdom. This abstract presents 3 families with no consanguinity. In 2 families first cousins had affected children and in a third 2 sisters had an affected child. Given the published low incidence of this disorder possible explanations for these events will be explored. Given that families with NPC are supported by a very good charity (NP UK) and also that networks amongst affected families, particularly of late with the ever increasing use of social media, are very strong, knowledge of these recurrences in extended families are known about which impacts markedly when offering genetic counselling.

PS06.51

The next-generation of the Niemann-Pick Type C Disease Gene Variation Database (NPCdb)

M. Stampfer[1,2], *H. Runz*[2,3];
[1]*Institute of Medical Genetics and Applied Genomics, University of Tuebingen, Tuebingen, Germany,* [2]*Institute of Human Genetics, University of Heidelberg, Heidelberg, Germany,* [3]*Merck Research Labs, Dep. Genetics & Pharmacogenomics (GpGx), Boston, MA, United States.*

Niemann-Pick Type C Disease (NP-C) is a rare, autosomal-recessive lysosomal storage disease. Two causative genes, NPC1 and NPC2, have been identified with mutations in NPC1 contributing to the large majority of cases.
In 2007 we established a locus-specific gene variation database that listed variants and associated haplotypes in NPC1 and NPC2 genes and related sequence to basic clinical information. Since then our knowledge has grown and next-generation sequencing studies of larger patient and control cohorts have provided us with further insights into the genetic architecture of NPC1 and NPC2, enabling a much better understanding of which genetic variation within these genes is truly disease-relevant.
Using a variety of sources, we have now assembled over 1400 exonic and intronic variants at the NPC1 and around 50 variants at the NPC2 locus and provide information on their functional consequences. Additionally, our resource provides information on allele frequencies, in silico predictions of the functional effects of a variant and allele-numbers in controls and reported patients. As a result it assists in evaluating the significance of a variant and thus aims to support molecular diagnostician in their challenge of making the correct diagnosis.
In recent years, efforts have been made to establish a clinical registry for Niemann-Pick diseases called "The International Niemann Pick Disease Registry". As we are collaborators in this project we aim to intertwine both registries, thus securing an ongoing input of information on the number and types of variants found in actual NP-C patients.
We are planning to launch this new resource for Niemann-Pick Disease type C in spring 2015.

PM06.52

Positive correlation between orphan receptor RORα and ABCA1, ABCG1 in visceral adipose tissue

A. Panteleeva[1,2], *V. Miroshnikova*[1,2], *E. Demina*[1], *T. Usenko*[1], *I. Semenova*[1], *E. Baranova*[2], *E. Bagenova*[2], *O. Berkovich*[2], *S. Pchelina*[1,2];
[1]*Petersburg Nuclear Physics Institute, St. Petersburg, Russian Federation,* [2]*First Pavlov State Medical University of St. Petersburg, St. Petersburg, Russian Federation.*

Obesity is associated with impaired lipid metabolism and cholesterol accumulation in the intra-abdominal adipose tissue. ATP-binding cassette transporters ABCA1 and ABCG1 play a major role in cholesterol efflux suggesting their role in elimination of excess cholesterol and maintaining cholesterol homeostasis in the adipocyte. RAR-related orphan receptor RORα have been implicated as one of the regulators of the lipid metabolism and may play a significant role in the regulation of ABCA1 and ABCG1 expression. However, the effect of RORα on ABCA1 and ABCG1 protein content in visceral fat during obesity is unknown.
The aim of this study is to investigate correlation between orphan receptor RORα and transporters ABCA1, ABCG1 in visceral adipose tissue with obesity.
Visceral fat was received from gastrocolic omentum during laparoscopic cholecystectomy from 37 individuals. Protein levels of ABCA1, ABCG1 and RORα were measured by western-blot.
All individuals were divided in 3 subgroups: morbidly obese (BMI≥31; N=8), overweight (25≤BMI<31; N=15) and normal weight (BMI<25; N=14). ABCA1 and ABCG1 protein levels were significantly higher in individuals with overweight when compared with normal weight ($p<0.01$; $p<0.05$, respectively). A positive correlation between RORα and ABCA1(-r=0.48; $p<0.05$) as well as ABCG1(-r=0.43; $p<0.05$) levels in visceral fat was shown. These data suppose that RORα may control ABCA1 and ABCG1 protein levels in visceral fat tissue and thus influence on the obesity development.
The research was supported by RFFR 14-04-31690 grant.

PS06.53

High prevalence of monogenic obesity in super obese individuals undergoing bariatric surgery

S. I. M. Alsters[1], *A. M. Yiorkas*[1], *M. Mueller*[1], *A. Sosinsky*[1], *A. Zekavati*[1], *N. H. Ramzi*[1], *N. A. Nor Hashim*[1], *J. Murphy*[1], *H. S. Chahal*[1], *S. Purkayastha*[1], *A. R. Ahmed*[1], *M. M. van Haelst*[2], *C. W. le Roux*[3], *J. L. Buxton*[4], *R. G. Walters*[5], *A. I. F. Blakemore*[1];

Introduction: Some forms of obesity are monogenic. We investigated the prevalence of monogenic obesity in super obese adults, and examined their weight loss trajectories after bariatric surgery.
Methods: A cohort of patients (n=282) with a body mass index (BMI) of >50 kg/m^2 were screened for MC4R deficiency. 48 patients (BMI range: 50.2-103.8 kg/m^2) were selected for further whole exome sequencing (WES) to screen for other pathogenic mutations in known obesity genes. Copy number variation analysis was carried out by read depth analysis, and Sanger sequencing or real-time PCR was used to confirm findings.
Results: Screening identified one patient carrying a rare *MC4R* mutation (E42K) predicted to be pathogenic. Five out of 48 patients (10.4%) investigated by WES carried a likely monogenic cause of their obesity: 16p11.2 deletion; a deletion within *NTRK2*; a nonsense mutation in *IGSF1*; and missense mutations in *SH2B1* and *NTRK2*. In addition, in a further six patients, novel or rare (population frequency <0.005) missense mutations, reported as pathogenic by multiple prediction tools, were found in *LEPR* (compound heterozygote), *NTRK2*, *SH2B1* or *MAGEL2* (three). Weight loss seen in the mutation carriers was not different one year after bariatric surgery from patients with a similar starting BMI.
Conclusion: *MC4R* screening and WES data revealed a markedly higher diagnostic yield (up to 22.9%) than previously reported in any obese cohort. Monogenic obesity is underestimated in the super obese.

PM06.54

Heterozygous SDHA mutation resulting in complex II deficiency with ocular, cardiac and neurologic involvement

C. Courage[1], *D. Hahn*[2], *J. Nuoffer*[2], *C. Jackson*[2], *S. Gallati*[1], *A. Schaller*[1];
[1]*Division of Human Genetics, Bern, Switzerland,* [2]*Institute of Clinical Chemistry, Bern, Switzerland.*

Mitochondrial respiratory complex II (succinate dehydrogenase, SDH, CII) deficiency is rare, accounting for ~2% of all respiratory chain deficiencies. Of the four nuclear encoded proteins composing CII (SDHA, SDHB, SDHC, SDHD) and its assembly factors (SDHAF1 and SDHAF2) mainly recessively inherited mutations cause mitochondrial disease phenotypes.
Here we report clinical, biochemical and molecular investigations of three patients harbouring a heterozygous mutation in the flavoprotein subunit SDHA previously associated with CII deficiency. The index patient presented with optic atrophy, ocular movement disorder, progressive polyneuropathy, psychiatric involvement and cardiomyopathy. His daughter deceased at the age of 7 months due to cardiac insufficiency. His 30-year-old son presents with optic atrophy and cardiomyopathy. Spectrophotometric and oxygen consumption measurements in skin fibroblasts revealed isolated CII deficiency in all patients. Sequencing of all complex II associated genes revealed a previously described heterozygous mutation (c.1351C>T; p.R451C) in SDHA in a highly conserved Flavin-binding domain.
Only few SDH gene defects are reported as an underlying cause of mitochondrial disease. However, SDH genes as tumor suppressor genes are frequently associated with hereditary cancer syndromes, including paraganglioma and pheochromocytoma and should be monitored also in patients presenting with mitochondrial disease. Contrasting to previously reported cases, our patients present with cardiomyopathy. The variability in disease-onset and phenotypic presentation of this mutation, therefore, suggest modifying factors influencing disease severity. Our report gives further evidence for an autosomal-dominant inherited mitochondrial disease caused by a heterozygous SDHA mutation.

PS06.55

Functional and structural analysis of novel missense mutations of phenylalanine hydroxylase

M. Pecimonova[1], *E. Polak*[1], *A. Soltysova*[1,2], *M. Stojiljkovic*[3], *K. Reblova*[4], *Z. Levarski*[1], *J. Krahulec*[1], *L. Schreiber*[5], *L. Kadasi*[1,2];

Phenylketonuria (PKU) and hyperphenylalaninemia are the most frequent disorders of amino acid metabolism. This group of disorders is primarily caused by mutations in human phenylalanine hydroxylase gene (PAH), leading to decreased or deficient enzyme activity. Phenylalanine hydroxylase (PAH) catalyzes the essential conversion of phenylalanine to tyrosine in the presence of molecular oxygen, iron and its natural cofactor tetrahydrobi-

opterin (BH4). In vitro analysis of PAH enzymes enables to determine the catalytic function of different mutated forms of PAH, thus to confirm that the amino acid change is the disease causing mutation. This is important in recent progress of PKU treatment and in the correlation between PAH residual activity and tetrahydrobiopterin therapy. The most worldwide frequent mutations of the PAH gene have been studied in vitro and in silico in the last two decades. In our recent study, three novel missense mutations were identified in the Slovak population (p.F233I, p.R270I and p.F331S). We cloned these variants in the pMAL-MBP fusion vector and expressed in E. coli XL1 blue expression system. Enzymes were isolated using affinity chromatography followed by size-exclusion chromatography. Wild type PAH and each mutated form were assayed and their activity was measured by quantification of produced tyrosine using tandem mass spectrometry. The residual activity of each mutation was assessed as percentual activity of the wild type enzyme. To clarify and extend the results, we changed experimental conditions by co-overexpressing each mutation with pGroESL plasmid (carrying chaperone genes GroEL and GroES). In addition, we performed structural analysis of all mutations using molecular dynamics simulations. This project was sponsored by grant APVV-0240-12.

PM06.56

Molecular heterogeneity of PAH gene in PKU patients from Republic of Moldova

K. Boiciuc, *D. Badicean, V. Scurtu, N. Usurelu, V. Sacara;*
Institute of Mother and Child, Chisinau, Moldova, Republic of.

Phenylketonuria (PKU) is an inherited metabolic disorder, autosomal recessive (OMIM 261600), caused by deficiency of phenylalanine hydroxylase (PAH, EC 1.14.16.1) that leads to severe mental retardation. The aim of our research was to appreciate prevalence of PKU in Moldavian population and of PAH gene mutations identified in PKU patients.
Materials and Methods: Research was performed on DNA collected from 99 Moldavian PKU patients accumulated during 25 years. PKU detection by neonatal screening was based on the fluorimetric method. Identification of 10 PAH gene mutations (R408W, P281L, R158Q, R261Q, R252W, IVS12+1G>A, L48S, R261X, G272X, IVS10-11G>A) was performed by PCR/RFLP.
The results: According to neonatal screening data the frequency of PKU in Republic of Moldova is 1:7325 newborns, the average screening rate being 75.2%. In PKU patients were identified following genotypes: R408W/R408W (27.6%), R408W/P281L (7.1%), R408W/R261Q (3.5%), R408W/L48S (3.5%), R408W/R158Q (2.3%) etc. The most frequent PAH gene mutation in Moldavian PKU patients is R408W (50,6%) followed by P281L (5.5%), L48S (4.9%), R261Q (3.1%), R158Q (3.1%), R252W (3.1%), IVS12+1G>A (2.4%), IVS10-11G>A (2.4%), R261X (1.2%) and G272X (0.6%). The mutation detection rate in PKU patients constituted 78.7% of the cases. L48S, R261X, G272X, IVS10-11G>A mutations are recently investigated in Moldavian PKU patients due to their high prevalence in neighboring populations as Serbia, Romania, Turkey etc.
Conclusion: The obtained data revealed a high degree of heterogeneity of Moldavian PKU patients in the PAH locus that could be the result of population heterogeneity open new possibilities for prenatal diagnostics in risk families.

PS06.57

Intractable seizures and tendency for cerebral and portal vein thrombosis in a family with inherited Glycosylphosphatidyl inositol deficiency due to a mutation in *PIGM*

B. Pode-Shakked[1,2,3], *G. Heimer*[4,2], *T. Vilboux*[5], *T. C. Markello*[5], *G. Kenet*[6,3], *B. Ben-Zeev*[4,3], *E. Rozenthal*[7], *M. Huizing*[5], *M. Soudack*[8,3], *D. Levinkopf*[1], *B. Weiss*[9,3], *W. H. Gahl*[5], *Y. Anikster*[1,3];

Defects of the glycosylphosphatidylinositol (GPI) biosynthesis pathway constitute an emerging group of inherited disorders of heterogeneous phenotype, which are a subgroup of congenital disorders of glycosylation. A mutation in the promoter of *PIGM* has been identified as the cause of portal vein thrombosis and persistent absence seizures in three patients known to date. In one patient, targeted treatment with Sodium-Phenylbutirate has been described.
We report of two siblings, born to consanguineous parents of Arab-Muslim descent, who presented with macrocephaly, absence seizures, and gastrointestinal bleedings due to portal vein thrombosis. An extensive diagnostic evaluation was futile, including Whole Exome Sequencing (WES) which failed to establish a diagnosis. However, focused sequencing of the *PIGM* gene including its promotor region found the patients to be homozygous for the -270C>G mutation previously described. One of the siblings died awating liver transplantation, while the other is treated with Sodium-Phenylbutirate with improvement in her seizure frequency and severity. Finally, during a new pregnancy, prenatal diagnosis was pursued via amniocentesis, and unfortunately had found the fetus as homozygous for the same mutation. A third affected sibling was born, and at 7 months of age had already shown portal vein thrombosis, as well as evidence of cerebral infarct, and Sodium-Phenylbutirate treatment was initiated.
In conclusion, we expand the current knowledge on *PIGM*-associated GPI deficiency, with further clinical, pathological and molecular delineation of this unique entity, including the first prenatal diagnosis, and additional insights into the targeted-treatment with Sodium-Phenylbutirate. This case also underscores one of the pitfalls of WES.

POLG mutations in late-onset ataxia of unknown origin

D. Piekutowska-Abramczuk[1], *A. Sułek*[2], *J. Trubicka*[1], *B. Brodacki*[3], *O. Emilianowicz*[1], *P. Hałat*[1], *D. Jurkiewicz*[1], *M. Pelc*[1], *E. Ciara*[1], *M. Krajewska-Walasek*[1], *E. Pronicka*[1];
[1]*Children's Memorial Health Institute, Warsaw, Poland,* [2]*Institute of Psychiatry and Neurology, Warsaw, Poland,* [3]*Military Institute of Medicine, Warsaw, Poland.*

Mutations in the mitochondrial DNA polymerase gamma (*POLG*) gene cause a highly heterogenic disease spectrum including inherited ataxias. The reports about their frequency in unclassified forms of ataxia yield equivocal results, thus leading to uncertainties about the role of *POLG* in these conditions. The most common pathogenic *POLG* variants associated with ataxic phenotype are c.1399G>A (p.A467T), c.2243G>C (p.W748S) and c.2542G>A (p.G848S).
We assessed the frequency of selected *POLG* mutations in a cohort of 427 individuals (211 females and 216 males) with clinical symptoms of late-onset spinocerebellar ataxia (SCA), in whom the most frequent dynamic mutations causing autosomal dominant SCA (SCA1, 2, 3, 6) were excluded. DNA samples were obtained from leukocytes of peripheral blood. Genotyping of the samples was performed by real-time PCR technique using specific TaqMan allele discrimination assays.
Two heterozygous carriers and one p.W748S homozygote were identified in the studied group. The 52-year old patient presented with progressive cerebellar syndrome, sensory-motor polyneuropathy and ophtalmoplegia with atrophy of cerebellum, and less pronounced atrophy of the brain stem in neuroimaging examination. The age of onset was 30. Positive family history was reported: his brother demonstrated similar clinical signs and his sister died at 33 years due to the epileptic seizures.
Our findings are in line with the literature data and confirm that *POLG* mutations are not a frequent cause of late-onset ataxia of unknown origin, but should be considered in the cases with sensory neuropathy and ophthalmoplegia.
The study was supported by the NCN project 2012/05/B/NZ2/01627 and EU POIG.02.01.00-14-059/09

ANALYSIS OF THE EXPRESSION OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTORS GAMMA (PPAR GAMMA) AND miR-27 IN OBESE PATIENTS

V. C. Rivero[1,2], *J. Triana*[3], *M. Pérez*[4,3], *M. Marcos*[4,3,5], *R. Gonzáles-Sarmiento*[5,2], *N. Matesanz*[6], *G. Sabio*[7];
[1]*Centro de investigación del Cáncer, Salamanca, Spain,* [2]*Molecular Medicine Unit. Department of Medicine. University of Salamanca., Salamanca, Spain,* [3]*Department of Internal Medicine University Hospital of Salamanca, Salamanca, Spain,* [4]*Molecular Medicine Unit. Department of Medicine. University of Salamanca, Salamanca, Spain,* [5]*Institute of Biomedical Research of Salamanca (IBSAL, Salamanca, Spain,* [6]*Department of Vascular Biology and Inflammation, Salamanca, Spain,* [7]*Department of Vascular Biology and Inflammation, Madrid, Spain.*

Obesity acts as a stress signal that induces multiple inflammatory responses in tissue, which plays an important role in the pathogenesis of cardiovascular disease and metabolic syndrome. The PPARgamma is a nuclear receptor that regulates adiposity differentiation, insulin sensitivity and lipid metabolism. Recent studies have shown that PPAR-γ may be regulated by miR-27a and miR-27b, pointing to a possible relationship with the development of obesity.

We compared 43 obese adults with body mass index (BMI) >35 who underwent bariatric surgery versus 19 healthy controls with BMI <25. Intraoperative biopsies of visceral fat and peripheral fat were taken. The expression of mRNA was examined by quantitative PCR analysis using a 7900 Fast Real-Time PCR machine. Statistical analysis was calculated by using the program SPSS.
Significant association was detected between a decrease in the expression of PPAR-γ1 in obese female patients and controls (P=0.045). We observed a negative correlation between expression of PPAR-γ1 in visceral adipose tissue, weight (P=0.016) and BMI (P=0.001). This inverse correlation was stronger in women group in which an inverse correlation of PPAR-γ2 was observed with weight (P=0.004) and BMI (P=0.001). No association was found in the expression of micro-RNAs in the group of cases and controls.
These findings suggest that obese patients with higher BMI have a lower expression of PPAR-γ1 in adipose tissue, particularly in women and visceral adipose tissue. The expression of PPAR-γ could be related to the metabolic status and the degree of obesity.

PM06.60
A case of neonatal progeroid syndrome: Widemann-Rautenstrauch or Petty-Laxova-Wiedemann ?

H. M. Kathom, *D. Avdjieva-Tzavella, R. Tincheva;*
Department of Clinical Genetics, University Pediatrics Hospital, Medical University Sofia, Sofia, Bulgaria.

Progeroid syndromes are a group or rare genetic disorders that mimic physiological aging. Some of the syndromes in this group are presented at birth and therefore are called neonatal progeroid syndromes. Many of those syndromes have clear genetic causes still both neonatal progeroid syndromes of Wiedemann-Rautenstrauch and Petty-Laxova-Wiedemann, remain with unknown causes.
We report a 9 month old boy with progeroid features presented at birth. The physical examination showed marmorated and loose skin, apparent macrocephally, sparse hair, prominent scalp veins, small and beak shaped nose, downslating papebral fissures, triangular face, dysplastic, low set ears with small lobes, sharp and pointed chin, thin squamous toe nails.
Our patient presents features of both Wiedemann-Rautenstrauch and Petty-Laxova-Wiedemann. Most progeroid syndromes which are part of the differential diagnosis were rejected with DNA analysis. Additional laboratory findings, follow-up and management will be further discussed.

PS06.61
Genotype-Phenotype Correlation in PIK3CA-related overgrowth

R. G. Knox[1], *V. E. R. Parker*[1], *A. Luchetti*[2], *I. A. Isaac*[1], *H. Martin*[2], *J. Harris*[1], *E. Maher*[2], *R. K. Semple*[1];
[1]*University of Cambridge Metabolic Research Laboratories, Institute of Metabolic Science, Cambridge, United Kingdom,* [2]*Clinical Genetics, Cambridge University NHS Trust, Cambridge, United Kingdom.*

Introduction: *PIK3CA* encodes the p110α catalytic subunit of phosphoinositide 3-kinase and is a key mediator of cellular growth, survival and metabolism. Mosaic activating mutations in *PIK3CA* give rise to a wide spectrum of clinical presentations which are critically dependent upon the timing of the mutation during embryogenesis, and the cell type affected. The extent of genotype-phenotype correlation has been less clear from studies to date.
Method: DNA derived from affected tissue of 96 probands was target-enriched with an Ion AmpliSeq™ panel, and sequenced on an Ion Torrent platform. Clinical diagnoses at presentation included hemihyperplasia (25%), macrodactyly (16%), MCAP/MPPH (13%), and CLOVES (8%). 48/96 (50%) probands to date have been found to have mosaic *PIK3CA* mutations. Genotype-phenotype correlation analyses were performed using Chi-squared testing to compare clinical features and mutation site grouped by p110α functional domain (ABD, C2, helical and kinase).
Results: The only significant correlation identified was between genotype and the presence of vascular abnormalities, with higher proportions of patients with ABD and C2 domain mutations bearing vascular abnormalities.

Clinical feature(s)	% of probands with clinical feature	Correlation with *PIK3CA* Domain Mutated	Chi-squared P value
Progressive disease	56	No	0.63
Syndactyly	19	No	0.22
Polydactyly	8	No	0.30
Epidermal naevi	15	No	0.53
Scoliosis	13	No	0.16
Lipoma/lipomatous mass development	13	No	0.54
Vascular abnormalities	25	Correlated with ABD and C2 domain mutations	0.001

Conclusions: This small analysis suggests that *PIK3CA* genotype may indeed influence clinical presentation. Larger numbers of genotype-phenotype correlations should be undertaken to clarify this, to allow improved prognostication and patient stratification for clinical trials.

PM06.62
Vitamin E therapy in Smith-Lemli-Opitz syndrome patients

K. Koczok[1], *G. P. Szabo*[2], *L. Horvath*[3], *N. A. Porter*[4], *I. Balogh*[1];
[1]*University of Debrecen, Department of Laboratory Medicine, Division of Clinical Genetics, Debrecen, Hungary,* [2]*University of Debrecen, Department of Pediatrics, Debrecen, Hungary,* [3]*University of Debrecen, Department of Pharmacy, Debrecen, Hungary,* [4]*Vanderbilt University, Department of Chemistry, Nashville, TN, United States.*

Smith-Lemli-Opitz syndrome (SLOS) is an autosomal recessive, multiple malformation syndrome caused by 7-dehydrocholesterol reductase enzyme deficiency. Decreased cholesterol, elevated 7-dehydrocholesterol (7-DHC) and oxidative derivatives of 7-DHC (oxysterols) are thought to contribute to the pathophysiology of SLOS. According to recent data vitamin E could be effective in reducing oxidative stress in SLOS patients. We have started vitamin E treatment (in addition to cholesterol supplementation) in seven SLOS patients. Starting daily doses of RRR-alpha-tocopheryl acetate were 230 mg for young patients (age group: 4 to 10 years) and 2x230 mg above 10 years of age. Plasma vitamin A and E concentrations of the patients were monitored monthly by HPLC method. Behavioral effects of the treatment were determined using the Aberrant Behavior Checklist (ABC). All patients had vitamin E deficiency before the treatment, while vitamin A concentrations were normal in all but one patient. Vitamin E levels reached reference range in five patients after one month and remained stable. According to four scores (irritability, lethargy, stereotypic behavior, hyperactivity) of ABC no positive effect on behavior could be detected after 3 months. The fact that our patients were vitamin E deficient but vitamin A concentrations were in the normal range except for one patient suggests a higher utilization of vitamin E and not an inadeqaute absorption. No positive behavioral effects of the treatment could be detected after the first three months.
This study was supported by the Hungarian Research Fund (K109076, I.B.).

Morphological and proteomic studies reveal autophagy as a main driver on Smith-Lemli-Opitz syndrome

M. L. Cardoso[1,2], *R. Vitorino*[3], *R. Pinto Leite*[4], *R. Arantes-Rodrigues*[4], *R. Fernandes*[2], *C. Amaral*[1], *C. Bernardo*[5], *H. Reguengo*[1,6], *R. Ferreira*[3], *F. Amado*[3], *F. Marques*[1,2];
[1]*Faculty of Pharmacy, University of Porto, Porto, Portugal,* [2]*Institute for Molecular and Cell Biology (IBMC), University of Porto, Porto, Portugal,* [3]*QOPNA, Mass spectrometry center, Department of Chemistry, University of Aveiro, Aveiro, Portugal,* [4]*Genetic Service, Cytogenetic Laboratory, Hospital Center of Trás-os-Montes e Alto Douro, Vila Real, Portugal,* [5]*Experimental Pathology and Therapeutics Group, Research Center, Portuguese Oncology Institute, Porto, Porto, Portugal,* [6]*Department of Clinical Chemistry, Porto Hospital Center, Porto, Portugal.*

Introduction: Studies reporting the dramatic consequences of low cholesterol levels on cells are scarce. In this study we used fibroblasts from Smith-Lemli-Opitz syndrome patients (SLOS) - a metabolic genetic disease affecting the cholesterol biosynthesis pathway - to investigate the consequences of cholesterol deficiency on cell morphology and protein expression.
Materials and methods : Morphological studies (MTT test, immunocytochemistry for LC3, MDC and acridine orange coloration as well as electron microscopy) and proteomic analysis (iTRAQ LC /MS-MS) were performed on fibroblasts from SLOS patients and human controls, simultaneously cultivated both on standard conditions and cholesterol depleted media.
Results: Morphological studies showed that when endogenous synthesis of cholesterol is inadequate (SLOS) and there is no appropriate supply to overcome cellular needs (cholesterol depleted media), cell proliferation in vitro becomes impaired and autophagy is activated.
Furthermore, SLOS cells in cholesterol depleted medium show an overexpression of a set of proteins. Mainly, these cells seems to increase MnSOD expression to combat oxidative stress derived from the increased amount of 7-dehydrocholesterol and its derivatives, caused by the inherited enzymatic deficiency and thus control cell proliferation, whereas heat shock 70 kDa protein 4, an autophagic protein (Atg2) also presents a cytoprotective activity and inhibits apoptosis.
Conclusion: We conclude that the mechanism by which SLOS fibroblasts handles their metabolic deficit, involves autophagy which plays an important role in cell survival. Furthermore this work provided powerful indications that may be useful to expand the knowledge about the mechanisms involved in cellular pathophysiology of SLOS.

Association of GLP1R and HTR2A Polymorphisms with Obesity and Metabolic Traits in a Malaysian Population

Y. D. Apalasamy[1], *S. Rampal*[2], *T. T. Su*[3], *F. M. Moy*[2], *H. Abdul Majid*[3], *A. Bulgiba*[2], *Z. Mohamed*[1];

[1]*Department of Pharmacology, University of Malaya, Kuala Lumpur, Malaysia,* [2]*Julius Centre University of Malaya, Department of Social and Preventive Medicine, University of Malaya, Kuala Lumpur, Malaysia,* [3]*Centre for Population Health, Department of Social and Preventive Medicine, University of Malaya, Kuala Lumpur, Malaysia.*

Obesity is frequently associated with metabolic complications such as hypertension, diabetes and cardiovascular diseases. Obesity is a complex disease with high heritability estimates (> 0.70). Glucagon-like-Peptide-1 receptor (GL1PR) plays important roles in glucose homeostasis and inhibition of appetite by acting on brain. On the other hand, Serotonin Receptor (HTR2A) is a neurotransmitter which works closely with leptin and insulin in metabolic response to dietary intake. It is largely unclear whether genetic variations in these receptor genes lead to individual differences in susceptibility to metabolic complications. Therefore we investigated the associations of single nucleotide polymorphisms (SNPs) of GL1PR and HTR2A genes with obesity and metabolic traits. A total of 676 Malaysian Malays, obese (n=197) and non-obese (n=479) were genotyped for the GL1PR rs2268641 and HTR2A rs912127 SNPs. Anthropometric, fasting plasma glucose, body fat and lipid levels were measured. Data were analyzed using Multivariate linear models. After adjusting the age and gender, it was found that GL1PR rs2268641 was significantly associated with hip circumference (HC), (p=0.015). The GA allele carriers had significantly higher HC (Mean (cm) =102.22±9.83) compared to GG and AA homozygotes. HTR2A rs912127 SNP was also significantly associated with waist hip ratio (WHR), (p=0.001) after adjusting the age and gender. AA homozygotes had higher WHR (Mean=0.89±0.10) compared to G allele carriers. However, both the SNPs were not associated with logBMI. While these findings require replication in larger studies, we provide new evidence that GLP1R and HTR2A receptor gene variants may involve in metabolic abnormalities in Malaysian Malays.

Exome sequencing identifies TMEM70 deficiency in a Hungarian Roma family with severe congenital lactic acidosis

K. Komlósi[1], *K. Hadzsiev*[1], *T. B. Haack*[2,3], *E. Pöstyéni*[1], *J. Bene*[1], *A. Szabó*[1], *M. Czakó*[1], *F. Fónai*[4], *T. Meitinger*[2,3], *B. Melegh*[1];

[1]*Department of Medical Genetics and Szentagothai Research Center, University of Pécs, Pécs, Hungary,* [2]*Institute of Human Genetics, Technische Universität München, Munich, Germany,* [3]*Institute of Human Genetics, Helmholtz Zentrum München - German Research Center for Environmental Health, Munich, Germany,* [4]*Department of Obstetrics and Gynecology, University of Pécs, Pécs, Hungary.*

Pyruvate dehydrogenase deficiency underlies over half the cases of congenital lactic acidosis in children of Roma ethnicity, while lactic acidosis is also a presenting symptom of various rare mitochondrial disorders. We report here a Hungarian Roma family with two boys affected by severe congenital lactic acidosis, poor feeding, lethargy, cardiomyopathy, hypotonia and respiratory failure. The first boy died at 6 months of age due to sepsis and acute metabolic crisis, while the second boy survived with early initiation of a ketogenic diet and shows severe developmental delay, hypotonia, growth retardation, microcephaly and cardiomyopathy at 2,5 years. Enzymatic analysis of patient fibroblasts did not reveal any abnormality in pyruvate dehydrogenase activity, and no mtDNA mutations were detected. Whole exome sequencing (WES) of the second son with SureSelect Human All Exon Kit and 100 basepair paired end sequencing was carried out on an Illumina HiSeq2500 system with >97% of target covered >20-fold. Applying an autosomal recessive model, 94 rare variants were identified, but only 3 out of 20 annotated genes were known to have a role in mitochondrial metabolism. Only *TMEM70* carried a homozygous predicted loss-of-function variant: the common c.317-2A>G splice site mutation resulting in ATP synthase deficiency. Segregation analysis revealed homozygosity in both affected brothers and heterozygosity in the parents and the healthy sister. We describe the first Hungarian family with TMEM70 deficiency, supporting the clinical utility of WES when addressing a group of disorders with large genetic heterogeneity.

Thioredoxin 2 deficiency causes early-onset neurodegeneration

E. Holzerová[1,2], *K. Danhauser*[3], *L. S. Kremer*[1], *C. Terrile*[1], *T. B. Haack*[1], *H. Prokisch*[1,2], *F. Distelmaier*[3];

[1]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany,* [2]*Institute of Human Genetics, Technische Universität München, Munich, Germany,* [3]*Department of General Pediatrics, Neonatology and Pediatric Cardiology, University Children's Hospital, Heinrich-Heine University, Düsseldorf, Germany.*

Thioredoxin 2 (TXN2) is a mitochondrial redox protein, which is ubiquitously expressed with the highest expression levels in brain tissue. It is encoded by a nuclear gene, *TXN2*, containing a mitochondrial targeting sequence. TXN2 plays a crucial role in oxidative stress defense and in the regulation of the mitochondrial apoptotic pathway. Animal studies suggest that TXN2 is essential during embryonic development.

Using exome sequencing in a 15-year-old adolescent suffering from an early onset neurodegenerative disorder with severe cerebellar atrophy, epilepsy, peripheral neuropathy, dystonia and combined respiratory chain deficiency in muscle tissue, we identified a homozygous stop mutation in *TXN2*. TXN2 protein was not detectable in patient fibroblasts, confirming the predicted loss of function. Cellular studies revealed increased reactive oxygen species (ROS) levels, impaired oxidative stress defence and secondary mitochondrial dysfunction with reduced cellular respiration and diminished ATP production. Lentiviral expression of TXN2 restored all these parameters confirming the causal role of the mutation. Supplementations with antioxidants effectively suppressed cellular ROS production, and lead to moderate clinical improvement during short term follow-up of the patient.

Our report on the first patient with TXN2 deficiency highlights the importance of TXN2 for neurodevelopment. Moreover, our results point to a potential role of antioxidant treatment in affected patients.

This project was supported by the BMBF funded German Network for Mitochondrial Disorders (mitoNET #01GM1113C), by the E-Rare project GENOMIT (01GM1207) and by EU FP7 Mitochondrial European Training project (317433).

A Patient with Ornithine Transcarbamylase Deficiency treated with Glycerol Phenylbutyrate: Preliminary Experience

R. S. ALTassan[1], *M. ALSayed*[1,2];

[1]*King FAisal specialist hospital and research center, Riyadh, Saudi Arabia,* [2]*King Faisal specialist Hospital and Research Center, Riyadh, Saudi Arabia.*

Control of hyperammonemic crisis in patients with Urea Cycle Disorders (UCDs) is of utmost importance to preserve cognition.

Glycerol phenylbutyrate (GPB) is an oral liquid formulation that has been recently approved by FDA for chronic management of patients >2 years old with UCDs that cannot be adequately managed by a protein- restricted diet. It has the same mechanism of action as Sodium phenylbutyrate NaPBA, but it is a sodium- and sugar-free pre-pro-drug of phenylacetic acid (PAA) that has little odor and taste.

Here we report a 13-year old OTC female with moderate cognitive delay, hyperactivity and recurrent hyperammonemic crisis (every 1-2 months). The patient had poor compliance to NaPBA due to it is salty taste and peculiar odor. After starting GPB, the patient showed significant improvement in the compliance as the medication was more tolerable compared to NaPBA. Her mother reported full compliance with the drug. Since starting the medication, there was significant decrease in ER visit/admissions with subjective improvement in activity.

Several short-term randomized controlled trials in adults and children with UCDs have supported the effectiveness of GPB in long term control of hyperammonemia, as well as significant improvement of behavioral function of UCDs patients. [1-5]

This is a preliminary report that supports the accumulating evidence of the effectiveness of this medication as a long term alternative choice for NaPBA non-complaint Urea Cycle patients.

PM06.68

Not typical North-European ATP7B gene mutation in Latvian patients with Wilson disease

A. Zarina[1,2], *L. Piekuse*[1,2], *M. Kreile*[1,2], *I. Tolmane*[3,4], *J. Keiss*[3], *G. Cernevska*[5], *I. Pukite*[5], *Z. Krumina*[5], *A. Krumina*[6];

[1]*Riga Stradins university Scientific laboratory of molecular genetics, Riga, Latvia,* [2]*Riga Stradins university Department of Biology and Microbiology, Riga, Latvia,* [3]*Riga East Clinical University Hospital, stationary "Infectology Center of Latvia", Riga, Latvia,* [4]*University of Latvia, Faculty of Medicine, Riga, Latvia,* [5]*Children Clinical university Hospital, Riga, Latvia,* [6]*Latvian Biomedical Research and Study Center, Riga, Latvia.*

Introduction.

Wilson disease (WD) is a disorder of copper metabolism, caused by mutations in gene *ATP7B*. More than 500 distinct mutations have been described in the *ATP7B* gene, from which 380 have a confirmed role in the pathogenesis of the disease (Wilson disease mutation database: http://www.wilsondisease.med.ualberta.ca/database.asp.). The most common mutation in the

Europe is H1069Q.
Materials and methods.
In total 235 patients have been sent for WD DNA diagnostics in Latvia. All the patients were first tested for the most common mutation H1069Q, by using PCR Bi-PASA method; 64 patients, clinically confirmed with WD, where the mutation H1069Q was not be found in both alleles, were tested for other possible mutations (in the exons 2, 3, 5, 6, 8, 11, 13, 14, 16, 18 of gene ATP7B – exons having the most common prevalence of mutations in WD patients) by direct sequencing.
Results.
Wilson disease was genetically confirmed in 42 patients. In total 68.94% of WD patients' alleles were identified: H1069Q (62.12%); M769Hfs*26 (2.27%); Val73GlufsX4 (1.52%) and D1267G, D765N, M645R, V1036I (0.76% for each); 31.06% of the alleles remained unidentified. Among the patients silent or not disease causing variants were found: R725R (2.27%); A1140V (12.12%); S406A (18.94%).
Conclusions.
1) The most prevalent mutation found in Latvian patients is H1069Q – in 62.12% cases;
2) Mutation Val73GlufsX4 presented in two patients is described among Sardinians and Bulgarians;
3) The study should be continued to test all the ATP7B gene, since the selective screening has not identified all the mutations.

PS06.69
Identification of a new CISD2 mutation in a French patient with a typical Wolfram syndrome

C. Rouzier[1], *C. Delorme*[2], *A. Chaussenot*[1], *S. Ait-El-Mkadem*[1], *K. Fragaki*[1], *S. Bannwarth*[1], *V. Serre*[3], *M. Catala*[2], *V. Paquis-Flucklinger*[1,4];
[1]*Reference center for mitochondrial disorders, Nice, France,* [2]*UMR 7622 CNRS et UPMC et Fédération de Neurologie, Université PIerre et, Paris, France,* [3]*Jacques Monod Institute, Paris Diderot University, Paris, France,* [4]*IRCAN UMR CNRS 7284 / INSERM U1081 / UNS, School of Medicine, Nice Sophia-Antipolis University, Nice, France.*

Wolfram syndrome is an autosomal recessive disorder characterized by diabetes mellitus and optic atrophy usually associated with diabetes insipidus, deafness, renal tract abnormalities or neuropsychiatric disorders, mainly associated with mutations in the WFS1 gene. Mutations in a second gene, CISD2, have also been described in patients with Wolfram syndrome type 2 characterized by diabetes mellitus and optic atrophy associated with peptic ulcer disease, bleeding tendency but without diabetes insipidus and psychiatric disorders. To date, only five families have been described and few data are available concerning both clinical phenotype and CISD2 function.
Among our French Wolfram syndrome cohort of 98 patients with at least diabetes mellitus and optic atrophy, we identified 2 WFS1 mutations in 78 patients (80%). We sequenced the CISD2 gene in the 20 patients with only one WFS1 mutation (7/98 patients, 7%) or without any mutation (13/98 patients, 13%). We identified a new missense homozygous CISD2 mutation, c.215A>G (p.Asn72Ser), in a patient with a «classical» Wolfram presentation without digestive or hematologic symptoms and who did not carry any WFS1 mutation. Segregation within the family, in silico analysis and absence in control individuals are in favor of the pathogenicity of this new variant.
In conclusion, we show that CISD2 must be analyzed in patients presenting with a «classical» Wolfram syndrome when WFS1 has been ruled out. Functional studies on primary fibroblasts, carrying the p.Asn72Ser CISD2 mutation, are in progress to determine the effects of this mutant and to understand the link between wolframin and CISD2 proteins.

PM06.70
Familial Chylomicronemia: Report of two Chinese infants presenting with lipemic plasma

J. Zhou[1], *Y. J. Zhang*[2], *W. X. Zheng*[1], *Z. Z. Lan*[1], *Z. W. Huang*[1], *H. Y. Yang*[1], *C. Liu*[1], *P. P. Jiang*[1], *R. Gao*[1];
[1]*BGI, ShenZhen, China,* [2]*Xin Hua Hospital Affiliated to Shanghai JiaoTong University School of Medicine, Shang Hai, China.*

We used a monogenic dyslipidemias panel paralleled next generation sequencing assay to detect disease causing mutations in two infants presented with severe hypertriglyceridemia and lipemic plasma.
Case Report-Case A: A 30-day-old Chinese boy, who was admitted to the local hospital for coughing for ten days, and the blood was found to be pink. Fasting serum lipids, which included triglyceride (TG) and cholesterol (CHOL) were abnormal, total cholesterol (TC) and triglyceridemia (TG) was 1270 and 757mg/dL, respectively. Subsequent genetic testing of the patient revealed compound heterozygosity of p.Arg270His and p.Trp421* mutations on LPL gene, both of which were known pathogenic mutations. Low-fat/low-cholesterol diet therapy was introduced. Unexpectedly, serum cholesterol level decreased dramatically, and normalized in 2 months.
Case Report-Case B: A 48-day-old Chinese boy initially presented with milk choking and polypnea, but no other co-morbidities. His triglyceride (TG) was 557mg/dL, but the cholesterol (CHOL) was normal. Genetic testing of the patient revealed compound heterozygosis of two known pathogenic mutations: one is p.Leu279Arg and another is a large fragment deletion on exon8/exon9/exon10. With a diet of low fat and vitamins added, the TG was controlled in a good level, and the baby was developing well in regard to stature, weight, and mind.
Based on the regional hybrid capture parallel next generation sequencing platform, both SNVs and large fragment deletion could be identified simultaneously. Familial Chylomicronemia is characterized by very severe hypertriglyceridemia and will lead to acute pancreatitis, which is often life-threaten. Timely diagnose and prevention is critical for patients' management and recovery.

PS07.01
A missense SNP in CNR2 gene is associated with childhood asthma severity and treatment outcome

C. E. P. Kozmus[1,2], **M. Deželak**[1], *V. Berce*[3], *U. Potočnik*[1,4];
[1]*Centre for Human Molecular Genetics and Pharmacogenomics, Faculty of Medicine, University of Maribor, Maribor, Slovenia,* [2]*Institute for Molecular and Cell Biology, University of Porto, Porto, Portugal,* [3]*Department of Pediatrics, University Medical Centre, Maribor, Slovenia,* [4]*Laboratory for Biochemistry, Molecular Biology and Genomics, Faculty of Chemistry and Chemical Engineering, University of Maribor, Maribor, Slovenia.*

Both the interaction of several genes as well as environmental factors influences the asthma pathogenesis. The rs2229579 is a missense SNP in the CNR2 gene that codes for the cannabinoid receptor 2.
We analyzed rs2229579 association with childhood asthma, and the effect of rs2229579 on the response to inhaled corticosteroids (ICS) or leukotriene receptor antagonist (LTRA) treatment and CNR2 gene expression. We studied a case-control cohort of 341 children mild/moderate persistent asthma and 245 controls. Blood samples were collected before treatment, and 4-6 weeks after treatment with ICS or LTRA.
Atopic asthmatic patients with CT genotype presented significantly higher FENO ($p=0.0303$), total IgE ($p=0.0146$) and lower log PC20 ($p=0.0403$). Non-atopic asthmatics with CT presented only significantly higher eosinophil count ($p<0.001$). After ICS treatment atopic asthmatics with CT genotype had less improvement of condition as measured by dFEV1/FVC ($p=0.0440$), while after LTRA treatment asthmatics with CT genotype had worsening condition measured by dFEV1/FVC ($p=0.0286$). No association was found between rs2229579 genotype and asthma or CNR2 gene expression. We found a significantly increased CNR2 gene expression in asthmatics before treatment compared to healthy controls ($p<0.0001$). Higher CNR2 gene expression was correlated with more severe asthma measured by FEV1/FVC ($p=0.0160$).
Our results suggest rs2229579 is associated with asthma severity and with ICS or LTRA treatment response in children with asthma, and suggest the involvement of the endocannabinoid system in asthma.

PM07.02
Association of NCOA5 gene rs2903908 variant with the Behcet's disease

A. Rustemoglu[1], *E. Erkol Inal*[2], *A. Inanir*[3], *D. Ekinci*[1], *U. Gul*[4], *S. Yigit*[1], *O. Ates*[1];
[1]*Gaziosmanpasa University, Faculty of Medicine, Department of Medical Biology, TOKAT, Turkey,* [2]*Suleyman Demirel University, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, ISPARTA, Turkey,* [3]*Gaziosmanpasa University, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, TOKAT, Turkey,* [4]*Akdeniz University, Faculty of Medicine, Department of Dermatology, Antalya, Turkey.*

Abstract
Behçet's disease (BD) is a multisystemic chronic inflammatory autoimmune disease of unknown etiology. Various genetic and environmental factors have effects on the pathogenesis of the Behcet's disease. NCOA5 gene encodes coregulator protein for ER-α which have affect in regulating autoimmunity, may have an impact on BD pathogenesis.
In this study, we aimed to clarify the impacts of the NCOA5 rs2903908 single nucleotide polymorphism (SNP) on susceptibility and clinical findings of BD.
This study included 300 BD patients and 288 healthy control patients. Genetic analyses were performed by using the TaqMan allelic discrimination assay. SPSS 16.0 Software was utilized to estimate OR and Chi-square tests.
The TT genotype of the NCOA5 rs2903908 SNP were significantly higher in

overall BD patients compared to those in healthy controls, and in patients with female gender compared to healthy female controls (p = 0.01, and p = 0.026, respectively). The CT genotype of the NCOA5 rs2903908 SNP was significantly higher in the patients with BD who had genital ulceration or uveitis compared to those in the patients group without genital ulceration and uveitis (p = 0.002, and p = 0.005, respectively). The C allele frequency was found statistically significantly higher in the BD patients with uveitis compared to those in the patients group who did not have uveitis (p = 0.0001, OR, 95%CI = 2.19, 1.48-3.23).
Our study represents the first time that the NCOA5 rs2903908 SNP seemed to be linked to BD susceptibility and clinical findings.

PS07.03
Frequency of the CCR5-delta 32 chemokine receptor gene mutation in the Czech population - study of 1 385 individuals

J. Jenčík, J. Thomayerová, K. Pavelcová, D. Panchártek, **R. Klubal***;*
Czech gene bank, Prague, Czech Republic.

Introduction: A direct correlation between HIV infection and mutation in the chemokine receptor (CCR5) gene has been established. The 32 bp deletion in the gene (CCR5-delta 32) alter function of the protein product, thereby altering chemokine binding/signaling. Homozygous carriers of the CCR5-delta 32 mutation are resistant to HIV-1 infection because the mutation prevents functional expression of the CCR5 chemokine receptor normally used by the most of HIV-1 strains to enter CD4 T cells. However, resistance is not absolute due to alternative CXCR4 co-receptor and HIV-1 isotropic switch.
Materials and methods: In the present study, we have determined by PCR the allelic frequency of the CCR5-delta 32 mutation in 1385 Czech individuals aged 4 - 86. CCR5-delta 32 homozygotes were confirmed by sequencing.
Results: 18,8% of studied individuals were heterozygous and 1,2% were homozygous for the mutation. Overall, the frequency for the CCR5-delta 32 allele was 10,6%. Distribution of the mutation was unaffected by sex or age.
Conclusion: The mutation is found principally in Europe and western Asia, with higher frequencies generally in the north. The frequency in the Czech population population is consistent with the origin of the mutation in northern Europe and natural gene flow into the central Europe. The CCR5-delta 32 mutation is a good example of an advantageous allele with a well-characterized geographic distribution, which may play important role in managing of HIV infection in the future. Allogeneic stem-cell transplantation or genome engineering represent the most promising HIV treatment options.

PM07.04
Expression analysis of Toll-like receptor pathway in celiac disease

I. Romero-Garmendia*, N. Fernandez-Jimenez, L. Plaza-Izurieta, A. Jauregi-Miguel, J. Bilbao;*
BioCruces Health Research Institute/Unibersity of the Basque Country, Leioa, Spain.

Introduction: Celiac disease (CD) is a chronic, immune-mediated gastrointestinal disorder that develops in genetically susceptible individuals due to an inappropriate immune response to ingested gluten. The only available treatment is a life-long gluten-free diet (GFD). Toll-like receptor (TLR) pathway is known to be crucial in the regulation of innate immunity, but also participates in the development of antigen-specific adaptive immunity. The aim of this study was to characterize a possible deregulation in TLR pathway in CD.
Materials and Methods: The expression of 28 genes related to TLR pathway was measured by RT-PCR in biopsies from 16 patients with active CD, 16 patients in a GFD and 15 non-celiac controls. The three groups where compared.
Results: Nine of the 28 genes were differentially expressed in active patients when compared to controls. *CXCL11*, *IFNG*, *CXCL10*, *IL10*, *IL6* and *CCL5* were overexpressed, whereas *TICAM1*, *TOLLIP* and *IRF3* were underexpressed. When treated patients and controls were compared, *IRF5* was underexpressed, and *TIRAP* overexpressed. *CXCL11*, *IFNG*, *CXCL10* and *IL6* were differentially expressed between active and treated patients. Results were contextualized with the results of 23 additional genes obtained recently in our laboratory.
Conclusions: Our results confirmed significant alterations in several genes. Patients treated with GFD showed a less altered pattern, although some genes remain altered suggesting a constitutive role in the pathogenesis of CD. Additionally, different degrees of alteration among the receptors, the pathway core and genes encoding costimulatory proteins, cytokines and interferons in active patients suggest a probable alteration downstream of the receptors.

PS07.05
Rapid detection of the three celiac disease risk genotypes HLA-DQ2.2, DQ2.5 and DQ8 by multiplex ligation dependent probe amplification.

R. Vijzelaar[1]*, A. van Gammeren*[2]*, E. van der Zwan*[3]*, R. Yilmaz*[1]*, I. van Hoogstraten*[4]*, A. Verheul*[5]*, E. de Baar*[2]*, L. Schrauwen*[2]*, W. Kortlandt*[5]*;*
[1]MRC-Holland, Amsterdam, Netherlands, [2]Laboratory of Clinical Chemistry and Hematology, Amphia Hospital, Breda, Netherlands, [3]Laboratory of Clinical Chemistry and Hematology, Sint Franciscus Gasthuis, Rotterdam, Netherlands, [4]Department of Pathology VU Medical Center, Amsterdam, Netherlands, [5]Laboratory of Clinical Chemistry and Hematology, Diakonessenhuis, Utrecht, Netherlands.

Celiac Disease (CD) is a chronic, small intestinal enteropathy and is associated with the HLA genotypes HLA-DQ2.5 (HLA-DQA1*05 / HLA-DQB1*02), HLA-DQ8 (HLA-DQA1*03 / HLA-DQB1*0302). More recently also HLA-DQ2.2 (HLA-DQA1*02 / HLA-DQB1*02) has been identified to predispose for CD. Genotyping of the HLA-DQA1 and HLA-DQB1 genes is important since genetic HLA-DQ2.2, -DQ2.5, and -DQ8 testing has a very strong negative predictive value. Testing for relevant alleles is therefore recommended for risk stratification of individuals genetically susceptible to CD.
The Multiplex Ligation-Dependent Probe Amplification (MLPA) probemix P438-D1 was developed to simultaneously detect the A and B subunits of the heterodimeric DQ2.2, DQ2.5, and DQ8 molecules. For each allele, i.e. HLA-DQA1*02, HLA-DQA1*03, HLA-DQA1*05, and HLA-DQB1*02, two probes have been added to the probemix. Three probes have been included to detect the HLA-DQB1*0302 allele of the HLA-DQ8 B-unit: one probe detects all HLA-DQB1*03 alleles while the other two probes detect HLA-DQB1*0302/*0303 or HLA-DQB1*0302/*0305.
Results obtained by the MLPA assay confirmed the results of 39 samples previously genotyped by conventional PCR-SSO, PCR-SSP and PCR-SSCP/HD methods, to accurately determine the presence of DQ2.2, DQ2.5 or DQ8 genotypes. In addition, MLPA has been shown to be able to distinguish between heterozygous or homozygous state of the alleles which is of importance since homozygous HLA-DQB1*02 in presence or absence of HLA-DQA1*02 or HLA-DQA1*05 also predisposes for CD.
The P438-D1 MLPA probemix provides a quick, reliable and complete method to determine all three HLA-DQ genotypes relevant for CD.

PM07.06
Frequencies of haplotypes associated with Coeliac disease in the Czech population

M. Koudová*, M. Blašková, M. Bittóová, Z. Vlčková, V. Indráková, M. Hlaváčová, V. Nedvědová, M. Rímska, I. Slepičková, L. Pavlíčková;*
GHC GENETICS, Prague, Czech Republic.

Celiac disease (CD) is a chronic small intestinal immune-mediated enteropathy precipitated by exposure to dietary gluten in genetically predisposed individuals. There are HLA-DQ heterodimers that especially increase an individual's predisposition to CD: DQA1*0501-DQB1*0201 in cis position (haplotype DQ2.5cis), DQA1*0505 - DQB1*0301/ DQA1*0201 - DQB1*0202 in trans position (haplotype DQ2.5trans) and DQA1*0301-DQB1*0302 in cis positon (haplotype DQ8.1). The aim of this study was to determine the frequency of mentioned CD-risk haplotypes in Czech population and to compare it with the previously published data.
216 healthy individuals (101 males and 115 females, age 18-69 years) of the Czech population were tested. DNA was isolated from oral mucosa or blood using MagCore HF16. CD-risk alleles were tested by strip assay certified method (CeliacStrip).
The overall frequency of CD-risk haplotypes in Czech population was 36.1%. Haplotype DQ2.5cis was detected in 18.5%, haplotype DQ8.1 in 14.8% and haplotype DQ2.5trans in 2.8% of samples. In 30.6% of samples no risk allele was detected.
The frequency and dominance of DQ2.5cis over DQ2.5trans haplotype is in agreement with previously published data, but the high frequency of DQ8.1 among individuals with genetic risk (41%) is surprising, because this haplotype is found only in 5% of patients with CD in Europe. This may indicate that DQ8.1 is among Czech patients with CD in higher frequency than in European or DQ8.1 haplotype means lower genetic risk to develop CD or it is associated with subclinical CD (non-typical or silent form) and patients with this haplotype are not diagnosed.

PS07.07
Genome-wide copy number variation analysis in systemic lupus erythematosus

F. B. Barbosa[1]*, M. Simioni*[2]*, F. R. Torres*[2]*, E. A. Donadi*[3]*, V. L. Gil-da-Silva-Lopes*[2]*,* **A. L. Simões**[1]*;*

Immunology, Department of Medicine, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto (SP), Brazil.

Systemic Lupus Erythematosus (SLE) is an autoimmune disease with a strong genetic background characterized by chronic inflammation and autoantibody production. Genome-wide association studies identified several loci associated with SLE pathogenesis. However, there are few studies that focus on the role of copy number variations (CNVs) in SLE etiology. The purpose of this study was to determine the role of CNVs in SLE patients. Lupus nephritis (LN) was a criterion of inclusion for this study. Blood cell lymphocytes from 23 SLE unrelated patients and 44 healthy subjects were submitted to the Genome-Wide Human Cytoscan HD Array (Affymetrix®) in order to screen for CNVs in genomic DNA. SLE patients and controls had no statistic difference in total CNV numbers, median size of CNVs, and the proportion of the genome covered by CNVs. However, our results showed that SLE patients have common and rare CNVs in the loci that may contribute to the increased risk for SLE. We identified six common copy number variation regions (CNVRs) as potential candidates involved with SLE in 8p11.22, 14q32.33, 22q13.33, Xp22.33 (2), and Xp26.2 loci (OR = 3.2–11.94; p = 0.0002–0.033). A total of 147 rare CNVs were detected and validated *in silico* in SLE patients. Rare deletions were found in two genes related to autoimmunity: *STAT4* and *CFHR5*. This is the first report describing CNVs and CNVRs encompassing these regions in SLE patients. Financial Support: FAPESP (2013/17062-9;2011/23794-7), CNPq (312547/2009-9) and CAPES.

Introduction: Common variable immunodeficiency (CVID) is the most common symptomatic primary immunodeficiency, with a prevalence between 1/ 30,000 to 1/200,000 and reported incidence of 1/75,000 births. The genetic defect underlying some of the primary immune deficiencies including CVID remains unknown, and the current hypothesis is that it might be multigenic. We have applied the next-generation sequencing technologies to the study of CVID.
Material and Methods: The study has been performed in 36 patients with CVID diagnosed from a Spanish cohort including sporadic as well as familiar cases. CVID diagnosis was made using current international criteria. Patients were analyzed by exome sequencing and copy number variants (CNV) analysis.
Results: We obtained an initial list of about fifty candidate genes for each patient. Candidate genetic variants were validated in the context of pedigrees, according to different genetic models for the disease. Functional classifications coupled with an in-house algorithm for prioritizing mutations generated a shorter list of candidate genes for each patient. The integrated analysis of genetic data, together with the collected clinical and laboratory data, narrowed down the list of candidate causal genes and mutations. Functional validation of candidate genes is being performed to test their role in the molecular origin of CVID.
Conclusions: Exome sequencing is a powerful tool to detect the causal variants in CVID cases with Mendelian inheritance. Our results also suggest an oligogenic model for the disease in some patients.
Funding: This work was funded by grant SAF2012-35025 from the Spanish Ministerio de Economía y Competitividad to FC.

Sanger sequencing of neutrophil elastase in a neonate with congenital neutropenia

B. J. Scally[1], *N. Roy*[1], *A. Qureshi*[2], *A. Pollard*[2];
[1]*Weatherall Institute of Molecular Medicine, Oxford, United Kingdom,* [2]*Department of Paediatrics, Oxford University Hospitals NHS Trust, Oxford, United Kingdom.*

Introduction: A male neonate presented with recurrent deep-seated skin infections within the first four weeks of life. Full blood count identified severe neutropenia. Separation of the umbilical cord was delayed beyond two weeks of life; physical examination of the neonate was otherwise normal with no dysmorphic features identified. Family pedigree was unremarkable.
Methods: Sanger sequencing of the ELANE gene was performed in the proband, mother and father. Sequencing was approved by the NHS National Research Ethics Service (12/SC/0044) with the purpose of accurate diagnosis prior to bone marrow transplant.
Results: Sequencing identified a single heterozygous missense mutation in Exon 2, not present in either parent. The mutation (c.193G>T) was predicted to result in an amino acid change p.(Val65Phe). This would alter the property of the specific amino acid from an aliphatic Valine to an aromatic Phenylalanine. SIFT analysis predicted this variant to affect protein function with deleterious effects that would not be tolerated (calculated probability of 0.00). Polyphen 2 analysis predicted this variant to be highly damaging (calculated probability of 1.00).
Conclusions: This is the first description of delayed separation of the umbilical cord associated with an ELANE c.193G>T mutation. Neonatal neutropenia due to a variety of causes is associated with delayed separation of the cord. Although the c.193G>T mutation has previously been reported in cases of congenital neutropenia, more detailed clinical phenotyping of these rare cases will help reduce time to diagnosis in this life-threatening and potentially treatable disease. The baby requires high doses of G-CSF (25 mcg/kg/day), which is in keeping with a severe phenotype.

PS07.11

Courier gene to deliver embedded DNA vaccine to immunize patients against intracellular human immunodeficiency virus

L. B. A. Scheiber II, *L. B. Scheiber;*
Osteoporosis & Arthritis Center, Trenton, MI, United States.

A DNA sequence has been designed to be embedded into the human genome (Table 1), when transcribed is intended to generate a mRNA, this mRNA when translated to produce a therapeutic Transcription Factor IIIA (TFIIIA) molecule to engage the HIV genome (GenBank K03455.1). We modified TFIIIA molecule (NC_000013), altering zinc fingers 1-5, to bond to HIV's unique identifier, ‚agcagctgctttttgcctgtactgg', nucleotides 431-455, the 25 nucleotides located between the TATA box and transcription start site. We studied amino acid-nucleotide binding characteristics. Permanently binding a TFIIIA to HIV's unique identifier is intended to prevent transcription of the HIV genome. Using a reverse transcription process, we developed a transcribable segment of DNA. The Tumor Necrosis Factor alpha (TNF) gene (AY214167.1) is active in CD4+ lymphocytes, including the reservoir for HIV. Transcribable sequence of DNA coding for the therapeutic TFIIIA molecule replaces the TNF's original mRNA's protein coding sequence from nucleotides 1750-4519. The modified TNF gene utilizes TNF gene's original 5' upstream and 3' downstream signaling segments. The modified TNF gene acts as a courier to transport the embedded DNA vaccine sequence. Likened to HIV genome, the modified TNF gene is inserted into the human genome and functions like an alternative copy of the TNF gene. The embedded DNA vaccine undergoes transcription, to produce mRNAs which generate TFIIIAs designed to seek out and silence the HIV genome, creating a cell defensible against intracellular HIV infection.

Genetic and acquired abnormalities causing dysregulation of the complement alternative pathway contribute to atypical hemolytic uremic syndrome (aHUS), a rare disorder characterized by thrombocytopenia, non-immune microangiopathic hemolytic anemia, and acute kidney failure. However, in a substantial proportion of patients the disease-associated alterations are still unknown.
We studied a family with infantile recessive aHUS, in whom whole-exome sequencing analysis with conventional variant filtering parameters did not reveal any obvious candidate mutation. The report of aHUS-associated mutations in *DGKE*, encoding diacylglycerol kinase epsilon, led us to re-examine the non-coding *DGKE* variants obtained from next-generation sequencing, allowing identification of a novel intronic *DGKE* mutation (c.888+40A>G) that segregated with disease. Sequencing of cDNA from affected individuals revealed aberrant forms of *DGKE* mRNA predicted to cause profound abnormalities in the protein catalytic site. The same mutation was found in compound heterozygosity with a second nonsense *DGKE* mutation in all affected siblings of another unrelated family. Homozygous and compound heterozygous patients presented similar clinical features, including aHUS presentation in the first year of life, multiple relapsing episodes and proteinuria, which are prototypical of DGKE-associated aHUS.
This is the first report of a mutation located beyond the exon-intron boundaries in aHUS. Intronic mutations such as these are underreported since conventional filtering parameters used to process next-generation sequencing data routinely exclude these regions from downstream analyses in both research and clinical settings. Our results suggest that analysis of non-coding regions of aHUS-associated genes coupled with mRNA sequencing might provide a tool to explain genetically unsolved aHUS cases.

PS07.13

Clinical exome sequencing of Finnish primary immunodeficiencies

M. Kaustio[1], *L. Trotta*[1], *H. Almusa*[1], *T. Martelius*[2], *M. Seppänen*[2], *J. Saarela*[1];
[1]*Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland,* [2]*Immunodeficiency Unit, Inflammation Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.*

Primary immunodeficiency diseases (PIDs) are disorders in which part of the immune system malfunctions as a result of mutations in immune related genes. To date, over 220 genes responsible for these diseases have been recognized, and this list is rapidly growing. The diagnosis of PIDs based on symptoms is often difficult, as they overlap between disorders and can also vary considerably between individuals with mutations in the same gene. To elucidate the genetic causes for disease, we are performing clinical whole exome sequencing on Finnish PID patients. Our cohort currently consists of roughly 150 index cases, about 100 of which have been sequenced by now. We have detected both previously identified and novel disease variants in known PID genes, as well as identified putative disease variants in genes that have not been previously associated with such diseases. For example, several variants in the *TNFRSF13B* gene have been previously described as predisposing to CVID, and interrogation of the exome sequence data of Finnish population cohorts (Sequencing Initiative Suomi) shows that some of these variants are enriched in Finland. This could partially explain why CVIDs seem to be overrepresented in Finland compared to the rest of Europe. Consistently with this, we have identified previously reported disease variants in *TNFRSF13B* in three patients with CVID. However, several of the sequenced CVID patients do not carry mutations in this or any other previously reported PID gene, and thus warrant further investigation.

PM07.14

Mapping of private variations in human MHC conserved extended haplotypes

T. Lam[1,2], *M. Tay*[1], *B. Wang*[1], *Z. Xiao*[1], *E. Ren*[1,2];
[1]*Singapore Immunology Network, ASTAR, SIngapore, Singapore,* [2]*National University of Singapore, Singapore, Singapore.*

Distinct long-range genetic fixation in the MHC region, known as conserved extended haplotypes (CEHs), have been described in numerous studies due to its unique genomic characteristic and strong association with many complex traits. However, despite the great interests, the limitations of technology and heterogeneous nature of MHC haplotypes have thus far prevented extensive study of sequence variation in CEHs. As such, the level of intra-CEH polymorphism and the possible effect of these variants are not well-understood. In the study, with the use of multiple MHC homozygous cell lines, we demonstrated extensive sequence conservation in two common MHC CEHs of Asian ancestry - A33-B58-DR3 and A2-B46-DR9 by high throughput genome sequencing. This approach has allowed us to assemble at least 90% phase-resolved MHC sequence representative of the A33-B58-DR3 and A2-B46-DR9 haplotype. We also for the first time described the extent of intra-CEH variation within the conserved boundaries of the MHC CEHs and revealed that the level of variation is non-homogenous across the MHC region. Importantly, our study showed evidence that these private intra-CEH variants could potentially have functional impact in the context of gene expression. The availability of these alternate Asian MHC sequences would complement the eight European MHC haplotype sequenced by the MHC Haplotype Project and provides a framework to study the MHC diversity and variations. This insight gained from the results of this study may also enable an improved approach to MHC genetic dissection of disease-causing variants and genes.

PS07.15

WRN helicase plays an important role in multiple myeloma proliferation and inhibition of its activity by NSC19630 induces cytotocixity

D. -. Akcora Yildiz[1], *T. Ozkan*[2], *M. Gunduz*[2], *Y. Yukselten*[2], *M. Ozen*[2], *M. Beksac*[2], *A. Sunguroglu*[2];
[1]*Mehmet Akif Ersoy University, Burdur, Turkey,* [2]*Ankara University, Ankara, Turkey.*

Multiple myeloma (MM) is a plasma cell malignancy characterized by proliferation of monoclonal plasma cells in the bone marrow. Despite several therapeutic approaches, including high-dose chemotherapy, stem cell transplantation and the usage of novel agents such as bortezomib, MM still remains an incurable disease. Extensive genomic instability associated with molecular heterogeneity is a major hallmark of MM cells. Unfaithful DNA repair has been implicated to promote the genomic instability and cancer cell survival. Werner Seyndrome (WRN) helicase is a member of RecQ helicase family and contributes to DNA replication, recombination and repair. The supression of WRN expression in cancer cells by siRNA or its inhibitor led to an increased succebility to agents generating DNA damage and cell death by stimulating apoptosis. Therefore, the inhibition of WRN expression might be a potential target for increasing the susceptibility of MM cells against chemotherapeutic drugs. In this study, we show the increased expression of WRN in both newly diagnosed and relapsed CD138+ myeloma plasma cells compared to both normal subjects and their CD138- non-tumorigenic cells. Furthermore, by using NSC19630 a specific WRN helicase inhibitor, we further show a decreased proliferation and an increased apoptosis in MM cells. These results show that WRN is involved in MM proliferation and its inhibition may serve to enhance the efficacy of chemotherapy.

PM07.16

NLRP3 and MEFV gene variants in PFAPA patients in Slovenia

D. Perko, N. Toplak, T. Avčin, **M. Debeljak**;
University Children's Hospital, University Medical Center, Ljubljana, Slovenia.

PFAPA syndrome is the most common autoinflammatory fever disorder in childhood, with recurrent fever, aphthous stomatitis, pharyngitis and adenitis. Mutations in the MEFV and NLRP3 genes cause syndromes with PFAPA overlapping symptoms which are rarely reported in patients from Slovenia. The aim was to assess the frequency of MEFV and NLRP3 gene variants in patients with PFAPA syndrome in order to determine whether genes involved in other autoinflammatory diseases, might play a role in PFAPA pathogenesis.
We collected clinical and laboratory data of PFAPA patients under the age of 5, who were followed at the University Children's Hospital Ljubljana. All 10

exons of MEFV and 9 exons of NLRP3 genes were directly sequenced.
30 PFAPA patients were tested for MEFV and NLRP3 gene variants. Ten patients (33%) had 11 variants, all in heterozygous state. 6 patients have Q703K variant in NLRP3, one E148Q in MEFV and one combination of I591T in MEFV and Q703K in NLRP3. Novel variant in NLRP3, P200T, was identified in one patient. One girl was found to have known variant in NLRP3 S726G, which is associated with CINCA syndrome. She has had typical PFAPA symptoms, but also epilepsy and developmental delay. Five different gene variants were identified in 10/30 PFAPA patients with MEFV variants found in 2 patients and NLRP3 variants in 9. Our results indicate genetic heterogeneity of PFAPA population and overlap with other periodic fever syndromes.

PS07.17
Whole-exome sequencing (WES) for the identification of underlying genetic events in patients with primary immune deficiency (PID)

E. Fronkova, *J. Stuchly, K. Fiser, M. Kotrova, A. Dobiasova, M. Novakova, R. Formankova, J. Stary, M. Kubricanova Zaliova, J. Trka;*
2nd Medical School, Charles University Prague, Prague, Czech Republic.

WES has become an attractive option for the genetic diagnostics in immunology. We tested the performance of WES in a cohort of 10 patients with PID selected based on the following criteria: three or more possible candidate genes based on the phenotype, or low amount of DNA available, not allowing for stepwise sequencing of candidate genes. The raw data from HiSeq1500 were analysed using an in-house pipeline and from the resulting vcf files the common variants (<1%) and variants predicted as tolerated by both PolyPhen and SIFT were discarded. Genes related to PID or aplastic anemia were chosen from the remaining variants. This approach identified underlying mutations in 5/10 cases: interleukin-7 receptor in infant with severe combined immunodeficiency (SCID); perforin in infant who died due to familial hemophagocytic lymphohistiocytosis; SLX4 and ASXL1 in two children with refractory cytopenia, and TACI in patient with common variable immunodeficiency (CVID). In another infant with SCID a mutation causing cartilage hair hypoplasia was missed by WES, because the RMRP gene was not covered in the sequencing library. The diagnosis was done by clinical geneticist only after stem cell transplant, which was performed at 2.5 months of age. In three patients (2x CVID, 1x neutropenia) possible disease-causing mutations were suggested but not yet verified. In one patient, no mutation explaining his phenotype (neutropenia, B lymphopenia) was identified. In conclusion, in our limited cohort the WES proved as highly useful but not universal diagnostic tool for difficult cases in immunohematology. *Supported by IGA NT14343 and CZ.2.16/3.1.00/24022OPPK.*

PM07.18
Utility of next generation sequencing (NGS) in primary immunodeficiency disorders (PIDs); cases based review

A. Bisgin[1], *M. Yilmaz*[2], *K. Karaer*[3], *D. Altintas*[2], *G. Bingol Karakoc*[2];
[1]*Cukurova University Faculty of Medicine, Medical Genetics Dept. of Balcali Clinics and Hospital, Adana, Turkey,* [2]*Cukurova University Faculty of Medicine, Department of Pediatric Allergy & Immunology, Adana, Turkey,* [3]*Intergen Genetic Diagnosis and Research Center, Ankara, Turkey.*

Introduction: Primary immune deficiency disorders (PIDs) are a group of diseases that the genetic basis of many has been identified. Although the traditionally diagnostics are often sufficient to confirm the suspicion of certain PIDs, molecular tests are required to permit a conclusive diagnosis. Genetic counseling together with clinical evaluation plays a critical role in the appropriate use of these tests, which have great potential to improve treatment outcomes. In this review by our experiences, we outline the algorithm for PIDs and the clinical utility of next generation sequencing (NGS).
Materials and Methods: We have designed a diagnostic algorithm and customized test panels via flow cytometry and then next-generation-sequencing by MiSeqSystem (Illumina). In-silico analysis for novel mutations was carried out using SIFT, Polyphen2 and MutationTaster.
Results: The causative mutation was identified in only 18 out of 38 patients with suspected PIDs and 9 out of 12 patients with chronic granulomatous disease (CGD). More than that, the identified mutations in 10 of 18 were novel mutations. Many of undiagnosed suspected patients (n=20 for PID, n=3 for CGD) whom immunophenotype does not help to identify them may have had as yet uncharacterized mutations in other genes.
Conclusion: In summary, the availability of molecular genetic testing has profound implications for immunologists and patients. The benefits of genetic testing are for diagnosis including the pre-symptomatic and screening, prevention including the prenatal and pre-implantation genetic diagnosis, treatment even including the gene therapy modalities, prognosis and research.
Moreover, the application of NGS has broadened the understanding PIDs and critical in modern disease classification.

PS07.19
Exome sequencing as a first tier test for primary immunodeficiencies

A. Simons[1], *A. Mensenkamp*[1], *K. van Gassen*[2], *W. van Zelst-Stams*[1], *A. Janssen*[1], *M. Netea*[1], *P. Arts*[1], *A. Hoischen*[1], *M. Nelen*[1];
[1]*Radboud University Medical Center Nijmegen, Nijmegen, Netherlands,* [2]*University Medical Center Utrecht, Utrecht, Netherlands.*

Primary immunodeficiencies (PIDs) are a heterogeneous group of diseases characterized by an increased susceptibility to infections, because of genetic defects in one or more components of the immune system. At the moment at least 250 genes/loci are known as genetic causes for PIDs. Exome sequencing (ES) allows simultaneous analysis of a large panel of genes in a single test. We have applied this approach as a first tier diagnostic test for PIDs since May 2013. First, we designed an "in silico" immunodeficiency gene panel which contains 270 genes (proven to be involved in PIDs and a few strong candidate genes). Since then we performed clinical diagnostic exome sequencing in >60 cases, all highly suspicious of having a PID. Analysis of variants present in the immunodeficiency panel, allowed us to establish a genetic diagnosis in 10% of the cases. In 15% of the negative cases we detected one pathogenic mutation in a recessive PID gene. It is not known yet whether this has an influence on the patients phenotype or whether a second mutation might be present. In 80% of the negative cases we performed exome wide analysis. In 15% of these we identified highly suspected variants in genes that likely play a role in the patients phenotype. Additional studies are ongoing to provide stronger causal evidence.

PM07.20
Nakajo-Nishimura syndrome: A mexican report with a new PSMB8 mutation

C. Palacios[1], *A. Espinosa*[1], *I. Palma*[1], *S. Chavez*[1], *O. Reyes*[1], *H. Rosas*[2], *M. Sierra*[1], *A. Cardenas*[2];
[1]*Hospital Juarez de Mexico, México, Mexico,* [2]*Hospital de Pediatria, Centro Medico Nacional Siglo XXI, IMSS, México, Mexico.*

Nakajo-Nishimura syndrome (NNS) (OMIM 256040) is a very rare hereditary autoinflammatory disorder with onset in infancy with fever, pernio-like rashes and gradually develops into partial lipodystrophy. It is a proteasome-associated auto-inflammatory syndrome caused by autosomal recessive mutations in the PSMB8 gene (proteasome subunit β type 8) mapped on 6p21.3. Mutations in this gene also causes JASL syndrome (Japanese Autoinflammatory Syndrome with Lipodystrophy), JMP (Joint Contractures, Muscle Atrophy, Microcytic Anemia, and Panniculitis-Induced Lipodystrophy Syndrome) and CANDLE (Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated Temperature).We report a mexican female with congenital left cleft lip and palate, low birth weight ans short stature. She had longstanding history of recurrent fevers and associated rash, gradaully developed partial lipodystrophy, developmental delay, pernio-like rashes. Abnormal laboratory tests included elevated triglycerides, IgG, IgE; ANAs were negatives. Different homozygous PSMB8mutations had been identified until now. In order to determinate and to confirm the mutation because of a NNS suspected, PSMB8 mutation screening was performed (6 exones included). We detect a distinct mutation not reported previously: the G783A nucleotide substitution. It causes a change from GCC codón to ACC, corresponding to protein Ala88Thr substitution.

PS07.21
Palmoplantar pustular psoriasis is associated to missense variants in CARD14, but not to loss-of-function mutations in IL36RN in Eueopean patients

U. D. Hüffmeier[1], *R. Mössner*[2];
[1]*Human Genetics, University of Erlangen, Erlangen, Germany,* [2]*University of Göttingen, Göttingen, Germany.*

Palmoplantar pustular psoriasis (PPP) is a less common manifestation of psoriasis characterized by sterile pustules on the palms and soles. Little is known on its genetic risk factors. In order to find out whether PPP has genetically more similarities with generalized pustular psoriasis (GPP) or psoriasis vulgaris (PsV), we screened 217 German PPP patients as well as 34 Estonian PPP patients for possible mutations in IL36RN and CARD14 and performed an association analysis of the most relevant genetic risk factor for PsV, the PSORS1 risk allele. We identified four heterozygous carriers of IL36RN mutations, but no evidence for association in comparison to genotyped controls and large, publicly available data of control individuals. Also, our studies confirm previous studies showing no evidence for association of PPP to PSORS1. In contrast, three different rare missense variants CARD14,

previously described to influence the activation of NF-κB, were identified in eight patients and significantly associated to PPP in this case control study (p= 3.81E-04). Thus, our investigations suggest that CARD14 variants might be overlapping risk factors for PPP, GPP and PsV, although, due to their rare frequency in PPP patients, their overall contribution to the genetic risk of PPP - as in other psoriatic entities - will remain small.

PM07.22

Decreased Severity of Experimental Autoimmune Arthritis in Peptidylarginine Deiminase Type 4 Knockout Mice

A. Suzuki[1], *Y. Kochi*[1], *E. Kanno*[1], *H. Matsumura*[1], *K. Yamamoto*[1,2];
[1]*RIKEN, Yokohama, Japan,* [2]*Univ. of Tokyo, Tokyo, Japan.*

Introduction
Peptidylarginine deiminase type 4 (PADI4) has been identified as a susceptibility gene for rheumatoid arthritis (RA) by genome-wide association studies. PADI4 is highly expressed in the bone marrow, macrophages, neutrophils, and monocytes. Peptidyl citrulline is an interesting molecule in RA because it is a target antigen for anti-citrullinated peptide antibodies, and only PADs (translated proteins from PADI genes) can provide peptidyl citrulline via the modification of protein substrates. The aim of this study was to evaluate the importance of the PADI4 gene in the progression of RA.
Methods
We generated Padi4 knockout (Padi4−/−) DBA1J mice. The Padi4−/− DBA1J and wild-type mice were immunized with bovine type II collagen (CII) to develop collagen-induced arthritis (CIA). The expression of various inflammatory cytokines and Padi genes in immune cells was detected by the real-time TaqMan assay. Cytokine concentrations in sera were measured by enzyme-linked immunosorbent assays. Localization of the PAD4 and PAD2 proteins was indicated by immunohistochemistry.
Results
We demonstrated that the clinical disease score was significantly decreased in the Padi4−/− mice and Padi4 expression was induced by CII immunization. In the Padi4−/− mice, serum anti-type II collagen (CII) immunoglobulin M (IgM), IgG, and inflammatory cytokine levels were significantly decreased compared with those in the wild-type mice. Padi2 expression was induced in the immune cells of the Padi4−/− mice as a compensation for the defect in Padi4.
Conclusion
Padi4 affected disease severity in the CIA mice and was involved in the enhancement of the collagen-initiated inflammatory responses.

PS07.23

Whole exome sequencing of Cold Medicine-Related Stevens-Johnson Syndrome/Toxic Epidermal Necrolysis (CM-SJS/TEN) with Severe Mucosal Involvement in Japanese population

Y. Hitomi[1], *S. Khor*[1], *M. Ueta*[2], *C. Sotozono*[2], *S. Kinoshita*[2], *K. Tokunaga*[1];
[1]*Department of Human Genetics, Graduate School of Medicine, the University of Tokyo, Tokyo, Japan,* [2]*Department of Ophthalmology, Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) are acute inflammatory vesiculobullous reactions of the skin and mucous membranes, and these reactions are reported to be caused by inciting drugs, viral infections, or malignant tumor. Although the occurance of SJS/TEN is rare at about 1-6 cases per million, mortality rates are higher than other drug rush (SJS: 3%, TEN: 27%). In addition, Quality-of-life (QOL) of the most survivors is often low, as severe ocular surface complications are often developed as the aftereffect.
Over 1,000 drugs have been reported as the so-called “causal medicine” of SJS/TEN, and susceptibility to SJS/TEN caused by some of them the medicines have been reported to be associated with HLA genes. As examples, HLA-A*31:01 and HLA-B*15:02 have been reported to be associated with carbamazepine-induced severe cutaneous adverse reactions (SCARs). Besides, HLA-B*58:01 have been reported as susceptible allele of Allopurinol related SJS/TEN. Recently, HLA-A and IKZF1 have been reported to be susceptible for Cold Medicine-Related Stevens-Johnson Syndrome/Toxic Epidermal Necrolysis (CM-SJS/TEN) in Asian populations by genome-wide association study (GWAS). However, remaining genetic susceptibility of CM-SJS/TEN including rare variants and structural variants remains to be discovered.
To identify the functional variants for CM-SJS/TEN with severe mucosal involvement, whole-exome sequencing was performed in about 121 Japanese CM-SJS/TEN patients with severe mucosal involvement using next generation sequencer (NGS) - ion Proton (Thermo-Fisher Scientific). Whole-exome sequencing data were then analyzed using CLC Genomics Workbench (CLC bio) software.
Here we will show the provisional results of Whole-exome sequencing for CM-SJS/TEN. This study illustrates novel diagnostic and therapeutic methods for CM-SJS/TEN.

PM07.24

Targeted high throughput sequencing identifies novel disease candidate genes for systemic lupus erythematosus in Swedish patients

S. V. Kozyrev[1], *F. H. Farias*[1], *M. Wilbe*[2], *J. Dahlqvist*[1], *D. Leonard*[3], *G. R. Pielberg*[1], *M. Eloranta*[3], *H. Hansson-Hamlin*[4], *G. Andersson*[2], *L. Rönnblom*[3], *K. Lindblad-Toh*[1,5];
[1]*Department of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden,* [2]*Department of Animal Breeding and Genetics, Swedish University of Agricultural Sciences, Uppsala, Sweden,* [3]*Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden,* [4]*Department of Clinical Sciences, Swedish University of Agricultural Sciences, Uppsala, Sweden,* [5]*Broad Institute, Cambridge, MA, United States.*

Systemic lupus erythematosus (SLE) is an autoimmune disorder with heterogeneous clinical manifestations. The etiology of SLE is complex, involving interplay between genetic, environmental and hormonal factors. Although many loci have been identified, only a small proportion of heritability of SLE is explained, indicating a demand for different approaches for discovery of disease-associated genes. The aim of this study was to identify novel rare genetic variants relevant for SLE. We performed targeted re-sequencing of 219 genes selected on the basis of their role in immune responses, general autoimmunity, and known associations with human SLE, or SLE-related disease in dogs. The study cohort included 144 Swedish SLE patients and 17 matching controls. The Nimblegen capture array was used for target regions enrichment, which were sequenced on Illumina HiSeq2000. Variants were filtered to be present only in cases, but not in controls or 1000 genomes or dbSNP. For further functional validation we chose three variants located in the genes MEF2D, TCRA and HAPLN3 and overlapping with DNase I hypersensitivity sites, ENCODE histone marks and ChIP-Seq peaks. The regulatory potential of the novel variants was investigated with EMSA and luciferase reporter assay, and indicated that two variants may influence gene expression. Additional genotyping of 742 Swedish controls demonstrated a higher frequency of the variants in SLE patients. A correlation between particular disease manifestations and the novel variants was also observed. Our study successfully combines the detection of novel rare variants, with functional and clinical data to generate hypothesis about specific disease mechanisms.

PS07.25

Identification of the risk HLA variants of Graves’ disease by applying the HLA imputation method to large scale Japanese genome-wide association study data

O. Yukinori[1], *Y. Momozawa*[2], *K. Ashikawa*[2], *K. Matsuda*[3], *Y. Kamatani*[2], *A. Takahashi*[4], *M. Kubo*[2];
[1]*Tokyo Medical and Dental University, Tokyo, Japan,* [2]*RIKEN Center for Integrative Medical Sciences, Yokohama, Japan,* [3]*Institute of Medical Science, The University of Tokyo, Tokyo, Japan,* [4]*RIKEN Center for Integrative Medical Sciences,, Yokohama, Japan.*

[Objectives] Graves’ disease (GD) risk is strongly associated with genetic variations within the major histocompatibility complex (MHC) region. However, its fine genetic architecture has not been elucidated.
[Methods] To fine-map GD risk alleles within the MHC region in Japanese, we newly constructed a population-specific HLA reference panel consisting of the healthy subjects of Japanese ancestry (n = 908). We conducted trans-ethnic comparisons of linkage disequilibrium (LD) and haplotype structures of the human leukocyte antigen (HLA) variants by introducing a novel framework that utilizes an entropy-based LD measurement and a visualization tool capturing high-dimensional variables. Finally, we applied our HLA imputation method to the large-scale Japanese GD genome-wide association study (GWAS) data (n > 9,000).
[Results] The Japanese population demonstrated stronger LD between the HLA genes compared to European or other east Asian populations, highlighted by one population-specific common long-range HLA haplotype spanning through the entire MHC region and HLA genes (frequency > 0.08). Application of the HLA imputation method to the Japanese GD GWAS data identified that amino acid polymorphisms of the multiple class I and class II HLA genes independently contribute to GD risk (HLA-DPβ1 amino acid positions 35 and 9, HLA-A amino acid position 9, HLA-B amino acid positions 45 and 67, and HLA-DRβ1 amino acid position 74; P < 6.0×10^-7), with the strongest impact at HLA-DPB1 (P < 1.0×10^-40).
[Conclusion] Our study illustrates the value of the population-specific HLA reference panel for HLA imputation, with successful fine-mapping of the MHC region risk of GD to multiple HLA amino acid polymorphisms.

PS08.01
16p13.11 microdeletion in a boy presenting with Mowat-Wilson phenotype

A. Singer[1], *S. Ben-Shachar*[2], *A. Bar-Shira*[2], *C. Vinkler*[3];
[1]*Genetic Institute, Ashkelon, Israel,* [2]*The Genetic Institute & Prenatal Diagnosis Unit,, Te-Aviv, Israel,* [3]*Institute of Medical Genetics,"Wolfson", Holon, Israel.*

16p13.11 microdeletion is a recently described syndrome characterized by developmental delay, microcephaly, epilepsy, dysmorphic features and behavioral problems. The deleted region contains more than 10 genes including NTAN1 and NDE1. These genes may be relevant to the neuro-cognitive phenotype of this syndrome. Variable phenotypic presentation has been described with partial penetrance. Most cases are de novo. Prevalence in the normal population is 4:10,000 . However 16p13.11 deletions is detected in 60:10,000 patients with a diverse spectrum of epilepsy syndromes.
Mowat Wilson syndrome (MWS) is a rare condition (1:60,000), characterized by a distinctive phenotype, mild to severe develeopmental delay, seizures, short stature, microcephaly, Hirschsprung disease or constipation, genitourinary defects, heart defect, and eye anomalies. Almost all cases are associated with ZEB2 mutations, located on chromosome 2q22.3.
We describe a 12y old boy with intellectual disability, behavioral problems, history of infantile spasms since the age of 3m, constipation, hypospadias, dysmorphic features and microcephaly. Parents are healthy and unrelated. He has a non-identical twin brother who has ADD but is otherwise healthy and has normal intelligence. MWS has been considered in this boy. However, routine workup included CMA testing diagnosed a 16p13.11 microdeletion. Clinical reevaluation of the patient in view of the CMA results revealed the overlapping between both syndromes.
We would like to suggest that 16p13.11 microdeletion may be a phenocopy of MWS. CMA in our report showed once again its importance in resolving cases with intellectual disability and suggested the existence of gene(s) in the deleted interval that may be responsible for a phenocopy of MWS.

PM08.02
De novo 19p13.2 microdeletion encompassing the part of NFIX gene in a girl with Sotos-like phenotype

M. Kucharczyk[1], *M. Młynek*[1], *M. Kugaudo*[1,2], *A. Cieślikowska*[1], *A. Jezela-Stanek*[1], *A. Gutkowska*[1], *M. Białecka*[1], *A. Marczak*[1], *D. Sielska-Rotblum*[1], *M. Krajewska-Walasek*[1];
[1]*Department of Medical Genetics, Children's Memorial Health Institute, Warsaw, Poland,* [2]*Department of Child and Adolescent Psychiatry, Medical University of Warsaw, Warsaw, Poland.*

19p13.2 microdeletion is a rare genomic disorder. To date, less than ten cases was described so far in the literature. This chromosomal syndrome manifests in developmental delay/intellectual impairment, postnatal overgrowth, macrocephaly, craniofacial dysmorphy, slender habitus, advanced bone age, and scoliosis. Hypotonia, unusual behavior with autistic traits, ophthalmologic, gastrointestinal, and hand/foot abnormalities are also frequent. Very similar phenotype is observed in the Sotos syndrome 2 (MIM #614753) that is caused by heterozygous mutations/deletions of the NFIX gene located on chromosome 19p13.2.
Here, we report on the case of a 7-year-old girl referred to genetic counseling because of psychomotor retardation, speech delay and dysmorphic features (macrocephaly, long/narrow and triangular face, high forehead, frontal bossing, downslanting palpebral fissures, dysplastic low-set ears, small nose, flat philtrum, micrognathia). At the examination, behavioral problems (anxiety, tantrums, autoaggression), seizures, and poor coordination were noted. Skeletal anomalies (advanced bone age, joint laxity, slender hands with long fingers, abnormal setting of the lower limbs), strabismus, hyperopia as well as constipations and abdominal pain were also diagnosed.
Whole-genome oligonucleotide microarray analysis revealed a de novo 158.18 kb (the smallest so far) deletion of 19p13.2 region (chr19:13,020,206-13,178,390; hg19) encompassing seven genes; three of them (NFIX, DAND5 and CALR) could be the candidate genes for the genotype-phenotype relationship.
This study contributes additional information for the newly identified 19p13.2 microdeletion syndrome and clarifies the clinical roles of genes in the involved region. Our results also confirm that haploinsufficiency of NFIX leads to Sotos-like phenotype.
This study was supported by the MNiSW Grant No. 0193/IP1/2013/72.

PS08.03
Phenotype and natural history of 1p36 deletion syndrome in five adult patients

A. Kattentidt[1], *R. Kersseboom*[2], *J. van de Berg*[3], *J. Jansen*[3], *L. van Zutven*[4], *M. Simon*[4];
[1]*Zuidwester, Spijkenisse, Netherlands,* [2]*Tragel Zorg, Clinge, Netherlands,* [3]*Ipse de Bruggen, Nootdorp, Netherlands,* [4]*Erasmus University Medical Centre, Rotterdam, Netherlands.*

1p36 deletion syndrome is one the most common subtelomeric deletion syndromes seen in humans. Uniform features of the syndrome include intellectual disability, characteristic dysmorphic facial features, cardiac and craniofacial anomalies. This syndrome has been well described in paediatric patients. However, in adult patients data on the natural history is still limited.
We describe five patients with a microdeletion 1p36, that were diagnosed during adulthood, to illustrate the variability of the clinical course. The most severe case was a male patient that was diagnosed with 1p36 deletion syndrome at the age of 18 years. He had a profound intellectual disability, seizures, challenging behaviour and bilateral congenital cataract. A few weeks after diagnosis he developed stroke caused by a newly discovered dilated cardiomyopathy, which is a common feature of 1p36 deletion syndrome. Unfortunately, 6 months later he died of heart failure that was exacerbated by a respiratory infection. This case illustrates the importance of early genetic diagnosis and syndrome specific follow-up in adult patients, to provide better care and early intervention in this challenging group of patients.

PM08.04
2p15-p16.1 microdeletion syndrome: further refining the critical region

M. Lamp[1], *M. Malacarne*[2], *M. Mogni*[2], *D. Coviello*[2], *C. Marciano*[1], *F. Faravelli*[1], *F. Forzano*[1];
[1]*Medical Genetics Unit, Galliera Hospital, Genoa, Italy,* [2]*Laboratory of Human Genetics, Galliera Hospital, Genoa, Italy.*

The 2p15-p16.1 microdeletion syndrome is a rare disorder characterized by developmental delay, intellectual disability, growth retardation, microcephaly, abnormal muscle tone, optic nerve dysplasia and a distinctive pattern of craniofacial features. Reported deletions' sizes range from 5.7 Mb, containing numerous genes, to 0.2 Mb, including a single gene, BCL11A.
We report a 4-year-old girl with delayed motor and language development, microcephaly, asymmetry in carpal bone maturation, facial hypotonia and peculiar craniofacial features. Array-CGH revealed a de novo deletion of 350 Kb in the locus 2p16.1, which only included a microRNA MIR4432 and part of the BCL11A gene, and a duplication of 123 Kb in 22q13.1, inherited from the proband's healthy mother. To our knowledge, this is the second smallest deletion associated with the 2p15-p16.1 microdeletion syndrome reported to date. Compared to the individual with the 0.2 Mb deletion, who presented with mild intellectual disability, abnormal muscle tone and expressive language delay, our proband also shows microcephaly and facial features evocative of the condition, while growth retardation and other features described in previous cases are absent.
In conclusion, the present case provides further evidence on the correlation of heterozygous 2p15-p16.1 deletions with specific clinical features. Furthermore, the small size of the current deletion might help to clarify the role of single genes in this complex phenotype.

PS08.05
2p25 deletion: involvement of SNTG2 in autism or behavioral troubles, and parental imprinting.

M. Plutino[1], *H. Karmous-Benailly*[1], *F. Giuliano*[1], *C. Massol*[1], *K. Wagner*[2], *V. Paquis-Flucklinger*[1], **M. Dayem-Quere**[1];
[1]*Hôpital de l'Archet II, CHU de Nice, Nice, France,* [2]*Hôpitaux Pédiatriques de Nice, CHU Lenval, Nice, France.*

Deletions of the terminal region of the short arm of chromosome 2 have been reported in the literature in less than 20 patients. These patients share common clinical features including early-onset obesity, intellectual disability and behavioral troubles or autism. A minimal critical region of 1.97 Mb has been estimated, encompassing seven genes (*SH3HYL1*, *ACP1*, *TMEM18*, *SNTG2*, *TPO*, *PXDN*, and *MYT1L*). Many recent studies pointed out *MYT1L* gene as the main candidate for ID and obesity. We present three new patients carrying 2p25 deletions: an autist female child with developmental delay and her depressive father, and a third unrelated patient who has psychomotor retardation and behavioral troubles. Moreover, our patients do not have an overweight phenotype, highlighting indeed the role of *MYT1L* in obesity, as none of the deletions encompasses *MYT1L*. The only common disrupted gene is *SNTG2*, thus redefining the smallest region of overlap for autism. *SNTG2* is expressed in brain. Its product interacts with neuroligins NLGN3, NLGN4X, and NLGN4Y, which are autism-related isoforms. Finally, the parental origin of the deletions seems to be of interest, as all inherited deletions described today appear to be inherited from the paternal side. We will discuss the possible imprinting of the 2p25 region and its role in autism.

PM08.06

A milder Angelman syndrome phenotype due to a novel molecular mechanism: a maternally inherited 30kb deletion of 15q11.2 including the main gene promoter and non-coding exon1 of UBE3A

D. H. K. Lim[1], *N. James*[2], *L. Reali*[2], *L. Steenpass*[3], *B. Horsthemke*[3], *R. Price*[2], *C. Hardy*[2], *D. McMullan*[2];
[1]*Clinical Genetics Department, Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom,* [2]*West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom,* [3]*Institut fuer Humangenetik, Universitaetsklinikum Essen, Universitaet Duisburg-Essen, Essen, Germany.*

We present a novel molecular cause of Angelman syndrome (AS) in a female patient with microcephaly, dysmorphism, global developmental and speech delay and intellectual disability. Her phenotype resembles a milder form of AS with no seizures and 20 words of speech at the age of 5 years. EEG investigation of the patient showed typical AS findings.
Suspecting a clinical diagnosis of AS, molecular analysis was undertaken using methylation specific PCR (MS-PCR) and revealed normal methylation at the SNRPN DMR ruling out UPD, deletion or an imprinting defect associated with the majority of AS. Sequencing of the coding exons of UBE3A revealed no pathogenic mutations. Microarray CGH identified a maternally inherited 30kb deletion at 15q11.2 involving exon 1 of UBE3A. This deletion was de-novo in the patient's mother and linkage analysis revealed the origin of the deletion in the grand-paternal allele, explaining the normal phenotype in the patient's mother due to genomic imprinting.
Although intragenic deletions of the maternal copy of UBE3A are a recognised cause of AS, to date there have been no reported deletions of exon 1. Exon 1 is non protein coding and therefore not routinely sequenced. The intragenic deletion in our patient also includes the main promoter of UBE3A adjacent to exon 1 and the milder phenotype in our patient may be explained by secondary promoters downstream producing transcripts.
We present the detailed clinical phenotype of our patient, discuss the initial difficulties of interpreting the clinical significance of this novel finding and present the subsequent RNA/expression analysis.

PS08.07

Mosaicism of truncanjting mutation in CASK is crucial for male patients' survival

C. Hatano[1], *T. Yokoi*[1], *Y. Kuroda*[1], *Y. Enomoto*[1], *T. Naruto*[1], *I. Ohashi*[1], *R. Anzai*[2], *M. Iai*[2], *K. Kurosawa*[1];
[1]*Division of Medical Genetics, Kanagawa Children's Medical Center, Yokohama, Japan,* [2]*Department of Neurology, Kanagawa Children's Medical Center, Yokohama, Japan.*

The CASK gene maps to Xp11.4 and is related to synaptic functions. Aberrations of this gene are associated with microcephaly with pontine and cerebellar hypoplasia (MICPIH), developmental delay, and nystagmus in females. We report a male patient with mosaicism of CASK mutation.
He was born to nonconsanguineous parents at 39 weeks. The parents were healthy and their family history was unremarkable. His birth weight was 2334g (-1.4SD), length 45cm (-1.5SD), and the head circumference 30.0cm (-2.2SD). He had ventricular septal defect, and had mitral valve regurgitation at 5 months old. He also had nystagmus. At 3 years and 6 months old, his weight was 9075g (-3.2SD), length 82.0cm (-4.0SD), head circumference 39.0cm (-7.2SD). He had severe intellectual disability. At 4 years old, he doesn't speak, nor does he keep sitting position. Chromosome studies showed a normal 46,XY karyotype. We performed cytogenetic microarray, which revealed no significant copy number variation. Next we performed targeted high-throughput sequencing of 4813 genes in which mutations had been described in patients with Mendelian genetic disorders. We confirmed a de novo mosaic mutation (c.725G>A:p.W242X) of CASK. The ratio of mutation was 93% in peripheral blood lymphocytes.
CASK knockdown mice are smaller than wild type mice but viable, whereas CASK knockout mice die at first day of their lives. For male patients, truncating mutation in CASK has been regarded as lethal. Next-generation sequencing confirmed a mosaicism masked by a high proportion of mutant cells. These results suggest that mosaicism seemed crucial for male patients' survival.

PM08.08

Homozygous deletion of CHL1 resulting in severe intellectual disability

S. F. Jose, **D. T. Pilz**, *S. M. Morgan;*
Institute of Medical Genetics, Cardiff, United Kingdom.

Hemizygous deletion of the CHL1 gene at 3p26.3 is a very rare finding, previously reported in 4 families. Cognitive impairment, in particular language difficulties, is a consistent phenotypic feature. However, due to the small number of cases reported to date, the clinical significance of deletions including CHL1 remains uncertain. Homozygous deletions of the region have never been reported.
Here we describe an eight year old boy, born to consanguinous parents, who has marked learning difficulties, absence of speech, stiffness in his lower legs and persistent drooling. Array CGH studies carried out using the BlueGnome CytoChip Oligo ISCA 8x60k (v2.0) array showed a deletion of the sequences detected by the oligonucleotide probes located from 93,979bp to 290,767bp. This equates to a 197kb interstitial deletion of the short arm of chromosome 3 at p26.3. This resulted in a partial deletion of the CHL1 gene. Real-time quantitative PCR (qPCR) studies with targets within introns 1 and 2 of the CHL1 gene, confirmed this deletion and showed that it was homozygous. Further qPCR studies in the parents of this proband showed they both had a hemizygous deletion of this region. The proband has therefore inherited one abnormal chromosome 3 from each parent who are both clinically unaffected.
This is the first case reported of a patient presenting with an abnormal phenotype with a homozygous deletion including part of the CHL1 gene at 3p26.3.

PS08.09

Copy number variant at Xp22.31: Clinical and genetic evaluation of 8 patients

N. Baena, *A. Ruiz, E. Gabau, M. Arasanz, M. Viñas, M. Guitart;*
Corporació sanitària Parc taulí, SABADELL, Spain.

Introduction:
Xp22.31 submicroscopic duplication has been reported as either a possible cause of intellectual disability (ID) and/or developmental delay or as a benign variant.
Methods:
Comparative genomic hybridization array (aCGH) (Agilent 60K) was used to analyse 511 patients affected by ID and/or dysmorphic features/congenital defects.
Results:
We detected potentially pathogenic copy number variants (CNV) in 94 out of 511 patients analysed (18%). A submicroscopic duplication in the Xp22.31 region was identified in 8 patients (5♀:3♂) ranging in size from 257 Kb to 1.7 Mb. In all individuals studied (four out of eight) the Xp22.31 duplication was inherited from the mother. The HDHD1, STS, VCX and PNPLA4 genes are included in four cases with a 1.6Mb duplication, who show autism spectrum disorder (ASD) and no dysmorphic features. Interestingly, two cases with a size below 580Kb, where only HDHD1 and STS genes are duplicated, show a more severe phenotype with multiple malformations. The largest duplication detected (from VCX3A to VCX2) is associated with language delay. The patient also carries a deletion at 6p23 of 1.3 Mb as a result of an unbalanced t(6;9). Finally, a duplication of 565Kb involving VCX and PNPLA4 was detected in a boy with psychomotor delay.
Conclusion:
We have detected an association of the Xp22.31 duplication with ID and ASD in both genders. According to the literature, there is a high variability in the Xp22.31 duplication associated phenotype, which may be due to incomplete penetrance, the different genes involved, a position effect and X-inactivation. Increased CNV on the X chromosome can contribute to deregulation of normal cognitive development.

PM08.10

Partial ARID1B gene deletion as a cause of Coffin-Siris syndrome in two (maybe three) siblings

B. Parmentier, *B. Grisart, S. Rombout, J. Désir;*
Institut de Pathologie et de Génétique, Gosselies, Belgium.

Coffin-Siris syndrome has been described as mental retardation associated with coarse facial features, hypertrichosis, and hypoplastic or absent fifth fingernails or toenails and other variable clinical manifestations. We report the case of a non consanguineous portuguese couple. Their first pregnancy of a female fetus was interrupted at 23 weeks because of corpus callosum agenesis and cardiac defect. No genetic analysis or autopsy was requested at this time. Their second pregnancy of a female fetus was also characterized by corpus callosum agenesis, and unique umbilical artery. At 2 years of age, she is affected by hydrocephalus, laryngomalacia, diaphragmatic hernia,coarse facial features, hypoplastic fifth toenails. No genetic analysis was requested before we saw her. Their third pregancy was characterized by a male fetus with left hydronephrosis, unilateral club foot, and corpus callosum poorly visualized. Microarrays CGH analysis was requested for the third fetus, using a 60K Agilent whole genome array. It revealed a 230 kb intragenic deletion of ARID1B gene (exons 6-10) at position 6q25.3. This discovery was clearly

suggestive for the phenotype of the living daughter and the analysis found the same deletion confirming a clinical suspicion of Coffin-Siris syndrome. Medical interruption of the third pregnancy was asked by the parents at 23 weeks, but no autopsy was requested. Parental CGH microarrays testing did not reveal any copy number abnormality at this 6q25.3 region. However, familial history with two siblings affected (possibly three but no genetic material was conserved for the first pregancy to verify this hypothesis) strongly suggest that one of the parents is a carrier of a germinal mosaicism.

PS08.11

Scavenging mRNA for Cognitive Function

C. Ng[1], *S. Mohammad*[1], *V. Taverniti*[2], *C. Bonnard*[1], *H. Lee*[3], *A. Eskin*[3], *S. F. Nelson*[3], *M. Al-Raqad*[4], *S. Altawalbeh*[4], *B. Séraphin*[2], *B. Reversade*[1,5];
[1]*Institute of Medical Biology, Singapore, Singapore,* [2]*IGBMC, CNRS UMR 1704/INSERM U964/Université de Strasbourg, Illkirch, France,* [3]*Department of Human Genetics, David Geffen School of Medicine, University of California, Los Angeles, CA, United States,* [4]*Queen Rania Paediatric Hospital, King Hussein Medical Centre, Royal Medical Services, Amman, Jordan,* [5]*Department of Paediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore.*

mRNA decay is an essential and active process that allows cells to continuously adapt gene expression to internal and environmental cues. There are two mRNA degradation pathways: 3' to 5' and 5' to 3'. The DCPS protein is the scavenger mRNA decapping enzyme which functions in the last step of the 3´ end mRNA decay pathway. We have identified a DCPS pathogenic mutation in a large family with three affected individuals presenting with a novel recessive syndrome consisting of craniofacial anomalies, intellectual disability and neuromuscular defects. Using patient's primary cells, we show that this homozygous splice mutation results in a DCPS loss-of-function allele. Diagnostic biochemical analyses using various m7G cap derivatives as substrates reveal no DCPS enzymatic activity in patient's cells. Our results implicate DCPS and more generally RNA catabolism, as a critical cellular process for neurological development, normal cognition and organismal homeostasis in humans.

Arginine supplementation in De Barsy syndrome due to ALDH18A1 mutations

Y. Capri[1], *D. Gras*[1], *C. Baumann*[1], *E. Bourrat*[1], *S. Dorgeret*[1], *M. Elmaleh*[1], *D. Martinelli*[2], *J. Haeberle*[3], *O. Boespflug-Tanguy*[1,4], *A. Verloes*[1,5];
[1]*CHU Robert Debre, Paris, France,* [2]*Bambino Gesu Children's Hospital, Rome, Italy,* [3]*University Children's Hospital, Zurich, Germany,* [4]*INSERM U1141, Paris, France,* [5]*INSERM U676, Paris, France.*

De Barsy syndrome is a rare autosomal recessive disease characterized by intrauterine and postnatal growth retardation, progeroid appearance, corneal clouding, joints hypermobility, osteopenia, athetoid movements and mental retardation. Dysmorphic aspect of the face and the skin includes microcephaly, frontal bossing, large dysplastic ears, thin lips, cutis laxa, wrinkled atrophic skin and reduced subcutaneous fat. To our knowledge, only two cases of De Barsy syndrome associated with blood vessels tortuosity have been described.

De Barsy syndrome is genetically heterogeneous since 2 genes have been identified: ALDH18A1 encoding delta1-pyrroline-5-carboxylate synthase (P5CS) and the gene encoding pyrroline-5-carboxylate reductase 1(PYCR1). Both genes are involved in proline biosynthesis pathway but pathological mechanisms leading to the syndrome are still misunderstood. Some patients carrying homozygote ALDH18A1 mutations have low level of proline, arginine, citrulline and ornithine.

We report the case of a boy displaying all the features of De Barsy syndrome including specific profile of plasmatic amino acid chromatography. He had also arterial tortuosity (which has been already reported twice in ALDH18A1 mutated patients) and his CT scan showed calcifications which has never been described yet in De Barsy syndrome. This patient carried compound heterozygote ALDH18A1 mutations.

According to the role of P5CS in the proline biosynthesis and as it was already done for another patient of the literature, supplementation with arginine was tried during one year but no improvement was observed on the psychomotor development. This failure suggest that disturbance of proline biosynthesis in P5CS deficiency would not be responsible of the neurological phenotype.

PS08.13

Diagnostic odyssey in severe neurodevelopmental disorders: The utility of clinical whole-exome sequencing

Steinmetz*[1], *C. Jugé*[2], *S. Nambot*[1], *S. Béjean*[5], *C. Peyron*[5], *F. Huet*[7], *M. Chouchane*[7], *V. Darmency-Stamboul*[7], *B. Aral*[8], *J. St Onge*[2], *C. Thauvin-Robinet*[1], *L. Faivre*[1], *J. Rivière*[2];
[1]*Centre de référence maladies rares, Dijon, France,* [2]*EA4271 GAD, Dijon, France,* [3]*Centre de référence maladies Héréditaires du Métabolisme, Nancy, France,* [4]*Centre de génétique, Strasbourg, France,* [5]*Laboratoire d'Economie et de Gestion, Pôle d'Economie et de Gestion, Dijon, France,* [6]*Laboratoire de cytogénétique, Dijon, France,* [7]*Service de Pédiatrie, Dijon, France,* [8]*Laboratoire de génétique moléculaire, Dijon, France.*

Objective: The current standard of care for diagnosis of severe intellectual disability (ID) and epileptic encephalopathy (EE) results in a diagnostic yield of ~50%. Affected individuals nonetheless undergo multiple clinical evaluations and low-yield laboratory tests often referred to as a "diagnostic odyssey". This study was aimed at assessing the utility of clinical whole-exome sequencing (WES) in individuals with undiagnosed and severe forms of ID and EE, and the feasibility of its implementation in routine practice by a small regional genetic center.

Methods: We performed WES in a cohort of 43 unrelated individuals with severe forms of ID and/or EE. All individuals had undergone multiple clinical evaluations and diagnostic tests over the years, with no definitive diagnosis. Sequencing data analysis and interpretation were carried out at the Dijon University Hospital Molecular Genetics Laboratory.

Results: The molecular diagnosis rate of WES reached 32,5% (14 of 43 individuals), with pathogenic or likely pathogenic variants associated with six autosomal dominant (ARID1B, CTNNB1, DYRK1A, SHANK3, NAA10 and TBR1), five autosomal recessive (ADCK3, GFER, SCN10A, TAF2 and SLC13A5 in two families) and two X-linked (CUL4B, and SLC16A2) conditions. Genetic diagnosis had implications for a personalised clinical management in four families, including prenatal diagnosis test in one family.

Interpretation: Our data emphasize the clinical utility and feasibility of WES in individuals with undiagnosed forms of ID and EE, highlight the necessity of close collaborations between ordering physicians, molecular geneticists, bioinformaticians and researchers for enhanced data interpretation, and support the use of WES as a first-line test for individuals with severe neurodevelopmental disorders.

[1]*Clinical Genetics Department, Guy's Hospital, London, United Kingdom,* [2]*West Midlands Regional Clinical Genetics Service, Birmingham, United Kingdom,* [3]*Centre for Genomic Medicine, Manchester, United Kingdom,* [4]*Clinical Genetics Department, Northampton, United Kingdom,* [5]*Clinical Genetics Department, Oxford, United Kingdom,* [6]*MRC Institute of Genetics and Molecular Medicine, Edinburgh, United Kingdom,* [7]*Clinical Genetics Unit, The Children's Hospital at Westmead, Sydney, Australia,* [8]*Clinical Genetics Department, Birmingham Women's Hospital, Birmingham, United Kingdom,* [9]*Centre of Human Genetics, Leuven, Belgium,* [10]*Department of Paediatric Cardiology, Leuven, Belgium,* [11]*Cytogenetics Department, Guy's Hospital, London, United Kingdom.*

DYRK1A has been the most extensively studied chromosome 21 gene during the last decade due to the correlation with Down syndrome neuropathologies. It is known to be expressed in adult human brain with the highest level of expression in the cerebellum. It is closely linked with brain growth in a gene dosage dependent manner. DYRK1A haploinsufficiency induces a reduced brain size in mice whereas a DYRK1A gain-of-function model would exhibit increased brain volume. DYRK1A has been implicated in tau phosphorylation and is becoming an attractive drug target since its overexpression may induce Down Syndrome-like neurobiological alterations.

Deletions or mutations involving DYRK1A have been reported in association with intellectual disability (ID) and microcephaly. We have identified 3 *de novo* deletions at 21q22.12 including DYRK1A and 8 DYRK1A *de novo* mutations in 11 unrelated patients through exome sequencing via the DDD project and other collaborations. All patients presented with microcephaly and ID. Ten patients presented with growth retardation, epilepsy and behaviour issues. Additional features such as cleft palate, eye, brain and heart malformations were identified.

We will review our patients' findings and compare them with those previously reported to further delineate the phenotypic spectrum of patients with DYRK1A abnormalities. We will also review public expression data set on fetal and adult human brain to understand the underlying molecular mechanisms for this emerging syndrome.

DYRK1A should be added to the list of genes responsible for syndromic ID

comprising microcephaly and epilepsy, such as ARID1B, SCN2A, ANKRD11, SATB2 and SYNGAP1.

Dyscalculia (or mathematical ability) is a condition where mathematical ability is severely impaired. Twin studies suggest that it is partly caused by a genetic component, which is yet to be understood at the molecular level. Recently, a coding variant (rs133885) in the Myosin-18B gene was shown to be associated with mathematical abilities with a specific effect among children with dyslexia. This association represents one of the most significant genetic associations reported to date for mathematical abilities. However, this association has not been replicated before. We conducted a replication analysis in different cohorts characterised with maths-related measures. The study was conducted primarily using the Avon Longitudinal Study of Parents and Children (ALSPAC) (N=3819), which was adequately powered for this analysis. We tested additional cohorts including the York Cohort (N=291), the Specific Language Impairment Consortium (SLIC) (N=367) and the Raine Cohort (N=667). Cohorts were stratified for a definition of dyslexia where possible. We did not observe any associations between rs133885 in Myosin-18B and mathematical abilities among individuals with dyslexia or in the general population. Our results then suggest that the Myosin-18B variant is unlikely to be a main factor contributing to mathematical abilities.

SP is a Royal Society University Research Fellow. The study in the ALSPAC cohort was supported by [Grant number G0800523/8647] and [Grant ref:102215/2/13/2]. MTRNR2L12: A candidate blood marker of early Alzheimer's disease-like dementia

M. Bik-Multanowski[1], *J. J. Pietrzyk*[1], *A. Midro*[2], *B. Stasiewicz-Jarocka*[2], *A. Dobosz*[1];
[1]*Department of Medical Genetics, Jagiellonian University, Krakow, Poland,* [2]*Department of Medical Genetics, Medical University Bialystok, Bialystok, Poland.*

Histological changes constantly reported in autopsied brain tissue of adult patients with Down syndrome are identical with those observed in Alzheimer's disease. Interestingly, many adults with Down syndrome never present with cognitive deterioration whereas in others, Alzheimer's disease-like dementia develops already in the fifth decade of life.

The aim of the study was to identify variations of genome expression in blood that could serve as markers of early dementia in adults with Down syndrome.

Methods:

Cognitive assessment was performed in a cohort of 48 adults with Down syndrome with subsequent microarray-based analysis of whole genome expression in leukocytes. The participants of the study were stratified with regard to their age and cognitive status to allow for comparison of group-specific expression profiles.

Results:

Analysis of microarray data revealed highly significant differences between groups of younger patients with severe cognitive disability and of older patients without dementia with regard to expression of *MTRNR2L12* gene, which is known to be associated with Alzheimer's disease. Subsequent comparison of another subgroup of younger patients with documented cognitive deterioration and the above group of older patients without dementia gave very similar results.

Conclusion:

The findings of the study suggest a protective role of MTRNR2L12 in development of early Alzheimer's disease-like dementia in adults with Down syndrome. Further studies should be performed to evaluate potential usefulness of this marker in patients with Alzheimer's disease.

The study was sponsored by the Polish National Science Centre (DEC-2011-/03/B/NZ5/01328).

Comprehensive genetic and metabolic investigation of undiagnosed early onset epileptic encephalopathies

S. M. Papuc[1], *K. Steindl*[1], *L. Abela*[2], *P. Joset*[1], *B. Oneda*[1], *L. Simmons*[2], *D. Mathis*[2], *B. Schmitt*[2], *G. Wohlrab*[2], *L. Crowther*[2], *M. Zweier*[1], *L. Gogoll*[1], *M. Papik*[1], *B. Plecko*[2], *A. Rauch*[1];
[1]*Institute of Medical Genetics, University of Zurich, Zurich, Switzerland,* [2]*Division of Child Neurology, University of Zurich, Zurich, Switzerland.*

Early-onset epileptic encephalopathies (EOEEs) represent a heterogeneous group of neurological disorders, often characterized by therapy-resistant seizures, electroencephalographic abnormalities as well as motor and cognitive deficits or decline. Despite the poor prognosis, early diagnosis in affected children may contribute to improve disease management and enables genetic counseling. Due to excessive heterogeneity in EOEEs, clarification of the etiology is difficult. We therefore studied the usefulness of comprehensive genetic and metabolomic testing in 63 consecutive patients with EOEE followed in the pediatric neurology division. We performed high-resolution chromosomal microarray analysis (CMA) using the Affymetrix Cytoscan HD array and high coverage (average more than 290fold) whole exome trio sequencing (WES) using the Illumina HiSeq 2500 platform. 6.3% of patients showed clearly pathogenic CNVs. In 5 (26.3%) out of 19 trios analyzed so far by WES, deleterious mutations in disease causing genes were identified; 2 (40%) of them represent autosomal dominant mutations, 2 (40%) were inherited in an autosomal recessive pattern and 1 (20%) was an X-linked condition. Furthermore, in another 5 (26.3%) trios we found deleterious variants in genes previously reported in association with epilepsy and/or ID, but not described in EOEEs. Metabolome analysis in plasma was so far completed in 36 patients and revealed abnormal profiles in 5 patients. In one case a novel plasma biomarker could be identified and matched with the mutated gene supporting the functional relevance of the respective mutation. Therefore, CMA and WES is a powerful diagnostic tool in EOES revealing a diagnosis in at least 33% of patients.

PM08.18

Genetic diagnosis in early infantile epileptic encephalopathy and severe neurodevelopmental delay using a gene panel: Our experience and results so far.

N. E. Trump[1], *A. McTague*[2], *M. Kurian*[2], *A. Papandreou*[3], *A. Ngoh*[2], *L. Jenkins*[1], *R. Scott*[4], **C. Boustred**[5];

The early infantile epileptic encephalopathy (EIEE) syndromes are a heterogeneous group of conditions characterised by intractable seizures and developmental delay or regression. We describe the successful implementation of a gene panel into diagnostic service, our experience so far and the results from 400 patients.

Two different custom enrichments (SureSelect, Agilent and TSCA, Illumina) were used to target 45 genes associated with EIEE and developmental delay followed by sequencing on the Illumina MiSeq. The custom SureSelect panel performed significantly better than TSCA and is now our chosen platform for this panel which has now been expanded to 66 genes.

Mutations in 21 different genes were identified in 67 patients giving a detection rate of 17%. The most frequently mutated genes were SCN2A (11 patients), CDKL5 and KCNQ2 (6 patients each). We found mutations in a number of genes in patients with electroclinical phenotypes not typical for the gene. Given genetic heterogeneity and phenotypic pleiotropy in EIEE, the panel is proving a useful and popular diagnostic tool for Neurologists and Clinical Geneticists, thereby allowing better disease prognostication and genetic counselling for these families, as well as reducing the number and cost of conventional diagnostic tests.

Recurrent CNVs within 17q12 region found in Bulgarian patients with complex epileptic syndromes

V. Peycheva[1], *N. Ivanova*[1], *S. Zhelyazkova*[2], *M. Bozhidarova*[3], *E. Slavkova*[4], *G. Sarailieva*[4],

G. Maksimov[4], D. Deneva[4], V. Dimova[5], I. Litvinenko[3], I. Tournev[2], V. Bozhinova[4], V. Mitev[1], A. Jordanova[6], R. Kaneva[1];
[1]Molecular Medicine Center and Department of Medical Chemistry and Biochemistry, Medical University-Sofia, Sofia, Bulgaria, [2]Clinic of Neurology, University Hospital "Alexandrovska", Department of Neurology, Medical University-Sofia, Sofia, Bulgaria, [3]University Pediatrics Hospital, Department of Pediatrics, Medical University-Sofia, Sofia, Bulgaria, [4]Clinic of Child Neurology, University Hospital of Neurology and Psychiatry "St' Naum", Department of Neurology, Medical University-Sofia, Sofia, Bulgaria, [5]Multiprofile Hospital for Active Treatment „Prof. Dr Stoyan Kirkovich", Stara Zagora, Bulgaria, [6]Neurogenetics Group, VIB Department of Molecular Genetics, University of Antwerp, Antwerp, Belgium.

Copy number variations (CNVs) often result from non-allelic homologous recombination (NAHR) during meiosis. They are frequent cause of intellectual disability (ID) and epilepsy. In the present study we performed comparative genomic hybridization (aCGH) using Agilent Microarray Kit, 4x180K in a sample of 71 Bulgarian patients with epilepsy and ID.
In 11 patients recurrent microaberrations within 17q12 region were found, approximately 1 Mb distal from the breakpoints of the classical 17q12 deletion/duplication syndromes. Four of them carried microduplications and seven - microdeletions. All of the examined patients show overlapping phenotype, involving generalized tonic-clonic, myoclonic and absence seizures, ID, behavior problems, speech impairment. Some additional features are ataxia, hypotonia, facial dysmorphisms and memory problems. All of the CNVs vary in size between 95 and 359 Kb, but the minimum shared region includes CACNB1 gene, encoding beta subunit of voltage- dependent Ca2+ channel. This gene is suggested as a strong candidate, responsible for epilepsy in mice. Moreover, mutations of a paralog of CACNB1- CACNB4 are associated with some types of epileptic conditions. Three of the deletions encompass part of FBXL20 gene, implicated in brain functions by modulating neuronal synaptic plasticity. This gene is ubiquitously expressed in brain and loss of function mutations in mice cause histopathological and behavior abnormalities. Therefore, disruptions of FBXL20 gene might contribute to the complex epileptic phenotype seen in our patients. Further investigations are needed to elucidate the effect of the microaberrations and to clarify the phenotype-genotype correlations.
The study was supported by DTK02/67/2009, funded by NSF.

BACKGROUND
For the identification of molecular defects in patients with suspected genetic disorders, whole exome sequencing (WES) has now entered in medical practice as a diagnostic approach and trios analysis as the most effective strategy to identify *de novo* causal variants.
METHODS
We performed exome sequencing using the Ion AmpliSeq™ Exome technology (Life Technologies) with Ion ProtonTM. Sequencing reads were analysed using Torrent Suite software. Trio annotated variants using ION Reporter were prioritized with an in-house analytical pipeline to identify causative genetic variants.
RESULTS
We present data on the first 50 probands for whom referring physicians ordered whole-exome sequencing trio analysis. Patients were mainly children with neurologic disorders including developmental and/or speech delay, autism, and intellectual disability. We identified 5 pathogenic and 14 probably pathogenic mutated alleles that were highly likely to be causative in 18 of the 50 patients, achieving a 36% molecular diagnostic rate. Among the 18 patients, 1 had X-linked dominant, 2 X-linked recessive, 1 autosomal recessive, and 14 autosomal dominant diseases. The X-linked dominant variant and all of the autosomal dominant mutant alleles occurred "*de novo*". Additionally, variants of uncertain significance were identified in 21 patients. These could be novel genes, however further studies are needed to define its role as causative events.
CONCLUSIONS
We have identified the underlying genetic defect in 36% of consecutive patients referred for evaluation of a possible genetic condition using WES. These data allow us to conclude that trio analysis is a powerful and effective diagnostic method for mendelian disorders.

PS08.21

A rare instability event in the FMR1 locus: clinical, molecular and genetic counselling implications

M. Soeiro e Sá*[1], I. Marques[2,3], O. Moldovan[1], P. Jorge[2,3], A. Fonseca[4], A. Paris[4], R. Santos[2,3], A. Sousa[1];*
[1]Serviço de Genética Médica, Departamento de Pediatria, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte, Centro Académico de Medicina de Lisboa, Lisbon, Portugal, [2]Unidade de Genética Molecular, Centro de Genética Médica Jacinto de Magalhães, Centro Hospitalar do Porto, Porto, Portugal, [3]Unidade Multidisciplinar de Investigação Biomédica, Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Porto, Portugal, [4]PIN-Progresso Infantil, Carcavelos, Portugal.

Fragile X syndrome (FXS) is caused by an expansion of a CGG repeat in the 5'UTR region of the FMR1 gene to over 200 triplets. In typical FXS cases, silencing of the FMR1 gene due to methylation of its promoter precludes protein expression. Loss of the FMR1 protein leads to the physical, neurocognitive and behavioural FXS features. Somatic mosaics in the FMR1 locus are uncommon and can be due either to the presence of alleles with various CGG repeat sizes or epigenetic differences in the extent of methylation. Mosaicism for more than two alleles is a particularly rare finding, although it has been previously described. These phenomena hamper prediction of the disease prognosis.
Herein, we report two independent male cases with a phenotype compatible with mosaic FXS who show atypical mosaic patterns for CGG repeat number, one a mosaic for a full mutation/normal allele and the other for a full mutation/premutation/normal allele. Their mothers were carriers of the premutation. Southern blot analysis, still considered the gold standard for molecular diagnosis of FXS, enabled the characterization of different size mosaics in both cases.
The mechanisms of trinucleotide repeat instability in the FMR1 locus are still not fully understood, although several have been proposed. Likewise, it is still not clear when the repeat expansion occurs (pre-zygotic vs. post-zygotic models). We discuss the possible mechanisms of repeat instability in our cases and present arguments in favour and against both repeat expansion models. Implications for clinical management, molecular diagnosis and genetic counselling are discussed.

PM08.22

Rapid and cost-effective first-tier tool for screening *Fragile X Mental Retardation 1* expansions using triplet-primed PCR and melt curve analysis

I. Rajan Babu*[1], H. Law[2,3], C. Yoon[2], C. G. Lee[1,4,3], S. S. Chong[1,5];*
[1]National University of Singapore, Singapore, Singapore, [2]KK Women's and Children's Hospital, Singapore, Singapore, [3]Duke-NUS Graduate Medical School, Singapore, Singapore, [4]National Cancer Centre, Singapore, Singapore, [5]National University Hospital, Singapore, Singapore.

Introduction: CGG-triplet repeat expansions in the 5'-untranslated region of the X-linked *Fragile X Mental Retardation 1* (*FMR1*) gene are associated with three *FMR1* related-conditions, including fragile X-associated tremor/ataxia syndrome, fragile X-associated primary ovarian insufficiency and fragile X syndrome. The high-cost factor and/or the labor-intensive nature of the currently available molecular diagnostic approaches prohibit their application as a first-tier screening test for *FMR1* mutation in large-scale population-based screening programs. We tested the utility of a simplified first-line screening strategy that relies on melt peak temperature (T_m) analysis of direct triplet-primed PCR amplicons (dTP-PCR MCA). Correlation between T_m and CGG-repeat size based on capillary electrophoresis (CE) of dTP-PCR amplicons was also evaluated.
Materials and Methods: The assays were initially optimized on 29 *FMR1* reference DNA samples, followed by a blinded validation on 107 previously characterized patient DNA samples.
Results: Samples carrying an expanded allele generated dTP-PCR melt profiles with pronounced rightward shift to higher T_m range. All normal and expansion carriers were accurately classified by dTP-PCR MCA, and the *FMR1* genotypic classification of the clinical samples was completely concordant with the previously determined genotypes as well as the dTP-PCR CE results. In addition, we also tested the ability of the assays in detecting low-level mosaicism for *FMR1* expansion using artificial DNA mixtures.
Conclusions: When used in a large-scale screening setting, this simple and cost-effective MCA-based first-line screening tool could rapidly screen out the large majority of unaffected individuals, thus minimizing the number of samples that need to be analyzed by Southern analysis.

This work was supported by Departmental research funds.

PS08.23

A novel HCN1 mutation not associated with epileptic encephalopathy

E. Bettella[1], *R. Polli*[1], *E. Leonardi*[1], *L. Zoccante*[2], *A. Murgia*[1];
[1]*Laboratory of Molecular Genetics of Neurodevelopment, Department of Women's and Children's Health, University of Padova, Padua, Italy,* [2]*Neuropsychiatry Unit, Department of Life Science and Reproduction G.B. Rossi Hospital, University of Verona, Verona, Italy.*

The hyperpolarization-activated cyclic nucleotide-gated channel (HCN1-4) family has important roles in the control of heart rate and neuronal excitability. HCN channels selectively conduct K+/Na+ inward current after hyperpolarized potential. In neurons, HCN channels participate in a variety of functions among which excitabily, dendritic integration and plasticity. Animal models have indicated that dysregulation of these channels is associated with several forms of epilepsy including febrile seizures, absence and temporal lobe epilepsy as well as other neurological disorders. Recently HCN1 point mutations have been found in individuals with early onset epileptic encephalopathy with features resembling Dravet syndrome but with different progression over time. All of them developed intellectual disability and autistic traits.
Here we report the case of a 9 year old girl with a Rett like phenotype, characterized by intellectual disability, hand stereotypies, absent speech, negative brain MRI and EEG data and no history of epilepsy. By NGS approach, with the use of a targeted intellectual disability/epilepsy gene panel, we found the girl to carry a novel de novo heterozygous missense mutation in exon 4 of the HCN1 gene. This mutation is located in the glycine-tyrosine-glycine (GYG) motif, which constitutes the ion selectivity filter typical of K+ permeable channels. This motif is highly conserved structurally and functionally during evolution.
This is the first report of a HCN1 mutation involved in a neurodevelopmental phenotype without epilepsy.

PM08.24

A novel HDAC8 mutation in a two-year-old girl with a CdLS-overlapping features but unrecognizable facial gestalt

B. Graffmann[1], *A. Green*[1], *F. Kaeiser*[2], **M. Stefanova**[1];
[1]*University Hospital Linköping, Linköping, Sweden,* [2]*Institut für Humangenetik, University of Lübeck, Lübeck, Germany.*

The HDAC8 gene encodes a regulatory factor of the cohesin complex. While several mutations in HDAC8 have been identified in patients with Corneliade-Lange-syndrome (CdLS) one single mutation identified in a large family with Wilsson-Turner-syndrome (WTS).
We have performed gene-panel-sequencing analysis on a two-year-old girl with unclear diagnosis and found a novel de-novo HDAC8 mutation. The identified mutation (c.910+1G>A) affects the conserved splice-donor site of the HDAC8 gene and is predicted to results in an aberrantly spliced mRNA that might be degraded by nonsense-mediated mRNA decay or encode a truncated HDAC8 protein.
The patient was born to healthy non-consanguineous parents, aged 38 mother and 42 father. The pregnancy and delivery were uneventful, born at 38 w.g., birth weight 2700 g, birth length 47 cm. The girl presented with a growth delay (length at -4SD, weight -3SD, head circumference -3SD), delayed fontanel closure, and delayed teeth eruption. She showed delayed psychomotor development, sitting steadily at the age of 15 months, did not walk and had no speech by the age of two years. The following dysmorphic features and anomalies were noticed: round face, low forehead, hypertelorism, deep-set eyes, epicanthus, concomitant convergent strabismus, entropion, astigmatism, thick eyebrows, synophrys, long eyelashes, hypoplastic supra-orbital ridges, flat zygomatic region, large nose with bread prominent base, prominent columella, short philtrum, thin lips, medial cleft palate, micrognathia, posteriorly rotated dysplastic ears, short neck, rocker-bottom feet, and impaired conductive hearing. Brain MRI showed hypoplastic vermis and wide ventricles. No inner organ anomalies.
The phenotypical spectrum of HDAC8 mutations is very broad and may not necessarily be recognized as CdLS.

PS08.25

Chromosome 1q21.1 recurrent imbalances in patients with developmental delay revealed by Array-CGH

L. M. Pires[1], *S. I. Ferreira*[1], *P. Paiva*[1], *M. C. Pinto*[1], *A. Jardim*[1], *C. Pais*[1], *M. Venâncio*[2], *J. B. Melo*[1,3,4], *I. M. Carreira*[1,3,4];
[1]*Laboratório de Citogenética e Genómica, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal,* [2]*Serviço de Genética Médica, Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal,* [3]*CIMAGO – Centro de Investigação em Meio Ambiente, Genética e Oncobiologia, Coimbra, Portugal,* [4]*CNC - Centro de Neurociências e Biologia Celular, Universidade de Coimbra, Coimbra, Portugal.*

Chromosome region 1q21.1 is structurally very complex formed by several segmental duplications that make it prone to non-allelic homologous recombination (NAHR). It can be divided into a proximal region containing 16 genes and a distal region containing 13 genes. Array-Comparative Genomic Hybridization (array-CGH) has led to the identification of new syndromes including microdeletion 1q21.1 and 1q21.1 microduplication. Clinical features of patients include intellectual disability (ID) and dysmorphic features. Clinical variability and lack of distinct facial dysmorphisms have been reported in individuals affected by these imbalances, making genetic counseling very challenging.
Oligonucleotide array-CGH analysis using an Agilent 180K platform was performed in 1200 patients with ID, autism spectrum disorders (ASD) and congenital anomalies. Fluorescence in situ hybridization (FISH) analysis usingc SureFISH probes was performed in patients for validation and in parents to determine the origin of 1q21.1 rearrangements.
We identified 8 probands with imbalances involving the distal 1q21.1 region (6 deletions and 2 duplications) and 1 proband with a duplication involving the proximal region. Inheritance was unknown in 5 patients, 2 microdeletions had arisen de novo and 2 microdeletions was inherited from an unaffected mother. All 9 patients with 1q21.1 imbalances revealed mental retardation, microcephaly/macrocephaly and dysmorphic features.
Array-CGH is a useful tool for 1q21.1 rearrangements screening. Duplications were less frequent in our cohort, consistent with recent studies for NAHR. Patients with 1q21.1 imbalances have a considerable phenotypic diversity that could be associated with incomplete penetrance and variable expressivity. Family studies and further clinical data are essential to improve genetic counselling.

PM08.26

PTBP1 Gene Synonymous Mutation In Intellectual Disability

A. Alkhateeb[1], *W. Habbab*[1], *S. Aburahma*[2];
[1]*Qatar Biomedical Research Institute, Doha, Qatar,* [2]*Jordan University of Science and Technology, Irbid, Jordan.*

Objectives: A patient with intellectual disability, developmental delay and basal ganglia abnormal signal on MRI was evaluated for disease gene identification. We aimed to identify the gene responsible for this patient's phenotype.
Methods: The patient is Jordanian Arab from a consanguineous marriage. Samples from her parents and two unaffected sisters were also collected and DNA extracted. Homozygosity mapping was analyzed using Illumina chip microarray. Candidate gene was sequenced using Sanger sequencing. Bioinformatic analysis was done utilizing web-based tools. **Results:** Different homozygosity intervals were characterized. *PTBP1* (poylpyrimidine tract-binding protein 1) gene was identified as a candidate gene within a homozygous interval. *PTBP1* relative expression level contributes to establishing neural-specific alternative splicing patterns and is a key player in alternative splicing of many genes associated to lineage-specific cell differentiation. Sequencing *PTBP1* identified a homozygous silent mutation in exon 7 (c.708C>T, pH236H) that co-segregated within the family.
This mutation was not reported in any database before nor was it detected in 400 control chromosomes from the same population. Bioinformatic testing of DNA sequence by exon splicing enhancer finder identified the sequence where the mutation lies as an exonic enhancer bound by SRSF1 (IgM-BRCA1) with a score of 2.03.
Conclusion: Our data suggest that this unique homozygous mutation might play a role in the pathogenesis of this patient. It is the first time to suggest the involvement of *PTBP1* gene in the etiology of a human genetic disease. Functional analysis should confirm the role of this mutation.

PS08.27

Expanding the phenotype associated with de novo mutations of the KDM5B gene

T. Bienvenu[1], *K. Poirier*[1], *C. Zordan*[2], *N. Lebrun*[1], *G. Viot*[3], *N. Bahi-Buisson*[4], *D. Lacombe*[5], *P. Billuart*[1];
[1]*Université Paris Descartes, Institut Cochin, Inserm U1016, CNRS (UMR8103), Paris, France,* [2]*Service de Genetique Medicale, Hôpital Pellegrin, Bordeaux, France,* [3]*Unité de Génétique, Maternité de Port-Royal, Hôpital Cochin, Paris, France,* [4]*Service de Neuropédiatrie, Hôpital Necker-Enfants Malades, Paris, France,* [5]*Service de Génétique Médicale, Hôpital Pellegrin, Paris, France.*

Histone lysine methylation influences processes such as gene expression and DNA repair. Thirty Jumonji C (JmjC) domain-containing proteins have been identified and phylogenetically clustered into seven subfamilies. Most JmjC domain-containing proteins have been shown to possess histone demethylase activity toward specific histone methylation marks.One of these subfamilies, the KDM5 family, included four members. KDM5A has been pre-

viously demonstrated as involved in autosomal recessive intellectual deficiency (ID), while KDM5C has been reported mutated in nonsyndromic and syndromic form of X-linked ID with or without epilepsy, short stature, or behavioral problems. Interestingly, de novo loss-of-function and missense mutations in KDM5B were identified in patients with ID and autism spectrum disorder but also in unaffected individuals. Here, we report three novel de novo mutations in the KDM5B gene identified by whole-exome sequencing and confirmed by Sanger sequencing. A frameshift mutation c.2642_2643del CT was identified in a girl with severe epileptic encephalopathy, a splicing mutation c.808+1G>A was found in 17 year-old boy with delayed speech development, mild facial features including prominent nasal bridge, and highly arched palate, and moderate intellectual deficiency, and a missense mutation c.1642C>T (p.Leu748Phe) described as probably damaging by bioinformatics tools in a 5-year-old boy with developmental delay, autism features, and mild facial features. We will discuss the effect of mutation position (such as the deletion of the C-terminal part or mutation in the JmjC domain) and the influence of double/multiple events in other genes involved in neuronal function (such as PIGA, Shank3, and Shroom4 also found mutated in these patients) on the clinical phenotype.

PM08.28

GenIDA: a social network and database to inform on natural history of monogenic forms of intellectual disability and autism

F. Colin[1], *T. Mazzucotelli*[2], *P. Parrend*[2,3], *A. Deruyver*[2], *J. L. Mandel*[1,4,5];
[1]*Translational medicine and neurogenetics dept., Institut de génétique et de biologie moléculaire et cellulaire (IGBMC) – INSERM U964 – CNRS UMR7104 – University of Strasbourg, Illkirch, France,* [2]*Engineering, informatics and imaging sciences laboratory (ICube) – CNRS UMR 7357 – ENGEES – INSA of Strasbourg, Illkirch, France,* [3]*ECAM, Strasbourg-Europe, Schiltigheim, France,* [4]*Genetic diagnostic laboratory, CHU, Strasbourg, France,* [5]*Collège de France, Chaire de génétique humaine, Paris, France.*

Intellectual disability (ID) has an incidence of 2% and overlaps with autism. It is characterized by a striking genetic heterogeneity that underlies a phenotypic heterogeneity in severity and in associated medical problems. Progress in genome analysis has allowed the identification of many recurrent CNVs and of more than 400 genes implicated in monogenic forms of ID/autism. An increasing number of genetic diagnoses are made in individuals with ID/autism but the genetic heterogeneity renders extremely difficult the determination of genotype-phenotype correlations and natural history. Symptomatic treatments for comorbidities are proposed with limited opportunities to assess their efficacies or potential adverse effects.
We have initiated the development of an alternative database model for specific genetic causes of ID/autism, organized in a social network format whereby most clinical information is entered by the family of the patient based on wide range questionnaires translated in different languages. Contacts between families affected by the same genetic cause is possible in an anonymous way, creating gene or CNV specific social-networks to which interested professionals could be associated, akin to disease specific patients associations. Anonymized summary data will be accessible to families and to professionals. We will present the structure and features of the GenIDA social network that is currently in its beta testing phase.
This innovative strategy to collect information on natural history and comorbidities of rare monogenic forms of ID/autism will promote families' empowerment and hopefully impact patients' care. The setting up of patient e-cohorts should favor international clinical studies.
Supported by USIAS and RaDiCo.

UNIGENE: Familial intellectual disability in Lithuanian patients

L. Ambrozaitytė[1], *A. Morkūnienė*[1], *Ž. Čiuladaitė*[1], *E. Preikšaitienė*[1], *E. Pranckevičienė*[1], *T. Rančelis*[1], *L. Cimbalistienė*[1], *L. Gueneau*[2], *K. Männik*[2], *N. Voisin*[2], *A. Reymond*[2], *V. Kučinskas*[1];
[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland.*

Intellectual disability (ID) affects 1-3% of the population. Genetic mutations account for about half of the 60% of cases that are currently undiagnosed. The main aim of our Swiss and Lithuanian collaboration is to identify novel genome variants that cause congenital neurodevelopmental disorders. (UNIGENE project has received funding from Lithuanian-Swiss cooperation programme to reduce economic and social disparities within the enlarged European Union under project agreement No CH-3-ŠMM-01/04)
We enrolled 132 families with one or two affected members according to the following standardised selection criteria (IQ<70 or developmental delay (for children under 6 years old) in cases of congenital malformations of central nervous system, not previously described multiple congenital anomalies/ID syndromes, sporadic cases of unspecific ID, etc.) totaling 147 Lithuanian patients with ID. Patients were first screened by arrayCGH, and 17 patients/families (12%) were found to carry causative CNVs such as del10q22.1-q22.3, del6q16.1-q22.31, del17p13.2-p13.3 and mos dup8p11.22-q11.23. The remaining patients are currently being exome sequenced. The first results of these analyses include several potentially causative variants. In particular the genes OTOG, PKHD1L1, IFI44, GFI1 and SYTL3 were found to carry extremely rare variants in evolutionary conserved codons as compound heterozygote in families with two affected individuals. The validation of these findings through identification of more patients with mutations in these genes, in vivo complementation, as well as engineering of animal models is warranted and under way.

PM08.30

Further delineation of MEF2C-related autosomal dominant ID: 6 novel mutations and one intragenic deletion

M. Zweier[1], *A. Baumer*[1], *C. Zweier*[2], *E. K. Bijlsma*[3], *M. Reuter*[2], *E. A. Peeters*[3], *M. Koopmans*[3], *M. Zollino*[4], *E. Wey*[1], *A. Gregor*[2], *C. Kraus*[2], *A. Reis*[2], *A. Rauch*[1];
[1]*Institute of Medical Genetics, University of Zurich, Zurich-Schlieren, Switzerland,* [2]*Institute of Human Genetics, University of Erlangen-Nuremberg, Erlangen, Germany,* [3]*Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,* [4]*Institute of Medical Genetics, Catholic University of the Sacred Heart, Rome, Italy.*

Haploinsufficiency of MEF2C, encoding a member of the myocyte enhancer factor 2 (MEF2) subfamily of transcription factors, was recently identified as the underlying cause of the 5q14.3q15 microdeletion syndrome, characterized by profound muscular hypotonia, severe intellectual disability, early-onset epilepsy and variable other anomalies. Including the first description of the phenocritical role of MEF2C in 2010, eleven patients with de novo point mutations or small indels were reported and only seven of them were described in detail.
We now report on six novel patients with de novo point mutations or small indels in MEF2C and one patient with an intragenic deletion identified by mutational screening of patients referred for Rett, Angelman or Pitt-Hopkins syndrome-like conditions. We provide functional characterization of the two detected missense mutations, both affecting the highly conserved MADS domain, by expression analysis of MEF2C and phenotypically related genes in vivo. In contrast to the generally observed absence of speech one of our patients harboring a novel missense mutation is the first reported patient being able to speak several single words at the age of 4 years functioning at the mild to moderate intellectual disability level (IQ55). In addition we observed absence of seizures in the second patient harboring a missense mutation indicating a milder phenotypic expression in some patients with missense mutations. In summary we expand the mutational spectrum of intragenic MEF2C defects, further delineate the associated phenotype resembling Rett and Angelman syndrome, and point to a milder clinical course in patients with missense mutations.

Clinical Exome Sequencing (CES) in Complex Syndromic Disorders

I. Vogl[1], *S. Doelken*[1], *S. H. Eck*[1], *S. Küçük*[1], *S. Rath*[1], *V. Hasselbacher*[1], *I. Rost*[1], *D. Wahl*[1], *H. G. Klein*[1], **S. Chahrokh-Zadeh**[2];
[1]*Center for Human Genetics and Laboratory Diagnostics, Martinsried, Germany,* [2]*Center for Human Genetics and Laboratory Medicine, Martinsried, Germany.*

Intellectual disability (ID) is defined by an IQ below 70 and observed in approximately 1.5 -2% of live births. Although ID can be caused by a variety of non-genetic factors, genetic traits contribute in 50% of the cases. 40% of these genetic cases can be elucidated by conventional diagnostic such as chromosomal analysis, aCGH, and fragile X testing, while 60% remain unsolved.In a pilot study, we used CES in 15 patients with ID in which conventional diagnostics yielded no causal aberration. Enrichment of target genes was performed using the Illumina TruSight One Sequencing Panel (4,813 genes associated with known clinical phenotypes). The analysis also included the unaffected parents (trio approach) and was performed on the HiSeq2500 Next-Generation Sequencing platform (Illumina, San Diego, CA, USA). Data analysis was performed using CLCbio Genomics Server (v5.5.2) (Qiagen, Hilden, Germany). 1,157 ID associated genes of the 4,813 enriched genes were chosen for further annotation and analysis. These evaluated genes were known from literature or databases to be associated with ID. In 5 of 15 patients, we were able to identify the likely cause of the ID. We detected mutations and possible pathogenic variants in different genes: ATRX, SPG20, UROC1, PMM2, EXOSC3. All detected mutations were confirmed by Sanger sequencing. Two were listed as pathogenic in the HGMD database and the patients' phenotypes were in accordance with the description in the literature. Therefore no further analysis was required. For the 3 other potentially pathogenic variants mRNA sequencing and metabolic testing were

performed.

PM08.32
NGS-based panel analysis of 20 children with intellectual disability and their healthy parents detects sporadic and compound heterozygous mutations

S. Beck-Woedl[1], *U. Grasshoff*[1], *S. Waldmueller*[1], *M. Sturm*[1], *S. Junker*[1], *O. Riess*[1], *I. Krägeloh-Mann*[2], *J. Gburek-Augustat*[3], *P. Bauer*[1];
[1]*Medical Genetics and Applied Genomics, Tuebingen, Germany,* [2]*Children's Hospital Paediatric Neurology and Developmental Medicine, Tuebingen, Germany,* [3]*Children's Hospital; Paediatric Neurology and Developmental Medicine, Tuebingen, Germany.*

Introduction: Intellectual disability (ID, IQ<70) affects up to 3 % of the general population. Until recently the underlying cause remained unknown in about half of the affected individuals. Next generation sequencing techniques help to elucidate the genetic background of ID. Apart from fragile X syndrome which is a common cause of ID (7%) and which has been part of the routine diagnostic work up for years, more than 1000 other genetic diseases for intellectual disability are known to date.
Material and Methods: Following in-solution enrichment of 526 ID-linked genes (exons and splice sites), we sequenced 20 female and male affected children and their parents (trio) in whom genomic imbalances and fragile X syndrome had been excluded.
Results: In three patients we detected de novo dominant disease-causing variants in the genes TUBA1A, MLL2 and GFAP. 6 patients were diagnosed with recessive childhood disorders inherited from their parents (ASPM, PCNT, PEX2, ATP2A2, CPS1 and ZFYVE26). Conclusion: In summary, the stepwise analysis of the index followed by carrier testing of the parents was replaced by immediate trio sequencing. This led to the direct identification of de novo variants and bi-allelic variants in 9 out of 20 cases. The data presented suggest that trio analysis may accelerate sequencing data interpretation and segregation analyses in families with cases of intellectual disability.

PS08.33
High throughput sequencing in molecular diagnosis of non syndromic intellectual disability. New mutations identified within 71 genes specifically selected for non syndromic ID.

F. Faletra[1], *A. Morgan*[1], *I. Gandin*[2], *P. Palumbo*[3], *O. Palumbo*[3], *E. Biamino*[4], *V. Dal Col*[5], *E. Laurini*[5], *S. Pricl*[5], *P. Bosco*[6], *M. Carella*[3], *G. B. Ferrero*[4], *C. Romano*[6], *A. P. D'Adamo*[7], *D. Vozzi*[2];

The technological improvements of the last years made possible considerable progresses in the knowledge of the etiology of Intellectual Disability (ID). However at present very little is known about the genetic heterogeneity underlying the Non-Syndromic form of ID (NS-ID). To investigate the genetic basis of NS-ID we analyzed 43 trios and 22 isolated NS-ID patients using a targeted sequencing (TS) approach. 71 NS-ID genes have been selected and sequenced in all subjects. We found probable pathogenic mutations in 7 out of 65 patients. The pathogenic role of mutations was evaluated through sequence comparisons and structural analysis was performed to predict the effect of alterations in a 3D computational model through molecular dynamics simulations. Additionally a genotype-phenotype correlation has been performed. This approach allowed us to find new pathogenic mutations with a detection rate close to 11% in our cohort. This result supports the hypothesis that many NS-ID related genes still remain to be discovered and that unlike the syndromic form, NS-ID is a more complex phenotype, likely caused by a deep and broad interaction between genes alterations and environment factors.

PM08.34
Searching for a novel gene responsible for mild to moderate intellectual disability syndrome

E. Yıldız[1], *S. Mümtaz*[2], *S. Malik*[2], *A. Tolun*[1];
[1]*Molecular Biology and Genetics Department, Boğaziçi University, Istanbul, Turkey,* [2]*Human Genetics Program, Department of Animal Sciences, Faculty of Biological Sciences, Quaid-i-Azam University, Islamabad, Pakistan.*

Introduction: Intellectual disability is a neurodevelopmental disorder that is characterized by impaired intellectual functioning, and it affects 1-3% of the population. We investigated a consanguineous Pakistani family afflicted with mild to moderate mental retardation. The affected individuals were poor in reasoning, judgement and mathematical skills as compared to normal age mates. However, they could be trained for simple life tasks under supervision. Materials and Methods: Parents and one unaffected and four affected sibs were available for study. Disease locus was identified by linkage mapping using SNP genotype data. Whole exome sequencing was applied to find rare/novel variants at the locus. Results: The disease locus was an approximately 2-Mb region at 2p23.3 and yielded a multipoint LOD score of 3.7. Only homozygous missense *PTRHD1* p.Cys52Tyr mutation segregated with the disease in the family. All the affected siblings were homozygous for this mutation and the unaffected sister was not. None of the 98 control samples from the Pakistani population tested positive for the mutation. The mutation was predicted as damaging by bioinformatics tools. *PTRHD1* encodes a peptidyl tRNA hydrolase belonging to the PTH2 family. The protein has 140 amino acids whose sequence is totally conserved between human and chimpanzee, and 52Cys is conserved across all vertebrates. The gene is expressed in many organs, including the brain.
Conclusion: *PTRHD1* is a novel gene for mild to moderate intellectual disability. We are planning to continue the population screen and to perform gene expression assays in various parts of human brain.
(Supported by Boğaziçi University BAP 7695)

PS08.35
A patient with syndromic intellectual disability and features reminiscent of Cornelia de Lange syndrome due to a de novo mutation of EP300

A. Eaton, *C. Smith, R. Lamont, D. Dewey, A. M. Innes, J. Parboosingh, F. P. Bernier; University of Calgary, Calgary, AB, Canada.*

Rubinstein-Taybi Syndrome (RTS) is associated with growth retardation, intellectual disability, and distinctive facial features with broad thumbs and toes. Causative mutations in two genes, CREBP (RTS1) and EP300 (RTS2), have been described, accounting for approximately 75%, and 3% of cases respectively. The phenotype of the RTS2 patients is generally appreciated to be milder, though only 14 cases have been reported. Recently, Woods et al (AJMG 2013) reported a novel EP300 mutation in a patient with features that overlap Cornelia de Lange syndrome (CdLS).
We describe an 8 year-old girl referred for dyspmorphic features, short stature, microcephaly, and global developmental delay. Her mother had severe pre-eclampsia during her pregnancy. Trio-based whole exome sequencing identified a de novo mutation in EP300 (c.2713_2714delCC). Her physical features include full eye lashes, thin arched eyebrows, a low-hanging columella, mild micrognathia and hirsutism on her back and arms, but with normal thumbs and toes. Her features were reminiscent of mild CdLS. Psychometric testing revealed a full scale IQ in the borderline range; however subscale discrepancies were noted with relative strengths in verbal comprehension. Additional deficits were noted on assessment of her attention, executive function, visual perceptual processing, social perception and motor skills. Her outgoing personality and verbal strengths are reminiscent of William syndrome, and her educational and social struggles are significant. Our case further supports that there may be a broader phenotypic spectrum caused by mutations in this gene, and brings into question whether testing for EP300 mutations in patients with CdLS may be warranted.

PM08.36
Validation of *PTPN23* as an intellectual disability gene through identification of a second likely disease-causing variant

K. Wessel[1], *N. Nahavandi*[1], *K. K. Kandaswamy*[1], *A. AlHashem*[2], *B. T. Melaiki*[2], *A. Rolfs*[1,3], *R. Abou Jamra*[1];
[1]*Centogene AG, Rostock, Germany,* [2]*Prince Sultan Military Medical City, Riyadh, Saudi Arabia,* [3]*Albrecht-Kossel-Institute for Neuroregeneration, Medizinische Universität Rostock, Rostock, Germany.*

Intellectual disability (ID) is an extremely heterogeneous disorder. In the last few years, whole exome sequencing (WES) has facilitated the identification of many new candidate genes in which mutations may lead to ID. However, often these results cannot be used in a clinical diagnostic setting, as no further mutations and/or patients have been described to provide a second independent validation of the initial results. Recently, Alazami *et al*. reported a missense variant in the *PTPN23* gene, c.3995G >T (p.Arg1332Leu), in one child with global developmental delay, epilepsy, brain atrophy, and some skeletal malformation.
Alazami concluded that this gene is a candidate gene for brain atrophy and global developmental delay. We performed WES in an 8-year-old boy presenting with global developmental delay and developmental regression, epilepsy, brain atrophy, microcephaly, ataxia and abnormal movements. In this analysis, we detected a homozygous variant, c.904A>G (p.Met302Val) in the *PTPN23* gene, which is highly conserved and predicted to be pathogenic by several but not all *in silico* programs. We observe a significant overlap of

symptoms between the two patients, and conclude that both mutations are probably causative.
Therefore, mutations in *PTPN23* are likely to be associated with an autosomal recessive form of ID with brain atrophy and epilepsy. Further symptoms such as skeletal malformation, regression and ataxia are reported in only one of the two patients and further studies are needed to precisely delineate the specific phenotype characteristics.

Title: Value of a diagnostic confirmation service by an accredited laboratory

S. Clasper[1], *T. Lester*[1], *U. Kini*[2], *H. Stewart*[2], *A. Seller*[1];
[1]*Oxford Medical Genetics laboratories, Oxford, United Kingdom,* [2]*Department of Clinical Genetics, Oxford, United Kingdom.*

The explosion of Next Generation sequencing has produced an unprecedented amount of valuable data which has enabled potential characterisation and diagnoses in disease for a vast array of patients. Many of these findings are produced by research laboratories and confirmation in a diagnostic laboratory enables patients and their families access to publically funded healthcare resources through the NHS that would not otherwise be available to them including; disease support, family testing and prenatal diagnosis (PND).
We present an audit of our referrals from the areas of paediatric developmental delay and dysmorphology covering eighteen months of our diagnostic confirmation service. We review two of these cases in more depth and use them to highlight the benefits of the interpretation provided by using a diagnostic service; such as providing a classification for a phenotype or re-classification of a proposed diagnosis, both of which may have implications for patient management.

KBG Syndrome: A DDD front-runner?

T. Ashraf[1], *M. Irving*[1], *N. Canham*[2], *S. Holder*[2], *N. Foulds*[3], *A. Magee*[4], *V. McConnell*[4], *R. Fisher*[5], *M. McEntegart*[6], *J. Tolmie*[7], *S. Joss*[7], *J. Clayton-Smith*[8], *DDD Study;*
[1]*Guys Clinical Genetics Service, London, United Kingdom,* [2]*North West Thames Regional Genetics Centre, London, United Kingdom,* [3]*Wessex Clinical Genetics Service, Southampton, United Kingdom,* [4]*Department of Genetic Medicine, Belfast City Hospital, Belfast, United Kingdom,* [5]*Institute of Genetic Medicine, Newcastle, United Kingdom,* [6]*St George's Clinical Genetics Service, London, United Kingdom,* [7]*Clinical Genetics Service, Southern General Hospital, Glasgow, United Kingdom,* [8]*Manchester Centre for Genomic Medicine, Manchester, United Kingdom.*

KBG syndrome (Omim #148050) is a rare genetic disorder caused by haploinsufficiency of the ANKRD11 gene. The phenotype has previously been described to include macrodontia of the mandibular central incisors, skeletal and craniofacial anomalies as well as intellectual disability. Many sources quote that the cognitive deficit and the clinical features in this condition can be mild, thus making it an underdiagnosed genetic condition.
The Deciphering Developmental Disorders (DDD) study aims to identify the underlying genetic cause in children with developmental delay and/or congenital abnormalities, where conventional genetic testing has failed. Exome sequencing of the first 1000 child and parent trios found several patients with likely pathogenic mutations in ANKRD11. This data suggests that KBG syndrome is not as rare or as benign as initially suspected which prompted a Complementary Analysis Proposal (CAP) to further explore the phenotype of this condition.
Questionnaires on detailed phenotypes were sent to the lead Genetic clinicians for all of the patients identified with ANKRD11 mutations through DDD so far. The data was amalgamated and photographs of the patients were obtained with parental consent.
Here we present a summary of the frequently reported clinical features, characteristic dysmorphology and genotype within this cohort of patients. Recommendations have been made about diagnostic clues and management strategies when this genetic diagnosis is suspected clinically.

PS08.39

Exome sequencing identifies three novel candidate genes implicated in intellectual disability

Z. Agha;
International Islamic University Islamabad, Islamabad, Pakistan.

Intellectual disability (ID) is a major health problem mostly with an unknown etiology. Recently exome sequencing of individuals with ID identified novel genes implicated in the disease. Therefore the purpose of the present study was to identify the genetic cause of ID in one syndromic and two non-syndromic Pakistani families. Whole exome of three ID probands was sequenced. Missense variations in two plausible novel genes implicated in autosomal recessive ID were identified: lysine (K)-specific methyltransferase 2B (KMT2B), zinc finger protein 589 (ZNF589), as well as hedgehog acyltransferase (HHAT) with a de novo mutation with autosomal dominant mode of inheritance. The KMT2B recessive variant is the first report of recessive Kleefstra syndrome-like phenotype. Identification of plausible causative mutations for two recessive and a dominant type of ID, in genes not previously implicated in disease underscores the large genetic heterogeneity of ID. These results also support the viewpoint that large number of ID genes converge on limited number of common networks i.e. ZNF589 belongs to KRAB-domain zinc-finger proteins previously implicated in ID, HHAT is predicted to affect sonic hedgehog, which is involved in several disorders with ID, KMT2B associated with syndromic ID fits the epigenetic module underlying the Kleefstra syndromic spectrum. The association of these novel genes in three different Pakistani ID families highlights the importance of screening these genes in more families with similar phenotypes from different populations to confirm the involvement of these genes in pathogenesis of ID.

PM08.40

Novel homozygous mutation in KPTN gene causing a familial intellectual disability-macrocephaly syndrome

S. Pajusalu[1,2], *T. Reimand*[1,2,3], *K. Õunap*[1,3];
[1]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,* [2]*Institute of Biomedicine and Translational Medicine, Department of Biomedicine, University of Tartu, Tartu, Estonia,* [3]*Department of Paediatrics, University of Tartu, Tartu, Estonia.*

BACKGROUND: Recently, Baple et al. (Am J Hum Genet 2014, 94(1):87-94) described a large Amish pedigree where homozygous or compound heterozygous mutations in KPTN gene encoding kaptin protein resulted in a clinically distinctive syndrome consisting of macrocephaly, global developmental delay, behavioural abnormalities, and seizures (MIM 615637). Here we report the second case of KPTN-related syndrome in two Estonian siblings with novel homozygous KPTN mutation and similar phenotype.
CASE REPORT: The probands are 32-years-old brother and 24-years-old sister from Estonia. The parents are non-consanguineous, but were born in the same parish. The brother and sister have macrocephaly, with occipitofrontal circumference of 63 cm (+4.5 SD) and 60 cm (+4 SD) respectively. Their intellectual disability could be classified as moderate. The verbal abilities are more affected than the motor development in both siblings. Behavioural problems and a few episodes of seizures were present only in the brother.
METHODS AND RESULTS: Whole exome sequencing identified homozygous one-nucleotide frameshift duplication in KPTN gene (c.665dupA:p.Q222fs). Homozygosity of both affected siblings and heterozygosity of parents was confirmed by Sanger sequencing. SNP-array showed a 1.5 Mb homozygous stretch encompassing KPTN gene in both siblings.
CONCLUSIONS: With this report we confirm the pathogenicity of KPTN gene mutations and delineate the core phenotype of the novel autosomal recessive genetic syndrome. We also prove the hypothesis of the first describing authors that KPTN-related syndrome is not restricted to Amish population.
This work was supported by the Estonian Research Council grant PUT355.

PS08.41

Intragenic deletion of DOCK3 gene in a patient with dysphasia and intellectual delay

T. AIT MOUHOUB[1], *E. LANDAIS*[1], *P. FEUCHER*[1], *A. LANNOY*[1], *C. CARREAU*[1], *P. JONVEAUX*[2], *H. DAGONET*[1], *H. EZZEDINE*[3], **M. DOCO-FENZY**[1,4];
[1]*CHU REIMS, REIMS, France,* [2]*CHU NANCY, NANCY, France,* [3]*CH CHARLEVILLE-MEZIERES, CHARLEVILLE-MEZIERES, France,* [4]*EA3801, Reims, France.*

DOCK3 (Dedicator of Cytokinesis 3) belongs to CDM family protein which regulates several biology process involved in the engulfment of apoptotic cells and in the cell migration. DOCK3 gene expression is restricted to the brain, notably in the occipital, frontal and temporal lobes where is the Wernicke's speech area implied in speech processing. To date, there is no well-defined clinical syndrome associated with DOCK3 gene mutation or deletion. The only clinical publication involving DOCK3 gene evoked a patient with attention deficit hyperactivity disorder-like phenotype and SLC9A9 and DOCK3 genes disruption.
Here, we reported a 11 year-old boy presenting with a phonological and synthaxic dysphasia, intellectual delay, without related dysmorphia, neither deafness nor visual acuity disorder. He was born at term, with these following parameters: weight 3730 g (75th percentile)- size 50.5 cm (50th percentile), HC 36 cm (75th percentile). His evolution was marked by mild cognitive delay, language impairment without motor delay. Cerebral MRI

was normal. His father and his three brothers have language impairment. We highlighted by array CGH (Agilent - 180K) an intragenic 156 kb deletion in DOCK3 gene located at 3p21.2. Familial exploration is in progress. This case is interesting because it could involve a new gene in language disorder associated with intellectual delay.

PM08.42

Identification of lncRNAs involved in neuronal development and intellectual disability

S. Vergult, *E. D'haene, E. Jacobs, B. Menten;*
Center for Medical Genetics Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium.

Background
Recent studies have assigned important functions to lncRNAs in gene regulation and protein interactions. Since many of these lncRNAs emerged recently during vertebrate and primate evolution, a crucial role in the human brain is anticipated. Here, we aimed at identifying candidate lncRNAs associated with neuronal development and intellectual disability (ID).
Methods
A strategy was defined using publically available data regarding neuron specific histon modifications, REST binding & DNAse 1 hypersensitivity. This was complemented with extensive expression profiling of both coding and noncoding genes in seven nonneuronal tissues and eight brain samples. As a proof-of-principle, this approach was first applied to all RefSeq coding genes.
Results
Of the coding genes, 4040 met the criteria of having a neuron specific H3K4-me3 mark, REST binding and DNAse 1 hypersensitivity in the promoter region (filter 1) as well as a relatively high expression in at least one brain sample (filter 2). A significant enrichment of ID genes was noted in this list (178/4040) and in 65 genes, a GWAS hit for neuropsychiatric disorders was observed; indicating the power of this approach.
When applied to 32108 lncRNA transcripts (lncipedia 2.1), 2980 lncRNAs passed filter step 1. While the majority of lncRNAs have a relatively low expression, an enrichment of lncRNAs passing filter step 2 was seen (215/2980 versus 1360/32108). A GWAS hit was noted in one of these lncRNAs.
Conclusion
Using this integrated approach, we identified 215 interesting candidate lncRNAs for neuronal development. These lncRNAs will be functionally validated.

PS08.43

Partial rescue of RTT-like symptoms in Mecp2-deficient mice after administration of a self-complementary AAV9 (scAAV9) construct expressing a codon-optimized Mecp2 transgene.

V. Matagne[1,2], *L. Villard*[1,2], *J. Roux*[1,2];
[1]*Inserm UMR_S 910, Marseille, France,* [2]*Aix Marseille Université, Marseille, France.*

Rett syndrome (RTT) is an X-linked neurodevelopmental disorder primarily affecting CNS functions. Most RTT cases are due to mutations in the methyl CpG binding protein 2 (MECP2) gene, a global transcriptional modulator. There is currently no cure for the disease and drugs alleviating symptoms are the only available therapies.
Recently, two different research teams reported that gene therapy in the Mecp2-deficient RTT mouse model partially cured the disease (Gadalla et al 2013; Garg et al 2013). Although both studies showed a rescuing effect, the overall benefits of this therapy seemed to depend on the age at which the virus was administered, as well as the viral construct.
In order to try and improve vector delivery and expression, we designed a plasmid construct expressing a codon-optimized version of Mecp2 that was used to generate a scAAV9 virus. Thirty day-old Mecp2-deficient male mice were injected with the virus through the tail vein (2*1011vg/mouse). Post-mortem analysis was carried out in 60 day-old animals and the percentage of transduced brain cells was quantified by immunohistochemistry. Despite a low percentage of Mecp2-expressing cells (6-10% of WT levels), we did find an improvement in spontaneous activity (Open field) and sensorimotor coordination (Rotarod), as well as a decrease in apneas that are characteristic RTT symptoms (plethysmography).
These preliminary data indicate that even a low level Mecp2 expression can improve RTT symptoms in Mecp2-deficient mice. Further studies will aim at confirming these data and investigating the potential therapeutic effect of the same viral construct in female RTT mice.

PM08.44

Biallelic mutations in the Notch pathway regulator MIB1 in two brothers with syndromic intellectual disability and distinctive facial features

M. A. van Slegtenhorst[1], *R. Oostenbrink*[2], *J. N. R. Kromosoeto*[1], *M. E. H. Simon*[1], *G. M. S. Mancini*[1];
[1]*Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, Netherlands,* [2]*Department of Pediatrics, Erasmus Medical Center, Rotterdam, Netherlands.*

Dominant mutations in the ankyrin domain and in the ring fingers domain of the E3 ubiquitin ligase MIB1, that promotes endocytosis of the NOTCH-ligand DELTA and JAGGED, have been linked to the etiology of familial non-compaction cardiomyopathy (NCCM) (Luxan et al 2013). In a large cohort of patients with unexplained intellectual disability (ID), de Ligt et al (2012) listed a de novo missense mutation in *MIB1* as candidate for ID. We observed a family consisting of three siblings born to healthy non-consanguineous Dutch parents. A girl died at the age of 9 months from complications of extra-hepatic bile duct atresia, abdominal situs inversus, polysplenism and intestinal malrotation. Two male siblings, at present 11 and 7.5 years old, presented with comparable problems consisting of failure to thrive, delayed motor developmental, microcephaly, intellectual disability, friendly behavior, delayed and nasal speech, large nose bridge and small nares, pointed chin, small mouth, high palate with teeth malocclusion, thin upper lip, featureless philtrum, large ears, short neck, fair complexion, kyphoscoliosis, barrel shaped chest. Cardiac screening of the eldest child at 2.5 years showed a slightly enlarged right ventricle, but was otherwise normal. Whole exome sequencing of DNA from both sibs showed two shared compound heterozygous changes in *MIB1*, one maternally inherited highly conserved missense variant,c.244G>A in the zinc finger domain and the other in the splice donor site for exon 3 (c.531+1G>T), adjacent to the Mib Herc2 domain. We hypothesize that biallelic recessive mutations in *MIB1* cause a severe and complex phenotype, including intellectual disability.

PS08.45

Detecting small Copy Number Variations, smaller than 400 kb, improves the diagnostic yield of CMA in intellectual disability

N. Chatron[1], *E. Fonteneau*[2], *M. Faoucher*[1], *C. Depienne*[2], *A. Labalme*[1], *E. Lejeune*[2], *M. Till*[1], *C. Mignot*[2], *C. Schluth-Bolard*[1], *C. Nava*[3], *A. Putoux*[1], *G. [1]*Service de génétique, Hospices Civils de Lyon, Lyon, France,* [2]*GH Pitié-Salpêtrière, Département de Génétique, Paris, France,* [3]*GH Pitié-Salpêtrière, CRicm UPMC Inserm UMR S975/CNRS UMR 7225, Paris, France,* [4]*GH Pitié-Salpêtrière, Département de Génétique, Lyon, France.*

Cytogenetic microarray (CMA) allows the elucidation of 15 to 20 percent of remaining unexplained cases of intellectual disability. A threshold of 400 kb is proposed to consider Copy Number Variants (CNV). Array use in diagnostic setting could detect smaller CNV mostly polymorphic generating numerous confirmations. Here, we propose to evaluate the diagnostic interest of small CNV (inferior to 400kb) in intellectual disability (ID). This collaborative study groups an Illumina SNP-array platform and an Agilent CGH-array platform for a total of 3330 patients explored for syndromic or isolated intellectual disability from 2011 to 2014.
Over 26,866 CNV detected, 22,683 (84.4%) were smaller than 400 kb. Among the 1440 CNVs considered as relevant, 850 (40.9 %) were smaller than 400 kb increasing by 70% the amount of necessary confirmation by another technique. We concluded that 44 of 605 (7.3%) of these CNVs (smaller than 400kb) were pathogenic. 36 were deletions which involved pathogenic gene in ID and 8 were duplications. It is noteworthy that, except a MECP2 duplication, all small duplications were either intragenic or probably truncating an ID gene possibly leading to haploinsufficiency.
To conclude, analyzing CNV smaller than 400 kb significantly increases the number of verification but enhances the diagnostic yield of 1.3 % in patients with ID, which is equivalent to 44 patients in our cohort. However, we propose not to consider small non-truncating duplications. While massively parallel sequencing techniques are becoming routine diagnosis, it seems preferable to detect as many pathogenic CNVs as possible using CMA.

PM08.46

Comparisons of Mcph1-deficient mouse embryonic fibroblasts

T. Staab, *D. Luehders, D. Schindler;*
University of Wuerzburg, Department of Human Genetics, Wuerzburg, Germany.

Biallelic mutations in the MCPH1 gene are the cause of primary microcephaly (OMIM 251200) associated with premature chromosome condensation (PCC) in G2 phase and delayed decondensation post mitosis. MCPH1 encodes a multifunctional protein that was reported to be involved in brain development, DNA damage response and the regulation of chromosome

condensation.
In this study we investigated mouse embryonic fibroblasts (MEFs) from three different types of published Mcph1 knockout mice. We failed to detect a delay in G2 checkpoint release after irradiation, as shown in earlier experiments of our group using patient derived MCPH1-deficient cells. However, we did observe a flatter slope of increase of the mitotic rate of MEFs from the Mcph1 knockout mice compared to controls.
Furthermore, we compared the rates of different DNA repair focus formation after irradiation of cells with 1 Gy or exposure to hydroxyurea. Analysis of yH2AX and 53BP1 indicated up to three times higher rates of foci-positive cells in knockouts than in control cells. In contrast, RAD51 and RPA foci appeared at similar rates and with similar time courses in Mcph1-deficient as in control cells.
Finally, we prepared mitotic chromosomes to compare the levels of PCC. The rate of prophase-like cells (PLCs) of Mcph1-deficient MEFs was increased compared to those of normal control cells. The Mcph1 knockout MEFs showed PLC rates between 0.7-4.5%, whereas the controls showed rates only between 0.2-0.3%.
Our results suggest that the presence of Mcph1 is necessary for the early DNA damage response after irradiation and that the effect of Mcph1 deficiency is confined to mitosis.

PS08.47

Homozygous mutation in the eukaryotic translation initiation factor 2alpha phosphatase gene, *PPP1R15B*, is associated with extreme microcephaly, short stature, and developmental delay

K. K. Kernohan[1], T. Martine[2], M. T. Geraghty[1], W. Qin[1], C. Care4Rare[1], J. Majewski[3], **J. Richer***[1], K. M. Boycott[1];*
[1]Children Hospital of Eastern Ontario, Ottawa, ON, Canada, [2]McGill University and Genome Quebec Innovation Centre, Montreal, QC, Canada, [3]2McGill University and Genome Quebec Innovation Centre, Montreal, QC, Canada.

Protein translation is an essential cellular process initiated by the association of a methionyl-tRNA with the translation initiation factor eIF2. The met-tRNA/eIF2 complex then associates with ribosomal subunits and other translation factors, which together comprise the translational machinery. This process is regulated by the phosphorylation status of the α subunit of eIF2 (eIF2α); phosphorylated eIF2α attenuates protein translation. Here we report a consanguineous family with severe microcephaly, failure to thrive and intellectual disability in two siblings. Whole-exome sequencing identified a homozygous missense mutation, c.1972G>A; p.R658C, in PPP1R15B, a protein which functions with the PPP1C phosphatase to maintain dephosphorylated eIF2α in unstressed cells. The p.R658C PPP1R15B mutation is located within the PPP1C binding site. We show that patient cells have greatly diminished levels of PPP1R15B-PPP1C interaction, which results in increased eIF2α phosphorylation and resistance to cellular stress. Finally, we find that patient cells have elevated levels of PPP1R15B mRNA and protein, suggesting activation of a compensatory program aimed at restoring cellular homeostasis which is ineffective due to PPP1R15B deficiency. PPP1R15B now joins the expanding list of translation associated proteins which when mutated cause rare inherited diseases.

PM08.48

6q22.33 microdeletion in a family with intellectual disability, variable major anomalies and behavioral abnormalities

L. Mackenroth*[1], K. Hackmann[1], A. Beyer[1], K. Hackmann[1], J. Schallner[2], B. Novotna[2], B. Klink[1], E. Schröck[1], A. Tzschach[1], N. Di Donato[1];*
[1]Institut für Klinische Genetik, Medizinische Fakultät Carl Gustav Carus, TU Dresden, Dresden, Germany, [2]Klinik und Poliklinik für Kinder- und Jugendmedizin, Universitätsklinikum Carl Gustav Carus, Dresden, Germany.

Interstitial deletions on the long arm of chromosome 6 have been described for several regions, such as 6q16, 6q22.1, and 6q21q22.1, and with variable phenotype such as intellectual disability/developmental delay, growth retardation, major and minor facial anomalies. An overview is given by Rosenfeld et al., reviewing twelve reported cases of the literature and proposing phenotype-genotype correlation [Rosenfeld et al. 2012]. However, an isolated microdeletion of the sub-band 6q22.33 has not been described so far and thus, no information is available concerning the specific phenotype associated with such a copy number variation.
Here we define the clinical picture of an isolated 6q22.33 microdeletion based on the phenotype of six members of one family with loss of app. 1 Mb in this region. Main clinical features included mild intellectual disability and behavioral abnormalities as well as microcephaly, heart defect, and cleft lip and palate. The mother attended supportive school; however she did not require a legal guardian and lived independently with regular social support regarding the childcare.References:Rosenfeld JA, et al. 2012. Genotype-phenotype correlation in interstitial 6q deletions: a report of 12 new cases. Neurogenetics 13(1):31-47

PS08.49

The costs and benefits of clinical genomic sequencing for monogenic disorders

D. J. Schofield*[1,2,3], B. Doble[3,4], T. Roscioli[3,5], J. Mattick[3,6];*
[1]University of Sydney, Camperdown Sydney, Australia, [2]Murdoch Children's Research Institute, Melbourne, Australia, [3]Garvan Institute of Medical Research, Sydney, Australia, [4]Monash University, Melbourne, Australia, [5]Sydney Children's Hospital, Sydney, Australia, [6]St. Vincent's Clinical School, UNiversity of New South Wales, Sydney, Australia.

Genetic disorders affect a large proportion of the population and result in substantial economic and social burden. The rapid advances in genome sequencing have created an opportunity to rapidly and more universally identify disease-causing gene mutations, facilitating more efficient diagnosis and improved disease management and prevention. Here we have compared the costs of disability resulting from gene mutations with the potential health and social benefits of implementing whole genome testing for the detection of significant monogenic diseases. We found that the annual costs of intellectual and physical disability are substantial with average costs ranging from about $40,000 per annum for children with an intellectual disability to over $400,000 for young adults with severe intellectual disability. The aetiology of many conditions associated with intellectual and/or physical disability can be identified through clinical genomic sequencing at a current cost (including analysis) of ~US$10,000, although that cost should decline rapidly with continued technological advances and especially the development of well-curated genotype-phenotype correlation databases. Different applications of clinical genomic sequencing offer varying abilities to avoid cases of disability with greater benefits likely to be realized the earlier in the reproductive cycle testing is offered. The potential to mitigate even a fraction of the costs and social impacts associated with disability through clinical genomic sequencing makes a compelling socioeconomic case for consideration of implementation of such testing as well as the construction of supporting national and international databases.

PM08.50

Whole gene duplication of SCN2A and SCN3A is compatible with normal intellectual development

A. Thuresson*, C. Soussi Zander;*
Dept. of Immunology, Genetics and Pathology, Uppsala, Sweden.

Duplications at 2q24.3 encompassing the voltage-gated sodium channel gene cluster are associated with early on-set epilepsy. All cases described in the literature also presented with different degrees of intellectual disability, and has apart from the sodium channel gene cluster also involved neighboring genes.
Here we describe a family including a mother and two daughters, all presenting with a duplication involving only SCN2A, SCN3A and the 5'-part of SLC38A11. All three had a normal cognitive development and infantile epilepsy with a spontaneous remission after one year. This suggests that an extra copy of SCN2A and SCN3A have an effect on epilepsy pathogenesis, which might be similar to what is seen in patients with SCN2A mutations. However, the number of copies of SCN2A and SCN3A does not seem to have an effect on cognitive outcome.

PS08.51

The power of next generation sequencing in identifying atypical presentations of known OMIM genes: the exemple of CUL4B

M. Lefebvre*[1], D. Martin-Coignard[2], J. Rivière[1], Y. Duffourd[1], J. Thevenon[1], C. Thauvin-Robinet[1], C. Redin[3], J. Mandel[3], C. Ben Signor[1], A. Piton[3], L. Faivre[1];*
[1]CHU Dijon, Dijon, France, [2]CH Le Mans, Le Mans, France, [3]CHU Strasbourg, Strasbourg, France.

Intellectual disability (ID) has an estimated prevalence of 2% in the general population and is more common in males. Mutation in CUL4B, a gene encoding for a member of cullin-RING complex, is known to cause Cabezas syndrome corresponding to a X-linked ID associated with aggressive outburst, seizures, hypogonadism and dysmorphism. To date, 35 males patients are reported with mutation in CUL4B, all of the propositus were diagnosed after the age of normal puberty. We report here 3 new patients of 2 families with CUL4B mutations, diagnosed with Next Generation Sequencing (NGS) at a younger age (4 to 19 years) and presenting with atypical features such as sensory neural deafness, iris heterochromia and patchy depigmentation of the skin (suggesting a Waardenburg syndrome), hypertrophic cardiomyopathy, or medullar ischemia in early infancy. All of them presented with mild to severe psychomotor delay, macrocephaly and facial dysmorphism. Short

stature, obesity, kyphosis, seizures and hypogenitalism were found in 2 out of 3 patients after reverse phenotyping. Due to these confounding factors, the diagnosis of Cabezas syndrome has not been clinically raised and needed NGS. Two novel truncating CUL4B mutations, were found, , inherited from the healthy mother of the 2 brothers in family 1, and de novo in the 3rd patient. In conclusion, the use of NGS and reverse phenotyping allowed to establish the diagnosis in these atypical presentation of the Cabezas syndrome.

PM08.52

Unexpected molecular diagnoses of intellectual disabilities: making headway with the Trusight One sequencing panel

A. Jacquette[1,2], *I. Marey*[1,2], *C. Mignot*[1,2], *S. Whalen*[3,2], *C. Depienne*[4], *C. Nava*[5], *P. Charles*[1,2], *A. Faudet*[1,2], *F. Lesne*[1,2], *B. Keren*[4], *D. Heron*[1,2];
[1]*département de génétique, Hôpital de la Pitié-Salpétrière, Paris, France,* [2]*centre de réference «déficiences intellectuelles de causes rares», Paris, France,* [3]*service de Génétique, Hôpital Trousseau, Paris, France,* [4]*UF de génomique du développement, Hôpital de la Pitié-Salpétrière, Paris, France,* [5]*UF de neurogénétique, Hôpital de la Pitié-Salpétrière, Paris, France.*

Recent advances in genetic technologies provide new opportunities to elucidate genetic defects. The introduction of NGS methods in the diagnostic of intellectual disabilities (ID) led to the identification of 20 to 50 % supplementary disease causing variants.
We applied the Trusight One technology (Illumina) which contains the 4813 genes already involved in human pathology.
We studied a series of 36 patients with ID who have been extensively investigated without diagnosis.
From our first results, this method allowed us to disclose diagnoses that were unexpected owing to:
- the mild phenotype of a known syndrome, well exemplified by a sibpair with apparently non syndromic ID carrying an ATRX mutation
- the limited knowledge about very rare and/or poorly described phenotypes or the lack of specificity of a given disorder, as illustrated by a patient with a GRIA3 mutation
- the limited knowledge about the early phenotype of some progressive diseases with developmental delay, as exemplified by a young patient with ID but without typical brain MR images carrying PANK2 mutations.
Among NGS approaches in ID, Trusight One technology is an interesting tool for the diagnosis of known but rare diseases.

PS08.53

Mutation in NRAS in familial Noonan syndrome - Case report and review of the literature

S. Gudmundsson[1], *S. Ekvall*[1], *M. Wilbe*[1], *J. Dahlgren*[2], *E. Legius*[3], *A. van Haeringen*[4], *O. Westphal*[2], *G. Annerén*[1], *M. Bondeson*[1];
[1]*Immunology, Genetics, Pathology and Science for Life Laboratory, Uppsala, Sweden,* [2]*Paediatrics, the Sahlgrenska Academy, Gothenburg, Sweden,* [3]*Human Genetics, Leuven, Belgium,* [4]*Clinical Genetics, Leiden, Netherlands.*

Noonan syndrome (NS), a heterogeneous developmental disorder associated with variable clinical expression including short stature, congenital heart defect, unusual pectus deformity and typical facial features, is caused by activating mutations in genes involved in the RAS-MAPK signaling pathway.
We present a clinical and molecular characterization of a family with Noonan syndrome. Comprehensive mutation analysis of *NF1, PTPN11, SOS1, CBL, BRAF, RAF1, SHOC2, MAP2K2, MAP2K1, SPRED1, NRAS, HRAS* and *KRAS* was performed using targeted next-generation sequencing. Result revealed a recurrent mutation in *NRAS*, c.179G>A (p.G60E), in the index patient. This mutation was inherited from patient's father, which also showed signs of NS.
Neither of the affected individuals in this family presented with juvenile myelomonocytic leukemia (JMML), which together with previously results suggest that the risk for NS individuals with a germline *NRAS* developing JMML is not different from the proportion seen in other NS cases. 50% of NS individuals with an *NRAS* mutation present with lentigines and/or Café-au-lait spots, demonstrating predisposition to hyperpigmented lesions in *NRAS*-positive NS individuals. Moreover, the affected father in our family presented with a hearing deficit since birth, which together with lentigines are two characteristics of NS with multiple lentigines (previously LEOPARD syndrome), supporting the difficulties in diagnosing individuals with RASopathies correctly. The clinical and genetic heterogeneity observed in RASopathies is a challenge for genetic testing. Advantages of next-generation sequencing allows screening of large number of genes simultaneously, which will have an important impact on the correct diagnosis, prognosis and treatment of these patients in the future.

PS08.55

Similar orofacial phenotype in a family with Xq24-Xq25 duplication

D. Belengeanu[1], *D. Marian*[1], *V. Belengeanu*[1], *C. Bratu*[2], *D. Misceo*[3];
[1]*University of West Vasile Godis Arad, Arad, Romania,* [2]*University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [3]*Department of Medical Genetics, Oslo University Hospital, University of Oslo, Oslo, Norway.*

Mandibular prognathism is a common dentofacial phenotype with a substantial genetic component, however, few susceptibility loci have been mapped.
Mandibular prognathism is a feature of the XXY, XXXY, and XXXXY syndromes and of interest is the progressive increase of this feature as the number of X chromosomes increases.
We refer a family, mother and two adult boys with the same orofacial morphological pattern, for clinical and craniometric assessment and for cephalometric analysis.
The index case - male of 30 years old with intellectual disability and obesity, dysmorphic features with triangular shaped face, short palpebral fissures, prognatism, macrostomia, and low set ears. Surprisingly, the brother of 32 years old and the mother of 60 years old presented the same orofacial features, associated with milder intellectual disability.
Given the intellectual disability, genetic testing was carried out. The karyotype was normal. As regards the array-CGH analysis, a Xq24-Xq25 ChrX:115.568.872-126.991.548 bp, microduplication was found, confirmed through quantitative Real Time PCR. BAC-FISH was done for all 3 family members and it revealed that the duplicated segment was located on chromosome X and it was likely to have a direct orientation. On extraoral examination, they presented oval face with appearance of long face due to the lower facial level predominance, through a short and flat philtrum, sharp chin, retrusive concave facial profile.
At craniometry they presented hyperbrachicephalic type according to the cranial index, hyperleptoprosop facial type according to the facial morphology index, and leptorrhine nasal type. Lateral cephalometric analysis showed skeletal class III malocclusion with prognathism.

PM08.56

Exploring possible genetic heterogeneity in Pitt-Hopkins syndrome combining whole-exome and targeted next-generation sequencing.

G. Marangi, *S. Ricciardi, S. Lattante, D. Orteschi, M. Zollino;*
Catholic University, Rome, Italy.

Pitt-Hopkins syndrome (PTHS) is characterized by ID, typical facial gestalt, and additional features, including breathing abnormalities. It is generally caused by the haploinsufficiency of TCF4 gene. However, no mutation can be identified in a relevant number of patients with an apparently typical phenotype.
We developed a clinical checklist based scoring system to select patients presenting with a phenotype that is highly suggestive of PTHS. We tested for pathogenic variants in TCF4 a total of 200 patients referred with a clinical suspect of PTHS, of whom 25 had a proven mutation in TCF4. Based on our score system we selected 75 subjects with a score >10 and normal TCF4 to be studied in search of the disease causative variant. Patients were further grouped into categories with homogenous phenotypes according to their score and the presence of additional clinical features.
Aiming to explore the possible genetic heterogenity underlying cases with PTHS-like phenotype but with negative molecular tests, a small group of these subject (n=4) already underwent whole exome sequencing (WES) analysis. It allowed us to identify a set of variants in shared genes to be considered for further validation.
Additionally, we have been performing targeted next generation sequencing on the remaining patients, by using a custom panel including both genes responsible for diseases that are to be considered in differential diagnosis of PTHS, and genes resulting from exome sequencing data filtering and prioritization.
Preliminary results are presented and discussed.
Supported by Telethon grant nr: GEP 14089.

PS08.57

Heterozygous deletion of 4 exons of the PTPRT gene confirms its contribution to intellectual disability.

D. Ilencikova[1], *G. Webersinke*[2], *S. Deutschbauer*[2], *M. Maurer*[1], *H. Duba*[1];
[1]*Department of Human Genetics, Landes-Frauen- und Kinderklinik, Linz, Austria,* [2]*Laboratory for Molecular Biology and Tumor Cytogenetics, Department of 1st Internal Medicine, Krankenhaus Barmherzige Schwestern, Linz, Austria.*

Understanding of the genetic basis of intellectual disability (ID) has been increased in recent years. The use of sensitive pangenomic techniques as aCGH and SNParray contributes to discover new genes associated with syn-

dromic and non-syndromic ID.
We reportan 18-month-old Turkish child with a psychomotoric developmental disorder who presents with unstable sitting, severe hypotonia and speech delay but without dysmorphisms. SNP array analysis identified a „de novo" 185 kbp deletion on chromosome 20q12 encompassing a deletion of 4 exons of a single coding gene, named PTPRT (Protein-Tyrosine Phosphase,Receptor Type T). The PTPRT gene entry in OMIM database (608712) includes a single variant of unknown significanceTHR1365MET [dbSNP:rs199947379].
This variant was revealed due exome sequencing in 3 Dutch sibs with severe intellectual disability, published by Schuurs-Hoeijmakerset al. (2013). Authors noted that the PTPRT gene is expressed in the brain or in neuronal tissue and encodes a transmembrane receptor of the protein tyrosine phosphatase family, which are important proteins in signal transduction. They described a complex phenotypein 5 affected sisters including behavioral problems, microcephaly, congenital heart defects, short stature, and diaphragmatic herniation. The combination of a heterozygous missense variant and a heterozygous intronic deletion of 150 kb suggests an autosomal recessive pattern of inheritance.
In our patient we considered no heart defects and diaphragmatic herniation. Due to age behavioral problems have not been evaluated until today.
In summary, we report a case of ID associated with a heterozygous deletion of the PTPRT gene, confirming a PTPRT haploinsufficiency, which contributes to intellectual disability.

PM08.58
Mutations in QARS, encoding glutaminyl-tRNA synthetase, cause normocephalic intellectual disability and seizures - expansion of the phenotype

R. Segel[1,2], *S. Gulsuner*[3], *N. Rosenfeld*[1], *H. Fridman*[1], *P. Renbaum*[1], *E. Levi-Lahad*[1,2], *A. Aran*[1,2];
[1]*Shaare Zedek Medical Center, Jerusalem, Israel,* [2]*Hebrew University Hadassah Medical School, Jerusalem, Israel,* [3]*University of Washington, Seattle, WA, United States.*

Intellectual disability (ID) and seizures are common characteristics of numerous neuro-genetic syndromes. Recessive loss of function mutations in QARS, encoding Glutaminyl-tRNA Synthetase, were recently described in 2 families as a cause of ID with intractable seizures in infancy, progressive microcephaly , and atrophy of the cerebral cortex, cerebellar vermis and cerebellar hemispheres (Zhang et al 2014).
We report two children with ID and seizures, born to first-cousin parents. Both were born at term, with normal birth weights. The affected boy had multiple-type seizures (atypical absence and drop attacks) from age 3 months, while his sister had mild atypical absences from age 6 years. Both siblings (currently 11.5 years and 10 years old respectively) have severe ID with expressive language impairment, but are both normocephalic with normal brain imaging and mild dysmorphic features.
Whole Exome sequencing revealed 5 possibly damaging coding variants homozygous in both affected children and heterozygous in the parents: 4 missense variants and one stop loss mutation. Only one was in a gene associated with a neurological phenotype: QARS c.858C>A; p.Phe286Leu, not reported in 1000 genome, EVS and ExAC. This missense mutation is predicted to be damaging by Polyphen (0.999). Two unaffected sibs were heterozygotes for the QARS mutation. Functional studies of this mutation will be presented.
Glutaminyl-tRNA Synthetase is a ubiquitously expressed class-I aminoacyl-tRNA synthetase. Our results suggest QARS mutations cause a wider spectrum of functional brain abnormalities, and should be considered as a candidate gene for non-syndromic ID with seizures.

PS08.59
RBFOX1 intragenic deletions detected by array-CGH - 6 new cases with neurological phenotype

N. Lavoura[1], *J. B. Melo*[1], *S. I. Ferreira*[1], *M. C. Pinto*[1], *C. Pais*[1], *A. Mascarenhas*[1], *L. Ramos*[2], *I. M. Carreira*[1];
[1]*Laboratório de Citogenética e Genómica, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal,* [2]*Serviço de Genética Médica, Hospital Pediátrico, Centro Hospital e Universitário de Coimbra, Coimbra, Portugal.*

Introduction: In the last couple of years, it has become evident the importance of whole genome array-CGH in the screening of de novo microdeletions or duplications in patients with phenotypic features of mental retardation (MR) and autistic spectral disorders (ASD). Copy number variations (CNV) in RBFOX1, also known as A2BP1, have been associated with human neurodevelopmental disease, including autism spectrum disease.
This gene, spanning 1.7 MB on chromosome 16p13.3, is one of the largest genes in the human genome, responsible for encoding splicing regulatory factors, specifically expressed in neurons and muscles, and having a regulatory action in alternative splicing of a large tissue-specific gene networks.
Materials and methods: Oligonucleotide array-CGH analysis, using an Agilent 4x180K platform, was performed in 1200 patients with mental retardation, autism spectrum disorders and congenital anomalies.
Results: In our cohort, we identified 6 cases with intragenic deletions in RBFOX1, 4 of them with additional CNV in other chromosomes. These CNVs are located at 16p13.3, extended in a 1,2Mb region between 6,087,983-7-,207,012 (GRCh37/hg19), which corresponds to intronic regions in 5 out of 6 patients. Five of these patients have an inherited deletion, from an unaffected progenitor, and one has an unknown inheritance pattern.
Conclusions: The phenotypes of all these children have in common, as widely described, neurological alterations. The rearrangements identified lead to a reduction in RBFOX1 expression, corroborating the importance of RBFOX1 haploinsufficiency in this phenotypes. The continuing follow-up of these patients and similar cases can help our understanding on the phenotypic diversity of these patients.

PM08.60
Mosaicism for a start codon mutation in MECP2 in a male with clinical features of Rett Syndrome: phenotypic description and review of the literature.

K. A. Davis[1], *R. E. Lamont*[1], *J. S. Parboosingh*[1], *R. L. Sparkes*[1,2], *J. Lemay*[2], *A. Innes*[1,2];
[1]*Department of Medical Genetics, University of Calgary, Calgary, AB, Canada,* [2]*Department of Pediatrics, University of Calgary, Calgary, AB, Canada.*

Rett Syndrome (RTT) is an X-linked neurodevelopmental disorder caused by mutations in the methyl CpG-binding protein 2 (MECP2) gene at locus Xq28, which presents with both classic and variant phenotypes in females. In males, mutations similar to those that cause RTT in females are usually lethal; however, somatic mosaicism for classic RTT mutations or less deleterious, nonsynonymous mutations result a spectrum of neurological features reminiscent of classic RTT in females. In this case, an 8-year-old male presented with clinical features of RTT including: microcephaly, Chiari I malformation, neurodevelopmental regression, seizures, bradykinesia, apnea and stereotyped midline hand movements. MECP2 analysis identified both a normal sequence and a c.1A>T (p.Met1?) mutation in peripheral blood and fibroblasts with normal dosage by multiplex ligation-dependent probe amplification (MLPA). This has only been reported in females with classic RTT. Somatic mosaicism for classic RTT mutations has rarely been reported in males, however, this is the first known case involving the start codon of MECP2, p.M1. Subsequent analysis by array comparative genomic hybridization (aCGH) did not identify copy number changes in MECP2 but did pick up a 172 kb deletion of Xq21.31, which is considered unlikely to contribute to the patient's phenotype. The unbalanced heterozygous mutation suggests somatic mosaicism. Although a small duplication cannot be ruled out given the limitations of our array and MLPA probes, this is felt to be less likely to be the mechanism. The phenotypic presentation of this patient is discussed along with a review of the current literature on males with RTT.

PS08.61
Syndromic X-linked intellectual disability segregating with a missense variant in RLIM

E. Tønne[1], *R. Holdhus*[2], *C. Stansberg*[2], *A. Stray-Pedersen*[1], *K. Petersen*[3], *H. G. Brunner*[4], *C. Gilissen*[4], *A. Hoischen*[2,4], *T. Prescott*[1], *V. M. Steen*[2,5], *T. Fiskerstrand*[2,5];
[1]*Department of Medical Genetics, Oslo University Hospital, Oslo, Norway,* [2]*Department of Clinical Science, University of Bergen, Bergen, Norway,* [3]*Department of Computational Biology Unit, University of Bergen, Bergen, Norway,* [4]*Department of Human Genetics, Radboud University Medical Center and Radboud Institute for Molecular Life Sciences (RIMLS), Nijmegen, Netherlands,* [5]*Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway.*

We describe a three generation Norwegian family with a novel X-linked intellectual disability (XLID) syndrome characterised by subtle facial dysmorphism, autism and severe feeding problems. By exome sequencing we detected a rare missense variant (c.1067A>G p.(Tyr356Cys) NM_183353.2) in the RLIM gene, in two affected male second cousins. Sanger sequencing confirmed the presence of the variant in the four affected males and in the three carrier mothers available for testing. The variant was not present in 100 normal Norwegian controls, has not been reported in variant databases and is deleterious according to in silico prediction tools (SIFT, Polyphen and MutationTaster). The clinical phenotype and the variant co-segregate, with a LOD score of 3.0 for linkage to the shared region (36.09 Mb). No other shared rare variants on the X-chromosome were detected, and all female carriers had an extremely skewed X-inactivation pattern.
RLIM encodes ring zinc finger protein 12 (RNF12), an ubiquitin ligase which is essential for X-inactivation in mice and which acts as a co-regulator of a range of transcription factors, particularly those containing a LIM homeo-

domain. Tyrosine in position 356 in RNF12 is located within a highly conserved domain essential for binding such transcription factors. Expression of RNF12 is widespread during embryogenesis, and particularly high in the outer layers of the cerebral cortex.
The detected variant likely disrupts an essential function of RLIM in neurodevelopment, and raises the possibility of important, previously unknown roles for this ubiquitin ligase.

PM08.62
Identification of an inherited splicing SCN8A mutation in a family with intellectual disability, autism, ataxia and seizures by whole exome sequencing

D. Prchalová[1], *M. Hančárová[1], K. Šterbová[2], V. Stránecký[3], M. Vlčková[1], M. Havlovicová[1], Z. Sedláček[1];*
[1]Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic, [2]Department of Paediatric Neurology, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic, [3]Institute of Inherited Metabolic Disorders, Charles University 1st Faculty of Medicine and General University Hospital, Prague, Czech Republic.

Whole exome sequencing (WES) can identify causes of abnormal clinical phenotypes. We report a 15-year-old boy and his 9-year-old brother with normal karyotypes and SNP array findings who showed moderate intellectual disability (ID), autism and speech delay. The older boy had abnormal EEG and showed absence seizures since the age of 9 years. The younger boy presented ataxia at the age of 5 years. Their mother showed mild ID, as did the maternal grandmother and a maternal uncle.
WES of the brothers and their mother identified a heterozygous splicing *SCN8A* mutation (NM_014191, c.1134+1G>A) which was absent in all exome databases. It was confirmed using Sanger sequencing in both boys, their mother, grandmother and uncle, and predicted to disrupt the splice donor of intron 9, with exon 9 skipping being one of the likely outcomes. Sequencing of lymphocyte cDNA of the carriers confirmed this aberrant transcript leading to frameshift and premature termination (p.G331GfsX11). The interpretation of this variant transcript is however complicated by its presence also in normal controls. Other variant transcripts and differences in transcript ratios are under study.
Multiple *SCN8A* mutations have been reported, mostly *de novo* missense variants in patients showing predominantly seizures, while one truncating variant segregated in a family with a broader spectrum of cognitive and behavioural deficits. Our findings may support the notion that while missense *SCN8A* mutations causing increased channel activity can be associated mainly with seizures, heterozygous loss-of-function mutations may predispose to a slightly different phenotype.

PS08.63
Single genes deletions/duplications detected by array-CGH: diagnostic relevance and suggestions for new disease genes.

D. Orteschi, M. Murdolo, E. Ponzi, A. Asaro, C. Cafiero, G. Marangi, S. Lattante, S. Ricciardi, G. Neri, **M. Zollino***;*
Institute of Medical Genetics, Catholic University, Rome, Italy.

During the application of array-CGH to the diagnosis of syndromic forms of intellectual disability (ID), a total of 39 Copy Number Variants (CNVs) limited to single genes were observed, with size ranging from 85 Kb to 1.3 Mb. They accounted for 1.5 % of cases (38/2600). Results were confirmed by a second independent experiment. Sequencing of the candidate gene on the normal homologous was performed in some cases, with normal results.
Based on gene content analysis and on biological properties of the genes, a total of 5/38 CNVs, encompassing FMR1, VPS13B, SCN1A, MEF2C and APC, respectively, were considered pathogenic, with clinical presentation in carriers recapitulating the expected phenotype. A total of 10/38 CNVs (nine recurrent deletions and one duplication, encompassing GPHN, AUTS2, CTNNA3, SHANK2, and CNTNAP2) were likely pathogenic variants, previously described as characterized by incomplete penetrance and variable expressivity, ranging from ID to ADS.
A total of additional three CNVs define new genetic conditions, most likely, never reported before. They include 1) duplication of ZIC3 in a male subject with complex malformations resembling the oculo-auriculo-vertebral spectrum, 2) partial NFIB deletion associated with trigonocephaly and ID, 3) partial CDC42SE2 deletion associated with periventricular heterotopia. The remaining 20 CNVs
were considered of uncertain significance.
These observations focus on rare small CNVs limited to single genes that should be analysed by direct sequencing in additional subjects with similar clinical presentations.

PM08.64
Homozygous missense mutation in SNIP1, encoding Smad Nuclear Interacting Protein 1, associated with severe autosomal recessive neurodevelopmental disorder

R. Maroofian[1], *E. Baple.[2], B. Chioza[1], M. Patton[1], A. Crosby[1];*
[1]Medical Research, RILD Wellcome Wolfson Centre, University of Exeter Medical School, Exeter, Devon, United Kingdom, [2]University Hospital Southampton NHS Foundation Trust, Wessex Clinical Genetics Service, Southampton, United Kingdom.

Introduction: Neurodevelopmental disorders are a highly heterogeneous and diverse group of genetic or acquired conditions that are responsible for brain or central nervous system dysfunction. Although many genes responsible for these conditions have been discovered, the aetiology and disease pathogenesis of most forms remains poorly understood.
Materials and Methods: Using a combination of autozygosity mapping and whole exome sequencing (WES), we studied an autosomal-recessive neurodevelopmental disorder with seizures, craniofacial dysmorphism and other features found among the Amish community.
Results: Whole-genome mapping of family members from two sibships using HumanSNPCyto-12 DNA Analysis BeadChip revealed a homozygous region on chromosome 1p34 common to the three affected children. Exome sequencing of one affected child identified a novel homozygous mutation in SNIP1 c.1097A>G (p.Glu366Gly) as the likely causative variant. The variant cosegregated with the disease phenotype in the families investigated as well as a further seven affected individuals from four other nuclear Amish families. Five heterozygous carriers of the mutation were identified among 350 Amish controls, which is not unexpected in this genetic isolate. Mutation pathogenicity was predicted through five in-silico programs.
Conclusions: Our findings define the clinical spectrum associated with biallelic mutation in SNIP1, which we show to be the likely cause of the severe neurodevelopmental disorder in these families. Assessing the functional outcomes of the missense mutation in the encoded protein and its regulatory function will expand our knowledge about the essential role of SNIP1 in growth and development of the brain or central nervous system.

Deciphering the biochemistry of Snyder-Robinson Syndrome: Metabolomics identifies a new biochemical marker in patients affected by Snyder-Robinson syndrome (SRS)

K. Steindl[1], *L. Abela[2], L. Simmons[2], B. Schmitt[3], P. Joset[1], M. Papuc[1], H. Sticht[4], A. Baumer[1], L. M. Crowther[2], D. Mathis[5], B. Plecko[2], A. Rauch[1];*
[1]Institute of Medical Genetics, University of Zurich, Zurich, Switzerland, [2]Division of Child Neurology, University Children's Hospital Zurich, Zurich, Switzerland, [3]Division of Epilepsy and Neurophysiology, University Children's Hospital Zurich, Zurich, Switzerland, [4]Institute for Biochemistry, University of Erlangen-Nuremberg, Erlangen, Erlangen, Germany, [5]Division of Clinical Chemistry and Biochemistry, University Children's Hospital Zurich, Zurich, Switzerland.

Snyder-Robinson syndrome (SRS) is a probably underdiagnosed X-linked disorder characterized by intellectual disability, dysmorphic face, muscle hypotonia, kyphoscoliosis, osteoporosis, seizures, and speech and gait abnormalities. SRS is caused
by mutations in spermine Synthase (SMS), but diagnosis of SRS has been hampered by lack of a specific biomarker that can be measured in body fluids or native cells. The balance of spermine and spermidine is maintained by SMS and is crucial for proper chromatin structure, ion channel regulation, transcription and translation.
We established the diagnosis of SRS by clinical exome sequencing in two novel monozygotic twin patients and subsequently demonstrated an abnormal spermine/spermidine ratio in cultured lymphoblasts. The novel Arg130Cys mutation is predicted to diminish enzymatic activity by decreasing dimer stability and affecting the structure of the adjacent spermine binding site. The third SRS patient investigated was published previously (Mastrangelo et al. 2013). Differential expression profiling of metabolites in the SRS patients revealed a high peak that was absent in controls. After identification of the SMS mutation, the abnormal peak could be readily identified as N-acetylspermidine, a polyamine intermediate product involved in spermine and spermidine metabolism. Thus we conclude that spermine synthase deficiency leads to intracellular accumulation of spermidine, which is converted to N-acetylspermidine and exported from the cell. Therefore targeted or untargeted plasma analysis of N-acetylspermidine represents a powerful screening marker for SRS relying on a single blood plasma sample.
Our study demonstrates the great potential of a combined genetic and me-

tabolomic approach and provides further insight into the metabolic dysregulation of SRS.

Compound heterozygous mutation in SZT2 gene in a patient with macrocephaly, epilepsy and severe intellectual disability

B. Albrecht[1], *H. Lüdecke*[1], *T. Strom*[2], *H. Engels*[3], *D. Wieczorek*[1];
[1]*Institut fuer Humangenetik, Essen, Germany,* [2]*Institut fuer Humangenetik, Helmholtz-Zentrum, München, Germany,* [3]*Institut fuer Humangenetik, Biomedizinisches Zentrum, Bonn, Germany.*

We report on a family included in a trio exome sequencing study performed on 250 patients with intellectual disability.
The 15 year old boy is the first and only child of healthy, non-consanguineous German parents, born at term after a pregnancy complicated by uterus myomatosus and gestosis. Birth measurements were normal but green amniotic fluid was noted. The boy walked independently with 2 ½ years and never learned to speak and he is not toilet trained. Seizures started with 4 years of age and could be treated effectively. Agitated behavior and autistic features needed medication. Brain MRI revealed reduced temporal gyri on the left. The patient attends a special school and behaves like a toddler. Body measurements were normal throughout life, but head circumference was above the 97th centile. The patient has a high and broad forehead, prominent lips and small hands and feet.
Trio exome sequencing revealed a maternally inherited frame-shift mutation (c.841delC, p.(Gly281Ser*fs**33)) and a paternally inherited missense mutation in *SZT2* gene (c.9787G>A, p.(Asp3263Asn)). The possibly damaging missense mutation may lead to a residual protein function and cause a milder phenotype resembling the three brothers described by Falcone et al (2013) who are homozygous for a 3-bp in-frame deletion. Patients with homozygous or compound heterozygous truncating mutations as described by Basel-Vanagaite et al (2013) show severe infantile encephalopathy with epilepsy. This sixth patient broadens the phenotypic spectrum caused by mutations in *SZT2* gene showing an intermediate clinical course compared to the patients published to date.

PM08.68

Targeted molecular diagnosis of intellectual disability with or without autism: update from 217 to 275 genes and 100 to 300 patients confirms a 20-25% diagnostic efficiency and highlights genes recently identified or recurrently mutated

A. Piton[1], *B. Gerard*[2], *F. Mattioli*[1], *E. Nourisson*[2], *C. Feger*[2], *J. Mandel*[1];
[1]*IGBMC, Strasbourg, France,* [2]*Laboratoire de diagnostic génétique, CHU Strasbourg, Strasbourg, France.*

We have recently reported the results of targeted sequencing (TS) of 217 genes implicated in intellectual disability in 106 patients (mostly males) with ID and no diagnosis after CGH array and phenotype-driven testing of candidate genes (Redin et al. J Med Genet 2014). The diagnostic yield after stringent evaluation was 26% (23% for sporadic ID cases). We have now extended this using an improved panel of 275 genes, and have tested another 200 patients. Our current results confirm a diagnostic yield of 20 to 25%. Our results indicate that de novo mutations in few genes, such as DYRK1A or TCF4, are found recurrently in ID patients and may account each for 1-2% of cases (ie not far from the incidence of fragile X). The update of our gene list allowed us to identify mutations in very recently identified ID genes, such as NAA10, TBR1, POGZ, TRIO, ZBTB20 (Primrose syndrome). We also report the first non-consanguineous and compound heterozygous case of AP4S1 ID with spastic paraplegia. Whole exome sequencing (WES) performed for fifteen individuals with no mutation identified after targeted sequencing (TS) did not reveal any obvious mutation in other genes not included in the panel. The large decrease in the depth of coverage obtained for WES compared to TS (60X vs 300X) made CNV analysis (with depth-of-coverage-based methods) and variant detection less efficient for our genes of interest. Therefore, until prices fall and coverage increase, targeted sequencing of candidate genes remains a useful method for routine diagnosis of intellectual disability.

PS08.69

A second family with THOC6 mutations and syndromic intellectual disability

A. Masurel-Paulet[1], *J. Thevenon*[1,2], *N. Jean*[1], *D. Lehalle*[1], *D. Minot*[1], *C. Thauvin*[1,2], *J. Rivière*[2], *L. Faivre*[1,2];
[1]*Hôpital d'Enfants, DIJON, France,* [2]*Equipe GAD, Université de Bourgogne, France.*

Exome sequencing is a new technology allowing the identification of the molecular bases of genetic conditions in patients without clinical diagnosis. We report the case of a 6-year-old boy with intellectual disability (ID) and severe language delay, hyperactivity, microcephaly, genital malformation with undescended testes, and peculiar dysmorphic features. MRI showed a dysplastic corpus callosum. Classical investigations, including array-CGH were negative. Exome sequencing found compound heterozygous mutations in THOC6 (p.Tyr45* and p.Gly190Glu). THOC6 is a member of the THO/TREX complex which is involved in coordinating mRNA processing with mRNA export from the nucleus, highly expressed in the midbrain and eyes. To date, a unique consanguineous Hutterite families comprising 4 affected children with common ancestors have been described with a THOC6 homozygous mutation. The patients have distinctive facial features, microcephaly, developmental delay, and possible heart and genitourinary malformations. Reverse phenotyping confirmed the presence of similar facial features, including tall forehead with high anterior hairline, deep-set eyes with short, upslanted palpebral fissures, long nose with low-hanging columella, and thick vermilion of the upper and lower lip. Other common features included the severe speech difficulties and the presence of genital malformations. Additional cases are requested to consider this gene as an undoubtful disease-causing gene.

PM08.70

Fast and effective genome editing to study dominant de novo mutations: the WDR45 example

C. A. Biagosch[1,2], *S. Hensler*[1,2], *D. Janik*[3], *F. Neff*[3], *L. Becker*[4,5], *W. Wurst*[5,6], *T. Meitinger*[1,2], *H. Prokisch*[1,2];

Increasing Trio sequencing for intellectual disability delivers more and more potentially disease causing de novo DNA variants. This situation necessitates an effective validation tool. We present an effective genome editing approach based on embryo microinjection of TALENs. We chose to generate a mouse model for the X-linked dominant form of NBIA (neurodegeneration with brain iron acculumation), caused by de novo loss-of-function mutations in WDR45. In humans, the course of disease is two-staged with developmental delay and intellectual disability in childhood and a second phase of rapid neurological deterioration characterized by parkinsonism and dementia occurring in early adulthood with characteristic neuroimaging findings such as hypointense signals in substantia nigra and globus pallidus. Microinjection of TALEN mRNA into oocytes resulted in 19% mutated founders (5/26). Mutations were deletions between 10 and 57bp with a frameshift in 4/5 mutations. From the in situ design and delivery of TALENs (~1month), over in vitro testing in cell culture to in vivo injection into embryo's (~2months) until the genotyping of founder mutants it took 4 months. The murine Knock-Out proved to not necessarily be de novo; therefore we chose a mouse harboring a 20bp deletion in Exon 2 for further breeding. Investigation of nine month old male brains (n=8) revealed numerous degenerated neurons and large axonal spheroids, clear signs of neurodegeneration in medulla oblongata, cerebral cortex and thalamus of mutant animals only. Furthermore, a neurobehavioral screen of 21 animals at the age of one year showed motor impairment (Balance Beam, p=0.004; Inverted Grid, p=0.018; Open-field, p=0.014).

PS08.71

A new ILRAPL1 point mutation: clinical report of a X-linked mental retardation family.

U. Ullmann, *S. Boulanger, P. Hilbert, V. Benoit;*
IPG, Gosselies, Belgium.

IL1RAPL1 (interleukin-1 receptor accessory protein-like 1) located at Xp21.3-21.2 has been shown to be deleted in X-linked mental retardation patients with contiguous gene syndrome. Rarely, intragenic deletions or mutations have been identified. Non-specific intellectual disability, behaviour impairment with autistic spectrum disorder (ASD) and mild dysmorphism are actually recognized to be associated with IL1RAPL1 mutations.
IL1RAPL1gene comprises 11 exons and harbors 3 extra-cellular Ig-like domains (NM_014271.3). IL1RAPL1 protein does not bind interleukin-1 but is regulating the formation of synapses of the cortical neurons. IL1RAPL1 forms with the protein tyrosine phosphatase rho (PTPrho) a complex inducing pre and postsynaptic differentiation (Hayashi et al., 2013).
So far, very few papers reported family with XLMR caused by point mutations in IL1RAPL1 gene (Ramos-Brossier et al., 2014). We report here a family

with XLMR with two brothers as probands, their mother and sister carrying a new point IL1RAPL1 mutation c.1054C>T (p.Arg352*). The mutation was identified after X-chromosome analysis by next generation sequencing technique. This new mutation lying in exon 8 induces a premature stop codon. The resulting truncated protein is predicted to lack part of extracellular domain, transmembrane domain and the entire cytoplasmic domain. To our knowledge, this substitution is not yet described in the literature but its pathogenic character is highly likely.
Interestingly, in contradiction with the so far published data, all the female carriers were found with mild learning disabilities, and some behaviour impairments without any X-skewed inactivation detected at the level of lymphocytes DNA.

PM08.72
Recurrent microduplications at Xp22.31 are not sufficient to convey a disease phenotype

C. Rigon, M. Donà, E. Micaglio, F. Pauro, M. Cassina, L. Salviati, M. Clementi, **E. Trevisson**;
Clinical Genetics Unit, Department of Woman and Child Health, University of Padova, Padova, Italy.

The pathogenicity of Xp22.31 duplications is still controversial. Recent studies have suggested a possible causal relationship of this genomic rearrangement with an abnormal phenotype, indicating that it may be a risk factor for intellectual disability.
In an effort to clarify the significance of these duplications we report the genotype, the inheritance and the clinical features of six females with interstitial duplications of Xp22.31 ranging in size from 1,48 Mb to 1.76 Mb found by array-CGH analysis. Five of these individuals presented intellectual disability, whereas the genomic rearrangement was an incidental finding in the sixth individual.
The duplicated X chromosome was inherited in all the five patients. The inheritance was mainly paternal and all parents were clinically unaffected. Although the Xp22.31 triplication has been suggested to be more penetrant than the corresponding duplication, we found four copy of this region in one patient and three copy in her unaffected father.
In contrast with the more recent reports that increased the confidence about the pathogenicity of the Xp22.31 microduplication, our findings do not allow to confirm its association with a disease phenotype and cannot exclude the possibility that this is a rare population variant.

Array Comparative Genomic Hybridization (CGH array), the first-tier diagnosis test for individuals with intellectual disability (ID), allows to describe numerous new microdeletion and microduplication syndromes. However, it is sometimes difficult to determine whether new Copy Number Variations (CNVs) are pathogenic or are benign variants because they are not well listed in the databases, their frequency in the general population is unknown and, most of the time, associated clinical data are missing.
Xq25 microduplication was first described by Bonnet et al. (2009) and Philippe et al. (2012) who reported a familial case and two sporadic cases respectively. These authors pointed out that the principal gene involved in this duplication was GRIA3. More recently, two publications by di Benedetto et al. (2014) and Yingjun et al. (2014) showed that the critical region involved the XIAP and STAG2 loci.
We report 11 individuals with Xq25 duplication diagnosed in the ACPA (Analyse Chromosomique sur Puce à ADN) network. This cohort consisted of 9 males and 2 females. The 11 duplications ranged from 180 to 965 kb. All these small duplications involved STAG2 and/or XIAP but only one duplication involved GRIA3. There was no minimum duplicated critical region shared by all these duplications. Ten individuals had mild to severe mental impairment but one individual was normally intelligent. In addition, the 11 individuals did not share any recognizable dysmorphic features. In conclusion, the findings in our case series do not provide evidence for the pathogenicity of the Xq25 microduplication.

PS09.001
Phenotypic expression of 15q11.2 microdeletion syndrome

K. Kosma[1], *G. Papageorgiou*[2], *B. Zouvelou*[1], *A. Xadaira*[3], *L. Maragoudaki*[1], *E. Kanavakis*[1], **S. Kitsiou-Tzeli**[1], *M. Tzetis*[1];
[1]*Department of Medical Genetics, Athens, Greece,* [2]*Department of Endocrinology,Hellenic Police Medical Centre, Athens, Greece,* [3]*1st Department of Pediatrics, Athens, Greece.*

The 15q11.2 BP1-BP2 microdeletion contains TUBGCP5, CYFIP1, NIPA2 and NIPA1 genes implicated in neurodevelopment and usually presents with autism spectrum disorder, attention deficit hyperactivity disorder, developmental delay, hypotonia, ataxia, dyspraxia, seizures, psychiatric imbalances and mild dysmorphic features while athrogryposis is described in one case so far. Arthrogryposis includes various different conditions leading to reduced movement and joint contractures. We present the clinical and molecular findings of 2 affected male siblings (4 and 1 years old respectively) with 15q11.2 microdeletion syndrome who were initially referred to the Department of Medical Genetics because of arthrogryposis and mild psychomotor delay. They were both born at full-term gestation to healthy unrelated parents. The oldest sibling presented arthrogryposis of the hands at the age of 2,5 years old and later extended to the knee and elbows, while the younger sibling developed arthrogryposis at the age of 10 days. Their neurologic examination didn't disclose any abnormality and their muscular strength and tone appeared normal. High resolution 4X180K Agilent arrays (> 236.000 probes, average resolution of 8.9 Kb) revealed that they both carried 15q11.2 microdeletion (of approximately 400Kb), containing the TUBGCP5, CYFIP1, NIPA2 and NIPA1 genes. This is the second report of arthrogryposis presenting with 15q11.2 microdeletion syndrome, thus extending the previously described phenotypic spectrum of developmental delay- autism.

PM09.002
Molecular characterization of a de novo chromosomal rearrangement and in utero interference define ENO1 as a candidate gene for 1p36 polymicrogyria.

B. El Waly[1,2], *C. Mignon-Ravix*[1,2], *P. Cacciagli*[1,2,3], *E. Buhler*[4], *B. Ben Zeev*[5], *L. Villard*[1,2];

While chromosome 1p36 deletion syndrome is one of the most common terminal subtelomeric microdeletion syndrome, 1p36 microduplications are rare events. We identified the smallest case of de novo 1p36 duplication reported to date using high resolution arrayCGH. The patient has intellectual disability, microcephaly, epilepsy and perisylvian polymicrogyria (PMG). PMG has frequently been observed in patients with 1p36 deletion syndrome. The duplicated segment in our patient is intrachromosomal and contains two genes : ENO1 and RERE, both disrupted by the rearrangement. Expression analysis of these two genes revealed a reduced expression in the patient cells, mimicking haploinsufficiency. We performed in situ hybridization during mouse development to study the developmental expression profile of these two genes. We also studied the consequences of their inactivation in vivo using in utero electroporation of shRNAs. These experiments allowed us to define the enolase 1 (ENO1) gene as the most likely candidate to explain the brain malformation phenotype of the studied patient and make it a good candidate for the malformations of the cerebral cortex observed in patients with 1p36 monosomy.

PS09.003
Genetic characterization of blood spot-derived DNA from 209 individuals known to carry 22q11Del reveals a new nested deletion

T. Sparsø[1], *S. Weinsheimer*[1], *W. Mazin*[1], *M. Bertalan*[1], *J. Grauholm*[2], *M. V. Hollegaard*[2], *D. M. Hougaard*[3], *D. M. Hougaard*[3], *C. B. Pedersen*[4], *P. B. Mortensen*[4], *L. Olsen*[1], *T. Werge*[1];
[1]*Biological Psychiatry, Mental Health Centre, Sct Hans, Roskilde, Denmark,* [2]*Danish Centre for Neonatal Screening, Department for congenital Disorder, Statens Serum Institut, Copenhagen, Denmark,* [3]*Danish Centre for Neonatal Screening, Department for congenital Disorder, Statens Serum Institut, Roskilde, Denmark,* [4]*National Centre for register-based Research, Aarhus, Denmark.*

Dried blood spot (DBS) samples from newborn babies are collected world-

wide to screen for diseases. In Denmark, blood spots have been stored since 1981 and combined with the well-characterized clinical information from the Danish registers, DBS is a valuable research opportunity for genetic population-based studies. The aim of this study is to evaluate the quality of copy number variants(CNV) in DNA derived from blood spots as well as to determine phenotypic risk with the known 22q11Del. DNA from 209 individuals identified from the Danish cytogenetic registry as carriers of a 22q11Del was extracted from DBS. Since blood spots contain limited amount of DNA, the DNA extraction step was carried out in parallel with and without the whole-genome amplification (WGA) step. The samples were genotyped with the Illumina Psych Array and PennCNV was applied for CNV prediction. Compared to unamplified genomic DNA, WGA DNA severely increases the CNV false positive rate. The true positive rate was not affected for the different versions of 22q11Del. Among the 209 individuals, 170 carried the common 3MB deletion, 15 the short 1.5MB deletion, 5 the atypical nested ~1MB deletion, 2 the atypical distal deletion and 4 carried a novel atypical deletion not previously described. The new deletion spans 6 genes and resides in the beginning of the common 22q11Del. This novel 22q11Del showed a similar psychiatric and somatic phenotype as the common deletion. The discovery of a novel 22q11Del that does not intersect with the well-studied candidate genes (TBX and COMT) underline the complexity of 22q11Del and the association to somatic and psychiatric diagnosis.

PM09.004

47, XXY (Klinefelter syndrome): Positive Effects of Early Hormonal Treatment (EHT) in Infancy and Hormonal Booster Treatment (HBT) between 5 and 8 years on Neurodevelopmental and Neurobehavioral Outcome.

C. A. Samango-Sprouse[1,2,3], *P. A. Lawson*[3], *T. Sadeghin*[2], *F. L. Mitchell*[2], *A. Gropman*[1,4];
[1]*George Washington University of the Health Sciences, Washington, DC, United States,* [2]*Neurodevelopmental Diagnostic Center for Children, Davidsonville, MD, United States,* [3]*The Focus Foundation, Davidsonville, MD, United States,* [4]*Department of Neurology, Children's National Medical Center, Washington, DC, United States.*

Background and Aims: 47, XXY occurs one in 500 live births and may result in complex neurodevelopmental and cognitive dysfunction. Three recent publications have demonstrated positive effects of Early Hormonal Treatment (EHT) during infancy.
Methods: 42 males prenatally diagnosed with XXY participated in comprehensive neurdevelopmental assesments. This retrospective study had three treatment groups: EHT with HBT, HBT-Only, and untreated. Data was analyzed one year before and one year after treatment. For the untreated group we used data points within 12 months of the treatment groups.
Results: The EHT+HBT group showed significantly better perfomance than the HBT-Only group on Fine Motor Control(p=.024) and PSI(p=.004). The EHT+HBT group also showed better performance than the untreated group on motor tests; Fine Motor(p=.017), Running Speed(p=.031), Strength(p=.032), the Motor Composite (p=.023), as well as on the WISC-VCI(p=.019), PRI(p=.021), and FSIQ(p=.004). The HBT-Only group performed significantly better than the untreated group on the VCI(p=.020) and PIQ(p=.010). There was a significant drop in PIQ in the untreated group over time (p=.033), while the treated groups did not decline.
Conclusions: Multiple positive effects of Testosterone replacement were observed in boys with 47, XXY, supporting the need for early identification and treatment of these boys. The significant results were observed in the EHT+HBT group. The untreated group showed a decline in PIQ over time. This suggests that, without treatment, some cognitive functioning may decline in young boys with 47,XXY. Androgen replacement prior to puberty may be important not only to improving cognitive function, but to preserving existing function in prepubertal males with XXY.

PS09.005

Severe psychiatric phenotype in a child with 47, XYY and multiple rearrangements detected in array CGH

M. Tzetis[1], *K. Kosma*[1], *A. Syrmou*[1], *A. Xaidara*[2], *L. Maragoudaki*[1], *T. Korpa*[3], *G. Kolaitis*[3], *E. Kanavakis*[1], *S. Kitsiou-Tzeli*[1];
[1]*Dept of Medical Genetics, Athens, Greece,* [2]*1st Department of Pediatrics, St. Sophia's Children's Hospital, Athens, Greece,* [3]*Psychiatric Department, "Aghia Sophia Children's Hospital", Athens, Greece.*

Co-occurrence of 47,XYY syndrome and other molecular rearrangements in the same individual is extremely rare. We report a boy referred for genetic evaluation at the age of 9 years old when he was admitted to the psychiatric unit of the Children's Hospital due to extended aggressive behaviour, which attributed to a severe psychiatric phenotype. He had no peculiar phenotypic findings, except for a unilateral iris coloboma. The proband's family and medical history were not indicative of any abnormality.

Cytogenetic analysis revealed a 47,XXY karyotype*, while the high resolution array based comparative genomic hybridization (aCGH) identified important rearrangements shown below:

Chromosomal region/ size	Position of 1st aberrant probe	Position of last aberrant probe	*Important Genes in aberrant region*	comments
DUP 7q11.23; 882.9Kb	74,144,422	75,027,348	*GTF2I, NCF1, GTF2IRD2, STAG3L2, PMS2P5, GATSL1, WBSCR16, GTF2IRD2B, NCF1C, LOC100093631, GTF2IP1, GATSL2, SPDYE8P, PMS2L2, STAG3L1, TRIM74, TRIM73*	Microduplication in the Williams syndrome region
DEL 11p15.5; 1.6Mb	383,89	2,014,937	*DRD4*	ADHD**
DEL 20q13.33; 907.3Kb	61,632,196	62,539,530	*HAR1B, HAR1A, CHRNA4, KCNQ2*	Psychotic behavior, ASD**, epilepsy

*Aberrations detected with aCGH due to 47XXY karyotype: DUP Xp22.33, 2.7Mb; DUP Xq21.31 - q21.32, 3.9Mb; DUP Yp11.32 - p11.2, 9.96Mb; DUP Yq11.21 - q12, 15.1Mb
ADHD ** Autism Deficit Hyperactivity Disorder; ASD: Autism Spectrum Disorder
This case underlines the utility of aCGH in addition to the routine cytogenetic analysis in cases with severe psychiatric phenotype for accurate diagnosis and complete genetic counselling.

PM09.006

Genetic overlap between Intellectual Disability and Attention-Deficit/ Hyperactivity Disorder

M. Klein[1], *A. van Rens*[1], *M. Hoogman*[1], *T. Guadalupe*[2,3], *Psychiatric Genomics Consortium ADHD Working Group, H. Brunner*[4], *A. Arias-Vasquez*[5], *B. Franke*[6];
[1]*Department of Human Genetics, Radboud university medical center, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands,* [2]*Max Planck Institute for Psycholinguistics, Language and Genetics Department, Nijmegen, Netherlands,* [3]*International Max Planck Research School for Language Sciences, Nijmegen, Netherlands,* [4]*Department of Human Genetics, Radboud University Medical Center, Radboud Institute of Molecular Life Sciences, Nijmegen, Netherlands,* [5]*Departments of Human Genetics, Psychiatry and Cognitive Neuroscience, Radboud university medical center, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands,* [6]*Departments of Human Genetics and Psychiatry, Radboud university medical center, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands.*

Attention-Deficit/Hyperactivity Disorder (ADHD) is a common neuropsychiatric disorder with a complex genetic background. Intellectual Disability (ID) and ADHD are often co-morbid, suggesting genetic overlap. We investigated whether genes, affected by rare genetic variations in patients with ID, also contribute to ADHD risk. Common single nucleotide polymorphisms (SNPs; MAF>= 1%) in 384 autosomal ID-related genes selected from the 'Intellectual Disability Gene Panel' (downloaded from https://www.radboudumc.nl/Informatievoorverwijzers/Genoomdiagnostiek/Documents/ngs-intellectual_disability_panel_181213.pdf) were tested for association with ADHD risk, on gene-wide and gene-set level, using ADHD meta-analytic data from of the Psychiatric Genomic Consortium (PGC; N=5,621 cases and 13,589 controls) using KGG v3.5. The ID gene-set was significantly associated with ADHD in the PGC ADHD meta-analysis ($P_{gene\text{-}set}$=2.19E-3). Further analysis showed that the findings were due to the inattention symptom domain ($P_{gene\text{-}set}$=5.00E-3) rather than hyperactivity/impulsivity in ADHD ($P_{gene\text{-}set}$=0.203). The *MEF2C* gene showed gene-wide association (corrected for multiple testing) with ADHD risk (P_{MEFC2}=3.92E-5). Two SNPs within the *MEF2C* locus were assessed on neuroanatomy using voxel-based morphometry (VBM) in the Brain Imaging Genetics cohort (BIG; N>1,300) and one SNP showed bilateral association with gray matter volume in the lateral occipital cortex. This study demonstrates the genetic overlap between ID and ADHD, showing that common SNPs in genes, known to be affected by rare genetic variations in ID patients, contribute to ADHD risk. We also identified *MEF2C* as a novel candidate gene for ADHD.
Grants were received from Netherlands Organization for Scientific Research (NWO Brain & Cognition Excellence Program (433-09-229)), Vici grant to B.F. (016-130-669), Netherlands Brain Foundation (grant 15F07[2]27), BBMRI-NL (CP2010-33), and European Community's Seventh Framework Programme (FP7/2007-2013; 602805).

Association study of DISC1 and COMT polymorphisms in Bulgarian patients with Alzheimer disease.

K. Mihova[1], *S. Mehrabian*[2], *R. Pavlova*[2], *A. Jordanova*[1,3], *V. Mitev*[1], *L. Traykov*[2], *R. Kaneva*[1];
[1]*Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Medical University, Sofia, Sofia, Bulgaria,* [2]*Clinic of Neurology, University Hospital „Alexandrovska", Department of Neurology, Medical University, Sofia, Sofia, Bulgaria,* [3]*VIB Department of Molecular Genetics, University of Antwerp, Antwerp, Belgium.*

Background: Alzheimer disease (AD) is the most common neurodegenerative disease characterized by dementia, cognitive impairment, memory and personality disorders resulting in progressive degeneration of the brain neurons. DISC1 (disrupted-in-schizophrenia-1) and COMT (catechol-O-methyltransferase) are associated with the pathogenesis of neurocognitive impairment. The Val158Met (rs4680, G>A) polymorphism in COMT and Ser736Cys (rs821616, T>A) in DISC1 genes have shown association with various neuropsychiatric and neurodegenerative diseases. Several studies implicated them in the cognitive impairment and different neuropsychiatric features.
Materials and methods: In this study 218 patients with AD and 125 healthy controls, matched to the patients by age, gender and ethnicity (HC) were included. Genotypes were determined using TaqMan assay (Applied Biosystems). Statistical analysis was done using PLINK .
Results and discussion: The Val158Met and Ser736Cys polymorphisms did not show significant difference in allele frequency distribution between the AD and HC group. The common Val158Met alleles of COMT were with almost equal allele frequencies (p=0.9, OR= 1.02). Ser736 variant of DISC1 was more frequent among AD patients, but did not reach significant association (p=0.08, OR=1.37). When a subgroup analysis depending on the age of onset was done, the Ser736 variant of DISC1 showed tendency of association (p=0.055, OR=1.51)
Conclusions: Our findings did not show overall association with the studied COMT and DISC1 SNPs in Bulgarian patients with AD, probably due to the limited sample size. Further studies in enlarged sample and with cognitive measures are needed to elucidate their role.

Analysis of allelic variants in endothelial function and cell death related genes in Spanish patients with vascular dementia and Alzheimer's disease

D. Martín-Sánchez[1,2], *R. Manso Calderón*[3,2], *M. Fernández Prieto*[1,2], *R. González Sarmiento*[1,2];
[1]*Molecular Medicine Unit, Department of Medicine. University of Salamanca., Salamanca, Spain,* [2]*Institute of Biomedical Research of Salamanca (IBSAL)., Salamanca, Spain,* [3]*Department of Neurology, University Hospital of Salamanca, Salamanca, Spain.*

INTRODUCTION: The two most common causes of dementia are Alzheimer's disease (AD) and vascular dementia (VD). The onset of dementia may be determined by genetic and environmental factors. Single nucleotide polymorphisms (SNPs) of genes encoding VEGF-A and its receptor, VEGFR-2, eNOS or TP53 might modulate the risk of these global health problems.
OBJECTIVES: We have analyzed the relationship of the following SNPs: -460C>T and -2578A>C of VEGFA, -604A>G of VEGFR2, +894G>T of eNOS and Arg72Pro of TP53 as well as sociodemographic and clinical risk factors VD develop (and its subtypes) and EA.
We have analyzed 150 patients with VD (corticalVD=74; subcortical VD=76), 147 patients with AD and 150 controls >70 years that there was no evidence of clinical or psychometric cognitive impairment. Genotyping was accomplished by DNA digestion with restriction nucleases (PCR-RFLP) and PCR with Taqman® probes (qRT-PCR).
RESULTS: Our results showed that VEGFA alleles 460C-2578A (OR:0.625, p=0.042) and eNOS allele +894G (OR:0.606, p=0.037) were associated with lower risk of EA in patients older than 80 years. The VEGFR2 allele -604A (OR:0.555, P=0.004) was associated with a lower risk of subcortical VD. The Pro72 allele of TP53 gene (OR:0.500, p=0.001) was associated with a lower risk of AD while the Arg72 allele (OR:1.768, p=0.026) was associated with an increased risk of cortical VD.
CONCLUSIONS: The results of our study suggest that polymorphisms associated with endothelial function and cell death may modulate the susceptibility to the risk of different subtypes of dementia.

Angelman syndrome due to a maternally inherited intragenic UBE3A deletion in a family of Chinese origin

A. Ververi[1], *L. Islam*[1,2], *B. Bewes*[1], *L. Bourdon*[1], *C. Sullivan*[1], *N. Canham*[1];
[1]*NW Thames Regional Genetics Service, Harrow, London, United Kingdom,* [2]*West Midlands Regional Genetics Service, Birmingham, United Kingdom.*

Angelman syndrome is characterised by global developmental delay, lack of speech, seizures, a characteristic behavioral profile with a happy demeanor, microcephaly, ataxia etc. More than 2/3 of cases are due to a 5 Mb interstitial deletion of the imprinted region 15q11.2-q13, which is usually de novo. The rest are associated with point mutations in UBE3A gene, imprinting defects and paternal uniparental disomy. Small intragenic UBE3A deletions have been rarely described. They are usually maternally inherited, increasing the recurrence risk to 50%, and may be missed by conventional testing (methylation studies and UBE3A gene sequencing). Herein a boy with Angelman syndrome due to an 11.7 kb intragenic deletion is described. The deletion was identified by array CGH and was subsequently detected in his affected first cousin and unaffected maternal grandfather, mother and aunt, confirming the silencing of the paternal allele. The patient had global developmental delay, speech impairment, a happy demeanor, microcephaly and an abnormal EEG, but no seizures by the age of 4 years. The family was given a recurrence risk of 50% and prenatal testing was offered. Delineation of the underlying genetic mechanism is of utmost importance for reasons of genetic counselling, as well as appropriate management and prognosis. Alternative techniques, such as array CGH and MLPA, are necessary when conventional testing for AS has failed to identify the underlying genetic mechanism.

PM09.010

Genetic diagnosis of ataxia using NGS

A. Romera[1], *D. Valero*[1], *A. Matilla*[2], *C. Collado*[1], *R. Rodríguez-De Pablos*[1], *V. Fernández-Pedrosa*[1], *V. Felipe*[1], *D. Cantalapiedra*[1], *M. Roca*[1], *G. Hernández*[1], *D. Diego-Álvarez*[1], *C. Baudes*[1], *J. Triviño*[1], *R. Miñambres*[1], *S. Santillán*[1];
[1]*Sistemas Genómicos, Paterna, Spain,* [2]*Hospital GermansTrias i Pujol, Barcelona, Spain.*

Hereditary Cerebellar Ataxia (HCA) is a slowly progressive disorder characterized by the presence of abnormal and uncoordinated movements that mainly affect walking, speech and eye movement. Its diagnosis is not straightforward, mainly due to the presence of nonspecific overlapping clinical symptoms and of genetic heterogeneity. A global approach using massive technologies such as NGS could be of great help to improve the diagnosis.
We present a dataset of 28 ataxic patients studied in our laboratory using a NGS targeted re-sequencing panel that included genes associated with Ataxia [between 1-30 genes]. Coding exons and splice-site regions of the genes associated with each pathology were analyzed. Enrichment and sequencing were carried out using SureSelect Enrichment System (Agilent) and SOLiD 5500/MiSeq(Life Technologies/Illumina). Mean depth was established at 200x.
In 6 out of 28 samples (21%), a genetic cause that justifies the clinical diagnosis was found. In 12 out of 28 patients the results were inconclusive. In these samples, 41 variants (confirmed by Sanger sequencing) were identified as variants of uncertain significance (VUS). According to their effect, missense (21), synonymous (13), in frame deletion (2), splice-site (5) mutations were found. In 10 out of 28 samples no variants (pathogenic/UV) were identified.
Based in our experience, we propose that:
• NGS is an effective approach for the diagnosis of Ataxias.
• Cosegregation studies and functional analysis are needed to better understand the effect of VUS and could aid in the diagnosis of a significant number of patients.

PS09.011

Diagnosing ataxia using a Next-Generation-Sequencing gene panel

J. K. Bickmann[1], *T. C. Benkert*[1], *M. Synofzik*[2], *S. Maul*[3], *M. Sturm*[1], *F. Lenz*[1], *M. Schulze*[1], *F. Harmuth*[1], *I. Krägeloh-Mann*[4], *T. Klockgether*[5], *T. Klopstock*[6], *D. Timmann-Braun*[7], *O. H. Riess*[1], *L. Schöls*[2], *P. Bauer*[1];
[1]*Institute of Medical Genetics and Applied Genomics, Tübingen, Germany,* [2]*University Department of Neurology, Tübingen, Germany,* [3]*Department of Neurology, Charité, Berlin, Germany,* [4]*University Children's Hospital, Tübingen, Germany,* [5]*University Department of Neurology, Bonn, Germany,* [6]*University Department of Neurology, Munich, Germany,* [7]*University Department of Neurology, Essen, Germany.*

Introduction: The exact use of escalated genetic testing in a heterogeneous group of ataxia patients is unknown. Especially patients with an onset beyond the age of 40 may be underdiagnosed. This is particularly relevant in the light of treatable metabolic defects but also genetic counselling and clinical work-up require a correct diagnosis.Materials and Methods: 139 patients were sequenced using a Haloplex (Agilent) enrichment of 61 ataxia genes, 40 metabolic genes associated with ataxia and 17 genes causing mitochondrial disorders on a MiSeq instrument (Illumina, 150 bp paired-end sequen-

cing).Results: 9% were immediately diagnosed (3x SCAR8, 2x EA2, 2xSCA14, SCAR10, SPG7, NPC, SCA28, GM1 gangliosidosis, APBD) (6 with onset before, 7 after 40 years, 2 of which had a negative family history). Another 12% of cases were probably solved unless the segregation (not completed) yields controversial results (13 with onset before, 3 after 40 years; negative family history in 1). In 39% we found either heterozygous mutations or likely pathogenic variants in recessive ataxia-related genes or candidate variants in dominant genes facilitating a targeted diagnostic work-up for the referring clinicians (25 with onset before, 29 after 40 years, 14 of which had a negative family history). Conclusions: NGS is powerful in diagnosing hereditary ataxias but also provides a large number of variants requiring careful clinical evaluation. As our results indicate it is possible to diagnose even patients with a late onset or negative family history for mutations in ataxia-related genes.<br

The National Paediatric Ataxia-Telangiectasia (A-T) Clinic in England

S. Pasalodos[1], *J. Bhatt*[1], *E. McDermott*[1], *G. Davies*[2], *A. M. Taylor*[3], *M. Suri*[1];
[1]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, [2]Great Ormond Street Hospital for Children, London, United Kingdom, [3]University of Birmingham, Birmingham, United Kingdom.

A-T is an early childhood progressive multisystem neurodegenerative disorder characterised by cerebellar ataxia, immunodeficiency, lung disease and a high risk of malignancy. Median survival is estimated at 25 years, but severity is variable and management is improving the quality of life and survival. A-T is recessively inherited and caused by mutations in the ATM gene on chromosome 11q.26. A-T is rare; in the UK and Ireland there are approximately 170 cases.
England has a nationally-commissioned Paediatric A-T Clinic based in Nottingham and sees children from the UK and overseas. There are two fundamental aims, to achieve an accurate diagnosis and to manage the patient holistically, addressing every aspect of the condition. The Clinical Team comprises over 20 specialists and collaborates with the A-T Society support group. Clinic is held 6 times a year and sees 6 children per clinic over 2 days. Generally, patients are reviewed every 2 years with ongoing contact with their local Paediatric Teams. We have recently published a guidance document on diagnosis and clinical care for children with A-T. Involvement in research and family education are integral parts of this Service.
The poster will describe the patient pathway, specific medical interventions undertaken in the clinic and/or arranged through local services as well as clinical outcomes and implications for management. Examples are the underlying ATM mutations, the nutritional status of patients, the prevalence of skin disease and scoliosis and the results of respiratory, immunological and other investigations undertaken.
We believe that this Clinic provides a paradigm for the optimal management of rare progressive multi-systemic genetic disorders.

PS09.013

Exome-wide association analysis of attention hyperactivity disorder in a genetically isolated population

D. Vojinovic[1], *I. Pappa*[2,3], *H. W. Tiemeier*[3,4], *C. M. van Dujin*[1,5,6], *N. Amin*[1];
[1]Department of Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands, [2]School of Pedagogical and Educational Sciences, Erasmus University, Rotterdam, Netherlands, [3]Generation R Study Group, Erasmus Medical Center, Rotterdam, Netherlands, [4]Department of Child and Adolescent Psychiatry/Psychology, Erasmus University Medical Center-Sophia Children□s Hospital, Rotterdam, Netherlands, [5]Netherlands Consortium on Health Aging and National Genomics Initiative, Leiden, Netherlands, [6]Center of Medical Systems Biology, Leiden, Netherlands.

Attention deficit hyperactivity disorder (ADHD) is highly heritable psychiatric disorder with a heritability estimates ranging from 60 to 90 %. To identify rare variants associated to ADHD, we performed exome-sequencing based association study in a genetically isolated population in the Netherlands. The study included 554 individuals whose exomes were sequenced and who were assessed for inattention, hyperactivity and ADHD index. All single nucleotide (SNVs) variants were tested for association applying additive linear modeling adjusting for age, sex and relatedness among the samples. Moreover Sequence Kernel Association Test (SKAT) was used to test the joint effect of multiple variants within the gene/region. Significant association of two rare SNVs (MAF = 0.27 %, β = 12.70, p-value = 9.36E-08) mapped to intronic part of multiple C2 domains, transmembrane 1 (MCTP1) gene on chromosome 5 was observed with inattention. Gene-based analysis revealed suggestive association of CEACAM19 (p-value = 1.91E-05) and SCYL2 (p-value = 1.35E-05) to inattention and hyperactivity, respectively. To conclude, present study identifies exome-wide association between ASD and two SNVs within MCTP1 gene, which play important role in Ca2+ signalling at membrane. However, further studies are needed to confirm these findings.

PM09.014

CNVs in the group of the patients with autistic spectrum disorders detected by MLPA and SNParray.

P. Capkova[1], *V. Curtisova*[1], *M. Godava*[1], *J. Srovnal*[2], *V. Becvarova*[3], *K. Adamova*[1], *H. Synkova*[1];
[1]Department of Medical Genetics, University Hospital of Palacky University, Olomouc, Czech Republic, [2]Institute of Molecular and Translational Medicine of the Faculty of Medicine of Palacky University, Olomouc, Czech Republic, [3]Gennet, Centre for Fetal Medicine and Reproductive Genetics, Prague, Czech Republic.

Autistic spectrum disorders (ASD) are characterized by simultaneous deficits in 3 domains of behavior: reciprocal social interaction, communication and stereotyped and restricted behaviors. Submicroscopic CNVs can have a causal or susceptibility-related role in heritability ASD.
Objective: We performed MLPA and SNP array study focused on detection of CNVs in the group of patients with ASD.
Method: Samples of DNA were tested by MLPA (SALSA MLPA P343 Autism 1, Microdeletions - P297, P245, Subtelomeres -P070, P036 and P106 MRX) and SNP array.
Results: In the group of the children with ASD (42) three likely pathogenic CNVs were discovered. Microduplication 16p11.2 (576 kb) inherited from father, microduplication 1q21.1q21.2 (1,3 Mb) de novo, unbalanced translocation with microdeletion 20q13.33 (1,58 Mb) and microduplication 22q13.33 (app. 190 kb - covering SHANK3) de novo. In another four cases, the inherited variants of unknown significance involving genes: NRXN1, SNRPN, MAPK3, and CD160 were detected.
The microdeletion 16p11.2 (611 kb) was incidentally found in the female patient with Mayer-Rokitansky -Kuster-Hauser syndrome (MRKHS) without autistic features. The loss of 1.3 Mb in 15q13.2q13.3 was also discovered by MLPA 343 Autism1 in the patient suffered from intellectual disability but without ASD.
Conclusion: SALSA MLPA probemix P343 Autism1 has proved to be efficient for detection CNVs in the group of children with ASD. However, the simultaneous tests with another probemixes (P297, Human Telomere 3 and 5 and so on) or simultaneous test with SNP or CGH array is recommended especially when intellectual insufficiency in the patient is present.

PS09.015

Whole exome sequencing identified a novel missense variant (c.425C>G or p.P142R) of the EN2 gene in two unrelated Thai patients with autism spectrum disorder

P. Limprasert[1], *A. Hnoonual*[1], *T. Sripo*[1], *J. Worachotekamjorn*[1], *R. Roongpraiwan*[2], *T. Sombuntham*[2], *T. Hansakunachai*[3];
[1]Faculty of Medicine, Prince of Songkla University, Songkhla, Thailand, [2]Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, [3]Faculty of Medicine, Thammasat University, Pathumthani, Thailand.

Autism spectrum disorder (ASD) is a group of neurodevelopmental disorders with largely unknown genetic defects. Recently, whole exome sequencing (WES) has been found to be a powerful technique for identifying new variants which may help to depict the complex genetics of ASD. Nine unrelated Thai patients with ASD and no pathogenic CNV were selected for WES study using the SureSelect Human All Exon V4 kit on the Illumina Hiseq2000. To identify potential pathogenic variants in candidate genes of ASD, the TruSight Autism gene list (101 genes) and SFARI AutDB database (667 genes) were used for reference databases. Interestingly, a novel heterozygous missense variant (c.425C>G or p.P142R) in exon 1 of the Engrailed 2 (EN2) gene, a homeobox transcription factor involved in brain development, was identified in two patients. In the first family, the G allele was also found in the patient's older brother with intellectual disability and his normal mother. In the second family, the G allele was transmitted from the patient's normal father, but it was not found in a male cousin with ASD. In addition, the variant was absent in the SNP database, the Exome Variant Server (EVS), the 1000 Genome Project, 100 Thai patients with ASD and 240 normal Thai controls suggesting that the new variant is very rare and has never been reported. Although this variant is predicted by the PolyPhen-2 to be possibly damaging to the EN2 protein function, EN2 protein function studies of the p.P142R are required to determine molecular basis of ASD pathogenesis.

PM09.016

The autism-associated long noncoding RNA MSNP1AS regulates a network of genes involved in neuronal process stability.

J. DeWitt, *N. Grepo, D. B. Campbell;*
University of Southern California, Los Angeles, CA, United States.

From genome-wide association studies (GWAS), a novel gene was discovered that has a highly significant association with autism spectrum disorder (ASD). The gene is a long noncoding RNA (lncRNA) designated *MSNP1AS* (moesin pseudogene 1, antisense). Expression of *MSNP1AS* was increased in the cerebral cortex of individuals with ASD and individuals with the ASD-associated genetic marker. Overexpression of *MSNP1AS* in human neuronal cells caused decreased expression of moesin (*MSN*) mRNA and moesin protein, which is involved in neuronal process stability and immune response. These data indicate one aspect of the potential contribution of increased *MSNP1AS* expression in ASD. However, there are likely to be additional transcriptomic impacts of this lncRNA. To determine the effects of altered *MSNP1AS* expression on the neuronal transcriptome, we transfected human neuronal progenitor cells with constructs that overexpressed *MSNP1AS* or transcriptionally silenced *MSNP1AS*. RNA-Seq analysis indicated altered expression of multiple genes that contribute to altered neuronal process stability and immune response, including *MSN*. However, our data indicate several genes that are impacted by *MSNP1AS* dysregulation more significantly than *MSN*, suggesting a network of genes that contribute to ASD risk. Ongoing experiments seek to define the role of the *MSNP1AS* gene network in neuronal process stability.

Introduction: ASD is a genetically complex disorder, highly heterogeneous and with unclear etiology. In this study we addressed the possible contribution of epigenetic factors to ASD etiology, focusing on deregulated MicroRNAs (miRNAs) expression. miRNAs are small noncoding RNA molecules that negatively regulate gene expression. miRNAs are thought to be released from pathological tissues to plasma in illness situations, and the strong correlation between circulating and tissue miRNAs indicates that plasma miRNAs may be useful disease biomarkers.
Methods: miRNA plasma profiles were obtained for patients with ASD and other neurodevelopmental disabilities (NDD), essentially disruptive behavior, language delay and psychomotor delay. Patients were all male, with a mean developmental coefficient of 92±18, and no obvious dysmorphisms. Exiqon human miRNome PCR panels (testing 752 miRNAs) were used for miRNA profiling.
Results: We identified 50 miRNAs differentially expressed in ASD vs NDD. Notably, of the 10 miRNAs with higher fold-change (increased 2.5-3.3X), 8 miRNAs had a target gene in common, MMP16. This gene is expressed at high levels in the brain, and a balanced de novo translocation in a ASD patient involving MMP16 has previously been described.
Conclusions: This is the first study of circulating miRNA profiles comparing patients with ASD and other NDDs. The preliminary results suggest that miRNA profilling may eventually improve differential diagnosis. The results also implicate novel pathological pathways in ASD, namely involving metaloproteinases. These are crucial molecules for the integrity of the extracellular matrix and consequently for cell migration and regeneration, processes thought to be involved in ASD.

PM09.018

Autistic variome: gene hunting through SNP-microarray genome analysis and bioinformatics

S. G. Vorsanova[1,2,3], *I. Y. Iourov*[1,2,4], *S. A. Korostelev*[5], *M. A. Zelenova*[1,2,3], *K. S. Vasin*[1,2,3], *A. P. Silvanovich*[1], *Y. B. Yurov*[1,2,3];
[1]*Mental Health Research Center, RAMS, Moscow, Russian Federation,* [2]*Russian National Research Medical University named after N.I. Pirogov, Separated Structural Unit "Clinical Research Institute of Pediatrics", Ministry of Health of Russia, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation,* [5]*The State Educational Institution of Professional Training under the Federal Agency of Health Care and Social Development, Moscow, Russian Federation.*

Despite of significant advances in bioinformatics and genomics, analyses of generalized data on copy number variation (CNV) or variome aimed at gene hunting still represent a major challenge. Here, we have used an approach towards identifying genes implicated in autism pathogenesis through evaluation of autistic variome addressed by microarray genome analysis with an original bioinformatic technology. To identify the spectrum of CNV, a high-resolution SNP-array genome scan (Affymetrix platform) was used. Bioinformatics analysis has represented a complex evaluation of CNV by simulations of transcriptional, interactomic and metabolomic activity of candidate genes using available genome, transcriptome and proteome databases (Iourov et al., 2014). Pathogenic CNV were found in 38 children with autism from the Russian cohort (n=212). Six chromosomal rearrangements were detected: deletions at 6p11.2 (PRISM2), 9q21.13 (GDA, ZFAND5, TMC1), 8p23.3p23.1 (46 genes), Xp22.12 (RPS6KA3, CNKSR2) and Yq11.223q11.23 duplications. Furthermore, bioinformatic analysis of CNV and single-gene deletions/duplications has defined following autism candidate genes: CBARA1, KRT83, RBFOX1, NDP, ATP6V1E1, CNKSR2, ATP1A2, FBXO21, ACSL3, ATP2B3, IMPA1, CNTNAP4. The latter allowed speculations on potential autistic molecular pathways involving genome instability, programmed cell death and axon guidance. Successful delineation of a panel of candidate genes suggests generalized variome analyses as a valuable source for gene hunting. These data supports the idea that additional bioinformatic technologies are able to give further insights into disease pathogenesis. Thus, a disease variome determined by SNP-array genome scan and addressed an original bioinformatic technology appears to be an issue for genomic studies. Supported by Russian Scientific Fund (Grant #14-35-00060).

Pedagogy, Psychology and Philosophy, University of Cagliari, Cagliari, Italy,* [4]*Center for Pervasive Developmental Disorders, Azienda Ospedaliera Brotzu, Cagliari, Italy.*

Autism Spectrum Disorder (ASD) is a severe neurodevelopmental condition with highly complex genetic predisposition. Recent discoveries have highlighted the importance of both sequence and structural rare variations in ASD susceptibility. In particular, focusing on rare copy number variants (CNVs) has already been highly productive in uncovering an increasing number of specific genes and chromosomal intervals conferring risk to ASD.
During a genome-wide CNV scan using a multi-algorithm approach on 9 multiplex ASD families from Sardinia, we identified a rare genic deletion of ~37 Kb, transmitted from the unaffected mother to both affected siblings. This deletion includes the entire *CAPG* gene and the last coding exons of *ELMOD3*. *CAPG* encodes a member of the gelsolin/villin family of actin-regulatory proteins, that might be involved in control of dendritic spine shape. ELMOD3 belongs to the engulfment and cell motility (ELMO) family, with recently proposed functional links to sound perception and actin cytoskeleton.
No deletions involving this genomic region were found in 4768 controls from published high resolution SNP-array data, while other two deletions encompassing *CAPG* and *ELMOD3* have been reported in two subjects with ASD, suggesting that *CAPG* and/or *ELMOD3* haploinsufficiency may have clinical relevance to ASD. In order to test this hypothesis together with a recessive model of inheritance, we first excluded that this deletion is a common polymorphism in Sardinia, then we performed expression and mutation analysis of both genes in the discovery pedigree, and a further clinical evaluation of all family members.

Bipolar disorder (BD) is a major psychiatric disorder affecting more than 1% of the world's population. The disease is characterized by recurrent manic and depressive episodes and shows a high heritability of about 70%. To date several genes contributing to BD susceptibility have been identified. However, the disease driving pathways and regulatory networks remain largely unknown. As the cumulative impact of common alleles with small effect may only explain around 38% of the phenotypic variance for BD (Lee et al., 2011), rare variants of high penetrance have been suggested to contribute to BD risk.

In the present study we investigated the role of rare nonsynonymous variants in two large Cuban families. The exceptional lifetime prevalence of BD in these pedigrees makes them promising candidates for identifying genetic risk variants of Mendelian-like effects. For this purpose we selected 16 affected individuals from both families and performed exome sequencing on the HiSeq platform. In addition, all family members with available DNA (n=34) were genotyped on the Illumina Psych Chip to create polygenic risk-score analyses in order to evaluate the contribution of common variants in the two pedigrees.

Exome sequencing has recently been completed. Preliminary results of the first family revealed 10 missense variants and two frameshift variants shared among all investigated individuals (n=4). Affected genes include ADCY3, a gene that has been suggested to play a role in major depressive disorder, and SEMA4C required for brain development. Further evaluation and interpretation of these results is currently underway and will be presented.

PS09.021

Delineation of the mutational spectrum in two susceptibility genes for bipolar disorder, neurocan (NCAN) and adenylate cyclase 2 (ADCY2)

S. B. Fischer[1], *S. Herms[1,2], T. W. Mühleisen[3], J. Strohmaier[4], M. Attenhofer[1], M. Bormann-Hassenbach[5], F. Streit[4], A. J. Forstner[6], A. Maaser[6], M. Albus[5], W. Maier[7], T. G. Schulze[8], M. Rietschel[4], M. M. Nöthen[2,6], S. Cichon[1,3,9], P. Hoffmann[10,2,6];*

Bipolar Disorder (BD) is a common, genetically complex neuropsychiatric disorder with a significant impact on the global burden of disease. Patients suffer from recurrent episodes of strongly elevated (mania) and depressed mood. The life-time prevalence ranges between 0.5-1.5%. Heritability for BD estimates between 60-80%.

We have recently published two large Genome Wide Association Studies (GWAS) that provide strong evidence for an involvement of genetic variants in neurocan (NCAN, Cichon et al. 2011) and adenylate cyclase 2 (ADCY2; Mühleisen et al. 2014) in BD. NCAN encodes a glycoprotein that plays a role in neuronal development. ADCY2 is a key enzyme in cAMP regulated GPCR signalling pathways.

For GWAS association signals, it is normally unclear whether they represent the functionally relevant variants or just proxies in linkage disequilibrium. Therefore, to uncover the whole mutational spectrum in NCAN and ADCY2 and to detect the putative functional variant underlying the GWAS association signal, we conducted a Next-Generation-Sequencing based re-sequencing in 960 German BD patients. We designed a custom amplicon panel using Illuminas TruSeq Custom Amplicon©-Kit and performed the sequencing on a MiSeq© System from Illumina©. Alignment and variant calling was done using the MiSeq reporter tool v2.4 and variant annotation according to HGVS was conducted in Illumina VariantStudio©. Three exons were separately sequenced using Sanger-Sequencing.

Our preliminary analysis with stringent quality criteria detected 178 unique variants, 78 of them being missense variants. We are currently focussing on the in silico functional characterization of the missense variants with the results being presented at the conference.

[1]Institute of Human Genetics, Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany, [2]Abteilung für Medizinische Genetik, Departement Biomedizin, Universitätsspital Basel, Basel, Switzerland; Institute of Human Genetics, Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany, [3]Institute of Neuroscience and Medicine, Research Center Jülich, Jülich, Germany, [4]Department of Genetic Epidemiology in Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany, [5]Institute of Human Genetics, Department of Genomics, Life and Brain Center, University of Bonn, Bonn, Germany & Division of Medical Genetics, University Hospital and Department of Biomedicine, University of Basel, Basel, Switzerland.

Bipolar disorder (BD) is a severe neuropsychiatric disorder and GWAS have robustly identified genetic variants implicated in disease susceptibility. However, the majority of loci are located in non-coding regions of the genome, thus requiring further functional annotation.

Enhancers are distal regulatory elements that control the activation of tissue- and cell-type specific gene expression. Large-scale identification of actively transcribed enhancers is performed by different techniques such as chromatin immunoprecipitation or cap analysis gene expression coupled with next-generation sequencing. The Fantom5 enhancer atlas (Andersson et al. 2014) represents a systematic resource for active enhancers in tissues including human brain. The integration of GWAS signals and these functional genomic regions provides novel opportunities to elucidate biological mechanisms underlying BD. Therefore, we investigated in this study whether brain related enhancers are enriched among top BD GWAS hits.

Results from the largest BP meta-analyses comprising a sample of 24,025 patients and controls (Mühleisen et al. 2014) provided the basis for this analysis. We mapped significant GWAS to brain enhancer regions defined by the Fantom5 study. Enrichment of associated SNPs in enhancers was assessed by permutation analysis comparing observed overlap for each enhancer to randomized enhancer regions.

An enrichment of GWAS hits was observed in neurons (p=0.015) but not in human brain enhancers suggesting a cell-type specific regulation. A detailed analysis of several brain regions is currently ongoing and will be presented. Overall, our results provide the first systematic integration of brain-related enhancers in the largest BP GWAS to date and subsequently enable the discovery of relevant biological processes suitable for further functional studies.

Bipolar disorder (BD) is a highly heritable disorder of mood with a lifetime prevalence of about 1%. BD shows substantial clinical and genetic overlap with other psychiatric disorders, particularly with schizophrenia (SCZ). However, research has not yet clarified what particular genes form the basis of this etiological overlap.

For both disorders several susceptibility genes have been identified. In the case of SCZ, a meta-analysis (36000 patients, 113000 controls) of the Psychiatric Genomics Consortium (PGC) identified 128 independent genome-wide significant SNPs.

The aim of the present study was to investigate whether these 128 SCZ-associated SNPs also contribute to BD development. We conducted association testing in our large GWAS dataset of BD (9747 patients, 14278 controls, Mühleisen et al., 2014). In this dataset we combined our data with the BD GWAS results of the PGC (Sklar et al., 2011). As different reference panels were used for the imputation of the genotype data in both studies, we reimputed the summary statistics of the PGC BD GWAS using a method by Pasaniuc and colleagues (2014) and performed a meta-analysis using METAL. Overall, 107 SCZ-associated SNPs could be mapped to our reimputed data. Our analysis revealed that 42 of the 107 SNPs showed nominally significant p values, providing further evidence that SCZ-associated loci contribute to BD development (p<2.2x10-16). Pathway analysis (INRICH, Ingenuity pathway analysis) for all 42 shared SCZ-BD SNPs revealed a total of 27 nominally significant pathways including calcium and glutamate signaling.
Our results may provide clues for new approaches to treatment and prevention of BD and SCZ.

PM09.024

C9ORF72-related FTD/ALS: a study of expansion size, gene expression and DNA methylation

A. G. L. Douglas[1,2], *M. Varela*[2], *Y. Aoki*[2], *M. J. A. Wood*[2], *K. Talbot*[3];
[1]Wessex Clinical Genetics Service, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [2]Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, United Kingdom, [3]Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom.

Introduction: A hexanucleotide GGGGCC expansion in *C9ORF72* accounts for up to 40% of familial ALS and up to 25% of familial FTD (c9FTD/ALS). The pathogenic mechanism of this disease remains unknown. One possibility is that the expansion induces *C9ORF72* loss-of-function. In support of this, methylation of *C9ORF72* promoter DNA has been reported in association with decreased gene expression. However, the relationship between expansion size, gene expression, and promoter methylation remains unclear.
Materials and Methods: Fibroblasts from c9FTD/ALS patients were cultured and analysed for hexanucleotide repeat size by Southern blotting. *C9ORF72* gene expression was determined by qRT-PCR and digital droplet PCR. The degree of promoter DNA methylation was assayed by methyl-DNA immunoprecipitation with qPCR. The expression of wild-type mouse *C9ORF72* orthologue was also assayed by qRT-PCR across ages from birth to 1 year.
Results: *C9ORF72* expansion size in fibroblasts did not correlate with either gene expression or promoter methylation. Surprisingly, there was a positive correlation between degree of methylation and levels of *C9ORF72* expression. Of the three described *C9ORF72* mRNA transcripts, one predominates that uses a first exon downstream of the expansion. In mice, brain expression of the *C9ORF72* orthologue was found to be significantly higher in the neonatal period.
Conclusions: This study demonstrates a wide variability in *C9ORF72* gene expression and promoter DNA methylation among patient cell lines carrying pathogenic hexanucleotide expansions. The high levels of expression in neonatal mice suggests a role in neurological development.
This work was funded by a Wellcome Trust Clinical DPhil Fellowship awarded to AGLD.

PS09.025

An audit of two years of diagnostic testing for the C9orf72 GGGGCC expansion in FTD/ALS

E. E. Mudanohwo;
National Hospital for Neurology and Neurosurgery, London, United Kingdom.

The GGGGCC expansion in the intronic/promoter region of C9orf72 was first described in October 2011 and is the most common monogenic cause of Frontotemporal Dementia and/or Amyotrophic Lateral Sclerosis (FTD/ALS). Non-pathogenic alleles are typically 2-20 repeats, and pathogenic expansions typically several hundred to several thousand repeats in length, with considerable somatic mosaicism. The smallest pathogenic repeat size is currently unknown. We have offered a diagnostic service for the expansion at the National Hospital for Neurology and Neurosurgery since January 2013. We employ repeat-primed and sizing PCRs to detect expansions and to size alleles in the non-pathogenic range, respectively. Southern blotting is used to confirm and size expansions and to exclude false negatives in patients who are homozygous with no expansion by PCR. Of 242 reports issued up to February 2015, 240 were diagnostic, with 2 predictive. Of the diagnostic tests, 27 were positive (11.25%), this is concordant with the published frequency of the expansion in FTD/ALS. Among our positive results 24 had a typical expansion. We have also identified one apparent homozygote, one patient with an expansion of 90 repeats in blood which had expanded to the typical pathogenic range in brain tissue, and one patient with a repeat from 60 to several thousand repeats in blood DNA. These cases, and the genetic counselling challenges they present, exemplify the necessity of performing Southern blotting for C9orf72 diagnostic testing, without which the precise nature of the mutations would not have been identified.

PM09.026

A 5-year-old boy with progressive epileptic encephalopathy and severe developmental delay caused by novel compound heterozygous mutations in the CACNA1A gene

K. Reinson[1,2], *E. Õiglane-Shlik*[3,2], *T. Reimand*[1,2,4], *R. Teek*[1,2], *S. Pajusalu*[1,4], *A. Õunapuu*[5], *Ü. Murumets*[1], **K. Õunap**[1,2];
[1]Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia, [2]Department of Paediatrics, University of Tartu, Tartu, Estonia, [3]Children's Clinic, Tartu University Hospital, Tartu, Estonia, [4]Institute of Biomedicine and Translational Medicine, Department of Biomedicine, University of Tartu, Tartu, Estonia, [5]Neurology Clinic, Tartu University Hospital, Tartu, Estonia.

Familial hemiplegic migraine type 1, episodic ataxia type 2, and spinocerebellar ataxia type 6 are autosomal-dominant neurological disorders associated with heterozygous mutations in the CACNA1A gene. Some patients may exhibit overlapping phenotypes, which combine various signs characteristic of these three conditions. The CACNA1A gene encodes the pore-forming α1 subunit of the neuronal voltage-gated calcium channel Cav2.1 mediating the action-potential-evoked neurotransmitter release in central nervous system.
In the index patient absent eye contact was noticed at the age of 2-months. Severe muscular hypotonia, arrested development and frequent epileptic seizures were observed later. At first MRI revealed white matter hypomyelinisation and thin corpus callosum, thereafter diffuse cerebellar and cerebral atrophy developed. At 5-years, he has profound developmental delay, muscular atrophy with rigidity, dysmorphic features and treatment resistant epilepsy. He is blind. Muscle biopsy showed lipid deposits in muscle fibers. His elder sister died at 5-years due to similar epileptic encephalopathy. Two elder sisters and both parents have mild intellectual disability. The mother has also ataxia and cerebellar atrophy.
Exome sequencing identified novel compound heterozygous mutations in the CACNA1A gene - a missense mutation c.4315T>A predicted pathogenic and a frameshift deletion c.472_478delGCCTTCC. Sanger sequencing confirmed both mutations in the index patient and his deceased sister. The mother and one elder sister carry c.4315T>A, and the father and the second elder sister carry c.472_478delGCCTTCC mutation.
This is the first description of a patient with a compound heterozygous mutation in the CACNA1A gene, which causes severe epileptic encephalopathy.
This work was supported by the Estonian Research Council grant PUT355.

PS09.027

Searching for a gene responsible for cerebellar ataxia and mild intellectual disability

R. Mavioglu[1], *B. Kara*[2], *A. Tolun*[1];
[1]Bogazici University Department of Molecular Biology and Genetics, Istanbul, Turkey, [2]Kocaeli University Medical Faculty Department of Pediatrics Division of Child Neurology, Kocaeli, Turkey.

Introduction: Ataxia is defined as lack of control in voluntary movements. It may affect walking, speaking, and eye movements. It is a neurological condition that generally results from dysfunction of the cerebellum. It can be the sole symptom in a patient or can be present with other clinical features. We investigated a consanguineous family with syndromic ataxia.
Materials and Methods: Candidate disease loci were detected by linkage analysis using SNP genotype data. Exome sequencing was applied to search for variants at the loci.
Results: The affected sib had ataxia, intellectual disability, and aggressive behaviour. The maximum multipoint LOD score was 2.15. We identified homozygous nonsense mutation p.Glu39X in *FAM160B1* in the patient. The mutation truncates the protein by 95% and is not present in 302 control samples. The sequence of the first 736 of the total 765 amino acids is highly conserved between human and chimpanzee, with a difference of only 5. The function of the protein is yet unknown,unknown and it is shown to be expressed in many different tissues. The conserved domain has homology to retinoic acid induced proteins. One gene encoding such a protein Retinoic acid-induced 1 (RAI1) is associated with several neurological diseases. GeneMANIA suggests that FAM160B1 interacts with ATXN1, deficit of which is a cause of spinocerebellar ataxia.
Conclusion: We propose that *FAM160B1* is most likely the gene responsible for this novel syndrome. We will perform gene expression studies and screen other ataxia patients for mutations in the gene.
(Bogazici University BAP Grant 7695)

Recently, we have identified a heterozygous mutation in the CHCHD10 gene in a large family with a late-onset complex phenotype including frontotemporal dementia (FTD), amyotrophic lateral sclerosis (ALS) and/or cerebellar ataxia, associated with mitochondrial myopathy and accumulation of multiple mtDNA deletions. CHCHD10 encodes a protein located in the mitochondrial intermembrane space and is likely involved in mitochondrial genome stability and maintenance of cristae junctions. Given the unawareness about the exact contribution of CHCHD10 in FTD-ALS spectrum, we evaluated, in this study, the frequency of CHCHD10 mutations in a large French cohort of 115 unrelated patients with FTD and FTD-ALS phenotypes, including 35 familial and 80 sporadic cases. We identified 2 heterozygous variants in 3 unrelated probands presenting FTD and ALS : the known p.Ser59Leu mutation in a familial case and the p.Pro34Ser variant in two sporadic cases. The phenotype of this probands is characterized by early and predominant bulbar symptoms. A short time ago, many studies confirmed the involvement of CHCHD10 in familial and sporadic ALS cases. However, this is the only study that demonstrates the implication of CHCHD10 in FTD-ALS spectrum. Although the frequency of mutations is low in this series (2.6%), our work suggests that CHCHD10 mutations should be searched particularly in presence of bulbar symptoms at onset, or evocative mitochondrial symptoms. The identification of CHCHD10 mutations in FTD-ALS spectrum opens a novel field to explore their pathogenesis and to understand the role of mitochondrial dysfunction. Further investigations in larger populations with different geographic origins are needed.

PM09.030

Functional studies of an LRSAM1 gene mutation causing Charcot-Marie-Tooth disease

A. Minaidou[1,2], *P. Nicolaou*[1,2], *K. Christodoulou*[1,2];
[1]*The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus,* [2]*The Cyprus School of Molecular Medicine, Nicosia, Cyprus.*

Introduction: Charcot-Marie-Tooth disease (CMT) is the most common inherited neuropathy of the peripheral nervous system affecting 1 in 2500 individuals. The LRSAM1 gene has recently been implicated in the CMT pathogenesis and very little is currently known about its role. LRSAM1 is an E3 ubiquitin ligase that has a significant role in endocytic and adhesion pathways in neuronal cells and mediates monoubiquitination of TSG101 at multiple sites. This study is focused on the functional analysis of the novel LRSAM1 c.2047-1G>A dominant splice-site point mutation. This mutation is located in the C-terminal RING finger domain of the encoded protein and leads to premature truncation (p.Ala683ProfsX3).
Materials and methods: Total RNA was extracted from available patient lymphoblastoid cell lines and the whole cDNA was synthesized. Initially, RNA levels of TSG101, the only known substrate of LRSAM1 E3 ubiquitin ligase activity, were investigated. Moreover, the RNA levels of E2 (ubiquitin) and additional molecules were examined. Selected molecules that possibly interact with LRSAM1 were detected using public protein-protein interaction databases.
Results: RNA levels of TSG101 and E2 were significantly reduced in patient compared to control levels. Furthermore, a statistically significant reduction of the levels of some of the selected molecules was observed. Western blot analysis to confirm the decrease of these molecules at the protein level is currently underway.
Conclusions: Our results provide more insight into the LRSAM1 pathways and molecular mechanisms, based on the alterations/disruptions caused by the LRSAM1 c.2047-1G>A mutation.
Acknowledgement: This study is funded by the Cyprus TELETHON (Grant #: 73115).

PS09.031

Recurrent microduplication of chromosome 15q11.2 pinpoints risk genes for neurodevelopmental disorders

C. Picinelli[1,2], *C. Lintas*[1], *I. S. Piras*[1,2], *S. Gabriele*[1], *R. Sacco*[1], *M. Verdecchia*[1], *A. M. Persico*[1,2];
[1]*Unit of Child and Adolescent NeuroPsychiatry & Laboratory of Molecular Psychiatry and Neurogenetics, University „Campus Bio-Medico", Rome, Italy,* [2]*Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy.*

Array-CGH analysis has shown that rare or common Copy Number Variants, both inherited and *de novo*, may significantly contribute to the etiology of neurodevelopmental disorders. A recurrent genomic aberrations associated with these phenotypes is the duplication of chromosome 15q11.2. Characterizing a cohort of 180 families using the Agilent 180K CGH array platform, we identified 4 patients carrying a 15q11.2 duplication involving the 4 genes TUBGCP5, CYFIP1, NIPA2 and NIPA1. Two were inherited from the healthy mother, one from an affected mother and one had an unknown parental origin. The duplication was confirmed by qPCR and a significant overexpression of the four duplicated genes was found using quantitative gene expression analysis. Two patients were diagnosed with Autism Spectrum Disorder, one with Developmental Delay and one is non-verbal and has a severe Intellectual Disability (the latter patient carries an additional pathogenic imbalance on the X chromosome). Strong evidence supports the role of this duplication in abnormal neurodevelopment. These four genes are all implicated in axonal growth, neuronal connectivity and morphology, especially CYFIP1 which regulates translation at the synapse by binding to FMRP. Phenotypically normal and mildly affected carriers complicate the phenotypic association and/or causality of this aberration. The explanation of this variability may be found in the reduced penetrance or altered gene dosage on a particular genetic background. This region likely represents a strong susceptibility region, as reported for other parts of the genome involved in neurodevelopmental disorders.

Corpus callosum (CC) is the major brain commissure connecting the homologous areas of both hemispheres at the midline. CC malformations (CCM) are the most frequent brain malformations with an incidence of 1/4000 newborn often associated with chromosomal anomalies or mendelian syndromes with recessive and dominant inheritance. Recurrence is observed in 5%. Children with CCM have an uncertain neuro-developmental outcome. Therefore, counseling remains challenging prenatally.
On a cohort of 64 fetuses with CCM as autopsy finding, and 34 children with CCM and mental retardation, we used a targeted high throughput sequencing strategy, Here we report 4 novel ZBTB20 mutations, the recently identified causing gene for Primrose syndrome. We describe the clinical and or neuropathological and imaging data of one fetus and 3 patients. The p.Arg613Cys, p.Cys636Arg and p.Cys611Tyr (NM_001164342.1) mutations occur within the Cys2His2 zinc finger domains of ZBTB20. Cys2His2 zinc fingers consist of two cysteines and two histidines that co-ordinate a zinc ion, and an alpha-helix that makes sequence-specific contacts with DNA. We predict that these variants would destabilize the structure of their respective zinc fingers. The p.Val185Ile substitution falls within the BTB domain of ZBTB20 that is predicted to form homodimers and leads to an apparently milder phenotype .
These results suggest that a ZBTB20 mutation found in 4/98 individuals of our series is a frequent cause of CCM.

PS09.033

Next generation sequencing for cortical brain malformations: two years of experience

M. Wilke, *D. Halley, R. van Minkelen, G. Bolman, J. Kromosoeto, W. de Valk, M. Wijgerde, G. Mancini, M. van Slegtenhorst;*
Department of Clinical Genetics, Erasmus MC, Rotterdam, Netherlands.

Cortical brain malformations (rare disorders of proliferation, neuronal migration or cortical organization) have been associated with mutations in a rapidly growing number of genes. This complicates molecular diagnostics by Sanger sequencing. In order to establish a Next-generation sequencing (NGS) based work flow for routine DNA diagnostics, we developed a gene panel consisting of 103 relevant genes.
This workflow involved the design of enrichment arrays (Agilent Sure Select) for all genes, followed by Miseq sequencing (paired-end, 150bp, Illumina). BAM files are generated with an in-house analysis pipeline and variant calling is performed using the SeqNext software package (JSI).The average vertical coverage for exons is about 300; very few fragments fail to reach the minimal required vertical coverage of 30.
Furthermore, we were able to detect deletions up to 65 bp, insertions up to 29 bp and somatic mosaicism. Sanger-sequencing is used to confirm (candidate) mutations. DNA samples of 168 patients were tested and 6% of the cases could thus far be solved, including familial segregation analysis and confirmation of parentage, even in the absence of phenotypic information. However, most of the identified alterations are variants of unknown clinical relevance. Despite the use of in silico prediction programs, evaluation of the conservation among species they cannot be judged without additional clinical information and feedback from the referring physician.
In conclusion, the targeted NGS-panel for neuronal migration disorders is a powerful tool for DNA diagnostics. In order to increase the diagnostic yield of cortical brain malformations, close collaboration between laboratory and referring specialist is mandatory.

PM09.034
Long non-coding RNAs FENDRR, RNCR3 and MEG3 are aberrantly expressed in Creutzfeldt-Jakob disease

A. Matjašič[1], *E. Boštjančič*[1], *M. Popovič*[2], *D. Glavač*[1];
[1]Department of Molecular Genetics, Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [2]Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.

Introduction: Non-coding RNAs, such as miRNAs and long non-coding RNAs (lncRNAs), are emerging as key regulators of cellular processes. Functional analyses of first lncRNAs revealed their significance in genome regulation and development. It is suggested lncRNAs *FENDRR*, *MEG3* and *RNCR3* are involved in brain and neurons development, and function. Regarding lncRNAs crucial role in various human diseases, our purpose was to investigate their possible involvement also in mechanisms of Creutzfeldt-Jakob (prion) disease and other neurodegenerative disorders.
Materials and Methods: We performed qPCR analyses to determine differential expression of three lncRNAs using autopsy brain tissue samples of cerebellum (C) and frontal lobe (FL) of 25 patients diagnosed with Creutzfeldt-Jakob disease (CJD), 20 non-CJD patients and 8 patients without neurological disease (WND). All results were compared to human brain reference RNA and statistically evaluated for significant expression differences.
Results: *MEG3* and *RNCR3* were strongly down-regulated in all sample groups, especially in CJD samples. *FENDRR* was up-regulated in all non-CJD and WND samples, and either down- or up-regulated in CJD samples. Statistical analyses showed significant over- or under-expression when we cross compared expression of CJD, non-CJD and WND patients. Moreover, significant expression differences were also observed between FL and C region within sample group.
Conclusions: Our findings support lncRNA's *FENDRR*, *MEG3* and *RNCR3* involvement in development of the prion disease and other neurodegenerative disorders, like Alzheimer's, and suggest they are necessary for normal brain function. Moreover, our results showed different spatial (cerebellum and frontal lobe) distribution that may contribute to the disease development.

PS09.035
Exome sequencing identifies SEC31A as a potenital candidate gene for schizophrenia

F. Degenhardt[1], *F. Schroeder*[1], *J. Strohmaier*[2], *A. Hofmann*[1], *S. Herms*[1,3], *L. Winkler*[1], *F. Neukirch*[1], *A. J. Forstner*[1], *M. Pfohl*[1], *M. Lang*[2], *P. Nürnberg*[4], *P. Hoffmann*[1,3], *H. Thiele*[4], *S. Cichon*[1,3,5], *M. Rietschel*[2], *M. M. Nöthen*[1];
[1]Institute of Human Genetics, Bonn, Germany, [2]Department of Genetic Epidemiology in Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, Mannheim, Germany, [3]Division of Medical Genetics, University Hospital Basel and Department of Biomedicine, Basel, Switzerland, [4]Cologne Center for Genomics (CCG), Cologne, Germany, [5]Institute of Neuroscience and Medicine (INM-1), Structural and Functional Organisation of the Brain, Genomic Imaging, Research Centre Juelich, Juelich, Germany.

Patients with schizophrenia (SCZ) suffer from a variety of symptoms, including delusions, hallucinations, disorganized speech and behavior. Even though studies have reported a reduced fecundity in patients with SCZ, the incidence rate of SCZ remains fairly stable. One hypothesis is that the mutations that are selected out of the gene pool due to strong negative selection are replaced by de novo mutations. Therefore, each gene identified to carry a de novo mutation is a potential SCZ candidate gene.
The exomes of 40 patients with a DSM-IV diagnosis of SCZ and their parents were analyzed. Exome DNA was captured from genomic DNA using NimbleGen in solution based capture and sequenced on an Illumina HiSeq 2000 sequencing instrument. The Varbank pipeline v.2.1 and interface were used for data analysis and filtering.
Subsequently, additional sources of genetic data were employed to gather more evidence for an involvement of the genes implicated: the genes were screened for the presence of CNVs using our existing genome-wide CNV dataset comprising of 1 637 patients and 1 627 controls. An association between common variants in these genes and SCZ was tested in the worldwide largest SCZ GWAS published by the PGC Schizophrenia Working Group analyzing more than 100 000 individuals.
So far, we have validated 28 different variants using Sanger Sequencing. Interestingly, our study is the third to report a de novo mutation in SEC31A. The combination of our exome sequncing and CNV data as well as the common variants will allow us to prioritize the variants identified regarding their relevance for the development of SCZ.

PM09.036
Clinical utility of gene panel testing: Case study using a 65-patient Dementia cohort

I. Delon, *K. Brugger, H. Martin, O. Spasic-Boskovic, F. Veryard, R. Littleboy, S. Abbs; Cambridge University Hospital Medical Genetics Service, Cambridge, United Kingdom.*

The increasing availability and affordability of whole exome sequencing is challenging the current testing algorithms typically including detailed family history and clinical characteristics, predicting a decrease for the need of probabilistic prioritisation of genetic testing. To evaluate this prediction, we have assessed a cohort of 65 patients referred for frontotemporal dementia (FTD) and compared the diagnostic yield of the initial referrals for single gene tests vs. a 16-gene dementia panel test using our clinical exome sequencing pipeline. This 16-gene panel includes mostly autosomal dominant rare Mendelian early onset Alzheimer and FTD genes, that despite being clinically different show a degree of phenotypic overlap justifying the use of a panel.
Although this approach has the clear potential to increase the diagnostic rate, we also aimed to determine its usefulness vs. the burden of finding variants of unknown clinical significance (VUS). Analysis showed a diagnostic rate of 6/65 for the initial targeted referrals with 4/65 VUS. Subsequent interpretation of panel data increased this rate to 7/65 for published pathogenic variants and added 19 variants which we are currently assessing for pathogenicity, including 3 PSEN2 variants reported in the AD&FTD database. Preliminary results on this small FTD cohort indicate that despite the complexity of the interpretation of gene panel data, the increase in diagnostic rate together with value for money should encourage clinicians to refer for gene panels.

IL-6 and adolescent depression: A Mendelian randomisation approach

H. M. Sallis[1,2], *G. Khandaker*[3,4], *J. Evans*[1], *L. Paternoster*[2], *G. Davey Smith*[2];
[1]Centre for Academic Mental Health, School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, [2]MRC Integrative Epidemiology Unit, School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom, [3]Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, [4]Cambridgeshire and Peterborough National Health Service Foundation Trust, Cambridge, United Kingdom.

Cross-sectional studies report an association between increased serum interleukin-6 (IL-6), an inflammatory marker, and depression. However, due to the nature of cross-sectional data, confounding and reverse causality cannot be ruled out as explanations for this observed association.
A recent study using data from the Avon Longitudinal Study of Parents and Children (ALSPAC) attempted to unpick this issue by investigating the association between levels of IL-6 at age 9 and depressive symptoms at age 18 (Khandaker et al., JAMA Psychiatry. 2014). This study found evidence of an association between increased IL-6 at age 9 and greater depressive symptoms at 18 (adjusted β=0.06, se=0.03)).
We expanded on this study using Mendelian randomisation (MR), an approach largely free from issues such as confounding and reverse causality. MR uses genetic instruments to proxy a modifiable risk factor and can thus strengthen causal inference using observational data.

Allelic risk scores for the IL-6 receptor have previously been developed. Following a recent genome-wide association study, we extended the score to increase instrument strength (F=87.4). The updated score contained 4 SNPs from the *IL6R*, *TDRD10* and *ABO* genes.
Although the estimate was in a consistent direction with the observational result, we found little evidence of a causal association. This will be expanded to a meta-analysis incorporating similar studies to improve precision of the causal estimate.
The UK MRC and the Wellcome Trust (092731) and the University of Bristol provide core support for ALSPAC. HS was funded by a Wellcome Trust 4-year PhD studentship (WT099871MA).

Seizures And Attention Deficit As Unique Clinical Hallmarks In A Patient With Digeorge Syndrome.

J. Juan, A. Lafuente, M. Ortiz, **A. Zuñiga**;
Hospital De La Ribera, Alzira (Valencia), Spain.

DiGeorge syndrome (DGS, OMIM 188400) is one of the most common chromosomal disorders, with an estimated prevalence of 1 in 4 000-6 000 live births. It is actually a well-defined primary immunodeficiency disorder classically associated with abnormal facial appearance, congenital heart defects, hypoparathyroidism with hypocalcaemia, as well as cognitive, behavioral and psychiatric problems. Pathological hallmarks include conotruncal abnormalities and absence or hypoplasia of the thymus and parathyroid glands. The facial appearance of patients with DGS is characterized by hypertelorism, micrognathia, short philtrum with fish-mouth appearance, antimongoloid slant, and telecanthus with short palpebral fissures. However, not all patients with DGS show these typical dysmorphic findings and the diagnosis can be delayed for many years. It has been reported that children and adults with DGS have high rates of behavioral, psychiatric and communication disorders. Here, we report the case of a patient that was 11 year-old boy born to unrelated healthy parents. Initially, he was admitted to the Neuropaediatric Department by seizures, attention deficit and socialization problems. The brain computed tomography CT revealed calcification located in the left basal ganglia. The EEG was abnormal due to generalized intermittent slow waves without any epileptiform discharges. Genetic analysis by MLPA technique (P245 MCR-Holland) showed a microdetion in 22q11 affecting to GP1BB, CLDN5 and SNAP29 probes, associated to a DiGeorge Syndrome. Clinical absence of the typical hallmarks of this syndrome should not exclude this disease due to variable phenotypes. Continuous efforts to define diverse clinical manifestations of this syndrome will lead to proper evaluation and intervention for patients.

DNA methylation of CACNA1C in bipolar disorder

A. Starnawska[1,2,3], A. Mcquillin[4], D. Demontis[1,2,3], A. Pen[1], A. Hedemand[1,2,3], M. Johannesen[1,2], F. Lescai[1,2,3], T. Als[1,2,3], J. Grove[1,2,3], N. Staunstrup[1,2,3], A. Nielsen[1,2], A. Jarram[4], N. O'Brien[4], O. Mors[2,5], A. Børglum[1,2,3], **M. Nyegaard**[1,2,3];
[1]Aarhus University, Aarhus, Denmark, [2]iPSYCH, The Lundbeck Foundation Initiative for Integrative Psychiatric Research, Aarhus, Denmark, [3]iSEQ, Centre for Integrative Sequencing, Aarhus University, Aarhus, Denmark, [4]Molecular Psychiatry Laboratory, Division of Psychiatry, University College London, United Kingdom, London, United Kingdom, [5]Department of Clinical Medicine-Psychiatry, Aarhus University, Aarhus, Denmark.

Introduction: Genome-wide levels of association between bipolar disorder (BPD) and schizophrenia (SZ) have been reported with the *CACNA1C* gene. This gene encodes the pore-forming unit of L-type voltage-gated calcium channels. The associated SNPs are located in a cluster in intron 3, however the functional effects of the associated SNPs remain to be determined. In this study we investigated if DNA methylation of *CACNA1C* in blood differed between BPD patients compared to healthy control subjects.
Material and methods: DNA methylation status of five CpG islands (CGIs) in the *CACNA1C* gene was investigated using Sequenom EpiTYPER in 630 bipolar disorder patients and 340 control subjects.
Results: Four out of five *CACNA1C* CGI islands were either fully methylated or fully unmethylated. In contrast one CGI showed intermediate methylation levels with substantial intra-individual variation. Follow-up analysis of this CGI identified a significant difference in DNA methylation levels between the BPD cases and healthy controls. Furthermore the methylation status of this CGI was highly correlated with the genotypes of the BPD and SZ risk SNPs.
Conclusion: The functional effects of the *CACNA1C* GWAS risk alleles may be mediated through changes in methylation status of intron 3.

PM09.040

Postnatal microcephaly in Dyggve-Melchior-Clausen syndrome is associated with hypomyelination and neuronal trafficking defects

S. PASSEMARD[1,2,3], *N. Dupuis[1,2], M. Vermelle-Andrzejewski[4], M. Abramowicz[5], A. Verloes[3], J. Bonaventure[6], F. Perez[6], Z. Csaba[1,2], P. Gressens[1,2], V. El Ghouzzi[1,2];*
[1]PROTECT INSERM U1141, Paris, France, [2]Univ Paris Diderot, Sorbonne Paris Cité, UMRS 1141, Paris, France, [3]AP-HP, Hôpital Robert Debré, Service de Génétique Clinique, Paris, France, [4]Hôpital Roger Salengro, Service de Neuropédiatrie, Lille, France, [5]Hôpital Erasme, Medical Genetics Dept, Université Libre de Bruxelles, Brussels, Belgium, [6]Institut Curie, Centre de Recherche, Paris, France.

Dyggve-Melchior-Clausen syndrome (DMC, MIM #223800) is a rare inherited dwarfism characterized by spondyloepimetaphyseal dysplasia, postnatal microcephaly and intellectual disability, and caused by loss-of-function mutations in the DYM gene encoding DYMECLIN, a Golgi-associated protein involved in intracellular trafficking. Interestingly, both skeletal growth defects and microcephaly develop during childhood and are therefore rarely diagnosed at birth. This suggests that the physiological mechanisms affected in DMC involve postnatal processes. We used Dymeclin-mutant mice to determine the cause of microcephaly and to identify defective mechanisms at the cellular level. Brain weight and volume were reduced in all mutant mice from postnatal day 5 onward. Mutant mice displayed a narrowing of the frontal cortex, although cortical layers were normally organized. Interestingly, the corpus callosum was markedly thinner, a characteristic we also identified in three unrelated DMC patients carrying the p.Gln483Ter nonsense mutation. Consistent with this, the myelin sheath was less compact and not properly rolled, while the number of mature oligodendrocytes and their ability to produce myelin basic protein were significantly decreased. Finally, cortical neurons from mutant mice and primary fibroblasts from DMC patients displayed substantially delayed endoplasmic reticulum to Golgi trafficking, that could be fully rescued upon Dymeclin re-expression. These findings indicate that Dymeclin is crucial for proper myelination and anterograde neuronal trafficking, two processes that are highly active during postnatal brain maturation.
This study was supported by INSERM, CNRS, the Paris 7 University, the DHU PROTECT and the French National Research Agency (project ANR-09-GENO-007 to VEG).

PS09.041

Molecular genetic investigations of a Norwegian dystonia cohort by gene-panel based next generation sequencing

Z. Iqbal[1], *J. A. Koht[2], L. Pihlstrøm[1,3], F. Hussain[1], S. P. Henriksen[1], M. Toft[1];*
[1]Department of Neurology, Oslo University Hospital, Oslo, Norway, [2]Department of Neurology, Vestre Viken Hospital Trust, Drammen, Norway, [3]Faculty of Medicine, University of Oslo, Oslo, Norway.

Dystonia is a group of clinically heterogeneous neurological disorders characterized by involuntary movements and prolonged muscle contraction, which may involve the entire body or only an isolated area. Several genetic forms of dystonia have been identified, but genetic testing has been limited by time-consuming and costly procedures. However, using next generation sequencing technology, it is now possible to develop inexpensive tests by which multiple genes can be screened in parallel.
We designed a panel including the coding sequences of 17 genes implicated in different forms of dystonia, using a similar method as described previously (Pihlstrøm L, *et al*., Ann of Hum Genet, 2014). We screened these genes in 116 clinically well-characterized Norwegian dystonia patients as well as 120 ethnically matched controls. The sequencing yielded high quality data with average 98% bases covered above 80x in the targeted intervals. Our bioinformatics pipeline identified 11 variants for further validation and confirmation. We identified variants in *ANO3*, *CIZ1*, *GCH1*, *NKX2-1*, *PNKD*, *PRRT2*, *SGCE*, *TOR1A*, and *TH*. Out of these, two confirmed variants are truncating changes located in *GCH1* and *CIZ1*. After the ongoing validation analysis, we will be able to establish a molecular diagnosis in a subset of patients.
Our approach of gene-panel based next generation sequencing will be able to gauge the potential of the method used and will point towards future directions for targeted screenings in such heterogeneous neurological disorders. Moreover, such fast, cost-effective, and robust screening methods will help improve molecular diagnosis, genetic counseling, and therapeutics.

PM09.042

Next Generation Sequencing in neurogenetics - our experience

I. Novakovic[1], *V. Dobricic[2], A. Maver[3], M. Stojiljkovic[4], K. Kacar[5], I. Petrovic[1,2], S. Pavlovic[4], B. Peterlin[3], V. Kostic[1,2];*
[1]Faculty of Medicine, Belgrade, Serbia, [2]Neurology Clinic CCS, Belgrade, Serbia, [3]Institute of Medical Genetics, CC Ljubljana, Ljubljana, Slovenia, [4]IMGGE, Belgrade, Serbia, [5]Institute of Cerebrovascular Diseases „Sveti Sava", Belgrade, Serbia.

Next Generation Sequencing (NGS) methods transform our approach in genetic testing of neurological disorders, particularly in the area of single gene diseases. NGS helps us to improve diagnostics of well known disorders, to detect rare mutations in genetic heterogeneous diseases, and to discover new disease causing genes. Growing number of experiences indicate huge NGS benefits, as well as some method limitations.
We describe here results of NGS method implementation in three different single gene/familiar diseases in patients from Serbia. We have analyzed: 1. one family with early onset dystonia - parkinsonism, negative for common DYT and PARK mutations, 2. one family with cerebral congenital cavernous malformation, negative for CCM1 gene mutations, 3. one sporadic case of Wilson disease with only one heterozygous ATP7B mutation (H1069Q) detected by screening of five mutation - prone exons. Mentioned DYT, PARK, CCM1 and ATP7B analyses were performed in Genetic laboratory of Neurology Clinic CCS, Belgrade, by Sanger's sequencing of targeted regions on ABI3500 Genetic Analyzer. NGS was performed on Illumina MiSeq platform using TruSight One panel. After bioinformatic analysis of NGS data we detected novel GIGYF2 (PARK11) gene variant (p.E531V) in dystonia - parkinsonism family and novel CCM2 gene variant (p.Y118X) in family with congenital cavernous malformation. Both changes are confirmed by Sanger sequencing and recognized as likely pathogenic by software's prediction. However, in the case of Wilson disease, NGS confirmed known mutation but did not detected second ATP7B gene change. Our results are good illustration of power and challenges of NGS methods.

PS09.043

Detection of disease-causing mutations in cases of unexplained early-onset ataxia by using panel based next-generation sequencing

F. Harmuth[1], *M. Synofzik*[2,3], *J. Wolf*[2,3], *M. Sturm*[1], *L. Schoels*[2,3], *P. Bauer*[1];
[1]*Institute of Medical Genetics and Applied Genomics, Tuebingen, Germany,* [2]*Department of Neurodegenerative Diseases, Hertie-Institute for Clinical Brain Research, Tuebingen, Germany,* [3]*German Research Center for Neurodegenerative Diseases (DZNE), Tuebingen, Germany.*

Spinocerebellar ataxias (SCAs) in patients with an onset age under 30 years (early-onset ataxias, EOAs) are mostly caused in autosomal recessive genes and show a wide range of clinical symptoms. Due to the large variability and overlap of phenotype and the rapidly increasing amount of (often very rare) ataxia related genes, it is challenging to find a molecular diagnosis in these patients.
The study cohort of 131 cases with EOA was negatively screened for dominant repeat expansion SCAs and FRDA. Patients with a genetic mutation sufficient to explain the ataxia or with neurodegenerative disease in more than one generation were excluded beforehand. Samples were processed with a custom-built ataxia specific HaloPlex panel (Agilent) for 132 genes and sequenced on a MiSeq (Illumina) followed by bioinformatics analyses using our in-house pipeline.
By this approach, on average, >95% of the target region was covered ≥20x with a mean coverage of 257 ± 71 reads. The analysis of filtered variants identified 18 patients (14%) with clear pathogenic biallelic mutations in 9 genes (e.g. 7x *SACS*, 1x *PLA2G6*, 1x *PNPLA6*, 2x *NPC1*, 2x *SYNE1*), 8 patients (6%) with probably pathogenic mutations in 6 genes (*SETX*, *SYNE1*, *ITPR1*, *KIF5C*, *SACS*, *TTPA*) and additional 8 patients (6%) with a potential de-novo mutation in a dominant ataxia gene (*ITPR1*, *PRKCG*, *SPTBN2*, *CACNA1A*).
Disease specific panel sequencing thus enables a highly effective, cost-efficient and fast detection of underlying mutation which could facilitate therapeutic treatment of symptoms or precise prediction of the course of the disease.

Introduction: Epileptic encephalopathies (EE) are specific age-related brain conditions with a detrimental effect of continuing seizures and electrographic discharges on the function of the developing brain. Early Infantile Epileptic Encephalopathies (EIEE) are EE with onset before age 3-4 months. Etiologies are heterogeneous and whole-exome sequencing (WES) techniques can help to clarify their etiopathogenesis.
Patients&Methods: Patients were retrospectively selected based on their clinical and electroencephalographic diagnosis of EIEE, registered at the Epilepsy Clinic of our Tertiary Hospital from 1995 to 2013. Exclusion criteria were: brain injury secondary to hypoxic-ischemic encephalopathy, trauma, stroke, infection and intracranial hemorrhage. We performed a descriptive analysis concerning demographics, epileptic phenotype and investigation. Selected patients without diagnosis are under WES analysis using TruSeq capture followed by sequencing on a HiSeq2500.
Results: From the 27 selected patients, median age for first manifestation was 45 days [1day-4months]. Six patients had electroclinical syndromes (four Ohtahara syndrome; two early myoclonic encephalopathy). The majority had severe DD. Brain MRI of 22 patients was diagnostic in nine (eight had malformation of cortical development, MCD). Six (22%) patients died. Ten patients (37%) had a confirmed molecular diagnosis (six metabolic diseases, three genetic syndromes, one MCD). All were sporadic situations. NGS analysis' results of eight patients will be presented at the Conference.
Conclusion: Our work reflects the metabolic etiology's impact in this group of EE, their clinical and etiologic heterogeneity. Children with EIEE have elevated mortality (22%) and morbidity (100%) rates. An accurate etiologic diagnosis for such disorders is helpful for an effective individual management, genetic counselling and sometimes therapeutic intervention.

Massively Parallel Sequencing in the Epilepsies: New gene pathways and challenging clinical dogma

L. M. Dibbens[1], *B. L. Hodgson*[1], *I. E. Scheffer*[2], *S. Mandelstam*[3], *D. E. Crompton*[4], *L. Licchetta*[5], *F. Bisulli*[6], *P. Tinuper*[5], *S. F. Berkovic*[2], *M. G. Ricos*[1], *S. E. Heron*[1];
[1]*University of South Australia, School of Pharmacy and Medical Sciences, Adelaide, Australia,* [2]*University of Melbourne, Melbourne, Australia,* [3]*Florey Neuroscience Institute, Melbourne, Australia,* [4]*University of Melbourne,, Melbourne, Australia,* [5]*University of Bologna, Bologna, Italy,* [6]*University of Bologna, Bologns, Italy.*

Purpose:
We set out to find the genetic cause of focal epilepsy in a family with individuals with lesional and non-lesional focal epilepsy, as detectable by MRI analysis. The family showed autosomal dominant inheritance and genome wide linkage analysis failed to identify a linkage region.
Methods:
We carried out exome capture and massively parallel sequencing on two individuals from the family who were affected with focal epilepsy and analysed the data using an in-house bioinformatics pipeline. Candidate causative genetic variants were validated by direct Sanger sequencing and were analysed for co-segregation with affected status and assessed for likely pathogenicity.
Results:
We identified a mutation in *DEPDC5* as being causative of lesional and non-lesional focal epilepsy in the family. We then identified *DEPDC5* mutations in additional families with mutation-positive individuals with lesional and non-lesional focal epilepsy. *DEPDC5*-associated malformations include bottom-of-the-sulcus dysplasia and focal subcortical band heterotopia.
Conclusion:
We have found that mutations in *DEPDC5* cause familial cases of focal epilepsy associated with structural brain lesions as well as in cases with no structural brain abnormalities. We have therefore shown that lesional and non-lesional epilepsy can have a shared genetic aetiology. This challenges the long held view that lesional and non-lesional epilepsy are distinct clinical entities with different causes. DEPDC5 negatively regulates the mTOR pathway which plays a key role in cell growth and metabolism. The clinical and radiological phenotypes associated with *DEPDC5* mutations share features with the archetypal mTORopathy, tuberous sclerosis, raising the possibility of new therapeutic avenues for patients.

Epilepsy is a neurological disorder that affects about 3% of the population and is characterized by sudden and violent seizures (focal or generalized). Different causes have been associated with epileptic disorders (brain injury,

stroke or brain damage at the time of birth) and in recent years, several genes mutations have been implicated in this complex disorder. However the mechanisms that connect many of the identified mutations/genes to epilepsy are still unknown.
We focused our attention on the *hnRNPU* gene in which two different loss-of-function *de novo* mutations (chr1:245019921 CATTTGTCTTT/C INDEL; chr1:243086781 C>T) have been identified in two different patients affected by epileptic encephalopathy. *hnRNPU* has an important role in mRNA processing, transcription and splicing. To better understand the neurobiological role of *hnRNPU* in epilepsy we used a Micro-electode array (MEA) platform that is able to record the field potential of electrically active cells from 768 electrodes simultaneously. We plated *wild-type* mouse cortical neurons on MEA plates and used the shRNA to knock-down *hnRNPU* gene in a half of the tested cells. Next, we constructed a tool to analyze the complex multi-dimensional output of the MEA recordings. This enabled us to observe a general effect of decreased expression on neuronal activity of treated neurons. Preliminary results specifically show that the *hnRNPU* knock-down results in characteristic changes in neuronal activity, where treated cells have prolonged bursts activity with increased firing rate compared to the wild, revealing a neuronal phenotype activity that can be compared with what is observed in-vivo in epileptic seizures.

Microelectrode array analysis captures seizure-like activity due to down-regulation of microRNA-128

K. McSweeney[1,2], *A. Gussow*[1,2], *S. Bradrick*[2], *S. Petrovski*[1], *D. Goldstein*[1];
[1]*Columbia University, New York, NY, United States,* [2]*Duke University, Durham, NC, United States.*

Microelectrode arrays (MEAs) are powerful tools for detecting spontaneous neuronal activity. MEAs have been used to detect the response of primary dissociated neurons to neurotoxins and are emerging as reliable drug screening platforms. Recent studies indicating the involvement of microRNAs in epilepsy phenotypes encouraged us to investigate the effect of modulating microRNA-128, on neuronal activity. Mice deficient in microRNA-128 are prone to fatal seizures. Modulating microRNA-128 in the MEA system allowed us to directly test whether MEAs are useful to screen other microRNAs that influence risk of seizures. In particular, we sought to evaluate whether down-regulation of microRNA-128 results in clear excitability phenotypes by MEA analysis. We used primary cortical neurons from wild-type postnatal day zero C57BL6 mice and a lentivirus delivered microRNA sponge to target the mature microRNA-128. Sponges are competitive microRNA inhibitors which express tandem repeats that are partially complementary to the microRNA sequence. We recorded neuronal activity on the MEA for 15 minutes each day to collect spike, burst, and network synchronicity data. Our data show that down regulation of microRNA-128 by inhibition with a sponge results in significantly increased neuronal activity. These features are consistent with the previous observations that microRNA-128 deficiency promotes neuronal excitability. These experiments illustrate the utility of the MEA platform in evaluation of microRNAs in regulation of network phenotypes.

PM09.048

Molecular characterization of a cohort of 352 patients sheds light on genetic heterogeneity in early onset epileptic encephalopathy.

M. Milh[1,2,3], *C. Lacoste*[4], *P. Cacciagli*[4,2,3], *C. Mignon-Ravix*[2,3], *J. Sutera-Sardo*[1], *C. Badens*[4,3,2], *L. Villard*[2,3];

We have studied a cohort of 352 patients suffering from early onset epileptic encephalopathy. This cohort was studied either in a diagnostic or in a research setting. All patients had epilepsy beginning before 3 months of age, abnormal interictal EEG, no brain abnormality and a normal metabolic screening. They all had abnormal neurological development. Globally, among the 352 patients, we identified 75 probably damaging mutations (21,3%). As a first step, all patients were screened for mutations in the KCNQ2 or STXBP1 genes. We identified 33 mutations in KCNQ2 (9,3% of the cohort) and 19 mutations in STXBP1 (5,4% of the cohort). If we consider the diagnostic cohort only (189 patients) the yield is 17,4% for KCNQ2 and 10% for STXBP1 mutations. All mutations in these two genes were de novo but two, which have been inherited from mosaic carriers.
In the research cohort (163 patients), we found mutations in the KCNT1, SCN8A, TBC1D24, SCN2A, KCNQ3, SLC13A5, GABRG2, CDKL5 and GRIN2A genes. High resolution arrayCGH analysis was also performed for 109 patients in the research cohort. This analysis revealed numerous rearrangements, most of which were inherited from the healthy parents, although they had not previously been reported in genomic variant databases. Several pathogenic rearrangements were also found including submicroscopic deletions of STBXP1, MEF2C, WDR45 and SCN2A. These results, together with our current strategy aiming at increasing the diagnostic yield, will be detailed at the conference.

Testing epileptic encephalopathy candidate genes in additional samples shows paucity of recessive hits

C. G. F. de Kovel[1], *E. H. Brilstra*[1], *R. van ,t Slot*[1], *R. Moller*[2], *A. Suls*[3], *S. Weckhuysen*[4], *I. Helbig*[5], *EUROEPINOMICS-RES, B. P. C. Koeleman*[1];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*Danish Epilepsy Centre, Dianalund, Denmark,* [3]*Universiteit Antwerpen, Antwerpen, Belgium,* [4]*Hôpital Pitié Salpêtrière, Paris, France,* [5]*Universitaet Kiel, Kiel, Germany.*

Aim: In recent studies of mutations underlying epileptic encephalopathies, numerous genes have been identified with unsufficient statistical support. We sought to increase support for at least some of those genes.
Methods: samples from 362 patients with epileptic encephalopathy were tested on a panel of 370 known and candidate genes. Thirty-eight patients had similarly affected sibs, 37 sporadics had consanguineous parents, 287 sporadics had no known parental relatedness. The genes had been collected from literature and earlier experiments in our labs. Eighteen genes had OMIM-annotations for epileptic encephalopathy; 66 genes were expected to be recessive, 288 dominant, 13 X-linked, the remainder unknown. In the first screen, no parents were included. We looked for novel coding variants.
Results: Thirty-eight patients had probably pathogenic variants in OMIM-annotated genes. One inbred patient was homozygous for a recessive candidate gene, four sporadic patients were compound heterozygous for recessive candidate genes. Some genes, e.g. *NFASC*, had more novel hits than expected from its length, while some genes with a known connection to severe epilepsies were NOT overrepresented relative to gene size. Of the genes with excess novel hits *COL7A1* and *FREM2* are known causes for the recessive diseases Epidermolysis bullosa and Fraser syndrome respectively.
Conclusions: Despite a likely enrichment for recessive forms of epileptic encephalopathy, through inclusion of multiplex and inbred families, very few patients had homozygous or compound heterozygous mutations in recessive candidate genes, suggesting that recessive epileptic encephalopathies are very rare. Sequencing of our patients' parents and further analysis will sort out new EE-genes.

PM09.050

A genetic study of Primary Familial Brain Calcification and Paroxysmal Kinesigenic Dyskinesia

G. Iannello[1,2], *M. Gagliardi*[1], *M. Morelli*[2], *G. Nicoletti*[1], *P. Perrotta*[1], *A. Gambardella*[2], *A. Quattrone*[1,2], *G. Annesi*[1];
[1]*Institute of Molecular Bioimaging and Physiology, National Research Council, Section of Germaneto, Catanzaro, Italy,* [2]*Institute of Neurology, Department of Medical and Surgical Sciences, University Magna Graecia, Catanzaro, Italy.*

Introduction: Primary Familial Brain Calcification (PFBC) also known as Fahr's disease is a rare genetic disorder including heterogeneous and progressive neurologic dysfunction, caused mainly by calcification in basal ganglia. Thus far, 3 genes have been identified to be involved in Fahr's disease, SLC20A2, PDGFRB and PDGFB. Recent evidence suggests that SLC20A2 might be associated with Paroxysmal Kinesigenic Dyskinesia (PKD).
Materials and methods: We performed a SLC20A2, PDGFRB and PDGFB gene analysis of 4 families with Fahr's disease and a SLC20A2 screening of a PKD family. The genomic DNA was extracted, genes amplified and then sequenced.
Results: Screening for SLC20A2 detected a novel missense mutation c.1618G>A in heterozygous form in two affected members of a PFBC family. This mutation leads to a Gly540Arg substitution in a highly conserved residue in transmembrane domain IX. A novel SLC20A2 deletion in heterozygous state c.21_21delG (p.Leu7Fs*10) was found in a patient of a second PFBC family.
Conclusion: As predicted the first mutation causes a loss of function of the protein while deletion causes a frameshift generating a truncated protein. SLC20A2 gene mutations shape the impairment of the uptake of Pi. In conclusion our study confirms that SLC20A2 mutations are mainly responsible for PFBC.

A modulatory trans-effect on age-at-onset in familial amyloid polyneuropathy (FAP) ATTRV30M in Portugal

M. Alves-Ferreira[1,2], A. Azevedo[1,2], T. Coelho[3], D. Santos[1,2], **J. Sequeiros**[1,2]*, I. Alonso[1], A. Sousa[1,2], C. Lemos[1,2];*

[1]Instituto de Investigação e Inovação em Saúde (I3S); and UnIGENe, IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal, [2]ICBAS, Univ. Porto, Porto, Portugal, [3]Unidade Corino de Andrade, HSA-CHP, Porto, Portugal.

Introduction: Early and late-onset forms of familial amyloid polyneuropathy (FAP) ATTR V30M (aka Val50Met) are not separate entities: they may coexist in the same family, with offspring often showing anticipation of age-of-onset (AO). Our aim was to identify modifiers closely linked to the TTR locus that may in part explain the wide variability in AO.
Methods: Eight variants at the TTR locus were analysed, in a sample of 722 individuals (588 V30M carriers). An intensive in silico analysis was performed to study a possible regulation of gene expression.
Results: Haplotype A was the most common in our population. Noteworthy, haplotype C was more frequent in early-onset carriers than in late patients (p=0.012). When we compared allelic frequencies of each SNP of haplotype C between very early (≤30yrs) and late-onset cases (≥50yrs), we found a significant association of the A allele of rs72922947 with early-onset (p=0.009), which remained significant after a permutation-based correction. Also, the GA genotype was associated with a decrease in mean AO of 8.6 yrs (p=0.014).
We also found interesting, unreported results in the in silico analysis. Several alterations in the mechanism of splicing, transcription factors binding and miRNAs binding were observed.
Conclusions: We found a common haplotype linked with V30M mutation and, importantly, a possible modulatory effect on AO by a genetic variant present in the normal chromosome. These putative mechanisms of regulation of gene expression, within the TTR gene, could be potential therapeutical targets.

PM09.052

Familial Fatal Insomnia in a large Portuguese family

P. Louro[1]*, L. Ramos[1], I. Santana[2], I. Baldeiras[2], A. Massano[2], G. Cordeiro[2], C. Bento[2], O. Rebelo[3], H. Ribeiro[4], R. Almeida[4], J. M. Saraiva[1,5];*

[1]Medical Genetics Unit, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, [2]Neurology Unit, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, [3]Anatomic Pathology Unit, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, [4]Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal, [5]University Clinic of Pediatrics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Fatal familial insomnia (FFI) is a rare human prion disorder, clinically characterized by progressive insomnia and dysautonomia preceding motor and cognitive deterioration. FFI is linked to the mutation D178N in the PRNP gene and to the presence of a methionine codon at position 129 of the mutant allele (D178N-129M haplotype).
We report the case of a 49-year-old man presenting with insomnia, attention deficits and sexual dysfunction. The following month he started having unsteady gait, behavioral changes and was unable to work due to executive dysfunction. Over the subsequent months he became agitated, with stereotyped behavior and vocalizations, and rapidly deteriorated, dying 10 months after onset.
In the investigation, EEG showed bursts of frontal slow waves, but no periodic activity was detected, and polysomnography revealed a normal pattern with the presence of sleep spindles and K complexes; MRI revealed mild fronto-temporal atrophy; CSF analysis was negative for 14-3-3 protein; necropsy study revealed a mild fronto-temporal atrophy, severe neuronal loss and astrogliosis in the thalamic nuclei, but no spongiform degeneration; Western blot analysis for protease-resistant prion protein did not detect the presence of the abnormal protein in frontal cortex. Finally, PRNP gene sequencing revealed a heterozygous D178N mutation associated with a homozygous methionine polymorphism at codon 129.
This patient's family has an autosomal dominant pedigree with several carriers and affected members, although with a phenotypic variability related, at least partly, to the specific polymorphism at codon 129 of the non-mutant allele of PRNP gene.

PM09.054

Friedreich ataxia and Limb-girdle muscular dystrophy type 2A segregating in a single pedigree from Bulgaria

A. Todorova[1,2]*, S. Tincheva[3,2], T. Todorov[4], V. Mitev[2];*

[1]Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria, [2]Genetic Medico-Diagnostic Laboratory "Genica", Sofia, Bulgaria, [3]Medical University Sofia, Sofia, Bulgaria, [4]Genetic-Medico Diagnostic Laboratory "Genica", Sofia, Bulgaria.

Friedreich ataxia (FRDA, MIM 229300) is an autosomal recessive form of ataxia, caused by mutations in the *FXN* gene (MIM 606829), localized at 9q21.11. Typically, the disorder is associated with an instable *GAA* trinucleotide expansion in intron 1. Homozygous expansion accounts for 98% of the cases of FRDA. However, about 2% of the FRDA patients are compound heterozygous for the expansion and a point mutation in the *FXN* gene.
Limb-Girdle Muscular Dystrophy Type 2A (LGMD2A, MIM 253600; Calpainopathy) is another autosomal recessive neuromuscular disorder presented with progressive proximal (limb-girdle) muscle weakness. LGMD2A is caused by mutations in the *CAPN3* gene (MIM 114240) localized at 15q15.1.
Here we report a single pedigree affected by these two different recessive neuromuscular disorders, namely FRDA and LGMD2A. The molecular genetic testing showed that in this family FRDA is caused by an expanded GAA repeat in compound heterozygous state with a novel point mutation c.442C>T, p.Gln148* in the *FXN* gene. This represents the first report of Bulgarian FRDA case carrying a point mutation in the *FXN* gene. The LGMD2A affected individual was found to be compound heterozygous for the two most common *CAPN3* mutations for the Bulgarian population (c.550delA, p.Thr184Argfs; c.967G>T, p.Glu323*).
To the best of our knowledge we are reporting the first Bulgarian family with two neurological disorders caused by mutations in genes on different chromosomes and segregating independently in the family. This single pedigree with four different mutations is an example for the high genetic heterogeneity of the Bulgarian population.

PS09.055

Fast detection of genetic variations in frontotemporal dementia using next-generation sequencing-based on a custom AmpliSeq™ panel and Ion Torrent PGM sequencing.

I. Manna[1]*, M. Morelli[2], L. Citrigno[3], D. Mendes Oliveria[3], C. Marinaro[3], A. Fratto[2], G. Viglietto[3], A. Gambardella[2], A. Quattrone[1];*

[1]CNR-1Institute of Molecular Bioimaging and Physiology (IBFM), Section of Germaneto;, Catanzaro, Italy, [2]2Institute of Neurology, Department of Medical Sciences, University Magna Graecia,, Catanzaro, Italy, [3]3Department of Experimental and Clinical Medicine, University Magna Graecia,, Catanzaro, Italy.

Frontotemporal dementia (FTD) is a syndrome characterized by profound behavioral changes and degeneration of the frontal and anterior temporal cortex and it is a clinically, pathologically and genetically heterogeneous disorder. Many candidate genes are associated with FTD. To set up a fast and comprehensive assay in order to determine genetic diagnosis in FTD, we employed the standard next-generation sequencing (NGS) workflow. We designed a custom AmpliSeq™ panel for sequencing the most prevalent FTD-causing genes (PSEN2, TARDBP, PSEN1, FUS, GRN, MAPT, APOE, PRNP, and APP) using the Ion Torrent Personal Genome Machine (PGM) Sequencer. Our AmpliSeq custom panel allowed us to efficiently explore 99% of targeted sequences. Few patients with a clinical diagnosis of FTD was screened to identify the disease-causing mutations. Using adjusted alignment settings, all genetic variants present in covered region were readily identified. We found in a patient two heterozygous mutations in two genes (Cys139Arg in GRN gene, and Glu318Gly in PSEN1 gene) previously described pathogenic. In all patients we identified the common genetic variant in the 3' untranslated region (3'UTR) of GRN gene (rs5848; c.*78C>T), associated with sporadic FTD, and several synonymous variants, classified not pathogenic, in the other genes. In conclusion, these results suggested that our NGS approach based on an ampliseq custom panel is a highly efficient, and can readily identify FTD-causing mutations that are associated with high phenotypic variability.

PM09.056

Mutations in PGRN, MAPT and C9ORF72 in Polish patients with frontotemporal lobar dementia

M. Berdyński[1]*, T. Gabryelewicz[1], A. Barczak[1], M. Kobryś[1], E. Narożańska[2], M. Barcikowska[1], C. Żekanowski[1];*

[1]Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland, [2]Department of Neurology, St. Adalbert Hospital, Gdańsk, Poland.

Introduction
Frontotemporal lobar degeneration (FTD) is the second most common form

of presenile dementia. FTD, is clinically, pathologically and genetically heterogeneous disorder. Up to 40% of FTD patients report family members with FTD supporting the important contribution of genetic factors. Seven genes are linked to FTD, with the most prevalent mutations located in *PGRN*, *MAPT* and *C9ORF72*.

Materials and Methods

The study group comprised 138 FTD patients (mean age of onset 56,3±11,8; 57 patients with familial FTD) and control group consisted of 257 neurologically healthy persons. *MAPT* and *PGRN* were direct-sequenced. Hexanucleotide repeat expansion located in *C9ORF72* was analyzed using repeat–primed PCR.

Results

In the group of FTD patients fifteen putative pathogenic mutations (six in *MAPT*, four in *PGRN*, and five in *C9ORF72*) were identified including three novel mutation: *MAPT* G55R, *PGRN* D317fsX11, and *PGRN* P439_R440fsX6. Mutation in three analyzed genes are responsible for 11% of all analyzed FTD cases and 31% of familial cases.

Conclusions

Although the mutations in the analyzed genes are responsible for a significant percentage of FTD cases from the Polish population, it is recommended to apply new generation sequencing methods (NGS) to detect mutations in the remainder FTD cases.

PS09.057

Progranulin levels in repeated blood withdrawals and cerebrospinal fluid in (pre)symptomatic frontotemporal dementia caused by progranulin mutations

H. H. Meeter[1], *E. G. P. Dopper*[1], *H. Patzke*[2], *J. C. van Swieten*[1];
[1]*ErasmusMC, Rotterdam, Netherlands,* [2]*FORUM Pharmaceuticals, Watertown, MA, United States.*

Introduction: Frontotemporal dementia (FTD) is the second most common form of presenile dementia characterized by progressive behavioral and/or language disorders. Mutations in progranulin (*GRN*, autosomal dominant inheritance), are causative for this disease in 5 -10 percent of cases, leading to reduced levels of progranulin protein levels due to haploinsufficiency. Upcoming therapeutic trials focus on enhancing progranulin production. To be able to correctly interpret effects of these agents, knowledge of natural variability and correlations between progranulin levels in blood and cerebrospinal fluid are essential.

Methods: We studied the variability of progranulin levels in 42 subjects (4 FTD patients with *GRN* mutation, 19 presymptomatic *GRN* carriers and 19 healthy controls). We performed lumbar punctures in 28 subjects (3 FTD patients with *GRN* mutation, 16 presymptomatic *GRN* carriers and 9 healthy controls).

Results: Progranulin levels are significantly lower in *GRN* carriers compared to healthy controls (mean 7866 pg/mL versus 27473 pg/mL, p=0.00). Progranulin levels in plasma are remarkably stable over time (mean variability per subject is 11%). Presymptomatic versus symptomatic carriers show equal median progranulin levels and variability (p=0.29 resp. p=0.26). In CSF, progranulin levels are also significantly lower in carriers (median 334 pg/mL) compared to controls (median 761 pg/mL, p=0.00). Plasma progranulin levels show a good correlation with CSF progranulin levels in the total cohort (Spearman's rho=0.82, p=0.00).

Conclusions: Peripheral progranulin levels are stable and correlate well with central levels, therefore plasma progranulin levels are a promising biomarker for subjects with *GRN* mutations.

In collaboration with FORUM pharmaceuticals. Fellowship grant HHM by Alzheimer Nederland.

PS09.059

Expanding the Clinical Spectrum of GABRG2 Mutations

N. Okamoto[1], *R. Fukai*[2], *N. Miyake*[2], *H. Saitsu*[2], *N. Matsumoto*[2];
[1]*Department of Medical Genetics,* Osaka Medical Center and Research Institute for Maternal and, Osaka, Japan, [2]Department of Human Genetics, Yokohama City University Graduate School of, Yokohama, Japan.

Gamma-aminobutyric acid (GABA) receptors are a family of proteins involved in the GABAergic neurotransmission of the brain. GABRG2 is a member of the GABA-A receptor gene family of heteromeric pentameric ligand-gated ion channels. Heterozygous mutations in the *GABRG2* gene have been found in the patients with childhood absence epilepsy, familial febrile seizures, and generalized epilepsy with FS plus. We analyzed whole exome sequencing in patients with neurodevelopmental disorders. We report two patients with atypical manifestations with novel *GABRG2* mutations.

Patient 1

This 5 year-old girl was born to nonconsanguineous healthy parents. Her developmental milestone was delayed from early infancy. She cannot walk alone. She showed severe intellectual disability (ID) and autism spectrum disorder (ASD). Microcephalus and dysmorphic features were noted. *De novo* heterozygous mutation in the *GABRG2* gene (p.A106T) was identified. EEG showed sporadic spikes. Epileptic seizure was not observed.

Patient 2

This 5 year-old boy was born to nonconsanguineous healthy parents His developmental milestone was delayed from early infancy. He cannot sit or walk. He showed severe ID and generalized epileptic seizures. He constantly moved his extremities. Microcephalus and dysmorphic features were noted. *De novo* heterozygous mutation in the *GABRG2* gene (p.R270G) was identified.

We suppose that mutations in the *GABRG2* gene may be responsible for ID and ASD. Patient 1 lacked seizures. Clinical spectrum of *GABRG2* mutation was expanded.

PM09.060

The emerging utility of genetic testing in clinical psychiatry

A. Kievit[1], *C. Bouwkamp*[1,2], *L. van Zutven*[1], *R. van Minkelen*[1], *I. Sterrenburg-van de Nieuwegiessen*[3], *V. Bonifati*[1], *S. Kushner*[2];
[1]*Dept. of Clinical Genetics, Erasmus Medical Centre, Rotterdam, Netherlands,* [2]*Dept. of Psychiatry, Erasmus Medical Centre, Rotterdam, Netherlands,* [3]*Delta Psychiatric Centre, Poortugaal, Netherlands.*

There is ample evidence that psychiatric disorders have a strong genetic basis. Family history is the strongest predictor of increased disease risk. Increasing knowledge about the genetic architecture in a substantial subset of patients with severe mental illness urges revising the clinical standard of care. We inform the field about the state of the art of clinical genetics applied to psychiatric practice. Furthermore, we present our findings in a cohort of patients with severe mental illness and comorbid mild to moderate intellectual disability, where in a considerably number of the cases a molecular diagnosis was provided, and give clinical guidelines as to when it is useful to request a clinical genetic evaluation in the setting of psychiatric care. Clinical genetic testing and counselling is warranted in patients with complex psychiatric syndromes, and especially in those with mental retardation and/or multiple congenital abnormalities and/or a positive family history.

PS09.061

Clinical and molecular-genetic characteristics of two Gerstmann-Straussler-Scheinker patients.

E. L. Dadali, *A. A. Stepanova, O. A. Sh'agina, A. V. Polyakov;*
Research Centre for Medical Genetics, Moscow, Russian Federation.

Gerstmann-Straussler-Scheinker disease is the rare autosomal-dominant disease with a prevalence of 1 in 10 million. We herein present a description of clinical and molecular-genetic characteristics of two unrelated probands with Gerstmann-Straussler-Scheinker syndrome in three generations.

Patient 1, a 35 years old man, complained at constrained muscles, change of speech, memory impairment. By 34 years dysarthria and memory impairment became evident. EEG showed moderate violation of bioelectric activity of a brain in the form of dysfunctions the diencephalic structures. MRI of a brain didn't show significant changes. Similar symptoms were observed in the proband's mother and brother, who died at the age of 37 and 38 years, respectively, 3 years after of the first symptoms. DNA - analysis identified the previously described mutation Ala117Val in the PRNP gene.

In Patient 2, a 43 years old women, the first symptoms of deasease noticed in 40 years when the severe ataxia revealed. In the neurologic status symptoms of static and dynamic cerebellar ataxy in combination with pyramidal symptoms were dominat. There was no expressed cognitive frustration, the patient complained only at reducing of memory on the current events. EEG and MRI of a brain didn't show significant changes. Similar symptoms were observed in the patient's mother and grandmother who died during 5 and 7 years, after the first symptoms were discovered. DNA- analysis identified the previously described mutation Pro102Leu in the PRNP gene.

These results confirm the opinion of many authors about so-called „telencephalic" type of disease at patients with a mutation Ala117Val in contrast to the „atactic" type observed at Pro102Leu mutation.

PM09.062

Genetic characteristics of hemiplegic migraine in Finnish migraine families

M. E. Hiekkala[1], *P. Vuola*[1,2], *E. Häppölä*[1], *E. Cuenca*[3,4], *S. Paavonen*[2], *V. Artto*[2], *M. Färkkilä*[2], *E. Hämäläinen*[5], *A. Palotie*[4,5,6], *M. Wessman*[1,5], *M. A. Kaunisto*[1,5], *M. Kallela*[2];
[1]*Institute of Genetics, Folkhälsan Research Center, Helsinki, Finland,* [2]*Department of Neurology, Helsinki University Central Hospital, Helsinki, Finland,* [3]*Wellcome Trust*

Sanger Institute, Wellcome Trust Genome Campus, Cambridge, United Kingdom, [4]Psychiatric and Neurodevelopmental Genetics Unit, Department of Psychiatry, Massachusetts General Hospital, Boston, MA, United States, [5]Institute for Molecular Medicine FIMM, University of Helsinki, Helsinki, Finland, [6]Department of Neurology, Massachusetts General Hospital, Boston, MA, United States.

Introduction: Hemiplegic migraine (HM) is a rare subtype of migraine with aura. Typical HM attacks are characterized by fully reversible motor weakness that is associated with visual, sensory or speech symptoms. Furthermore, attacks may occur with basilar-type symptoms, prolonged hemiplegia, confusion, coma, fever or seizures. To date several mutations have been identified for HM locating in three ion-transporter genes: *CACNA1A, ATP1A2* and *SCN1A*.

Materials and Methods: In order to study the involvement of the three HM genes in the Finnish HM patients we have exome sequenced (Agilent/Illumina: Sanger Institute) 303 patients from 252 families fulfilling the criteria for HM. The mean sequence depth of the target exome was 86. The minor allele frequencies of exonic variants were checked against The Exome Aggregation Consortium (ExAC) and 1000G project data. Validation and segregation analyses of all novel and rare exonic and splice site variants are ongoing.

Results: Exome sequencing analyses revealed 43 potentially functional, unknown, low or rare frequency variants in the three FHM genes. One of the identified variants was the well-known mutation - p.Thr666Met - in *CACNA1A*. The variant was found in one family segregating perfectly.

Conclusions: Most of the so far studied variants do not seem to segregate with the HM phenotype. Hence, after validation and segregation analyses we will study whether different variant composition including e.g. several less deleterious variants, could predispose to HM susceptibility. In addition, the exome data will be screened genome-wide to identify whether variants in other genes could contribute to HM.

PS09.063

Uniparental disomy causing hereditary spastic paraplegia: Paternal disomy in FA2H causing homozygous SPG35 in two non-consanguine families

T. W. Rattay[1,2], *A. S. Soehn[3], K. N. Karle[1,2], S. Wiethoff[1,2], J. Reichbauer[1], M. Döbler-Neumann[4], U. Gaiser[4], P. Bauer[3], S. Züchner[5], R. Schüle[1,2], L. Schöls[1,2];*
[1]Hertie-Institute and Center for Neurology, University of Tübingen, Tübingen, Germany, [2]German Center of Neurodegenerative Diseases (DZNE), Tübingen, Germany, [3]Institute of Medical Genetics and Applied Genomics, University Tübingen, Tübingen, Germany, [4]Department of Neuropediatrics, Tübingen University School of Medicine, Tübingen, Germany, [5]Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, United States.

Hereditary spastic paraplegias (HSPs) are degenerative diseases of upper motor neurons characterized by a progressive spastic gait disorder. They are genetically highly heterogenous. SPG35 is an autosomal-recessive (AR) HSP caused by mutations in the fatty acid 2-hydroxylase (FA2H), which is essential for maintenance of the neuronal myelin sheath. Thus far approx. 20 mutations have been described in 13 SPG35 families with 36 affected patients.

Genetic screening was performed by whole exome sequencing in patient #1 and by a HaloPlex assay providing high coverage of all known HSP genes ("HSP panel") in patient #2. MLPA was used to screen for FA2H deletions and microsatellite marker analysis by PCR to identify uniparental disomy (UPD).

We detected different novel homozygous FA2H mutations in two non-related non-consanguine families. Segregation analysis revealed both fathers being heterozygous mutation carriers whereas both mothers did not carry FA2H mutations. We presumed a maternal macro deletion within SPG35 to be causing a hemizygous genotype, but a MLPA assay failed to confirm our hypothesis. Finally, a microsatellite array revealed paternal disomy in both families leading to homozygous SPG35 mutations.

UPD has rare been described as causative mechanism in neurodegenerative diseases. This is the first report of UPD as a cause for HSP. Interestingly, we identified this rare mode of inheritance in two families with the rare genotype SPG35. We are not aware of any mechanism how SPG35 mutations may trigger UPD.

Since UPD seems to be a relevant factor in AR HSP we recommend segregation analysis especially in non-consanguine homozygous index cases to unravel further UPD cases in this field.

Spinocerebellar neurodegeneration results in a spectrum of clinically and genetically heterogeneous syndromes that frequently impose a diagnostic dilemma. Pure forms of hereditary spastic paraplegias (HSP) and hereditary ataxias (HA) represent both ends of the spectrum. Screening of 74 known spasticity culprit genes was performed on 51 patients from 21 extended Sudanese families with multiple consanguinity loops. Genetic diagnosis was established in 5 families with autosomal recessive complex spastic ataxia. SPG11 nonsense [exon 34: c.6349G>T / p.Glu2117*, exon 21: c.3568A>T / p.Lys1190*] and frameshift [exon 36: c.6709del / p.Ala2237Gln*7] mutations were identified in 3 families with HSP with atrophy of the corpus callosum. Two other families carried homozygous mutations in SACS gene [exon10: c.7739G>A / p.Trp2580*] and in SPG57/TFG gene [exon 2: c.64C>T / p.R22W].

The c.6709del SPG11 mutation was previously reported in one Somalian patient with spastic ataxia but with slightly different clinical presentation including the age at onset (2 years versus 10-17 years in Sudanese patients). All other 4 mutations were novel.

The family with TFG missense mutation (p.R22W/ PB1 highly conserved domain) is the second SPG57 family worldwide. It presented with motor rather than the visual impairment presentation of the first SPG57 Indian family (p.R106C / coiled-coil domain). The Sudanese SPG57 family had multiple MRI abnormalities (and uniquely hemorrhages in one patient) as seen in collagen disorders.

This study shows the great genetic heterogeneity of HSP in Sudan and demonstrates that more genes will come in the future to explain the nosology of these diseases.

PS09.065

TFG mutation hot spot causes varied hereditary spastic paraplegia phenotypes

G. V. Harlalka[1,2], *M. E. McEntagart[2], N. Gupta[3], B. Chioza[1], R. C. Trembath[4], M. A. Patton[1], A. Sreekantan-Nair[1], A. Pereira[5], H. Modarres[5], H. Moore-Barton[2], M. A. Simpson[4], M. Kabra[3], A. H. Crosby[1];*

Block, All India Institute of Medical Sciences, New Delhi, India, [4]Division of Genetics and Molecular Medicine, King's College London School of Medicine, Guy's Hospital, London, United Kingdom, [5]Department of Neurology, Atkinson Morley Wing, St. George's Hospital, London, United Kingdom.

The hereditary spastic paraplegias (HSPs) are a clinically and genetically heterogeneous group of degenerative motor neuron disorders in which the cardinal clinical feature is progressive lower limb spasticity. This feature may occur in isolation ('pure' HSP), or be accompanied by other neurological or non-neurological clinical features ('complicated' HSP). We investigated the genetic basis of disease in two unrelated families, one with pure HSP, and the second with a complicated HSP associated with optic atrophy and neuropathy. Genome-wide SNP mapping in both families identified a single notable region of homozygosity peculiar to affected family members on chromosome 3q12.2, indicating that the disease gene was likely located in this region in each family. Exome sequencing in an affected individual from the pure HSP family identified a homozygous missense mutation (p.Arg106His) within the *TFG* gene, located within the mapped region. Subsequent analysis of the *TFG* gene in the complicated HSP family revealed another sequence alteration, again affecting arginine 106, although this time resulting in its substitution with cysteine (p.Arg106Cys). Thus both sequence alterations result in the substitution of the highly conserved arginine 106 residue with two different amino acids with distinct chemical properties, indicating that the clinical severity of disease may relate to the differing chemical properties of the substituted amino acid. Taken together, our findings confirm a causative role of *TFG* mutation in HSP and identify residue arginine 106 of *TFG* as a mutation hotspot to be considered for diagnostic screening in both pure HSP as well as complicated forms of HSP. This research is supported by MRC grant G1002279.

Hereditary Spastic Paraplegias (HSPs) are a heterogeneous group of neurodegenerative disorders characterized by lower limb spasticity and weakness. Genetically, HSPs are complex with four modes of inheritance described and with >60 genes identified. Approximately 60% of the families persist without molecular diagnosis reinforcing their genetic heterogeneity.
In Portugal, a cohort of 98 families with spastic paraplegia remained without molecular diagnostic. In order to identify the disease-causing mutation in these families, 2 custom sequencing kits were developed to search for mutations in known genes, covering 34 and 74 genes, respectively, that included some genes causing a similar phenotype and some candidate and newly identified genes found by the SPATAX partners.
In these 98 families we identified the responsible gene in 22, resulting in a frequency of 22,5%. This low frequency could be explained by the fact that these families were the ones remaining after the exclusion of the most frequent HSP genes. Variants with unexpected inheritance modes and phenotypes were found in known genes. Our results show the importance of testing families with all modes of inheritance for the same set of genes and also, the importance of testing genes causing overlapping phenotypes.
These results suggest that there is still a large set of genes responsible by spastic paraplegia and probably more mechanisms leading to the disease to be uncovered.

PS09.067

Genetic testing for Huntington's Disease in consanguineous families

J. Campbell, *G. Karbani, S. Coulson, E. Hobson;*
Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

The Yorkshire Regional Genetics Service has contact with all patients who undergo predictive and diagnostic genetic testing for Huntington's Disease (HD) within the NHS in North, East and West Yorkshire, as well as some areas of Northern Lincolnshire. HD occurs in all ethnic groups, but is more prevalent in the European population.
Our local population includes a significant proportion of individuals of South Asian origin. Genetic counselling and genetic testing in families from this group present different challenges to those encountered in other populations. In a recent study of our Bradford population, 28% of babies were born to consanguineous parents (18% were born to parents who were first cousins). In consanguineous families there is a risk that individuals with HD may be homozygous for the disease-causing CAG expansion. Homozygous expansions do not significantly alter the clinical phenotype in HD, but if detected on genetic testing this would significantly affect the offspring risk (which would be 100% for developing HD rather than the 50% expected following autosomal dominant inheritance). A homozygous result would also confirm that both parents of the proband are at risk of HD, when perhaps only one parent is aware of their diagnosis.
We present examples of consanguineous families where at least one individual has been diagnosed with HD. We will discuss the genetic counselling issues raised, and the approach taken to the reporting of genetic testing in individuals at risk of being homozygous for an HD expansion.

PM09.068

Making a new diagnosis of Huntington's Disease; the experience of a UK regional genetics service.

H. E. Musgrave, *J. Campbell, E. Hobson;*
Yorkshire Regional Genetics Service, Leeds, United Kingdom.

The Yorkshire Regional Genetics Service has contact with all patients who undergo genetic testing for Huntington's Disease (HD) on an NHS basis in North, East and West Yorkshire, and parts of North Lincolnshire. This cohort includes patients, referred by neurologists or psychiatrists, in whom a diagnosis of HD is suspected on clinical grounds but who have no known family history of the condition.
We have reviewed the data of individuals tested over the last 10 years and noted an increase in the number of people diagnosed with HD in the absence of a known or assumed family history of the condition.
In our experience, these families present different counselling challenges to those encountered in families already known to be affected by HD. For example, adult children of a person diagnosed with HD in later life may perceive HD as a benign condition affecting only older people, even when genetic anticipation has been explained. When a new diagnosis is made in an older adult, not only has the tested individual completed their family, but often their own offspring are in the midst of child-bearing or have completed their families too. This can mean that decisions about predictive testing, reproductive choice, and disclosing information about the diagnosis may be faced over a shorter time period than in people who have grown up with the knowledge of their HD risk.
Here we present our data and discuss the challenges created by making a new diagnosis of HD in a family.

PS09.069

Association analysis of narcolepsy without cataplexy and idiopathic hypersomnia

T. Miyagawa[1], *S. Khor*[1], *H. Toyoda*[1], *H. Kojima*[2], *T. Futagami*[2], *M. Yamasaki*[1], *H. Saji*[2], *K. Mishima*[3], *Y. Honda*[4], *M. Honda*[5], *K. Tokunaga*[1];
[1]*Department of Human Genetics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,* [2]*HLA Foundation Laboratory, Kyoto, Japan,* [3]*Department of Psychophysiology, National Institute of Mental Health, National Center of Neurology and Psychiatry, Tokyo, Japan,* [4]*Japan Somnology Center, Neuropsychiatric Research Institute, Tokyo, Japan,* [5]*Sleep Disorders Project, Department of Psychiatry and Behavioral Sciences, Tokyo Metropolitan Institute of Medical Science, Tokyo, Japan.*

Narcolepsy without cataplexy (NA w/o CA) is a lifelong disorder characterized by excessive daytime sleepiness and REM sleep abnormalities, but does not exhibit cataplexy. Several studies have reported that NA w/o CA is associated with human leucocyte antigen *HLA-DQB1*06:02* similar to narcolepsy with cataplexy (NA-CA). The sample sizes of the studies were small because NA w/o CA is an infrequent condition. We have therefore formed a collaborative research group to promote the study. In this study, we examined *HLA-DQB1* in 146 Japanese patients with NA w/o CA and 1,418 controls. The frequency of *DQB1*06:02* in the patients was significantly higher than that in the controls (allele frequency: 16.8% vs. 7.6%, $P = 1.6\times10^{-7}$, OR = 2.40). After controlling for the effect of *DQB1*06:02*, distributions of *HLA-DQB1* alleles were compared between NA w/o CA and NA-CA to assess whether the genetic backgrounds of the two diseases have similarities. The distribution of *HLA-DQB1* alleles in *DQB1*06:02*-negative NA w/o CA was significantly different from that in NA-CA ($P = 8.4\times10^{-7}$). On the other hand, the patterns of the *HLA-DQB1* alleles were similar between *DQB1*06:02*-positive NA w/o CA and NA-CA. *HLA-DQB1* analysis was also performed in 171 Japanese patients with idiopathic hypersomnia (IHS). No significant associations were observed. The findings suggest that *DQB1*06:02*-positive NA w/o CA has an autoimmune pathogenesis in common with NA-CA, but *DQB1*06:02*-negative NA w/o CA and IHS might be unique from NA-CA. We also performed a genome-wide association study to identify genetic markers associated with *DQB1*06:02*-negative NA w/o CA and IHS. We will discuss the results of the study.

PM09.070

Exome sequencing identifies a novel SNX14 mutation and confirms a new syndrome with intellectual disability and cerebellar atrophy

A. Bertoli Avella[1], *M. Alfadhel*[2], *M. Weiss*[1], *D. Trujillano*[1], *R. Abou Jamra*[1], *A. Rolfs*[1,3];
[1]*CENTOGENE GA, Rostock, Germany,* [2]*Department of Pediatrics, King Saud bin Abdulaziz University for Health Sciences, King Abdulaziz Medical City Riyadh, Riyadh, Saudi Arabia,* [3]*Albrecht-Kossel-Institute for Neuroregeneration, Medical University Rostock, Rostock, Germany.*

Clinical exome sequencing has open possibilities for diagnosis of previously unrecognized genetic disorders. Here we describe a consanguineous family with two children presenting with global developmental delay and subtle dysmorphic features, accompanied by cerebellar atrophy and small vermix, originating from Saudi Arabia.
By whole exome sequencing and family analysis we identified a novel mutation in the SNX14 gene (c.2722C>T, p.Gln908*), which introduces a premature termination codon in exon 27 of the gene. This mutation is located in the PX associated domain C (PXC) of the SXN14 protein and will likely cause a loss of function or lead to nonsense mediated decay. This novel mutation was found in homozygosis in both affected children and the parents were confirmed to be heterozygote carriers. Two unaffected siblings were also heterozygote carriers of this mutation confirming co-segregation of the disease and the p.Gln908* mutation.
Recently, Thomas et al. described a new syndrome in three consanguineous families from Portuguese and Turkish descent in whom homozygous mutations were identified in the SXN14 gene. The mutations (partially) remove the

RGS, PX or PXC domains and were shown to lead to loss of function which is also the pathogenic mechanism suspected in our family. Our results confirm that homozygous mutations in the SNX14 gene cause a new syndrome with intellectual disability and cerebellar atrophy. Retrospective exome analysis of cases with this specific phenotype is recommended.

PS09.071

New genetic makers in young ischemic strokes

S. Redon[1,2], *S. Timsit*[1,2], *T. Ronzière*[3], *B. Guillon*[4], *C. Breuilly*[5], *C. Blanchard*[6], *V. Golfier*[7], *C. Vaduva*[7], *G. Taurin*[8], *M. Guillaume*[9], *S. Debiais*[10], *C. Bergot*[11], *C. Férec*[1,2];

Strokes are today one of the leading causes of mortality, as well as of subsequent serious long-term physical and mental morbidity, among patients in many different countries all over the world. Ischemic stroke (IS) is a complex genetic disorder caused by a combination of multiple genetic and environmental factors and incidence rates for IS increase exponentially with increasing age but 10-15% of patients are under 45 years of age. When atherosclerosis is the leading cause of strokes in the elderly, there are multiple etiologies in young (arterial,cardiac,genetic...) and nearly half of strokes is of unknown cause. The aim of our work is to search risk and genetic susceptibility factors contributing to the occurrence of IS in a french young population (300IS<40 years) compared with 300 young controls. First results show that hypertension, migraine, tobacco and drugs are significant risk factors for ischemic strokes in our young population (OR=35, 3.8, 4 and 2.8, respectively). Then, we tried to identify genomic susceptibility loci using array-CGH approach. Some copy number polymorphisms (CNP) observed, a deletion may be candidate for a protective role in IS. We also observe uncommon CNV, some of them being particularly reccurent in patients or already associated with strokes like ALOX5AP ou PRKCE. We also applied a candidate-gene approach on coagulation genes and a significant association was found for the C677T in the MTHFR gene (5,10-methyltetrahydrofolate) and young IS (OR=2.39, p=0.02 for TT genotype). In conclusion, this study confirmed the implication of environmental and genetic factors in ischemic strokes before 40 years and suggests new genetic risk factors for IS.

PM09.072

A comprehensive molecular diagnostic service for Joubert syndrome and related disorders

E. Packham[1], *J. Williams*[1], *M. Shanks*[1], *P. Clouston*[1], *H. Matten*[1], *A. Nemeth*[2], *J. Vogt*[3], *J. McGaughran*[4], *A. Seller*[1];
[1]*Oxford Medical Genetics Laboratories, Oxford, United Kingdom,* [2]*Clinical Genetics, Oxford, United Kingdom,* [3]*West Midlands Regional Clinical Genetics Service, Birmingham, United Kingdom,* [4]*Genetic Health Queensland, Brisbane, Australia.*

Joubert syndrome (JS) is an autosomal recessive ciliopathy characterised by the molar tooth sign on MRI, hypotonia and developmental delay with or without oculomotor apraxia and breathing abnormalities. Joubert syndrome and related disorders (JSRD) describes individuals with JS and additional clinical features including retinal dystrophy, renal disease, hepatic fibrosis and polydactyly. JSRDs are genetically heterogeneous with at least 27 causative genes described that encode proteins of the primary cilium or centrosome. Molecular diagnosis enables accurate prognosis and disease management based on known genotype-phenotype correlations; e.g. hepatic fibrosis (*TMEM67*) or nephronophthisis (*NPHP1, RPGRIP1L* and *CEP290*).
Our diagnostic service for JSRD has evolved from a targeted Sanger Sequencing and MLPA screen in 6 genes to a NGS approach using Agilent's Haloplex Targeted Enrichment system to capture all known JSRD genes. This capture system is very flexible; the initial NGS panel of 18 genes was increased to 21, and currently comprises 27 genes. Next generation sequencing is undertaken on Illumina's MiSeq platform.
Of the 100 patients that have undergone testing a molecular diagnosis has been made in 42%. Pathogenic mutations have been identified in the following genes: *AHI1*, *ARL13B*, *C5ORF42*, *CC2D2A*, *CEP290*, *INPP5E*, *NPHP1*, *OFD1*, *RPGRIP1L*, *TCTN1*, *TCTN2*, *TMEM231* and *TMEM67*.
A service update and a selection of interesting cases will be presented. These include a *TCTN2* single exon deletion identified using NGS coverage data, a Joubert patient with two *NPHP1* frameshift mutations and 2 cases that employed RNA analysis to support pathogenicity of *TMEM67* splice variants.

Wang*[2], *Y. Chen*[1], *C. Hsieh*[1], *S. Chou*[2], *Y. Liu*[1], *H. Chen*[1], *H. Chen*[1], *H. Liao*[1], *C. Wang*[1], *S. Chen*[1], *L. Lu*[1], *Y. Chen*[1];
[1]*Inst. of Biomedical Sciences, Taipei, Taiwan,* [2]*Chang Gung Memorial Hospital, Linkou Medical Center, and Chang Gung University College of Medicine, Taoyuan, Taiwan,* [3]*Chang Gung Memorial Hospital, Chiayi Branch, and Chang Gung University College of Medicine, Chiayi, Taiwan,* [4]*Chang Gung Memorial Hospital, Kaohsiung Medical Center, and Chang Gung University College of Medicine, Kaohsiung, Taiwan.*

Background: Ischemic stroke is a major cause of death and disability in the world. A major ischemic stroke subtype (large artery atherosclerosis [LAA]) has been suggested to have some genetic components in individuals of European ancestry. However, whether genetic predisposition to LAA varies by ethnicity remains unknown.
Methods and Materials: We sought to identify novel genetic variations that predispose individuals to large-vessel ischemic stroke by using a genome-wide association study (GWAS) in 444 individuals with LAA and 1,727 controls in a Han Chinese population residing in Taiwan. We replicated the study in an independent Han Chinese population comprising an additional 319 cases and 1,802 controls. We identified five SNPs, including rs2415317 (P = 3.10 × 10−8), rs934075 (P = 4.00 × 10−9), rs944289 (P = 3.57 × 10−8), rs2787417 (P = 1.76 × 10−8), and rs1952706 (P = 2.92 × 10−8), at one novel locus on chromosome 14q13.3 within PTCSC3 (encoding papillary thyroid carcinoma susceptibility candidate 3) that were associated with large-vessel ischemic stroke at genome-wide significance (P < 5 × 10−8).
Conclusions: The newly identified SNPs within PTCSC3 gene for LAA are not only found for the first time to reach genome-wide statistical significance but also locate in a risk locus correlated with papillary thyroid carcinoma (PTC), which strongly suggest the need of future studies on the association between LAA and PTC. Our findings provide insights into the genetic basis of large-vessel ischemic stroke and identify a novel pathway that might be applicable for future therapeutic intervention. Grant support: Academia Sinica Genomic Medicine Multicenter Study, Taiwan (40-05-GMM).

The hunt for genes in undetermined Leukodytrophies

I. Dorboz[1,2], *F. Renaldo*[1,3], *H. Fettah*[1,3], *J. Masliah-Planchon*[1,4], *D. Tonduti*[1,5], *E. Eleonore*[6], *S. Samaan*[4], *S. Kuzbari*[4], *M. Elmaleh*[7], *D. Rodriguez*[8], *O. Boespflug-Tanguy*[1,3];
[1]*INSERM, Paris, France,* [2]*European Leukodystrophy Association (ELA), Paris, France,* [3]*Robert Debré Hospital, Paris, France,* [4]*Genetic Department; Robert Debré Hospital, Paris, France,* [5]*University of Pavia, Pavia, Italy,* [6]*Department of Cytogenetic, Clermont-Ferrand, Clermont Ferrand, France,* [7]*Departement of Pediatric Radiology, Robert Debré Hospital, Paris, France,* [8]*Department of Neuropediatrics, Armand Trousseau Hospital, Paris, France.*

Leukodystrophies are a heterogeneous group of orphan genetic diseases that affect the white matter (WM) and its main component, the myelin. Despite the large number of mutations and disease-related genes identified, 60% of families remain without genetic marker. We performed Exome sequencing in 75 patients selected from consanguineous family, non-consanguineous family with more than one affected children and few sporadic cases with specific clinical presentation We identified disease-causing mutations in 56% of cases. Our cohort was subdivided in three groups 15% genes already known in leukodystrophies, 9% genes known in leukoencephalopathy with atypical clinical presentation and 32% potential candidate variants, functional analysis are currently performed. For the remaining 44% of cases the variants identified need further analysis. This study underlines the role of Exome sequencing in the diagnosis of leukodystrphies by resolving diagnostic confusion arising from atypical or incomplete presentations and identification of new disorders.

PS09.075

A novel mutation in *LGI1* gene found in a series of consecutive epileptic patients with auditory aura

F. Kesim[1], *S. Ugur Iseri*[1], *G. Altiokka Uzun*[2], *E. Yucesan*[1], *F. Tuncer*[1], *O. Ozdemir*[1], *N. Bebek*[2], *U. Ozbek*[1], *B. Baykal*[2];
[1]*Institute for Experimental Medicine, Istanbul, Turkey,* [2]*Istanbul University, Istanbul Faculty of Medicine, Department of Neurology, Clinical Neurophysiology Unit, Istanbul, Turkey.*

Introduction: Autosomal Dominant Lateral Temporal Epilepsy (ADLTE) is characterized by focal seizures with a typical involvement of auditory aura. Auditory symptoms occur during seizures that are produced by the primary or association auditory cortices within the lateral temporal lobe. The disease may onset both in juvenile and adult terms, where good management is usually accomplished through antiepileptic drug treatments. Mutations in

leucine-rich glioma-inactivated 1 (*LGI1)* gene have been implicated in ADTLE both in familial and sporadic forms.
Material and Methods: All coding exons of *LGI1* were screened for mutations in a cohort of 26 individuals affected with ADTLE. Physical and neurological examinations were performed and detailed information on family history was collected for all affected individuals.
Results: A heterozygous novel variant resulting in a missense change within the LRR (Leucine rich repeats) domain of LGI1 protein was detected in one individual with a negative family history for epilepsy. This variant was not present in his parents and two unaffected sisters suggesting a *de novo* change. The pathogenicity of our novel variant is supported by its evolutionary conservation, its absence in 289 control individuals and *in silico* protein prediction tools.
Conclusions: Identification of rare *LGI1* gene mutations in sporadic cases is especially important for genetic counseling, supporting diagnosis, therapeutic decisions and understanding the pathogenesis of the disease. Screening of *LGI1* in independent patient series is required in order to establish genotype-phenotype correlations that will assist relevant diagnostic testing.
This study supported by IU-BAP and TUBİTAK (Project numbers 26263 and 113S331.)

PM09.076

Is the *MACROD2* gene a potential risk factor for developing ASD?

A. Battaglia, *R. Igliozzi, G. Scarselli, F. Apicella, R. Milone, R. Tancredi;*
Stella Maris Clinical Research Institute for Child and Adolescent Neuropsychiatry, Pisa, Italy.

Autism spectrum disorders (ASDs) are common, affecting 1% of children in the US population with a 4:1 male to female ratio, and have a strong genetic basis; yet the cause of about 70-80% ASDs remains unknown. *MACROD2* gene, on chromosome 20p12.1, is one of the several genes previously associated with risk for autism (Anney et al., Hum Mol Genet 2010, 19: 4072-4092). We report on two brothers aged 8ys3m and 9ys6m, respectively meeting the DSM-5 clinical criteria for Autism Spectrum Disorder. Both were assessed on the ADI-R and the ADOS-2. Each child underwent a cognitive assessment by the Wechsler Intelligence Scales, depending on the age. Both had a low average total IQ, and did not show congenital malformations or minor anomalies. An array-CGH showed, in both, an interstitial deletion on the short arm of chromosome 20 (20p12.1), sizing 72 Kb, with paternal segregation. The deletion encompassed the *MACROD2* gene. This was associated in the younger brother with an interstitial duplication on 16q21, sizing 366 Kb, with paternal segregation, encompassing the *RPS15AP34* gene; and, in the older one, with an interstitial deletion on 7p21.2, sizing 135 Kb, with maternal segregation, encompassing no genes. The father reported significant impairments in verbal and non-verbal communication and social interactions with his peers during childhood and adolescence; associated with specific difficulties in mathematics.
Our observation seems to strengthen the role of the *MACROD2* gene as a potential risk factor for developing ASD.

PS09.077

Megalencephalic leukoencephalopathy with subcortical cysts (van der Knaap disease): study of two families

W. Manoubi[1], *A. Mili*[1], *A. Ayadi*[2], *A. Mlika*[3], *S. Sassi*[1], *A. M'sakni*[1], *I. Ben Charfeddine*[1], *A. Amara*[1], *I. Chatti*[1], *A. Gdissa*[1], *R. Ben Sghaier*[1], *D. Hmida*[1], *a. Saad*[1], *M. Gribaa*[1];
[1]*Laboratory of Human Cytogenetics, Molecular Genetics and Reproductive Biology Farhat Hached University, Sousse, Tunisia,* [2]*Department of Pediatrics,Tahar Sfar University Hospital, Mahdia, Tunisia,* [3]*Department of Pediatrics, Farhat Hached University Hospital, Sousse, Tunisia.*

Introduction: Megalencephalic leukoencephalopathy (MLC) with subcortical cysts is an infantile-onset inherited autosomal recessive disease. Patients typically show macrocephaly, motor abnormalities, seizures, and almost constant late-onset mild mental deterioration. Brain magnetic resonance imaging (MRI) reveals specific patterns in the anterior temporal and frontoparietal regions. The MLC1 gene is responsible of this disease. Mutations in this gene have been identified in families from different ethnic backgrounds.
Objective: In this context, we report two Tunisian families having children affected with MLC. Indirect genetic analyzes showed a transmission profile for the mutant MLC1 gene. Patients and methods: It is about two Tunisian consanguineous families. The first family shows a girl and a boy with macrocephaly, seizures, ataxia and MRI confirmation. The second family has four daughters; of which, one had clinical and radiological signs for MLC. Genotyping by analysis of four microsatellite markers surrounding or inside the MLC1 gene, helped to establish the haplotype of each individual and to follow the transmission of haplotype associated with the disease.
Results: the indirect study by genotyping revealed the presence of a homozygous haplotype associated with the disease among all affected children in the two families. Discussion and conclusion: The diagnosis of MLC is based on a combination of clinical and radiological features and requires a genetic confirmation. The indirect study by genotyping is important to show the type of haplotype transmission among patients. This is expected to be followed by sequencing of MLC1gene looking for variation. This MLC genetic study could be important for prenatal diagnosis and mental deterioration prevention by therapy development.

MicroRNA expression profiling of methamphetamine dependence in rat hippocampal tissue

M. Sim[1], *I. S. Parhar*[2], *T. Soga*[2], *P. Vijayapandi*[1], *Z. Mohamed*[1];
[1]*Department of Pharmacology, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia,* [2]*Brain Research Institute, School of Medicine and Health Sciences, Monash University, Sunway, Malaysia.*

Metamphetamine is a highly addictive psychostimulant that induces behavioral changes, the hippocampus being the part of the brain that plays the important role in these changes, especially in drug addiction. However, little is known about the underlying mechanisms of methamphetamine effects on global miRNA expression. The objective of this study was to determine the global miRNA profiling of the methamphetamine dependence from the rat hippocampal tissue and to identify the miRNAs which are associated with methamphetamine use and dependence. The study comprised of 18 male rats which were divided into 3 groups: continuous methamphetamine treatment (0.5,1,2,3,4,5,5.5mg/kg), single dose acute methamphetamine treatment (5.5mg/kg), and a control group. Addiction behavior was determined using Conditioned Place Preference task. The analysis of the miRNA profiling was performed using Affymetric microarray GeneChip® System. For behavior test, we found that the addiction behavior only occur with continuous treatment of methamphetamine, but not in acute treatment. Differential profiling of miRNAs indicated that 30 miRNAs were significantly up-regulated and 1 down-regulated when the acute treatment was given; 40 miRNAs were up-regulated and 1 down-regulated in the continuous methamphetamine treatment group. Comparing between acute treatment without addiction and the continuous treatment with addiction, 29 miRNAs were up-regulated with 1 down-regulated for addiction phenotype. The miRNAs were selected when there are more than 2 times fold changes, ANOVA test with $p<0.05$ and FDR test with $p>0.05$. Conclusion, our results suggest that dynamic changes occur in the expression of miRNAs, which may be associated with the methamphetamine use and dependence.

Molecular and clinical delineation of the 2p15-16.1 microdeletion syndrome and proposal of a new candidate gene for microcephaly

J. LEVY[1], *A. COUSSEMENT*[2], *C. DUPONT*[1], *F. GUIMIOT*[1], *C. BAUMANN*[1], *G. VIOT*[2], *Y. CAPRI*[1], *S. DRUNAT*[1], *C. LEROY*[1], *B. BENZACKEN*[1], *J. DUPONT*[2], *A. TABET*[1];
[1]*Genetic departement, Robert Debré hospital, AP-HP, Paris, France,* [2]*Cytogenetic unit, Cochin hospital, AP-HP, Paris, France.*

Interstitial 2p15-p16.1 microdeletion is a rare microdeletion syndrome previously reported in 14 patients. It is characterized by moderate to severe intellectual disability, autism spectrum disorder, microcephaly, short stature, dysmorphic features, structural brain anomalies and multiple congenital organs defects. It is considered a contiguous gene syndrome involving deletion of several genes. Deletions previously reported are variable in size (from 203 kb to 6.9 Mb) and have non recurrent breakpoints. We report here three additional patients carried a 2p15-p16.1 microdeletion shown by SNP-array analysis (Cyto12-SNP, Illumina) : a prenatal case and two postnatal cases. The prenatal and one of the postnatal cases share an overlapping 2p15p16.1 deletion of 105 kb including only XPO1 and the distal end of USP34. Both patients presented features overlapping the clinical spectrum of the 2p15p16 microdeletion syndrome including dysmorphic facial features and brain structural abnormalities. We confirm that one or both genes are probably involved in facial dysmorphic features, cognitive impairment and brain structural abnormalities observed in 2p15p16.1-deletion syndrome.
The third patient we reported on is a 4 years-old male with an heterozygous de novo a 427 kb deletion at 2p16.1 (chr2:60624940-61051867) containing BCL11A and PAPOLG and a phenotype characterized by speech delay, autistic traits and stereotyped behavior but without microcephaly.
Considering previous deletions in the 2p15p16.1 region and our three new cases, we precise the genotype-phenotype correlation of the microdeletion syndrome. Moreover we suggest that the REL gene could be considered as a candidate gene for microcephaly.

A new dominant form of microcephalic primordial dwarfism

V. El Ghouzzi[1,2], S. Drunat[1,3], P. Gressens[1,2], A. Verloes[1,2,3], **O. Boespflug**[1,2,3]*, S. Passemard[1,2,3];*
[1]Inserm, U1141, PROTECT, Paris, France, [2]Université Paris Diderot, Sorbonne Paris Cité, Paris, France, [3]AP-HP, Hôpital Robert Debré, Département de Génétique Clinique, Paris, France.

Primary microcephaly (PM) is a rare and heterogeneous group of affections characterized by a reduction in brain volume and intellectual disability. In some circumstances, PM is also associated with primordial dwarfisms (microcephalic primordial dwarfisms, such as Seckel, MOPD2 and Meyer Gorlin syndromes). Interestingly, all microcephalic primordial dwarfisms reported to date are recessively inherited and genes identified so far encode centrosomal proteins. However, they account for less than half of cases in Europe, indicating that other genes remain to be identified.
Here, we report on a new form of microcephalic primordial dwarfism with an autosomal dominant inheritance, in which no known PM gene was found to be mutated.
The father (25 years old) and his daughter (3 years old) shared common features in their medical history: Intrauterine growth retardation followed by postnatal growth failure (length -4 SD), microcephaly (-5 SD), and dysmorphic features including microretrognathia, hypotelorism, shortening of fore-arms and legs and muscular hypertrophy. In addition, the father had a micropenis, a hypoplasia of the scrotum and developed an early onset cataract at the age of 7. The daughter had a cleft palate, and feeding difficulties that needed nutritional support until the age of 2. Her cranial MRI showed isolated microcephaly.
This case report enlarges the frontiers of microcephalic primordial dwarfism to dominant forms that are likely linked to impairments of new specific PM genes.
This study was supported by PHRC (P100128) and ANR (ERARE2-2013).

A functional miR-124 binding-site polymorphism in IQGAP1 affects human cognitive performance

L. Yang[1], R. Zhang[1], M. Li[1], X. Wu[1], J. Wang[1], L. Huang[1], X. Shi[2], Q. Li[3], **B. Su**[1,4]*;*
[1]Kunming Institute of Zoology, Chinese Academy of Sciences, Kunming, China, [2]Department of Biochemistry, Qujing Normal University, Qujing, China, [3]College of Life Science, Liaoning Normal University, Dalian, China, [4]Yunnan Key Laboratory of Primate Biomedical Research, Kunming, China.

As a product of the unique evolution of the human brain, human cognitive performance is largely a collection of heritable traits. Rather surprisingly, to date there have been no reported cases to highlight genes that underwent adaptive evolution in humans and which carry polymorphisms that have a marked effect on cognitive performance. IQ motif containing GTPase activating protein 1 (IQGAP1), a scaffold protein, affects learning and memory in a dose-dependent manner. Its expression is regulated by miR-124 through the binding sites in the 3'UTR, where a SNP (rs1042538) exists in the core-binding motif. Here we showed that this SNP can influence the miR-target interaction both *in vitro* and *in vivo*. Individuals carrying the derived T alleles have higher IQGAP1 expression in the brain as compared to the ancestral A allele carriers. We observed a significant and male-specific association between rs1042538 and tactile performances in two independent cohorts. Males with the derived allele displayed higher tactual performances as compared to those with the ancestral allele. Furthermore, we found a highly diverged allele-frequency distribution of rs1042538 among world human populations, likely caused by natural selection and/or recent population expansion. These results suggest that current human populations still carry sequence variations that affect cognitive performances and that these genetic variants may likely have been subject to comparatively recent natural selection.

Variants in the NR3C2 gene as possible genetic predisposition for the development of multiple sclerosis

H. Verhelst[1], G. Mets[2], P. Verloo[1], M. D'Hooghe[3,4], A. Symons[3], G. Nagels[3,4], B. Menten[2], J. Debruyne[5], R. Van Coster[1], **O. M. Vanakker**[2]*;*
[1]Department of Paediatric Neurology, Ghent University Hospital, Ghent, Belgium, [2]Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, [3]National Multiple Sclerosis Center, Melsbroek, Belgium, [4]Department of Neurology, University Hospital, Center for Neurosciences, Vrije Universiteit Brussel, Brussels, Belgium, [5]Department of Neurology, Ghent University Hospital, Ghent, Belgium.

Multiple Sclerosis (MS) is an autoimmune disease of the central nervous system caused by a complex interaction between multiple genes and environmental factors. We report on the incidental observation of two variants in the NR3C2 gene, involved in type 1 pseudohypoaldosteronism (PHA), in young MS patients and investigated whether NR3C2 might be a susceptibility gene for MS and autoimmune disease.
Case 1 is a male 12 years-old MS patient harboring a 112-181 kb deletion in NR3C2. He had no symptoms of PHA but serial blood investigations confirmed a mild elevation of aldosterone. Segregation analysis revealed that his mother and maternal aunt, both of which developed autoimmune thyroiditis, carried the same microdeletion.
Case 2 is the mother of a child with PHA. She presented at age 28 with MS and was known to carry the same NR3C2 splice-site mutation (c.1757+1G>C) as her daughter. The mother had elevated aldosterone levels.
In an independent cohort of 100 MS probands, NR3C2 sequencing detected a loss-of-function mutation (p.Ser585X) in a single patient with early-onset MS and a positive familial history. She had no symptoms of PHA but a mild reproducible elevation of aldosterone.
Our data suggest that NR3C2 loss-of-function variants may associate with a predisposition for developing autoimmune disease, particularly for MS. Though further validation of our findings in a larger cohort is necessary, the involvement of the renin-angiotensin-aldosterone system in the pathogenesis of MS may have important implications in counseling and management of patients with NR3C2 mutations and opens novel perspectives for MS treatment.

PS09.083

Increased first exon usage of THEMIS in resting CD4+ T-cells is associated with a genotype that is protective against the development of multiple sclerosis

J. Davies, *M. Ban, H. Kaur Sandhu, S. Thompson, S. Sawcer, A. Coles, J. Jones;*
University of Cambridge, Cambridge, United Kingdom.

Genome wide association studies and subsequent fine mapping have identified a number of loci containing genetic variants associated with susceptibility to multiple sclerosis (MS), including the THEMIS/PTPRK locus on chromosome 6q. At this locus, associated SNPs are predominantly intergenic, suggesting that they may have a role in the regulation of gene expression. Both THEMIS and PTPRK are indispensable for the thymic production of CD4+ T cells, a process known to be defective in MS. The aim of this study was to investigate the functional mechanisms underlying SNP rs13204742, identified in the fine mapping Immunochip study as being the most significantly associated SNP at the THEMIS/PTPRK locus.
PBMCs were isolated from 73 genotyped, healthy individuals, obtaining near-equivalent numbers from each genotype at SNP rs13204742. The biological significance of this variant was investigated by studying genotypic effects on both total and isoform-specific expression of THEMIS, PTPRK and RP11-103C16.2 (an antisense gene to PTPRK), in ex vivo and stimulated CD4+ and CD8+ T-cells by quantitative PCR. Genotypic effects on thymic activity were determined by measuring sjTRECs and circulating CD4+ recent thymic emigrants (CD4+CD45RA+CCR7+CD31+ T-cells).
In ex vivo CD4+ T-cells, there was a significant decrease in THEMIS first exon usage with an increasing genetic load of the risk allele at SNP rs13204742 ($p=0.0055$, ANOVA). This difference was absent upon T-cell stimulation. Alternative first exon usage is a mode of regulating gene expression in a cell specific manner. Therefore our findings suggest that SNP rs13204742 may influence the risk of developing MS by affecting CD4+ T-cell specific THEMIS expression.

Results of targeted NGS strategy for the diagnosis of NBIA in a cohort of 71 patients

S. Moutton[1,2]*, P. Macquere[1], N. Houcinat[1], A. De Pindray[1], C. Plaisant[1], J. Deforges[1], D. Lacombe[1,2], B. Arveiler[1,2], C. Goizet[1,2], P. Fergelot[1,2];*
[1]Service de génétique médicale - CHU de Bordeaux, Bordeaux, France, [2]Laboratoire MRGM: Maladies Rares, Génétique et Métabolisme, Université de Bordeaux, Bordeaux, France.

In the expanding field of neurodegeneration with brain iron accumulation (NBIA), the development of sensitive brain imaging played a major role to characterize iron-related damages in patients. In the past years, new genes have been identified allowing genotype-phenotype correlations. However, overlapping phenotypes and non-informative pedigrees are still sources of delayed diagnosis.
For these reasons, a Next Generation Sequencing analysis was developed and tested in our series of 71 patients, comprising 32 patients in addition to the 39 patients previously analysed for FTL and PANK2 mutations by Sanger sequencing, including 3 FTL and 2 PANK2 diagnosed patients. Seven additional NBIA genes (ATP13A2, CP, C19orf12, DCAF17; FA2H, PLA2G6

and WDR45) were included in a custom panel of 35 genes dedicated to our routine molecular diagnosis platform. Two libraries of amplicons were designed with the AmpliSeqTM technology. Sequencing was performed on a PGM. The Torrent Suite (Life Technologies), SeqNext (JSI) and AlamutTM interface (Interactive Biosoftware) were used for read alignment, variant calling and interpretation respectively. Workflow analysis was validated on FTL and PANK2 positive patients. Recurrent artefacts were not considered. In silico, AmpliSeq design covered 99% of NBIA genes targeted regions, of which 98% were sequenced at least 40X. Uncovered regions were sequenced using Sanger technology.
Among the 32 additional patients, 1 CP and 1 PANK2 patients were diagnosed.
NGS is a powerful and cost-effective tool to search for mutations in heterogeneous genetic disorders but analysis effectiveness of known genes still remains disappointing in NBIA (10% molecular diagnosis, n=7/71).

PM09.086

Neurodegeneration with iron accumulation in brain (NBIA): Clinical assessment and genetic characterization by a means of a Spanish multi-center research network

C. Espinos[1,2], *V. Lupo*[1,2], *C. Tello*[1], *A. Darling*[3,4], *M. Serrano*[3,4], *A. Decio*[5], *S. Aguilera*[6], *I. Gastón-Zubimendi*[6], *M. Tomás-Vila*[7], *M. Madruga*[8], *M. Pujol*[9], *D. Quadras*[10], *A. López*[11], *M. Martí*[12], *L. Martorell*[3], *B. Pérez-Dueñas*[3,4];

Neurodegeneration with brain iron accumulation (NBIA) is due to several genetic defects causing movement disorders and brain iron deposition in children, PKAN (pantothenate kinase associated neurodegeneration) being the most common one. Despite advances in the research of novel therapies for PKAN, validated international disease rating scales (DRS) to be used in clinical trials are lacking. We aim to identify and genetically characterize the Spanish population with NBIA and to design and validate a quantitative method for clinical assessment of PKAN patients within a cross-sectional multi-center project.
To date 43 NBIA patients from 20 Spanish hospitals have been recruited and assessed according to a new DRS for PKAN (PKAN-DRS) and genetic testing of the most frequent genes (PANK2, PLA2G6 and C19orf12) involved in NBIAs have been performed. Twenty-three patients have been diagnosed as PKAN and 11 patients carry mutations in the PLA2G6 gene. Moreover, 13 PKAN patients (median age 33 years) have been evaluated according to the PKAN-DRS (range 29-71). It is striking that the six Gypsy patients included in this research harbor the PANK2 p.T528 mutation in homozygosis which suggest a founder effect in our population, and present with lower PKAN-DRS scores for all subscales when compared with the group of patients with other mutations.
This cross-sectional multi-center has helped us to improve the diagnosis of NBIA patients. The proposal of a PKAN-DRS seems to be a reliable method mainly targeted to the evaluation of the neurological symptoms associated to PKAN.
Funds: Fundación La Marató de TV3.

Neurodegeneration with Brain Iron Accumulation (NBIA): insights from gene coexpression networks

C. Bettencourt[1], *S. Wiethoff*[1], *P. Forabosco*[2], *J. Botia*[3], *U. UK Brain Expression Consortium*[4], *J. Hardy*[1], *H. Houlden*[1], **M. Ryten**[5,1];
[1]*UCL Institute of Neurology, London, United Kingdom,* [2]*Istituto di Ricerca Genetica e Biomedica, Cittadella Universitaria di Cagliari, Monserrato, Italy,* [3]*King's College London, London, United Kingdom,* [4]*UCL Institute of Neurology/ King's College London, London, United Kingdom,* [5]*Guy's Hospital, London, United Kingdom.*

Neurodegeneration with brain iron accumulation (NBIA) constitutes a group of neurodegenerative diseases characterized by a prominent extrapyramidal movement disorder, intellectual deterioration and a characteristic iron deposition in the basal ganglia. Ten genes have been identified so far, but limited information exists regarding expression and function of these genes within the human brain. To address possible relationships between known NBIA genes, predict their functions, and identify overlapping pathways, we used a systems-biology approach based on whole transcriptome gene expression analysis. As part of the UK Human Brain Expression Consortium (UKBEC), we analysed the expression profiles of 101 neuropathologically normal individuals (10 distinct brain regions each). Weighted gene co-expression network analysis (WGCNA) was used to cluster genes into co-expression modules. The overrepresentation of NBIA transcripts in basal ganglia modules (substantia nigra and putamen hereby studied) was assessed. Six NBIA-containing modules were found for the substantia nigra, but none was significantly overrepresented. Two putamen modules were significantly enriched for NBIA transcripts, namely the brown (PANK2, ATP13A2, C19orf12, COASY; P= 0.003) and green (FTL, DCAF17, FA2H; P= 0.021) modules. Enrichment analysis of these two putamen modules revealed an overrepresentation of gene ontology terms and KEGG pathways, including: brown module - synaptic vesicle endocytosis and axon cargo transport (biological processes), synaptic membrane (cellular component), and synaptic vesicle cycle KEGG pathway; green module - ensheathment of neurons, neuronal action potential and oligodendrocyte development (biological processes), myelin sheath (cellular component), and cadherin binding (molecular function). Our data suggests shared processes and pathways in NBIA gene networks.

PM09.088

Neurodegeneration and Brain Iron Accumulation: Clinical and genetic heterogeneity in the Hungarian population

R. Bencsik[1], *Z. Grosz*[1], *P. Balicza*[1], *A. Gal*[1], *V. Harsfalvi*[1], *G. Tamas*[2], *P. Ács*[3], *P. Klivenyi*[4], *B. Kalman*[5], *J. Molnar*[1];
[1]*Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary,* [2]*Department of Neurology, Semmelweis University, Budapest, Hungary,* [3]*Department of Neurology, University of Pécs, Pécs, Hungary,* [4]*Department of Neurology, University of Szeged, Szeged, Hungary,* [5]*Markusovszky County Hospital, Szombathely, Hungary.*

Neurodegeneration with Brain Iron Accumulation (NBIA) comprises a group of disorders characterized by progressive motor symptoms and cognitive decline. The genetic background of NBIA is heterogeneous. Not only the number of genes associated to the disease is increasing continuously, but the variety of the presenting clinical is increasing too.
Aim: The identification of the phenotype and genotype correlation of Hungarian NBIA patients in order to understand the dysfunction of proteins which are associated with NBIA and to collect genetic epidemiology data of the Hungarian NBIA patients.
Patients and Methods: We examined 20 patients having different extrapyramidal signs and cerebral brain iron accumulation confirmed by MRI (9 male, 11 female, mean age 35.1 years). The entire coding regions of the genes *PANK2, PLA2G6, MPAN* and *CP* were sequenced with Sanger method in the patients and in their family members.
Results: Pathogenic *MPAN* gene mutations were verified in 6, *PLA2G6* gene mutations in 3, *PANK2* gene mutations in 5, *CP* gene mutation in 3 patients. The NBIA syndromes were characterized by remarkable clinical heterogeneity. The clinical symptoms varied from the mild Parkinsonism over the isolated torticollis to severe dystonia.
Conclusion: In the Hungarian population the mutations of *MPAN* gene are more frequent compared to other populations. The symptoms caused by particular mutations of the single genes are not specific, although the extrapyramidal motor dysfunction with various degrees was observed in almost all cases. Both biallelic and heterozygous dominant mutations of the MPAN gene may result in clinical symptoms.

PS09.089

Diagnostic yield of next generation sequencing in neurodegenerative diseases

R. van Minkelen, *M. Wilke, D. J. J. Halley, J. N. R. Kromosoeto, R. van de Graaf, G. M. Bolman, M. van Tienhoven, P. Elfferich, W. G. de Valk, A. M. W. van den Ouweland, G. M. S. Mancini-Verheijen, A. J. A. Kievit;*
Department of Clinical Genetics, Erasmus MC, Rotterdam, Netherlands.

Neurodegenerative diseases are hereditary or sporadic disorders which are characterized by progressive nervous system dysfunction (e.g. dementias, Parkinson, Amyotrophic Lateral Sclerosis). Molecular diagnostics by Sanger sequencing is limited to testing common genes (e.g. *PARK2* for Parkinson) (there are too many rare genes to offer by Sanger testing). Therefore we developed a Next-Generation Sequencing (NGS) based workflow for DNA diagnostics for several neurodegenerative diseases (Ataxia: 49 genes; Dementia: 44 genes; Neurodegeneration with brain iron accumulation: 10 genes; Parkinson: 43 genes; Paroxysmal dyskinesia: 5 genes). This workflow was based on enrichment arrays (Agilent Sure Select) for all 151 genes and Miseq sequencing (paired-end, 150bp, Illumina). BAM-files are generated with an in-house analysis pipeline and variant calling is performed using SeqNext (JSI). The average vertical coverage for exons is ~300, very few fragments fail to reach the minimal required vertical coverage of 30. We were able to

detect deletions up to 65bp, insertions up to 29bp and somatic mosaicism. Sanger-sequencing was used to confirm the identified variants. Additionally, MLPA and repeat expansions tests were performed. We consider 12% of the cases solved (e.g. pathogenic PLA2G6 mutation and PLA2G6 exon 5-8 duplication). In 52% of the individuals an "unclassified variant" was found. Despite the use of in silico prediction programs, classification is difficult without additional clinical information, further patient/family studies and functional tests. In conclusion, the NGS-panels for neurodegenerative diseases are a powerful approach for DNA diagnostics. In order to increase the diagnostic yield, close collaboration between laboratory, clinical geneticist and referring specialist is required.

PM09.090

Estimating risk for neurofibromatosis type 1 among individuals with isolated café au lait spots

S. Ben-Shachar[1], *T. Dubov*[2], *H. Toledano-Alhadef*[3], *S. Constantini*[4], *L. M. Messiaen*[5];
[1]The Genetic Institute, The Gilbert Israeli Neurofibromatosis center, affiliated to Sackler Faculty of Medicine, Tel Aviv university, Tel Aviv, Israel, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]TheThe Gilbert Israeli Neurofibromatosis center, The Pediatric Neurology Unit and Child Development center, affiliated to Sackler Faculty of Medicine, Tel Aviv university, Tel Aviv, Israel, [4]The Gilbert Israeli Neurofibromatosis center, Pediatric Neurosurgery Department, affiliated to Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [5]Medical Genomics Laboratory (MGL), Department of Genetics, University of Alabama, Birmingham, AL, United States.

Background: Neurofibromatosis type 1 (NF1) is caused by heterozygous mutations in the *NF1* gene. Isolated café-au-lait spots (CALS) are usually the first sign of NF1. However, not all individuals with isolated CALS will eventually be diagnosed with NF1. We aimed to estimate NF1 risk among individuals with isolated CALS.
Methods:Individuals with isolated CALS undergoing follow-up till age >6 years in a specialized NF center were included. NF1 status was determined based on mutation detection in blood and/or meeting the NIH disease criteria.
Results: Of 74 individuals with isolated CALS followed up in specialized NF center, 17 (23%) were eventually diagnosed with NF1. None had <6 CALS or atypical CALS at initial visit, as opposed to 67% and 33% respectively, amongst individuals without established diagnosis (P<0.001). Older paternal age (>40 years) was associated with NF1, while younger age (<30 years) was associated with non-NF1 (P<0.05). Genetic analysis performed in blood of children with isolated CALS at the MGL revealed disease causing mutations in 168/421 (40%). Among them, only 4.1% had <6 CALS compared with 28% among these without mutations (P<0.001). Mean age at testing was much younger among these with detected mutations: 1.47 years compared to 6.3 years for mutation negative patients (P<0.001). In addition, reported atypical CALS by referring physician was 6 times more common among these with detected mutations.
Conclusions: Estimation of risk for NF1 may be refined for individuals with isolated CALS based on clinical parameters
thus, may help with earlier management and follow up.

PS09.091

Whole genome sequencing and brain imaging of extreme phenotypes of Neuroticism in Korean women

H. KIM[1], *H. Kang*[2], *S. Kim*[1], *Y. Chang*[3], *S. Ryu*[3], *H. Shin*[3], *D. Lee*[2], *H. Kim*[1];

Neuroticism is a personality trait that has been associated with several psychiatric disorders, and considered one of the risk factors for developing major depression and anxiety disorders. It is a multifactorial trait influenced by the interaction between environmental and genetic factors. The aim of this study is to identify genetic variants contributing to Neuroticism using next-generation sequencing (NGS) technology, and associations between the genetic variants and variations of brain structure. We used an extreme phenotype study design to discover genetic variants and variations of brain structure for Neuroticism. We performed a whole genome sequencing and structural MRI of brain in 10 participants with two extreme of Neuroticism. Highly neurotic individuals showed decreased-volumes in the right dorsal premotor cortex and the left inferior frontal cortex comparing to lowly neurotic individuals. Whole genome analysis is in progress. We are going to link genomics with neuroscience to find individual differences in Neuroticism traits.
This research was supported by the National Research Foundation of Korea, funded by the Ministry of Education (NRF-2013R1A1A2062702 and NRF-2014R1A2A2A04006291).

Rare inherited diseases often show complicated phenotypes and thus impose a relevant medical challenge. In Middle Eastern societies consanguinity is a deeply rooted cultural trait. This predisposes these societies for the occurrence of rare diseases with recessive traits. This study is an ongoing collaboration between physicians and scientists from Israel, the Palestinian Authority, and Germany aiming to investigate the molecular background of rare inherited diseases.
Patients were selected for inherited forms of neurological or ophthalmological disorders in 79 consanguineous families. Homozygosity mapping was performed using Agilent 250 K SNP arrays when applicable. Whole exon sequencing (WES) was done mainly using Agilents Sure Select All Exon V5 enrichment on an Illumina HiSeq2500 sequencer. Data analysis was accomplished using an in house bioinformatics pipeline.
Exome sequencing results in a large number of variants (>25.000), filtering for rare variants (Inhouse NGS database; 1000g; ESP6500) and for functional relevance reduced this count to <1.200. Due to the consanguineous background of the families, this amount could be further reduced comparing against mapping data or focusing on homozygous variants. An evaluation of the WES performance showed high coverage (~80% cov 20X) and target enrichment (~80X depth on target) parameters. Several disease causing mutations could be identified resolving the molecular background in 23 (~29%) families. For 16 families (~20%) promising candidate genes are under investigation.
WES offers an affordable and fast possibility to screen patients for disease causing variants. A consanguineous family background allows the discovery of mutations for neurodegenerative diseases in a high proportion of the patients.

The contribution of Niemann-Pick SMPD1 mutations to Parkinson disease in Ashkenazi Jews

E. Dagan[1], *I. Schlesinger*[2,3], *M. Ayoub*[4], *A. Mory*[4], *M. Nassar*[2], *J. Peretz-Aharon*[2,3], *R. Gershoni-Baruch*[4,3];
[1]Department of Nursing, University of Haifa, Haifa, Israel, [2]Department of Neurology and the Cognitive Neurology Institute, Rambam Health Care Campus, Haifa, Israel, [3]The Ruth and Bruce Rappaport Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel, [4]Institute of Human Genetics, Rambam Health Care Campus, Haifa, Israel.

Objective: To evaluate the prevalence of Ashkenazi three founder mutations in the sphingomyelin phosphodiesterase 1 (SMPD1) gene in Ashkenazi patients diagnosed with Parkinson's disease (PD); and their impact on PD phenotypic expression. Mutations in SMPD1 cause Niemann-Pick disease.
Methods: A case (n=287) control (n=400) study was undertaken following Institutional Review Board approval at Rambam Health Care Campus. All patients underwent physical, neurobehavioral, and neurologic examinations that incorporated the Unified Parkinson's Disease Rating Scale. Genetic testing for the three Ashkenazi mutations in SMPD1 gene was undertaken. The contribution of SMPD1 mutations to Parkinsons' clinical characteristics was studied on its own and elaborated subject to the presence of Ashkenazi founder mutations in the glucocerbrosidase (GBA) and the leucine-rich repeat kinase 2 (LRRK2) genes, both known to be associated with PD.
Results: Nine (3.1%) PD patients compared to two (0.5%) individuals from the control group were found to carry one of the three Ashkenazi SMPD1 founder mutations (c.996delC (fsP330), p.L302P and p.R496L) (p=0.007). The overall clinical characteristics of PD patients carrying SMPD1 mutations were similar to those of PD patients with no mutations in either of SMPD1, GBA and LRRK2 (n=189).
Conclusion: We maintain that disruptive mutations in SMPD1 constitute a risk factor for PD.

PM09.094

Molecular Analysis of Saudi Patients with Parkinson's Disease

B. R. Mubarak[1], *S. Boholega*[1], *T. Alkhairallah*[1], *A. Magrashi*[1], *E. Naim*[1,2], *B. Al Younes*[1,2], *M. AlTurki*[1], *B. AlTawil*[1], *H. Abou Al-Shaar*[1], *M. ElKalioby*[1,2], *A. Tahir*[1], *M. Abouelhoda*[1,2], *D. Monies*[1,2], *N. Al Tassan*[1,2];
[1]*King Faisal specialist hospital and Research center, Riyadh, Saudi Arabia,* [2]*King Abdulaziz City for Science and Technology, Riyadh, Saudi Arabia.*

During the past two decades, a significant research effort was focused on dissecting the genetic architecture of complex neurodegenerative disorders including Parkinson's disease (PD). Linkage analysis and next-generation sequencing, facilitated identification of disease-causing mutations in more than six genes, while genome-wide association studies revealed several genetic susceptibility factors. Research into the genetics of PD was mainly conducted on American, European and Asian populations, whereas such research in Arab populations (excluding North African Arabs), specifically in Saudis, is lacking. This study aims to explore the genetic causes of PD in Saudis. A total of 85 PD-cases (sporadic and familial) were recruited and screened for potential pathogenic mutations in PD-established genes; *SNCA*, *PARKIN*, *PINK1*, *DJ-1*, *LRRK2* and other PD-associated genes; *UCHL1*, *GIGYF2*, *FBXO7*, *VPS35* using direct sequencing. Surprisingly, among the 105 variants detected, only a single potentially pathogenic mutation was identified in *PINK1* in two affected siblings. This is intriguing, as recessive monogenic-causes of the disease are anticipated to account for a significant portion of familial cases, given the consanguineous nature of the Saudi population and the high percentage (40%) of familial cases reported here. However, absence of potential pathogenic mutations in the ORF of the screened genes by no means exclude the possibility of gene expression/dosage alteration nor does it eliminate the possibility of the involvement of novel genes. We therefore, performed whole-exome sequencing on a subset of patients' samples. The analysis revealed a number of novel high priority candidate genes harboring potential pathogenic mutations, currently undergoing further validation.

Genetic mutations in early-onset Parkinson's disease in Hungarian patients

A. Illés[1], *A. Kékesi*[1], *P. Balicza*[1], *A. Gál*[1], *B. Bereznai*[1], *A. Takáts*[2], *P. Klivényi*[3], *G. Dibó*[3], *E. Hidasi*[4], *I. Balogh*[5], *M. J. Molnár*[1];
[1]*Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary,* [2]*Department of Neurology, Semmelweis University, Budapest, Hungary,* [3]*Department of Neurology, University of Szeged, Szeged, Hungary,* [4]*Department of Neurology, University of Debrecen, Debrecen, Hungary,* [5]*Department of Laboratory Medicine, Medical and Health Science Center, University of Debrecen, Debrecen, Hungary.*

Background: Mutations and copy number changes in *PARK2*, *PINK1*, and *DJ*-1 have been associated with autosomal recessive, *LRRK2* with autosomal dominant early-onset Parkinson's disease.
Aims: The estimation of the frequency of *PARK2*, *PINK1* and *LRRK2* mutations in Hungarian patients with early-onset Parkinson's disease.
Patients and methods: 140 Hungarian patients with early-onset Parkinson's disease were analyzed (men:women rate is 1:1, average age is 54). The complete sequences of *PARK2* and *PINK1* genes and the hot spots (28% of the coding regions) of the *LRRK2* gene were directly sequenced by Sanger method. Exon dosage was determined in the *PARK2* and *PINK1* genes by multiplex ligation-dependent probe amplification. The most common *LRRK2* mutation (S1647T) has been excluded by PCR-RFLP method.
Results: The presence of Q34R and R275W mutations in heterozygous genotype were found in 2 unrelated patients in the *PARK2* gene. The I803T mutation was found in heterozygous genotype in 1 patient in *LRRK2* gene. The common *LRRK* G2019S mutation was not present in the Hungarian patients, but a modifying factor (S1647T) was present in homozygous genotype in 11 patients. In the *PINK1* gene no pathogenic mutation was detected.
Conclusion: The prevalence of heterozygous mutations in *PARK2* observed in our cases support the concept that single heterozygous mutations in recessive Parkinson's disease genes may play a pathogenic role in the Hungarian patients as well. The analysis of the prevalence of the mutation frequencies of different genes associated to early onset Parkinson disease have important implications for genetic counseling of Hungarian patients with Parkinson's disease.

Algorithms of MPS data evaluation in patients with Parkinsonism from genetically isolated population

R. Vodicka, *R. Vrtel, P. Kanovsky, M. Godava, K. Mensikova, M. Kaiserova, P. Otruba, E. Krejcirikova, J. Böhmova, H. Filipova, R. Kratochvilova;*
University Hospital and Palacky University Olomouc, Olomouc, Czech Republic.

Introduction:
Parkinson's disease (PD) can be caused by genetic changes in many genes. The effect of these changes is determined by the nature of the mutation and ranges from weak associations to pathogenic mutation which leads to loss of protein function. Our study is based on epidemiological data which show significantly increased prevalence of PD (2.9%) in an isolated population of South-Eastern Moravia in the Czech Republic.
Objective:
Using MPS technology to compare our findings in DNA from 28 PD patients in the genes responsible for Parkinsonism (ADH1C, ATP13A3, EIF4G1, FBXO7, GBA + GBAP1, GIGYF2, HTRA2, LRRK2, MAPT, PARK2, PARK7, PINK1, PLA2G6, SNCA, UCHL1 and VPS35) to:
1) Already been described pathogenic mutations
2) Twelve control DNA samples from isolated population
Method of data assessment:
MPS data processing and trimming from FASTAQ through BAM to VCF files was done parallel by Ion Reporter and NexGene software.
Variants were than filtered using following parameters: AQ>20; Read coverage >20; MAF<0,002; SIFT: 0 - 0,1; PolyPhen: 0,15 -1; Grantham 6-215
Results:
After filtering out, there were found three missense mutations in LRRK2 gene: rs33995883 in 6/1 patient/control (p/c), rs33958906 in 1/1p/c, undescribed p.Ser633Phe in 3/0p/c, one missense mutation in MAPT gene rs63750072 in 6/1p/c and one mutation in HTRA2 rs72470545 in 3/1p/c.
Conclusion:
Our findings together with detailed clinical characteristics of patients could contribute to further understanding of PD molecular pathogenesis and to creating a clinically applicable diagnostic procedure.

The PCSK6 intronic region associated with handedness controls expression of a novel shorter isoform

R. J. Shore[1], *K. Pettigrew*[1], *R. Diaz*[1], *Y. Xu*[1], *E. Wootton*[1], *L. Covill*[2], *W. Brandler*[2], *J. B. Talcott*[3], *D. F. Newbury*[2], *A. Monaco*[2], *J. Stein*[4], *S. Paracchini*[1];

We recently reported the first gene, PCSK6, associated with handedness at genome-wide significance level (P< 0.5*10-8, Brandler et al. 2013). A Variable Number Tandem Repeat (VNTR) within the same PCSK6 locus has been found to be associated with degree of handedness in an independent study (Arning et al. 2013). Interestingly, PCSK6 is known to activate NODAL, a morphogen involved in a highly conserved pathway known to regulate left/right body axis determination. Our previous data suggest these pathways controlling development of LR asymmetry in the body are reused for brain midline development, which in turn influence functional asymmetries such as handedness (Brandler and Paracchini 2014). All previous most significant associations fall within a linkage disequilibrium (LD) block containing a secondary promoter our data show to be bidirectional in nature and controlling transcription of both a novel PCSK6 isoform and a long non-coding antisense RNA. Taking forward previous GWAS findings, we have conducted a detailed functional analysis using a combination of further genetic analysis, in-silico predictions, and molecular assays. Our functional studies support an allele-specific effect on transcription factor binding affinity for a previous top-associated SNP rs11855425 however our genetic data could not find any evidence supporting a VNTR role. With this study we have dissected the molecular mechanisms underlying the PCSK6 association with handedness, indicating the regulatory effect the region has on specific RNA isoforms. Future work will focus on understanding the function of the novel shorter PCSK6 isoform and confirming the identity and role of the transcription factors binding at the secondary promoter.Neurodys018696, WT090532/Z/09/Z, MRCG090074791070, G1000569/1 and MR/J003719/1.

Finland, University of Helsinki, Helsinki, Finland, [5]Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland, [6]Department of Clinical Genetics, Helsinki University Hospital, Helsinki, Finland, [7]Norio Centre, Rinnekoti Foundation, Helsinki, Helsinki, Finland, [8]Program in Medical and Population Genetics, Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, MA, United States, [9]Analytic and Translational Genetics Unit, Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States.

PEHO syndrome (Progressive encephalopathy with Edema, Hypsarrhythmia and Optic atrophy; MIM 260565) is an autosomal recessive inherited progressive infantile encephalopathy. The main features of PEHO syndrome are hypotonia, infantile spasms and hypsarrhythmia, psychomotor retardation, absence or early loss of visual fixation, edema of the face and limbs, and typical dysmorphic features. A founder mutation in a novel gene underlies PEHO in 30 Finnish patients. A number of patients present with many, but not all, clinical features of PEHO, but are negative for mutations in the novel PEHO gene. This group is clinically heterogeneous suggesting genetic heterogeneity. To characterize the genetic background of these PEHO-like patients, we performed exome sequencing for 27 sporadic patients. In 4 cases also the parents were exome sequenced. As the group clinically overlaps with early-infantile epileptic encephalopathies, where new mutations account for a substantial proportion of patients, we focused on analysis of de novo mutations. Utilizing the Finnish exome database SISu, which included data from 3200 individuals, we were able to significantly restrict the number of candidate variants. We have identified a likely pathogenic mutation in 16 individuals, of whom 13 were exome sequenced without parents and three with parents. Of the 16 identified mutations 14 were validated to be de novo by Sanger sequencing in full trios. Four of the validated de novo mutations were in genes previously not associated with disease. Our data imply that exome sequencing combined with an ethnically matched reference database is an efficient method for identification of de novo mutations and does not necessitate sequencing of full trios.

PS09.099

PRX-related neuropathy with cataract: expansion of the clinical spectrum of perxiaxin associated neuropathies and identification of a novel mutation.

C. Vinkler[1,2], *D. Lev*[3,2], *I. Nezer-Kaner*[4], *M. Michelson*[4], *E. Leshinsky-Silver*[5], *T. Lerman Sagie*[6,2,7], *M. Ginzberg*[8,2];

[1]Institute of Clinical Genetics, Holon, Israel, [2]Metabolic Neurogenetic Clinic, Wolfson Medical Center, Holon, Israel, [3]Institute of Clinical Genetics Wolfson Medical Genetics, Holon, Israel, [4]Institute of Clinical Genetics Wolfson Medical Center, Holon, Israel, [5]Molecular Genetic Laboratory, Wolfson Medical Center, Holon, Israel, [6]Pediatric Neurology Unit, Wolfson Medical Center, Holon, Israel, [7]Sackler Medical School, Tel Aviv University, Tel Aviv, Israel, [8]Pediatric neurogenetic unit Wolfson Medical Center, Holon, Israel.

Hereditary neuropathies are a heterogeneous group of congenital neurological disorders. The gene encoding the periaxin protein (PRX) is responsible for autosomal recessive early onset demyelinating neuropathy: Charcot-Marie Tooth disease 4F (CMT4F) or its severe form Dejerine Sottas neuropathy Periaxin protein is essential for maintenance of the peripheral nerve myelin. It also functions as a scaffold protein that plays a role in lens membrane organization . We present a boy diagnosed with hereditary neuropathy and cataract carrying a novel homozygous mutation mutations in the PRX gene. The proband is a 5 year old boy with normal cognition he had delayed motor milestones and subcapsular cataract. His healthy parents are of Muslim-Arab origin and unrelated. He has experienced frequent falls since early age, however, his motor deficiencies tend to ameliorate with time. Neurological examination revealed: weakness of the distal lower limbs muscles and absence of deep tendon reflexes. NCV demonstrated dramatic symmetrical reduction of sensory and motor velocity of the lower limbs, compatible with a demyelinating process. Whole exome sequencing of the boy's DNA revealed a novel homozygote frameshift mutation, c.418-419insG (p.M149 fs) in the PRX gene, confirmed by Sanger sequencing. The parents are heterozygote carriers of the mutation. Hence this seems to be the disease causing mutation in this boy. This is a new clinical manifestation of PRX-related hereditary neuropathies. Lens abnormality caused by mutations in the PRX gene were shown only in knock out mice. It is suggested that careful eye examination should be done in patients with congenital neuropathy in order to rule out PRX associated hereditary neuropathy.

Partial deletion of *SLC20A2* as a rare cause of PFBC

K. Freimann[1], *C. B. Volpato*[2], *K. Lohmann*[1], *A. Hicks*[2], *C. Klein*[1], *P. Pramstaller*[2,3], *A. Westenberger*[1];

[1]Institute of Neurogenetics, University of Lübeck, Lübeck, Germany, [2]Center for Biomedicine, European Academy Bozen/Bolzano (EURAC), Bolzano, Italy, [3]Department of Neurology, General Central Hospital, Bolzano, Italy.

Bilateral accumulation of calcium in the brain, most commonly in the basal ganglia, but also in the cerebellum, thalamus, and brainstem can be inherited in an autosomal dominant fashion and is then referred to as primary familial brain calcifications (PFBC). PFBC is a clinically and genetically heterogeneous disorder. Despite prominent calcifications some individuals remain asymptomatic while others become severely affected by motor, cognitive and psychiatric symptoms. To date, mutations in three genes (*SLC20A2*, *PDGFRB*, and *PDGFB*) have been linked to PFBC. Interestingly, a whole gene deletion of *SLC20A2* has recently been identified indicating that copy number variations may play a role in the pathogenesis of PFBC.

We screened eleven PFBC patients (four sporadic cases and seven patients from four families) for exonic deletions or multiplications in the *SLC20A2* gene. All patients were tested negative for point mutations in *SLC20A2*, *PDGFRB*, and *PDGFB*. The presence of copy number variations of *SLC20A2* was investigated by quantitative real-time PCR. Each of the eleven exons of *SLC20A2* was tested. A sample carrying a heterozygous deletion of all *SLC20A2* exons was included as a positive control. Quantification of *SLC20A2* revealed a large deletion encompassing exons six to ten in one patient from an Italian family. No additional alterations were found in the other screened individuals.

This result further underlines the importance of copy number variations in the etiology of PFBC. In conclusion, quantitative mutational screening of *SLC20A2* is warranted in affected families without pathogenic small sequence changes in known PFBC genes.

PS09.101

Expanding the PNKD mutation spectrum

R. W. Labrum[1], *S. McCall*[1], *A. Gardiner*[2], *M. Athanasopoulou*[2], *J. Hayward*[1], *J. Polke*[1], *M. G. Sweeney*[1], *B. Turner*[3], *H. Houlden*[1,2];

[1]University College London Hospital, London, United Kingdom, [2]University College London, London, United Kingdom, [3]London Bridge Hospital, London, United Kingdom.

Paroxysmal non-kinesigenic dyskinesia (PNKD) is an autosomal dominant movement disorder characterised by attacks of dystonia, chorea and athetosis. To date, 3 mutations in the mitochondrial targeting sequence (MTS) of the PNKD gene account for all the cases in the literature. We describe a family in which the proband presented with a 'stroke-like' episode aged 43. Symptoms, including cognitive dysfunction and impaired motor function, subsided after 2 hours leaving the patient with a severe headache. Extensive investigations showed no evidence of a stroke. The patient's father has had over 50 episodes of weakness, labelled 'strokes', from a young age but without residual deficit. In light of this, screening for 'hemiplegic migraine' was requested. Sequencing using a next generation sequencing (NGS) panel of 11 genes encoding brain ion channel proteins detected a deletion of a C nucleotide in the last exon of the PNKD gene, c.1022delC p.(Pro341fs), in the patient and her father. This deletion results in a premature stop codon 3 amino acids downstream and a slightly truncated protein. While it is unlikely that the protein will undergo nonsense mediated mRNA decay (functional work is ongoing to confirm this), the function of the hydroxyacyl glutathione hydrolase domain may be disrupted leading to the build-up of the toxic metabolite methylglyoxal and related compounds which may reasonably be assumed to cause the phenotype. This case report expands the PKND mutation spectrum, resolves the diagnosis for this family and emphasises the usefulness of NGS in a diagnostic setting.

PM09.102

tRNA processing defects in pontocerebellar hypoplasia

B. Appelhof, *V. R. C. Eggens, T. van Dijk, A. L. M. A. ten Asbroek, M. A. J. Weterman, F. Baas;*

Academic Medical Center, Amsterdam, Netherlands.

Introduction: Pontocerebellar hypoplasia (PCH) represents a heterogeneous group of neurodegenerative disorders with a prenatal onset. Symptoms are hypoplasia and/or atrophy of the pons and cerebellum and patients suffer from severe cognitive and motor defects. Aberrations in different tRNA processing genes, e.g. the tRNA splicing endonuclease (TSEN) genes and cleavage and polyadenylation factor 1 subunit 1 (CLP1), have been associated with PCH. However the disease mechanism remains elusive. Our research focuses on further revealing the link between PCH and tRNA processing. For this, we select genes of the tRNA processing pathway and assess their possible involvement in the PCH disease mechanism

Material and methods: Exome sequencing was performed in 25 PCH patients and 5 trios. Candidate genes were knocked down in zebrafish using morpholinos and resulting phenotypes were analyzed using ISH and TUNEL

assay.
Results: On the bases of its function we selected RNA 3'-terminal phosphate cyclase (RtcA) as an essential part of the tRNA processing pathway. Knockdown of RtcA results in microcephaly, aberrant movement and abnormal brain development in zebrafish. Exome sequencing revealed a homozygous missense mutation at the active site of RtcA in a PCH2 patient.
Conclusion: RtcA is possibly involved in the same pathway as other PCH associated genes and invigorates the involvement of the tRNA processing pathway.

PS09.103
Pontocerebellar hypoplasia type III caused by nonsense mutation in PCLO

B. A. Chioza[1], *M. Y. Ahmed*[1], *A. Rajab*[2], *K. Schmitz-Abe*[3], *A. Al-Khayat*[4], *S. Al-Turki*[5], *E. L. Baple*[1], *M. A. Patton*[1,6], *A. Y. Al-Memar*[7], *M. E. Hurles*[5], *J. N. Pontocerebellar hypoplasia (PCH) is a group of disorders that share a common feature of an abnormally small cerebellum and pons. Involvement of the cerebrum, such as progressive microcephaly, is also common. It is highly heterogeneous, and eight subtypes on clinical and genetic basis have been known. PCH type III (PCH3) is one of the subtypes we reported in an Omani pedigree and mapped to chromosome 7q11-21. We have extended the study of this pedigree performing genetic analysis including genome-wide SNP genotyping, linkage analysis and whole-exome sequencing identifying a homozygous nonsense mutation in the gene Piccolo (PCLO) as the cause of PCH3. The variant was predicted to eliminate the PDZ and C2 domains in the C-terminus of the protein. PCLO is a component of the presynaptic cytoskeletal matrix. It localizes to the synaptic active zone, and is thought to be involved in regulation of presynaptic proteins and synaptic vesicles. Our findings suggest that PCLO is crucial for the development and survival of a wide range of neuronal types in the human brain.
Supported by grants from the Medical Research Council (G1002279) and Newlife Foundation for Disabled Children.

PM09.104
Mosaic uniparental disomy of chromosome 15q in an atypical PCH patient

T. van Dijk[1], *B. Appelhof*[1], *V. R. C. Eggens*[1], *A. D. C. Paulussen*[2], *J. C. F. M. Dreesen*[2], *A. L. M. A. ten Asbroek*[1], *M. A. J. Weterman*[1], *P. G. Barth*[1], *B. Poll-The*[1], *F. Baas*[1];
[1]*AMC, Amsterdam, Netherlands,* [2]*MUMC, Maastricht, Netherlands.*

Pontocerebellar hypoplasia (PCH) describes a heterogeneous group of neurodegenerative disorders with a prenatal onset. Common features are hypoplasia/atrophy of the cerebellum and ventral pons, progressive microcephaly and severe mental and motor retardation. Ten subtypes (PCH1-10) are described based on differences in phenotype and/or genotype. The majority of the PCH genes are involved in RNA processing. In about 40% of patients a mutation in one of the PCH related genes is identified, in 60% the genetic cause remains unknown. One of the goals of our research is to identify new candidate genes involved in PCH. Here we describe an atypical PCH patient with a neuronal migration disorder. A SNP array and read number analysis of exome data was suggestive of a mosaic paternal uniparental disomy (UPD) of chromosome 15q24.2- 15qter, which was confirmed by single cell genotyping. 34% of cells were homozygous for the paternal allele in this region and 64% of cells were heterozygous. The supposed mechanism is a somatic recombination. Upon re-examination of the exome variants, a deleterious heterozygous mutation in the *POLG* gene was identified on the maternal allele. POLG is essential for the replication of mitochondrial DNA and homozygosity for this mutation is supposed to be lethal. This probably explains the absence of cell homozygous for the maternal 15q allele. Tentatively, we would like to hypothesize that this cell line existed but died at some point during fetal development, leading to the brain phenotype in this patient.

PS09.105
Familial porencephaly - clinical and neuroimaging manifestations in persons with COL4A1 gene mutation.

K. Simenson[1], *Ü. Krikmann*[2], *T. Tomberg*[3], *Ü. Murumets*[1], *N. Tõnisson*[1], *K. Õunap*[1,4];
[1]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,* [2]*Neurology Clinic, Tartu University Hospital, Tartu, Estonia,* [3]*Radiology Clinic, Tartu University Hospital, Tartu, Estonia,* [4]*Department of Pediatrics, University of Tartu, Tartu, Estonia.*

Mutations in the COL4A1 gene have been found to cause autosomal-dominant porencephaly and leukoencephalopathy. Additionally infantile hemiplegia, migraines, seizures, intracerebral hemorrhage, ischaemic stroke, hematuria, arrhytmias may occur. We report here a family with a novel COL4A1 gene mutation and different clinical phenotype.
Our index patient is a 50-year-old woman, who has had migraine like headaches during last 5 years, hypertension since she was 30, microhematuria and unspecified eye damage since childhood. Last year she had transitorial ischaemic attack. Brain MRI showed left frontal horn porencephalic enlargement of the lateral ventricle, leukoencephalopathy and small T-2 hyperintensities in area of basal ganglia. A novel heterozygous mutation (c.1826G>A, p.Gly609Asp) was identified in COL4A1 gene. This mutation has not been described previously, but is predicted pathogenic because Gly substitution hampers the formation of the triple helix. Patient´s daughter (25y) had congenital hydronephrosis, no other symptoms and nonspecific MRI findings. Patient´s son (20y) had a subclinical stroke in perinatal period and an episode of supraventricular tachycardia at age 2 months. His physical and mental development is normal. His MRI is similar to mothers. He has arrhythmic episodes, frequent epistaxis and he becomes easily tired. Patient´s sister (30y) has had severe headaches during last 10 years. Patient´s mother died from cerebral infarction at age 69. Their genotypes have not been investigated.
It is noteworthy that our patient´s phenotype is quite mild and her daughter has no complaints, however she carries the same mutation. Consequently clinical picture among COL4A1 gene mutation carriers can be very variable.

PM09.106
Report on two families with inherited PTEN associated white matter lesions and neuropsychiatric disease presentation

T. B. Balci[1,2], *J. Davila*[3], *E. Sell*[4], *J. Richer*[1], *D. C. Lewis*[5], *A. Boafo*[5], *E. Tomiak*[1,6], *M. A. Lines*[7,6], *S. L. Sawyer*[1,6];
[1]*Department of Medical Genetics, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada,* [2]*University of Ottawa, Ottawa, ON, Canada,* [3]*Department of Medical Imaging, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada,* [4]*Division of Neurology, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada,* [5]*Department of Psychiatry, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada,* [6]*Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada,* [7]*Division of Metabolics, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.*

Recently, white matter (WM) lesions have been identified in patients with PTEN hamartoma tumor syndrome (PHTS). It is unclear how/if these findings correlate with the neurocognitive features associated with PTEN mutations, such as autism spectrum disorder (ASD) or developmental delays. We report two families with PTEN mutations and WM changes on their brain magnetic resonance imaging (MRI). The first family presented with neuropsychiatric features, and the second with developmental delays in the child. All have macrocephaly and WM hyperintensities on their MRIs in varying degrees and localizations. The father in the first family has an adult onset intermittent movement disorder (other possible causes ruled out) and no reported developmental difficulties, with a remote history of bipolar disease. His MRI shows multifocal leukoencephalopathy with subcortical and periventricular confluent areas of signal abnormality. His daughter has obsessive compulsive disorder and a mild learning disability. Her MRI shows much smaller bilateral subcortical WM lesions. The father in the second family presented with macrocephaly and penile freckling, and has subcortical and periventricular WM lesions, in keeping with the WM lesions seen in patients with PTEN mutations. His son has motor delays and has similar periventricular changes on his MRI. Previous reports identified a static WM disease in children with PHTS and developmental delay. A correlation between the extent of WM changes, reduced PTEN expression and cognitive function in ASD has been proposed. Clinical features in our patients with PHTS suggest an expanded PTEN phenotype spectrum, including previously unreported neuropsychiatric disease with possible progression in some individuals.

PS09.107
Pyridoxine-dependent epilepsy in Bulgarian dizygotic twins: a novel mutation in the ALDH7A1 gene

S. Tincheva[1,2], *T. Todorov*[2], *A. Todorova*[1,2], *I. Yordanova*[2], *T. Kadiyska*[2], *I. Litvinenko*[3], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*Child neurology clinic, Department of pediatrics, University Pediatric Hospital, Sofia, Bulgaria.*

Pyridoxine-dependent epilepsy (PDE, MIM 266100) is rare autosomal recessive disorder clinically characterized by a combination of various seizure types. The seizures usually present in the first hours of life and can not be

controlled with conventional antiepileptic medications but respond both clinically and electrographically to large daily supplements of pyridoxine (vitamin B_6). The dependence is permanent, and the interruption of daily pyridoxine supplementation leads to recurrence of seizures. The disease is caused by mutations in the *ALDH7A1* gene (MIM 107323) which is localized at 5q23.2 and encodes antiquitin, an alpha-aminoadipic semialdehyde dehydrogenase.

Here we report a dizygotic twin pair with classical form of PDE. Two hours after birth the infants presented with multifocal clonic seizures, resistant to anticonvulsive therapy. Direct sequencing of the *ALDH7A1* gene revealed one novel (c.297delG, p.Trp99*) and one already reported (c.328C>T, p.Arg110*) mutation. This represents the first genetically proven PDE case in Bulgaria. Our study enriches the spectrum of observed *ALDH7A1* mutations presenting a case with one novel single nucleotide deletion, located in exon 3 outside this "hotspot" region of the *ALDH7A1* gene containing ~60% of the reported mutations.

We emphasize that in patients with clinical diagnosis of PDE, even from Caucasian origin, it is necessary to examine the whole gene in order to confirm the diagnosis on molecular level. The increased number of described *ALDH7A1* mutations and genetically proven cases would help determining the real PDE frequency.

The study was supported by the project No 146/12.01.2015, Medical University Sofia, Bulgaria.

Network analysis of Parkinson's disease genes identifies a novel function of RAB39B

J. Vandrovcova*[1,2], *P. Forabosco**[3,2], *D. Trabzuni**[1,4], *A. Abramov*[1], *H. Plun-Favreau*[1], *J. A. Botía*[1,2], *S. Guelfi*[1,2], *K. D'Sa*[1,2], *M. Matarin*[1], *V. Varghese*[2], *A. Ramasamy*[1,2,5], *C. Smith*[6], *The UK Brain Expression Consortium (UKBEC), J. Hardy*[1], *M. E. Weale*[2], *M. Ryten*[1,2];

[1]UCL Institute of Neurology, London, United Kingdom, [2]Department of Medical & Molecular Genetics, King's College, London, United Kingdom, [3]Istituto di Ricerca Genetica e Biomedica, Monserrato, Italy, [4]Department of Genetics, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, [5]Jenner Institute, University of Oxford, Oxford, Austria, [6]MRC Sudden Death Brain Bank Project, University of Edinburgh, Department of Neuropathology, Edinburgh, United Kingdom.

Gene coexpression network analysis assumes no prior biological knowledge, making it a very powerful tool for the identification of novel pathways and gene interactions. In Parkinson's disease (PD) more than 40 genes and loci have been identified so far, but how their disruption leads to a single clinically identifiable disorder remains to be elucidated. As part of the UKBEC project, we used Weighted Gene Coexpression Network Analysis (WGCNA) to explore the brain transcriptomes of 101 neuropathologically normal individuals to investigate the biological relationships between known PD genes and PD-associated loci. In substantia nigra, the region most affected by PD pathogenesis, we identified two modules; one significantly enriched for Gene Ontology terms related to mitochondrion and oxidative phosphorylation, and the other for synapse related terms. We then assessed the predictive power of this analysis by using the network constructions to investigate the function of RAB39B, a recently identified cause of X-linked intellectual disability and early onset Parkinson's disease and a member of Rab family of proteins known to be important for regulation of vesicular trafficking. As predicted by RAB39B's membership within the module related to oxidative phosphorylation, we show that RAB39B disruption in vitro leads to mitochondrial complex 1 inhibition and decrease in mitochondrial membrane potential supporting the role of RAB39B in regulation of mitochondrial function. Our work validates the use of gene coexpression networks to predict novel biological functions, and provides new insights into molecular pathways and interactions of PD genes and loci.

Genetic diagnosis of Rett syndrome by New Generation Sequencing: our experience.

E. Gerotina Mora[1], *N. Brandi Tarrau*[2], *S. Vidal Falcó*[1], *M. O'Callaghan Gordo*[2,3], *À. Garcia-Cazorla*[2,3], *M. Pineda Marfa*[1,3], **J. Armstrong Morón**[2,3];

[1]Fundació Sant Joan de Déu, Esplugues de Llobregat, Spain, [2]Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain, [3]CIBERER, Madrid, Spain.

Rett syndrome (RTT) is an early-onset neurological disease that almost exclusively affects girls and is totally disabling. The RTT has a prevalence of 1/15000 being responsible for 10 % of severe mental retardation in females.

The clinical diagnosis is essential, since the discovery of a mutation confirms the diagnosis, but does not necessarily establish. Several genes that cause disease had been described: MECP2, CDKL5 and FOXG1.

We present a genetic study of patients using RTT -like New generation sequencing (NGS) .

We have designed a gene panel of 17 genes related to the RTT -like clinic presentation by HaloPlex Target technology. Enrichment System, for Illumina Sequencing. Sanger sequencing was used in exon not well covered and MLPA was done by causative RTT genes (MECP2, CDKL5 and FOXG1).

We studied patients with clinical RTT without genetic diagnosis and RTT patients with negative results by Sanger and MLPA of MECP2, CDKL5 and FOXG1 genes.

NGS results have been verified by Sanger sequencing and studied the origin of the mutation in the parents.

We have detected mutations in RTT-like patients in RTT genes and genes that do not cause RTT pathology, but overlap some features of RTT patients.

The genetic study by NGS allows to study a larger number of genes associated with RTT simultaneously, significantly reducing response time and the cost of the study. It also allows us to study other related clinical RTT and thus to redirect the clinical diagnosis to another disease genes.

Verification by Sanger of the progenitors of the mutations detected by NGS remains essential for their characterization.

PM09.110

RNA-seq based co-expression networks on human substantia nigra and putamen

J. A. Botía[1,2], *P. Forabosco*[3,2], *J. Vandrovcova*[1,2], *S. Guelfi*[1,2], *K. D'sa*[1,2], *M. Matarin*[1], *V. Varghese*[2], *D. Trabzuni*[1], *A. Ramasamy*[1,2,4], *The UK Brain Expression Consortium (UKBEC), J. A. Hardy*[1], *M. Ryten*[1,2], *M. E. Weale*[2];

[1]Department of Molecular Neuroscience, UCL Institute of Neurology, London, United Kingdom, [2]Department of Medical & Molecular Genetics, King's College, London, United Kingdom, [3]Istituto di Ricerca Genetica e Biomedica, Cittadella Universitaria di Cagliari, Sardinia, Italy, [4]Jenner Institute, University of Oxford, Oxford, United Kingdom.

The substantia nigra and putamen are key brain regions implicated in the pathogenesis of Parkinson's Disease, one of the most common neurodegenerative disorders. We used Weighted Gene Coexpression Network Analysis (WGCNA) to identify common and private gene modules in these brain regions.

As part of the UKBEC project, we analysed RNA-seq data from 134 neuropathologically normal controls to construct co-expression networks (signed correlation, soft threshold =11) separately for each tissue using gene level expression. Gene expression values (GC-corrected normalised RPKM) were corrected for batch effects and other biases using 9 PEER axes. We analysed ~16k Ensembl annotated genes for both brain regions, with per-gene QC filters of RPKM>0.05 and missingness<20%.

Our substantia nigra and putamen networks revealed 73 and 56 modules containing between 33-1316 and 33-1171 genes respectively. We studied enrichment with ToppGene and found enrichment for similar Gene Ontology terms in both tissues, including brain-related terms like neuronal signalling, development of nervous tissue, neurotransmitters, oligodendrocytes and glial cell formation. We also found enrichment for relevant pathways, including axon guidance, and for diseases including epilepsy, neuroticism, and substance related disorders.

We investigated the putative biological function of the 613 lincRNAs that were expressed in our data. We found that 18 and 30 were highly associated with 3 and 6 modules in the substantia nigra and putamen networks respectively, providing immediate hypotheses for their previously unknown regulatory function. Our results demonstrate the utility of performing RNA-seq based gene coexpression network analysis in the human brain.

PS09.111

SHANK3 variants confer risk for schizophrenia and indicate a genetic overlap with autism spectrum disorders

S. Berkel[1], *A. de Sena Cortabitarte*[1], *F. Degenhardt*[2], *B. Weiss*[1], *R. Roeth*[1], *M. Rietschel*[3], *M. Noethen*[2], *G. Rappold*[1];

[1]Institute of Human Genetics, Heidelberg, Germany, [2]Institute of Human Genetics, Bonn, Germany, [3]Central Institute of Mental Health, Mannheim, Germany.

The SHANKs are
postsynaptic scaffolding proteins at glutamatergic synapses in the brain that
are essential for proper synapse formation
and maintenance. The *SHANK* gene
family (comprising *SHANK1*, *SHANK2* and *SHANK3*) is linked to a spectrum of neurodevelopmental disorders,
including intellectual disability and autism spectrum disorders (ASD). Schizophrenia
(SCZ) is a neuropsychiatric disease with high variability in the clinical phenotype, characterized by major impairments in perception of reality

and
disorganized thought or behavior. Different studies have already pointed to an
impairment of glutamatergic synaptic plasticity as an underlying cause of SCZ
pathology. To elucidate a putative contribution of genetic *SHANK3* variants to the etiology of SCZ, we sequenced the gene in
500 affected individuals and compared the sequencing results to ancestrally
matched controls. Novel SHANK3 missense
variants were identified in 1.6 % of the screened individuals, three of which
were predicted as deleterious by at least two different algorithms. We identified association of 5 genetic variants, with study-wide significance (P<0.001). Combined with previous studies, the rare G>V variant was found
in 4 out of 1543 SCZ patients and in 4 out of 2147 individuals with autism spectrum disorders (ASD), but not in 9315 controls.
We conclude that the *SHANK3* gene harbors different genetic
variations predisposing to SCZ, ranging from common and uncommon variants to
rare deleterious missense mutations. The SHANK3-G>V variant was found in
both ASD and SCZ patients, pointing to an overlapping genetic contribution of *SHANK3* to both neuropsychiatric
disorders.

PM09.112
Study of genetic association of HLA-DQ2.5 with circulating IgG antibody to cow's milk casein in schizophrenia

R. T. McLean[1], *L. Halley*[1], *M. Doherty*[1], *P. Wilson*[2], *J. Wei*[1];
[1]*University of Highlands and Islands, Inverness, United Kingdom,* [2]*University of Aberdeen, Aberdeen, United Kingdom.*

Introduction: An increase in anti-casein antibodies has been reported in schizophrenia. Genome-wide association (GWA) study suggested that there was a lower frequency of the HLA-DQ2.5 genotype in schizophrenia patients than control subjects. The present work was thus designed to investigate the relationship between the HLA-DQ2.5 genotype, schizophrenia and circulating IgG antibody to cow's milk casein.
Methods: A TaqMan genotyping protocol was applied to genotype HLA-DQ2.5 in a total of 169 patients with schizophrenia and 261 healthy control subjects. Plasma samples from these subjects were used to detect IgG antibodies against 3 linear peptide antigens derived from α-casein (CSN1S1) and κ-casein (CSN3-1 and CSN3-2) using an in-house enzyme-linked immunosorbent assay.
Results: There was no association found between schizophrenia and circulating IgG to these three antigens. However, we observed an increase in IgG to CSN3-1 (p=0.035) and a decrease in IgG to CSN3-2 (p=0.0086) in DQ2.5 carriers compared with non-DQ2.5 carriers in the control group but not in the patient group. In addition, the frequency of HLA-DQ2.5 genotype was significantly higher in healthy controls than schizophrenia patients.
Conclusions: This study suggests that circulating IgG to cow's milk casein is not associated with schizophrenia but its secretion may be genetically controlled by the HLA-DQ2.5 genotype.

PS09.113
Schizophrenia-associated SNPs proximal to neurotransmission genes impact cognitive functions in patients and controls.

D. Cosgrove[1], *D. Hogan*[2], *Wellcome Trust Case Control Consortium 2, Psychiatric Genomics Consortium, A. Corvin*[2], *M. Gill*[2], *D. Morris*[1], *G. Donohoe*[1];
[1]*NUIG, Galway, Ireland,* [2]*TCD, Dublin, Ireland.*

Schizophrenia (SZ) is characterised by positive, negative and cognitive symptoms. As SZ is highly heritable, research has focused on GWAS, the most recent of which identified 83 new regions of interest associated with SZ. The link with specific functions in SZ is currently unknown. To take these results forward, these need to be identified, be that at the level of protein, neural pathway or phenotype. To characterise the effect of specific SNPs on cognitive function, selection was carried out based on the following classifications 1) proximity of SNP to gene, 2) unique association of gene to SNP, and 3) gene involvement in neurotransmission, which is disrupted in SZ. This resulted in nine SNPs in close proximity to genes involved in glutamatergic neurotransmission (GRM3, GRIN2A, SRR, CLCN3), signalling (CACNB2, HCN1, RIMS1) and receptor genes (DRD2, CHRN). To assess the impact of each SNP on cognitive function, neuropsychological measures (Table 1) were analysed. Analyses indicate significant effects on measures of cognition in patients and controls. SNPs showed an effect on scores of tests of social cognition such as the IPSAQ, Reading the Mind in the Eyes, and the Hinting Task showing that risk variants located within/proximal to gene regions involved in neurotransmission have significant effects on cognitive functions. Future work will aim to further elucidate this in conjunction with impact on imaging measures. Outcomes from such investigations may point towards neurotransmission pathways contributing to the disorder.

PM09.114
An immunological study of 3 schizophrenia susceptibility genes identified by GWA study

P. Hallford, *C. Mackenzie, J. Wei;*
Division of Health Research, University of the Highlands and Islands, Inverness, United Kingdom.

Introduction: Schizophrenia is a highly heritable disease based on family adoption and twin studies. A number of genome wide association (GWA) studies have been published, which have identified hundreds of genetic loci associated with an increased risk of schizophrenia. Interestingly, a recent study suggests most schizophrenia associated genes were highly expressed in B-lymphocytes, suggesting that dysfunction of humoral immunity may be involved in the pathophysiology of the disease.
In this study, we looked at the immunological response against 3 different antigens encoded by schizophrenia associated genes identified by GWA studies, including those coding for transcription factor 4 (TCF4), tripartite motif containing 26 (TRIM26) and disrupted in schizophrenia 1 (DISC1).
Methods: We developed an in-house enzyme linked immunosorbent assay (ELISA) to measure circulating IgG against the above 3 antigens in 100 patients with schizophrenia and 119 control subjects.
Results: The student's T test suggests that there was no significant difference in antibody levels for TRIM26 and DISC1 between the patient group and the control group (P>0.05), while a significant increase in TCF4 antibody levels was found in patients with schizophrenia compared to control subjects (P<0.05).
Conclusions: This study suggests that an autoimmune component is likely to be involved, in which circulating IgG to TCF4 may play a role, in the development of schizophrenia.

PS09.115
The involvement of DISC1, GRIA2A, GAD2 genes polymorphic loci in schizophrenia

K. O. Kinyasheva, *A. Gareeva, E. Khusnutdinova;*
Institute of Biochemistry and Genetics Ufa Scientific Center of RAS, Ufa, Russian Federation.

Schizophrenia is a severe multifactorial disease with a morbid risk of 7.2 per 1,000 and is affected by genetic and environmental factors. The disruption of the glutamatergic and the GABAergic systems, neuroplasticity changes are considered as an essential component of the pathogenesis of schizophrenia.
The aim of the current study was to determine the association of two polymorphic loci rs821597, rs843979 of DISC1 gene, two polymorphic loci rs2236418, rs928197 of GAD2 gene and polymorphic locus rs4403097 of GRIA2A gene with the schizophrenia in a sample of 338 cases (50% Russians and 50% Tatars) and 350 controls (50% Russians and 50% Tatars) from Volga-Ural region of Russia. The genotyping of these polymorphic loci was carried out by PCR-RFLP. The Haploview 4.1 program was used to determine the pairwise linkage disequilibrium and haplotype analysis. Odds ratios (OR) with 95% confident intervals (CI) were calculated.
The GAD2*A/A genotype (OR=3,62; P=0,0009) and the GAD2*A allele (OR=3,11; P=0,002) of polymorphic locus rs2236418 of GAD2 gene were found to be a risk markers of schizophrenia in Tatars ethnic group. The haplotype GAD2*AT from block which constructed of two polymorphic loci

rs2236418, rs928197 of GAD2 gene was identified as the high risk marker of schizophrenia in Tatars ethnic group (OR=2,15; P=0,0001). However previously mentioned polymorphic loci rs821597, rs843979 of DISC1 gene, rs4403097 of GRIA2A gene, rs928197 of GAD2 gene were not associated with the schizophrenia in Tatars and Russian ethnic groups.

This work was supported by the Russian Foundation for Basic Research grant #14-04-97012p_povolzhie_a.

PM09.116

Schizophrenia associated variants in cognition: a schizophrenia GWAS follow-up

K. M. Kendall, *J. T. Walters;*
MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff, United Kingdom.

In 2014, the Psychiatric Genetics Consortium (PGC) reported a schizophrenia genome-wide association study (GWAS) identifying 128 single nucleotide polymorphisms (SNPs) at 108 independent loci as associated with schizophrenia. This study aims to examine these variants for association with cognition in an independent schizophrenia sample. Genotypes at 125 SNPs were combined with MATRICS Consensus Cognitive Battery scores in a regression analysis for 592 individuals with schizophrenia. The social cognition domain was excluded due to reliability difficulties. 40 SNPs demonstrated nominally significant association with one or more cognitive domains. 8 SNPs were associated with the composite cognition score. 4 SNPs were associated with other cognitive domains following correction for number of domains examined (table 1). This study suggests a role for previously identified schizophrenia associated variants in influencing cognition. We will be attempting to replicate this in further independent samples.

Table 1. SNPs and association with cognitive domains.

PS09.117

Assessing disease relevant interactions in schizophrenia.

B. Ambroise[1], *J. T. R. Walters*[1], *J. L. Moran*[2], *S. A. McCarroll*[2,3], *M. J. Owen*[1], *M. C. O'Donovan*[1], *V. Escott-Price*[1], *A. J. Pocklington*[1];
[1]*Cardiff University, Cardiff, United Kingdom,* [2]*Broad Institute of MIT and Harvard, Boston, MA, United States,* [3]*Harvard Medical School, Boston, MA, United States.*

Schizophrenia is a highly heritable disorder in which genetic factors account for ~80% of the variability in liability. Genome wide association studies (GWAS) have shown that there are potentially thousands of risk loci associated with the disease (Sullivan et al. 2003). Although it has been shown that risk for schizophrenia is partially explained by additive effects of top-ranking single SNPs, interaction between SNPs may help to explain additional heritability that contributes to risk above and beyond that explained by single polymorphisms (Hemani et al. 2014; Zuk et al. 2012).

The CLOZUK dataset (Hamshere et al. 2013) consists of 5,199 cases ascertained through facilitation with Novartis, the manufacturer of a proprietary form of clozapine (Clozaril), and consisted of individuals with treatment-resistant schizophrenia. 5,873Controls were drawn from the Welcome Trust Case Control Consortium 2 (WTCC2) and the UK National Blood Transfusion Service by Cardiff University. Genotyping was done on two different chips.

As comprehensive pair-wise SNP-SNP interaction analysis is time consuming and computationally intensive, LD pruning was used to reduce the number of SNPs involved in the analysis. All pair-wise interaction effect sizes were calculated separately for each chip using logistic regression and then combined by meta-analysis.

Although no single interaction survived Bonferroni correction, there was evidence for enrichment of disease-relevant interactions amongst genes most highly associated with schizophrenia. The effect was more pronounced for interactions at higher significance levels. Similar effects were originally observed in a smaller, independent dataset (International Schizophrenia Consortium, 2008).

PM09.118

Association of COMT and MTHFR genetic variation with symptoms of schizophrenia

H. Kandratsenka, *I. Halayenka, N. Danilenko, T. Shatarnova, O. Davydenko;*
Institute of Genetics and Cytology of NAS of Belarus, Minsk, Belarus.

Background. Schizophrenia is a common, complex multifactorial psychiatric disorder with a lifetime incidence of 1-2%. Changes in functioning of dopaminergic metabolism and intracellular methylation which are controlled by COMT and MTHFR genes could be risk factors of overall schizophrenia.

Aims. To investigate the role of a COMT (rs4680) and MTHFR (rs1801133) gene polymorphisms in the etiology of schizophrenia according to the severity of symptoms (PANSS rating criteria), in the Belarusian population.

Materials and methods. 125 schizophrenia patients and 90 controls were studied. Patient inclusion criteria were: ICD-10 schizophrenia diagnosis, age 27-65 (46.9 ± 9.5) years.

Results. No differences in allele and genotype frequencies of both MTHFR and COMT loci between schizophrenia patients and controls were observed. The Mann-Whitney test has demonstrated an association of MTHFR T-allele with greater scores of conceptual disorganization (p=0.001), grandiosity (p=0.051), mannerisms and posturing (p=0.009) symptoms while COMT G-allele - with greater scores of blunted affect (p=0.023), poor rapport (p=0.019), lack of spontaneity and flow of conversation (p=0.037), stereotyped thinking (p=0.052), motor retardation (p=0.027), poor attention (p=0.003) symptoms for polymorphism in schizophrenia patients. Notably, we observed significant associations of rs1801133 MTHFR T-allele with increased summation of ratings of Positive Scale and rs4680 COMT G-allele with greater summation of ratings of Negative Scale (p=0.014), General Psychopathology Scale (p=0.024), PANSS Total score (p=0.024) for patients.

Conclusions. Our results have shown that rs1801133 MTHFR affects the intensity of positive syndrome. Polymorphism rs4680 COMT influences the severity of patient's negative syndrome and symptoms of General Psychopathology Scale in clinical characteristics of schizophrenia.

PS09.119

An intersection of retroviral infection/reactivation, epigenetics and genetics in schizophrenia

R. P. Loewe[1], *M. Schneider*[2];
[1]*GeneWake GmbH, Neuried, Germany,* [2]*University Hospital Ulm, Ulm, Germany.*

Schizophrenia is a disorder that can present itself in a broad spectrum of phenotypic variability ranging from single mild episodes to a dire need of life long treatment in a mental institution with around the clock care. The underlining concept of this seems to be driven not only based on the environment or the physical and mental health status upon onset, but is essentially attenuated via retroviral infection and epigenetic alterations in the context of an as yet undefined genetic landscape. Past efforts were in part not holistic enough to elaborate on the vastness in the plasticity of this psychiatric disease. The combined analysis of dendritic cells with viral particles in the cerebrospinal fluid, miRNA expression pattern derived from CSF-derived microparticles, the methylation analysis and gene alterations will be presented to derive signalling pathways explaining inflammation and virus reactivation in the CSF of patients with schizophrenia. Multi-parametric analysis is introduced as a sub-classifier with potential impact not only on more specific diagnosis, but furthermore to merit patient specific treatment in the future. Potential here lies in the use of anti-viral and immune modulating compounds as well as novel therapeutics shifting epigenetic signatures.

PM09.120

Genome organization and instability in the schizophrenia brain

Y. B. Yurov[1,2,3], *I. Y. Iourov*[1,2,4], *S. G. Vorsanova*[1,2,3], *T. Liehr*[5];
[1]*Mental Health Research Center, RAMS, Moscow, Russian Federation,* [2]*Russian National Research Medical University named after N.I. Pirogov, Separated Structural Unit "Clinical Research Institute of Pediatrics", Ministry of Health of Russia, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation,* [5]*Institute of Human Genetics, FSU, Jena, Germany.*

It has been repeatedly noted that chromosome/genome instability and abnormalities do affect the schizophrenia brain (Yurov et al., 2001; 2008). Alternatively, specific changes of the genome organization should co-occur with genome instability suggesting the existence of a cellular (endo)phenotype. Here, genome organization at chromosomal level has been addressed by a set of molecular neurocytogenetic techniques. Interphase chromosome-specific multicolor banding (ICS-MCB) was used to analyze genome organization and instability in the schizophrenia brain. The evaluation of 12 samples of the diseased brain and 12 control samples has shown a striking

discrepancy between schizophrenia and unaffected counterparts. Chromosome arrangement in interphase nuclei of the schizophrenia brain was completely different from the unaffected brain. The diseased brain has exhibited 10-40% of cells affected by genome/chromosome instability manifested as aneuploidy and chromosome breakage of chromosome 1. Additionally, remaining cells have almost all demonstrated a phenotype specific for chromosome instability. More precisely, 23-48% of cells in the schizophrenia brain were featured by the chromosome 1 localization at the nuclear periphery in contrast to controls characterized by chromosome 1 positioning near the nucleolus. Since such nuclear organization characterizes cellular populations affected by chromosome instability, we have suggested that these changes are likely to mediate genome instability in the schizophrenia brain. Accordingly, intranuclear organization of chromosomes in brain cells seems to be a new (previously unrecognized) epigenetic mechanism for schizophrenia.

PS09.121

SCN8A mutation associated with intrauterine tremor, arthrogryphosis multiplex congenita and severe respiratory distress

S. Berland[1,2], *H. Dalen*[2], *G. Houge*[1], *R. Holdhus*[3], *B. I. Haukanes*[1], *K. Petersen*[3], *C. Gilissen*[4], *A. Hoischen*[4,3], *T. Fiskerstrand*[1];
[1]*Haukeland University Hospital, Bergen, Norway,* [2]*St. Olav University Hospital, Trondheim, Norway,* [3]*University of Bergen, Bergen, Norway,* [4]*Radboud University Medical Center, Nijmegen, Netherlands.*

A newborn girl presented with severe respiratory distress needing intubation, continuous coarse tremor, lung hypoplasia, dysmorphic features, bell-shaped thorax and arthrogryphosis. EEG was initially normal but pathological at age 2 weeks. Two cerebral MRIs were normal. EMG findings suggested lower motor neuron disease. Epilepsy progressed and was refractory to treatment. She died after extubation at age 4 weeks. The mother felt tremor from the second trimester and no other fetal movements, and tremor was also observed by ultrasound in gestation week 24.
Methods and results: SNP-array and tests for SMA, Schinzel-Gideon syndrome and patUPD14 were normal. Whole exome sequencing revealed a de novo novel missense variant in SCN8A: c.718A>G p.(Ile240Val). Missense mutations in this gene cause epileptic encephalopathy with intellectual disability. SCN8A encodes Nav1.6, the α-subunit of a voltage gated neuronal sodium channel. This variant is located in an intracellular loop in juxtaposition to a transmembrane segment that operates as a gate sensor. Notably, an Ile to Val substitution in an equivalent position within another transmembrane domain (highly similar structure) was reported in a boy with neonatal epileptic encephalopathy, multiple congenital anomalies and movement disorder (Vaher et al; J Child Neurol 2014).
Conclusion: We report the first data on prenatal onset of movement disorder, including severe respiratory distress, likely caused by a missense variant in SCN8A. Dysmorphic features and arthrogryphosis are probably secondary to fetal akinesia. Our data adds to previous literature extending the phenotypic spectrum of variants in this gene.

Identification of seizure genes from 748 probands with developmental disorders

J. McRae[1], *D. Fitzpatrick*[2], *H. Firth*[1], *R. Scott*[3], *S. Joss*[4], *M. Hurles*[1], *The Deciphering Developmental Disorders Study;*
[1]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom,* [2]*University of Edinburgh, Edinburgh, United Kingdom,* [3]*University College London, London, United Kingdom,* [4]*NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

The Deciphering Developmental Disorders (DDD) study aims to advance diagnosis of developmental disorders in the United Kingdom and Ireland through applying the latest genetic diagnostic technologies to samples from probands and their parents (trios). Children with developmental disorders may exhibit a variety of clinical phenotypes. One of the most common phenotypes observed in probands in the DDD study is seizures.
To date, the DDD study has analysed 4295 trios, 748 (17.4%) present with seizures. We attempted to identify mutations in genes that contribute to seizures within the subset of probands with at least one subtype of seizures. We sequenced the exomes of the members of each trio and interrogated genetic variants from the exome for *de novo* mutations within the probands. We identified genes significantly enriched with *de novo* mutations. Mutations in many of these enriched genes are reported to have a causative role in seizures, however we identified one mutated gene not previously linked to seizures and consider this a potentially novel gene implicated in seizures. We present the findings of our analysis and the potentially novel gene implicated in seizures.

PS09.123

Additional case of SLC6A1 and SLC6A11 (3p25.3) deletion in an autistic child with intellectual disability and EEG anomalies

V. Seidel[1], *P. de Castro*[2];
[1]*Clinical Genetics, Pediatrics Department, Hospital MI Gregorio Marañón, Madrid, Spain,* [2]*Child Neurology, Pediatrics Department, Hospital MI Gregorio Marañón, Madrid, Spain.*

Introduction: Recently, three cases of overlapping microdeletions 3p25.3 showing a consistent phenotype with developmental delay, epilepsy, poor speech and stereotypes have been described. We present a forth case: A seven year old girl with intellectual disability (ID), absent speech and stereotypic movements.
Case report: Family history and perinatal period were unremarkable. Overall growth parameters were normal. Global developmental delay was noticed before age twelve months, her language development stopped and autistic behaviour became more apparent. Seizures presented at age five years, with fever. On physical examination she had a normal head circumference, poor eye contact, bruxism and an unusual but not ataxic gait. No specific dysmorphic features were observed. Brain imaging and metabolic screen were normal. EEG showed slow wave activity while awake and a diffuse epileptic activity. She is free of seizures under lamotrigine. Genetic investigations included fragile X testing and sequencing of CDKL5, which were normal.
Results: Chromosome microarray (180K array CGH) detected a 1.09 Mb microdeletion at 3p25.3, including SLC6A1 and SLC6A11. These genes encode gamma-aminobutyric acid (GABA) transporters. Alterations to any of these two genes have not been previously associated with human disease. However, biochemical and animal study data support the plausibility of a link between these two genes and EEG anomalies and ID. Variants in other neurotransmitter transporter genes (eg SLC6A4) have been found to increase the risk for psychiatric disease such as obsessive-compulsive disorder and autism.
Conclusion: We provide further evidence of an association between deletions affecting neurotransmitter transporter genes and autism spectrum disorders.

PM09.124

NGS reveals new causes for spastic quadriplegia in Roma patients

R. V. Vazharova[1,2], *S. Ivanov*[3], *L. Balabanski*[2], *I. Tournev*[4], *T. Chamova*[4], *S. Bichev*[5], *A. Savov*[5], *D. Toncheva*[6];
[1]*Department of Biology, Medical genetics and Microbiology, Faculty of Medicine, Sofia University "St. Kliment Ohridski", Sofia, Bulgaria,* [2]*Gynecology and Assisted Reproduction Hospital „Malinov DM", Sofia, Bulgaria,* [3]*Genomic laboratory, Gynecology and Assisted Reproduction Hospital „Malinov DM", Sofia, Bulgaria,* [4]*Sofia Medical University, Department of Neurology, Sofia, Bulgaria,* [5]*National Genetic Laboratory, Medical University-Sofia, Bulgaria, Sofia, Bulgaria,* [6]*Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria.*

We report on findings obtained by NGS of 552 genes in a small group of Roma patients affected with complicated spastic quadriplegia. Recently the homozygosity for a founder mutation in the PDHX gene (p.R446*) among Roma ethnic group was found to account for around 60% of cases presenting early in life with metabolic acidosis, spastic paraplegia/ quadriplegia, developmental delay and epilepsy and screening for this mutation was suggested as first step in clinical workup. Patients were selected on the basis of clinical presentation. We used the TruSight Inherited diseases panel, Illumina and the MySeq sequencing system. The search for the disease-causing mutations focused on variants with a quality score ≥ 30 and coverage ≥ 20 ×, located outside of segmental duplications and simple repeats. The step-wise filtering criteria included: allele frequency ≤ 1% in the 1000Genomes or NHLBI Exome Sequencing projects; "deleteriousness" predictions (RadialSVM Pred scores > 0.83357), splice-site (± 15 nt), nonsense, non-stop, and small in-frame or frame-shift in/dels. Six patients of Roma descent who were negative for the p.R446* founder mutation in PDHX gene were included in the study. We found causative mutations in two of them: RNASEH2B, p.Ala177Thr homozygous and AP1S2, p.Tyr86Ter hemizygous. The mutation in AP1S2 is novel. Our results show that recessive monogenic diseases such as Aicardi Goutieres syndrome 2 and Mental retardation, X-linked syndromic 5 may manifest at an early age, resembling cerebral palsy. NGS not only shortens the time for establishment of a diagnosis, but may alter the clinical course, if it reveals disease for which treatment is possible.

PM09.126

Missense variants as a possible cause of GRID2-related spinocerebellar ataxia type 18

M. Calvo[1], *D. Trujillano*[1], *N. Nahavandi*[1], *A. Rolfs*[1,2], *M. Tarnopolsky*[3], *R. Abou Jamra*[1];
[1]*Centogene AG, Rostock, Germany,* [2]*Albrecht-Kossel-Institute for Neuroregeneration, Medical University Rostock, Rostock, Germany,* [3]*Department of Pediatrics, McMaster University, Hamilton, ON, Canada.*

GRID2 is a member of the ionotropic glutamate receptor family of excitatory neurotransmitter receptors. Very recently, GRID2 has been associated with autosomal recessive spinocerebellar ataxia type 18 (SCAR18, OMIM: 616204) that is characterized by early onset severe cerebellar ataxia, ocular movement abnormalities, and intellectual disability with progressive cerebellar atrophy. So far, only in three families homozygous or compound heterozygous large deletions encompassing single or several exons of *GRID2* have been described as disease-causing. We performed whole exome sequencing (WES) in a Canadian patient and identified two *in trans* missense variants in the GRID2 gene: c.2128C>T (Arg170Trp) and c.2218G>A (p.Val740Ile). Based on ExAc, c.2128C>T was identified 6 times (MAF 0.00005) and c.2218G>A was identified 132 times (MAF 0.001, two homozygous cases). Both variants are located in highly conserved amino acid positions. Several, but not all, prediction programs suggested pathogenicity. qPCR experiments are ongoing to exclude large deletions/duplications. The patient has since the age of 8 months an early-onset episodic ataxia, failure to thrive, developmental delay, dystonic posturing and seizures. At the age of 12 years, the patient shows in addition progressive cerebellar atrophy. We see most symptoms of the patient clearly overlapping with those previously described in the three families with SCAR18. Although further characterization is needed, our results suggest that also missense variants, and not only deleterious deletions, might be disease-causing for SCAR18 with a comparable phenotype.

PM09.128

Dominance and recessiveness, two faces of the same coin? Illustration with two new genes in autosomal dominant spinocerebellar degenerations

Introduction: Cerebellar ataxias (CA) and hereditary spastic paraplegias (HSP) are opposite ends of a wide spectrum of neurodegenerative disorders known as spinocerebellar degenerations. Approximately 200 causative genes have been identified, and transmission follows all classical modes. Therefore, next generation sequencing (NGS) is of great help in their molecular diagnosis, as well as for identifying new causative genes in unresolved families.

Methods: We used a combined approach of whole genome linkage analysis and exome sequencing in two families with either CA or HSP, aiming to identify the causative genes. Their involvement was validated with panel sequencing approaches, and functional studies when available.

Results: In a CA family, we identified a missense mutation in *GRID2*, heterozygous in late-onset affected adults, and homozygous in a child with congenital CA. In two patients with congenital CA, we identified *GRID2* mutations mimicking the *Lurcher* mouse model. In a family with HSP, a *ALDH18A1* missense mutation segregated with dramatically low plasma levels of citrulline, making it a potential trait biomarker. Four additional pedigrees, and in vitro analyses of ornithine metabolism, allowed establishing protein dysfunction.

Conclusion: Both *GRID2* and *ALDH18A1* had been implicated in autosomal recessive disorders in humans. With functional evidence, we established, in both cases, that AD transmission can occur, and is linked to a different phenotype. Aside from the novelty in the field of spinocerebellar degenerations, this illustrates the permanent landscape remodelling that occurs in human genetics since the arousal of NGS.

PS09.129

An association between variants within the APOE gene and concussion profile: a preliminary investigation

S. Abrahams[1], *S. Mc Fie*[1], *J. Patricios*[2,3], *J. Suter*[4], *M. Posthumus*[1], *A. September*[1];
[1]*University of Cape Town, Cape Town, South Africa,* [2]*Morningside Sports Medicine Clinic, Johannesburg, South Africa,* [3]*University of Pretoria, Johannesburg, South Africa,* [4]*Constantiaberg Sports Medicine Clinic, Cape Town, South Africa.*

Introduction: Concussion is the transmission of biomechanical forces to the head resulting in neurological deficits, stimulating elevated release of brain tissue damage markers and promoting neural cell death. Apolipoprotein E is involved in nerve tissue integrity and encoded by the *APOE* gene. The ε4 allelic variant of the *APOE* gene was associated with greater severity for brain injury in boxers. Therefore, this study's aim was to investigate the association between *APOE* variants and concussion profile in rugby players.

Materials and Methods: In this case-control genetic association study, 198 previously concussed cases and 129 non-concussed, sport-matched controls (age: 15 - 39 years old) were recruited from rugby playing schools and clubs. Participants were genotyped for rs405509 (G/T), rs429358 (ε3/ε4) and rs7412 (ε2/ε3) variants within the *APOE* gene. Sport, concussion and medical history were recorded. Inferred haplotype analyses were conducted.

Results: No significant genotype or allele frequency differences were noted between cases and controls (>P=0.149) and for concussion symptom duration in cases (>P=0.253). However, the frequencies of the age-adjusted inferred G-ε4-ε3 (28% vs. 24%; P<0.001) and G-ε3-ε2 (25% vs. 19%; P=0.001) haplotypes, of the *APOE* variants (rs405509-rs429358-rs7412), were significantly greater among cases compared to controls, respectively.

Conclusion: Although the independent *APOE* genotype frequencies were not associated with concussion susceptibility or severity, the combined effect of the three *APOE* variants implicates *APOE* in concussion susceptibility. Further exploration is needed to understand the complex role of *APOE* in susceptibility.

PM09.130

Mosaic dominant TUBB4A mutation in a highly consanguineous family with complicated hereditary spastic paraplegia

D. Kancheva[1,2], *T. Chamova*[3], *V. Guergueltcheva*[3], *V. Mitev*[1], *D. N. Azmanov*[4], *L. Kalaydjieva*[5], *I. Tournev*[3], *A. Jordanova*[1,2];

Background: Mutations in TUBB4A have been recently associated with a spectrum of autosomal dominant neurological conditions, ranging from the severe hypomyelination with atrophy of the basal ganglia and cerebellum syndrome (H-ABC) to the clinically milder dystonia type 4 (DYT4). The presence of extrapyramidal symptoms was initially considered the only common hallmark of these disorders.

Methods: Clinical, neurological and neuroimaging examinations, followed by whole exome sequencing and mutation analysis were performed in a highly consanguineous pedigree with five affected children.

Results: We identified a novel c.568C>T (p.H190Y) TUBB4A mutation in a highly consanguineous pedigree mimicking autosomal recessive inheritance. The mutation have originated de novo in the mosaic mother of five children affected by complicated hereditary spastic paraplegia (HSP). The patients presented with an early onset, slowly progressive spastic paraparesis of the lower limbs, ataxia and brain hypomyelination, in the absence of dystonia or rigidity.

Conclusions: Our study adds complicated hereditary spastic paraplegia to the clinical spectrum of TUBB4A-associated neurological disorders. We establish genotype-phenotype correlations with mutations located in the same region in the tertiary structure of the protein.

Tuber**O**us **SC**lerosis registry to increase disease **A**wareness (TOSCA), a multicenter, international disease registry, to study the manifestations, interventions, and outcomes in patients with tuberous sclerosis complex (TSC), has enrolled >2000 patients. The genetic research project of TOSCA, which is limited to European countries, aims to improve our understanding of genotype/phenotype correlations in TSC. TSC is most often attributed to *TSC1/TSC2* mutations, but limited genotype/phenotype correlations have been described so far due to the large number of mutations and the relatively small sample size of studies. Nevertheless, it has been shown that patients with *TSC2* mutation tend to be more severely affected, but with significant clinical overlap between individuals with *TSC1* and *TSC2* mutations, to the extent that it is inadvisable to make a clinical judgment based on an individual's mutation type. At first interim analysis of TOSCA, molecular testing had been performed on 301 of 508 (59.3%) patients. Pathogenic mutations were reported in 224 (74.4%) patients. Median time from clinical diagnosis to molecular testing was 30 months (range, 0-655). Overall, 125 (24.6%) patients had ≥1 relative diagnosed with TSC. TSC was diagnosed prenatally in 27 patients (5.3%; ultrasound finding in 19; family history in 8). As previously described in the literature, some features of TSC appeared to be more common in patients with *TSC2* mutations (ie, subependymal giant cell astrocytoma, infantile spasms, and renal angiomyolipoma). Given the larger size of the TOSCA cohort, quantitative analysis of more subtle and in-depth genotype/phenotype correlations will be performed, with the hope of improving the clinical utility of such findings.

PM09.132
Exome sequencing of a patient with Corpus Callosum agenesis

K. Tveten[1], *Ø. L. Busk[1], L. Strand[1], E. Bryne[2], G. J. Braathen[1], Ø. L. Holla[1];*
[1]Telemark Hospital, Skien, Norway, [2]Vestfold Hospital, Tønsberg, Norway.

Background
A 1 year old boy was referred to genetic counselling with an unresolved developmental disorder and corpus callosum agenesis. Previous genetic testing revealed a 245 kb deletion on chromosome 7p22.2 which was assumed to be of no significance as it was maternally inherited. MR caput revealed agenesis of the corpus callosum, whereas MR SPECT and EEG were normal.
Material and Methods
Exome trio sequencing was performed of the patient and his parents.
Results
We identified two heterozygous mutations in the EPG5 gene. The first mutation was a missense mutation inherited maternally and the second mutation was a frame-shift duplication inherited paternally. Both mutations were novel. Recessive mutations in *EPG5* are known to cause the rare Vici syndrome characterized by corpus callosum agenesis, hypopigmentation, cardiomyopathy, immunodeficiency and cataracts. Of these characteristics, only corpus callosum agenesis was present in this patient.
Conclusion
Although the patient does not fulfill the clinical criteria for Vici syndrome, we believe the two novel heterozygous mutations are the likely cause for the corpus callosum agenesis. Apparently he has a milder phenotype than previously reported in literature.
EPG5 mutation analysis may be of importance in other patients that presents with corpus callosum agenesis without other features.

Infantile spasms syndrome (ISs) is an epileptic encephalopathy characterized by clinical spasms with ictal electrodecrement, usually occurring before the age of 1 year and frequently associated with cognitive impairment. Etiologies of ISs are widely heterogeneous and an increasing number of genetic causes have been reported during the last years. However, the etiological diagnosis remains unknown in up to 40% of patients. We searched for de novo mutations in 10 ISs probands and their unaffected parents using WES. Inclusion criteria were the lack of consanguinity and of family history of epilepsy, as well as exclusion of common causes of ISs by brain MRI, metabolic screening, array-CGH and screening for mutations in CDKL5 and STXBP1, and for ARX duplications in males. We found a probably pathogenic de novo mutation in four patients. Two of them were missense mutations in SCN2A and in KCNQ2, in two patients who had no history of epilepsy prior to the onset of ISs. The third mutation, found in a female patient, involved, ALG13, located on the X chromosome. This mutation has been recently reported in three unrelated females with ISs. The fourth mutation was a three base-pair in-frame deletion in NR2F1, a gene whose mutations have been shown to cause intellectual disability and optic atrophy. In this study, we showed that WES can significantly improve the diagnosis yield in patients with sporadic ISs.

PM09.134
Unexpected molecular genetic findings by Next-Generation-Sequencing in a young ataxia patient

K. Grundmann[1], *S. Nia[2], M. Schulze[1], M. Sturm[1], B. Kootz[1], C. Baumgartner[2], P. Bauer[1], J. K. Bickmann[1];*
[1]Institute of Medical Genetics and Applied Genomics, Tübingen, Germany, [2]2nd Department of Neurology, Center of Neurology Rosenhügel, Vienna, Austria.

Introduction: An 18 year-old patient of non-consanguineous parents had ataxic symptoms since age 16. The symptoms in the once excellent student were accompanied by progressive dementia, psychiatric changes, ocular apraxia, vertical ophthalmoparesis and non-specific elevations of liver enzymes, lactate and CK. He has a similarly-affected younger brother. His maternal grandfather had psychiatric issues, his mother's brother suffers from schizophrenia, autism, hypotonia and gait disturbance.Materials and Methods: The patient was evaluated for Niemann-Picktype C disease and SCA17 but no mutation could be identified. His DNA was then subjected to Next Generation Sequencing of 128 ataxia-associated genes and the results worked up clinically and segregated in the brother and mother.Results: The patient has a heterozygous SYNE1 variant once associated with autosomal dominant Emery Dreyfuss Muscular Dystrophy (EDMD4) as well as heterozygous mutations in WFS1 and PEX7, and a likely pathogenic variant in VPS13A. Of those, only the WFS1 mutation was also present in his brother. All mutations had been inherited through the mother. VPS13A alone has not been segregated. The genetic diagnosis of EDMD4 was not confirmed by muscle biopsy. In the course of disease his brother developed diabetes insipidus and signs of celiac disease. Both brothers have deteriorating vision that could indicate optic atrophy (ophthalmologic exam is pending).
Conclusion: The clinical presentation is now in line with Wolfram syndrome but a second mutation is warranted. We are currently establishing a microarray covering SNPs of ataxia-related genes. This may reveal a second WFS1-mutation in the two brothers and their father.

DIAGNOSIS AND MANAGEMENT OF ROMANIAN CHILDREN WITH WILLIAMS-BEUREN SYNDROME (WBS)

OBJECTIVE: The present study focuses on the evaluation of the clinical characteristics of pediatric patients with WBS, to design a personalized management plan, to prevent the complications and to improve the prognostic.

MATERIAL AND METHODS: 22 children clinically and genetically diagnosed with WBS. The clinical diagnosis was based on the WBS diagnostic scoring system; FISH tests were performed to confirm the diagnostic.

RESULTS: All children were refered to our department for intellectual disability; 35% of them associated motor delay and 48%, poor language development. All children presented specific facial dysmorphism. Most children had particular behavior: temporal-spatial disorientation, hyperacusis, and attraction to music (100%); hypersociability (65%); hyperkinesias (35%); fussy eating patterns (12%). 17% of the children had cardiovascular disorders and 6% presented hypercalcemia. Some children presented atypical features: 2 children had autism and 1 child associated Marfan syndrome. 29% of patients were enrolled in physical therapy, and 42%, in different types of cognitive and behavioral therapy. Most of these children improved in their psychomotor development, well-integrating in regular education. 12% of the children were not enrolled in any therapeutic program and presented very slow psychomotor aquisitions, thus preventing their enrollment in any type of education.

CONCLUSIONS: Most of our patients presented the classical picture of WBS, but some children had different particularities which contributed to a delayed diagnosis. The management of WBS patients requires a multidisciplinary approach, and is essential for a better social integration of these children.

Homozygous deletion involving WWOX confirms causality in early Infantile Epileptic Encephalopathy and allows for extensive detailed phenotyping in large consanguineous families

D. J. McMullan[1], *G. K. Hall*[1], *D. A. Arafah*[2], *L. Cooper-Charles*[1], *D. Bohanna*[1], *J. Vogt*[3], *H. Cox*[3];

[1]*West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom,* [2]*Makkah Maternity and Children Hospital, Makkah, Saudi Arabia,* [3]*West Midlands Regional Genetics Service, Birmingham, United Kingdom.*

WWOX (OMIM #605131) encodes WW domain-containing oxoreductase and acts as a tumour suppressor with a role in esophageal squamous cell carcinogenesis. A very recent association with early Infantile Epileptic Encephalopathy (IEE) has been reported, initially in a single child (of consanguineous parents) with a homozygous nonsense mutation and subsequently in eight individuals from two families with a clinical diagnosis of spinocerebellar ataxia type 12 and in two siblings with IEE, with compound heterozygous deletions and/or nonsense mutations (Mignot, 2015).

We present a very large consanguineous family with eight living and one deceased infant with undiagnosed encephalopathy investigated by array-CGH. A ~440kb homozygous deletion was identified at 16q23.1(77.75-78.19Mb). Homozygous deletions segregated entirely with affected children. Healthy siblings and parents were either heterozygous or normal. The deletion contains four RefSeq genes (NUDT7, VAT1L, CLEC3A and exons 1-4 of WWOX). Collation of our cohort and those published to date suggest an emerging pattern of poor postnatal growth, microcephaly and onset of seizures in the first year of life. Visual impairment and hypotonia are also observed, together with multiple deaths, mostly related to epilepsy. Specific genotype-phenotype granularities, potentially related to differing mutational mechanism / CNV gene content are presented.

IEE has heterogeneous causes including many single gene disorders that can be inherited or de novo; most are impossible to distinguish from each other on clinical grounds alone and the identification of WWOX reiterates the essential movement towards whole genome SNV and CNV analysis as prerequisite in clinical assessment.

PS09.137

Early onset epileptic encephalopathy in a male patient carrying an Xp11.23 deletion including the WDR45 gene.

A. Abidi[1,2], *C. Mignon-Ravix*[1,2], *P. Cacciagli*[1,2,3], *N. Girard*[4], *M. Milh*[1,2,5], *L. Villard*[1,2];

Mutations in the WD repeat 45 (WDR45) gene been have recently identified in patients suffering from neurodegeneration with brain iron accumulation (NBIA). NBIA is a genetically and phenotypically heterogeneous condition. WDR45 mutations cause a childhood onset encephalopathy accompanied by neurodegeneration in adulthood and iron accumulation in the basal ganglia. WDR45 mutations have been almost exclusively found in females and male lethality was suggested. Here, we describe a male patient suffering from a severe and early neurological phenotype, initially presenting as neonatal stormy seizures associated with an altered interictal EEG pattern and abnormal neurological development. This patient is a carrier of a microdeletion of chromosome Xp11.23 containing three genes, including WDR45. These findings reveal that deletions of WDR45 are viable in males and can initially be diagnosed as early onset epileptic encephalopathy without brain iron accumulation.

X-linked recessive dystonia-parkinsonism is a rare movement disorder that is highly prevalent in Panay Island in the Philippines. Earlier studies identified seven different genetic alterations within a 427-kb disease locus on the X chromosome; however, the exact disease-causing variant among these is still not unequivocally determined. To further investigate the genetic cause of this disease, we sequenced all previously reported genetic alterations in 166 patients and 473 Filipino controls. Singly occurring variants in our ethnically matched controls would have allowed us to define these as polymorphisms, but none were found. Instead, we identified five patients carrying none of the disease-associated variants, and one male control carrying all of them. In parallel, we searched for novel single-nucleotide variants using next-generation sequencing. We did not identify any shared variants in coding regions of the X chromosome. However, by validating intergenic variants discovered via genome sequencing, we were able to define the boundaries of the disease-specific haplotype and narrow the disease locus to a 294-kb region that includes four known genes. Using microarray-based analyses, we ruled out the presence of disease-linked copy number variants within the implicated region. Finally, we utilized in-silico analysis and detected no strong evidence of regulatory regions surrounding the disease-associated variants. In conclusion, our finding of disease-specific variants occurring in complete linkage disequilibrium raises new insights and intriguing questions about the origin of the disease haplotype, the existence of phenocopies and of reduced penetrance, and the causative genetic alteration in XDP.

Primary fibroblasts cultures reveal TDP-43 abnormalities in Amyotrophic Lateral Sclerosis patients with and without SOD1 mutations

a. moncada, *M. Sabatelli, a. conte, A. Del Grande, G. Marangi, P. doronzio, m. lucchini, m. mirabella, a. romano, a. romano, r. piacentini, g. bisogni, s. lattante, m. luigetti, p. rossini, m. zollino;*

Catholic University of Sacred Heart, roma, Italy.

A landmark in Amyotrophic Lateral Sclerosis research was the discovery of TDP-43 as major component of the abnormal protein aggregates that form skein-like and spherical inclusions or appear as diffuse granular material in neuronal and glial cells. Additional studies have confirmed that TDP-43 plays a central role in the pathogenesis of ALS and related neurodegenerative conditions, including frontotemporal lobar degeneration with ubiquitin positive aggregates. Studies on ALS patients have consistently shown that, in addition to cytoplasm accumulation, TDP-43 undergoes post-translational modifications, including hyperphosphorylation, ubiquitination and cleava-

ge into small C terminal fragments (CTFs). In the present study we examined TDP-43 expression in primary fibroblasts cultures from 22 ALS patients, including cases with SOD1, TARDBP, FUS, C9ORF72 mutations and nine patients without genetic defects. By using a phosphorylation-independent antibody, fifteen patients showed notable alterations of TDP-43 level in the nuclear or cytoplasmic compartments. In particular, a marked accumulation of TDP-43 was observed in the cytoplasm of all cases with C9ORF72 and TARDBP mutations, in one patient with FUS mutation and in three patients without genetic defects. In patients with SOD1 mutations, TDP-43 was significantly reduced in the nuclei and it lacked cytoplasmic mislocalization. These changes were associated with the presence of truncated and phosphorylated TDP-43 species. Our findings show that fibroblasts from ALS patients recapitulate some of hallmark TDP-43 abnormalities observed in neuronal cells. Though TDP-43 appears to be differentially processed in fibroblasts versus neuronal cells from ALS patients, primary fibroblast cultures may represent a helpful tool to investigate TDP-43-mediated disease mechanisms.

PM10.02

A novel mutation in the *MYBPC1* gene causes atypical Arthrogryposis Multiplex

N. Ekhilevitch[1], *A. Kurolap*[1], *D. Oz-Levi*[1], *A. Mory*[1], *T. Hershkovitz*[1], *H. Mandel*[2,3], *H. N. Baris-Feldman*[1,3];

[1]*The Genetics Institue, Rambam Health Care Campus, Haifa, Israel,* [2]*Metabolic Unit, Rambam Health Care Campus, Haifa, Israel,* [3]*Rappaport School of Medicine, Technion – Israel Institute of Technology, Haifa, Israel.*

Introduction

Arthrogryposis multiplex congenita (AMC) is characterized by nonprogressive multiple joint contractures appearing at birth. We present a 20-months-old boy, the third child of Israeli-Druze first-degree cousins. He presented with AMC, hypotonia, hearing impairment, FTT and mild motor delay. His older deceased sister was described with a similar but more severe phenotype, which included AMC, cleft palate, feeding problems and severe developmental delay. The extended family includes a 16 y/o cousin presenting with isolated AMC, whose deceased sister was described with AMC and cleft palate.

A variable intra-familial phenotype and expected autosomal recessive inheritance prompted molecular diagnosis by whole-exome sequencing.

Methods

Following informed consent by the parents, whole-exome sequencing was conducted on the child's genomic DNA. Variant analysis focused on rare homozygous changes, followed by validation of candidate variants via Sanger sequencing and segregation analysis.

Results

Exome analysis revealed a homozygous missense variant in the *MYBPC1* gene, NM_001254718.1:c.481G>A (p.E161K), affecting the last nucleotide of exon 6. This novel variant was not observed in the common variant databases and segregated as expected within the extended family.

Discussion

The *MYBPC1* gene encodes a slow skeletal muscle isoform, essential for muscle contraction. Heterozygous mutations in this gene are associated with distal arthrogryposis type 1b, whereas a homozygous nonsense mutation is implicated in lethal congenital contracture syndrome 4. Our family expands the phenotypic spectrum of *MYBPC1* mutations. Our novel c.481G>A variant alters the last nucleotide of the exon 6 and therefore may affect splicing, allowing residual protein function which leads to a milder phenotype.

PS10.03

Mutation screening in rare myopathies

E. Horváth[1], *N. Nagy*[1,2,3], *S. Tamási*[4], *K. Farkas*[2], *M. Széll*[1,2];

[1]*Department of Medical Genetics, University of Szeged, Szeged, Hungary,* [2]*Dermatological Research Group of the Hungarian Academy of Sciences, University of Szeged, Szeged, Hungary,* [3]*Department of Dermatology and Allergology, University of Szeged, Szeged, Hungary,* [4]*Géza Hetényi Hospital of the Jász-Nagykun-Szolnok County, Szolnok, Hungary.*

The myopathies are neuromuscular disorders in which the primary symptom is muscle weakness due to dysfunction of muscle fiber. Other symptoms of myopathy can include include muscle cramps, stiffness, and spasm. The aim of our study was to identify the underlying genetic abnormalities in case of two patients with rare myopathies. A 4-year-old Hungarian boy presenting with the clinical and histological findings of nemaline myopathy type 2, and a 5-month-old infant with the histological diagnosis of centronuclear myopathy were investigated. Peripheral blood samples were taken from the patients and genomic DNA was isolated. Direct sequencing of the NEB and MTM1 genes was performed. The mutation screening of the NEB gene revealed two previously unreported heterozygous mutations: a deletion (c.24527_24528delCT p.P8176fsX8179) in exon 174 and a duplication (c.24250_24253dupGTCA p.T8085fsX8100) in exon 171 in the DNA sample of the patient with nemalin myopathy. In case of the patient suffering from centronuclear myopathy, the genetic analysis detected a hemizygous nonsense mutation (c.1456C/T p.Arg486X CM990881) in the MTM1 gene. These mutations result in the formation of premature termination codons, thus tey presumably leading to truncated nebulin and myotubularin proteins. Our investigations have great importance for the affected families since they help family planning. Hopefully, these findings might also provide the basis of future studies for the development of novel therapeutic modalities in neurogenetic disorders.

PM10.04

Exome sequencing in a patient with Charcot-Marie-Tooth disease

G. J. Braathen[1,2,3], *K. Tveten*[1], *H. Høyer*[1], *Ø. L. Holla*[1], **Ø. L. Busk**[1];

[1]*Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway,* [2]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway,* [3]*Campus AHUS, Akershus University Hospital, University of Oslo, Nordbyhagen, Oslo, Norway.*

Background

Charcot-Marie-Tooth disease (CMT) is characterized by progressive loss of the peripheral motor and sensory nerves and is the most common inherited neuropathy, affecting 1 per 1,214 persons in the general population. More than 70 CMT genes have been identified. The duplication of peripheral myelin protein 22 (PMP22) causes 20-50% of all CMT cases while point mutations are assumed to cause the remaining CMT cases.

Genetic analysis to discover point mutations have traditionally been performed with the laborious and time consuming Sanger sequencing.

High-Throughput Sequencing (HTS) is fairly quick and to a low cost compared with old methods when sequencing many genes simultaneously. Exome sequencing is a technique for sequencing all the protein-coding genes in a genome.

Material and Methods

A sporadic CMT case and her parents were investigated with exome HTS sequencing.

Results

We identified a novel homozygous missense variant in the SET binding factor 1 (SBF1) gene probably causing CMT in this family.

Conclusion

To our knowledge, this is the second CMT family with SBF1 mutation.

PS10.05

Copy number variations in a population-based study of Charcot-Marie-Tooth disease

H. Høyer[1,2,3], *G. J. Braathen*[1,2,3], **A. K. Eek**[1], *G. B. N. Nordang*[1], *L. Strand*[1], *C. F. Skjelbred*[1], *M. B. Russell*[2,3];

[1]*Section of Medical Genetics, Telemark Hospital, Skien, Norway,* [2]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway,* [3]*Campus Akershus University Hospital, University of Oslo, Nordbyhagen, Norway.*

Copy number variations (CNVs) are important in relation to diversity and evolution, but can sometimes cause disease. The most common genetic cause of the inherited peripheral neuropathy Charcot-Marie-Tooth disease is the *PMP22* duplication; otherwise, CNVs have been considered rare.

We investigated CNVs in a population-based sample of Charcot-Marie-Tooth (CMT) families. The 81 CMT families had previously been screened for the *PMP22* duplication and point mutations in 51 peripheral neuropathy genes, a genetic cause was identified in 37 CMT families (46%). Index patients from the 44 CMT families with an unknown genetic diagnosis were analysed by whole-genome array comparative genomic hybridization to investigate the entire genome for larger CNVs, and multiplex ligation-dependent probe amplification to detect smaller intragenomic CNVs in *MFN2* and *MPZ*.

One patient had the pathogenic *PMP22* duplication not detected by previous methods. Three patients had potentially pathogenic CNVs in the *CNTNAP2*, *LAMA2* or *SEMA5A*, i.e. genes related to neuromuscular or neurodevelopmental disease. Genotype and phenotype correlation indicated likely pathogenicity for the *LAMA2* CNV, the *CNTNAP2* and *SEMA5A* CNVs remained potentially pathogenic.

Except from the *PMP22* duplication, disease causing CNVs are rare but may cause CMT in about 1% (95% CI 0-7%) of the Norwegian CMT families.

PM10.06

Identification of causal genes in Congenital Myasthenic Syndrome by whole exome sequencing.

E. O'Connor, *A. Töpf, J. Müller, S. Laval, H. Lochmüller;*
MRC Centre for Neuromuscular Diseases, IGM, Newcastle University., Newcastle Upon Tyne, United Kingdom.

Background
Congenital myasthenic syndromes (CMS) are a group of genetically heterogeneous disorders characterised by compromised function at the NMJ. CMS manifests in childhood with fatigable weakness of limb, ocular and bulbar muscles. There are ~20% patients with a clinical diagnosis that still remain genetically undiagnosed despite over 20 known CMS genes.
Aims
To identify novel CMS genes by whole exome sequencing (WES).
Methods
DNA from a cohort of patients with a clinical diagnosis of CMS was sent to deCODE genetics for WES. Variants in the exome were filtered to exclude those with a frequency greater than 1%, those unlikely to significantly impact the protein or not compatible with the inheritance model. Remaining variants were segregated within the families. Three potential candidate genes were identified in four families, which were then analysed *in vitro* and *in vivo* where possible. Zebrafish orthologues were identified for two of the genes, these were then knocked down via antisense morpholino oligonucleotide (MO) injection and phenotype investigated.
Results
MO injection in zebrafish for two genes caused abnormal movement in response to tactile stimulation, shortening and abnormal branching of motor axons, poorly defined somites and disorganisation of muscle fibres.
Conclusion
Three genes have been identified as possible causative genes in CMS by WES. The preliminary studies carried out on zebrafish demonstrated phenotypes consistent with CMS such as disorganisation of muscle architecture and abnormal branching of motor axons. To confirm results obtained using MOs, we plan to utilise CRISPR technology to target the genes in zebrafish.

PS10.07

A case of TTN-related autosomal recessive congenital centronuclear myopathy

T. Adyan[1], *G. Rudenskaya*[1], *S. Artemieva*[2], *V. Sukhorukov*[2], *A. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Research Institute for Clinical Pediatrics Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

Gene TTN (titin; locus 2q31.2) is responsible for several phenotypes: cardiomyopathies and skeletal myopathies with or without heart involvement differing by inheritance, age of onset and other features. Centronuclear (myotubular) myopathy, in its turn, is clinically and genetically heterogeneous, MYF6-, DNM2-, BIN1-, MTM1-, CCDC78-related forms are known. Recently several cases of TTN-related recessive congenital centronuclear myopathy were described (Ceyhan-Birsoy et al, 2013). We present another case in 7-year-old boy, an only child in Russian family. In three weeks he underwent surgery on coarctation of aorta. By 1-2 years congenital myopathy became evident. Myopathy was predominantly proximal, with CPK 1000-1300 U/l, early knee and ankles contractures, kyphoscoliosis, pectus carinatum, feet deformation, mild facial dysmorphism and no cardiomyopathy. Mental development and brain MRI were normal. Muscle biopsy performed in five years detected centronuclear myopathy. DNM2 and MTM1 mutations were not found. By that time the boy sat independently and crawled actively. With further periodic treatment in China he was improving and recently began to walk with bent spine and self-support (hands on knees). In Beijing DEYI Clinical Laboratory exome sequencing was performed. Of numerous findings those in TTN were of probable diagnostic value: compound heterozygosity for mutations c.94123G>T (exon 358) and c.98868insA (exon 360) of paternal and maternal origin correspondingly were detected. We tested results by Sanger sequencing. Clarified TTN genotype was: c.[94120insA,94123G>T] + [98868insA]. The diagnosis permits prenatal/preimplantation DNA testing in the family. Coarctation of aorta in the child is evidently independent.

PM10.08

Mutation of SLC5A7 associated with distal hereditary motor neuropathy

K. E. S. Barwick[1], *M. A. Bower*[2], *M. M. McEntagart*[3], *D. Walk*[4], *A. H. Crosby*[1];
[1]*RILD Wellcome Wolfson Centre, University of Exeter, Exeter, United Kingdom,* [2]*Genetic Counselling, University of Minnesota, Minneapolis, MN, United States,* [3]*St. George's University of London, London, United Kingdom,* [4]*Department of Neurology, University of Minnesota, Minneapolis, MN, United States.*

Neurodegenerative diseases are becoming increasingly prevalent with the aging population, and are among the major contributors to disability and disease worldwide. The identification of the gene defects responsible has played a major role in our understanding of the pathogenic processes involved, and provided opportunity to develop targeted treatment strategies.
The neuromuscular junction (NMJ) is a specialised synapse with a complex molecular architecture that provides for reliable transmission between the nerve terminal and muscle fibre. We previously identified a mutation in SLC5A7, which encodes the presynaptic choline transporter critical for normal NMJ signalling, as the cause of a dominantly-inherited motor neurone disease (distal hereditary motor neuropathy type VII; dHMN-VII). We established that the mutation responsible resulted in the dominant-negative interference of the mutant molecule with function of the wild type choline transporter, resulting in significantly reduced (although not completely abolished) transporter activity. Here, we investigated a second family with clinical features overlapping those of dHMN-VII. We identified a distinct frameshift *SLC5A7* mutation indicative of a similar dominant-negative disease mechanism. We also modelled the mutation identified in a cell-based system to investigate transporter function. Together our findings corroborate a dominant-negative disease mechanism arising from SLC5A7 mutation as a cause of dHMN-VII, and provide further insight into the role of aberrant choline transporter function in neurological disease.
Supported by MRC grant G1002279 and the Neurosciences Research Foundation.

PS10.09

Algorithm of molecular genetic investigation in Duchenne muscular dystrophy (case report)

P. Hedvicakova[1], *J. Haberlova*[2], *J. Drabova*[1], *Z. Musova*[1], *L. Apltova*[1], *J. Zamecnik*[3], *F. Losan*[4], *A. Krepelova*[1];
[1]*Institute of Biology and Medical Genetics, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic,* [2]*Department of Paediatric Neurology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic,* [3]*Institute of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic,* [4]*Genetika Plzeň, Ltd., Plzen, Czech Republic.*

Duchenne/Becker muscular dystrophy (DMD/BMD) is an X–linked neuromuscular disorder characterised by progressive muscular weakness. The incidence is 1 in 3500 male births.
We present an atypical case of a 6-year-old boy without family history, with a partial deletion of exon 51 of the DMD/BMD gene, which has not been described yet. We show the algorithm of investigation and methods used.
MLPA investigation performed at the age of 2 years has proved neither a deletion, nor a duplication. Sequencing of the whole gene revealed a possible partial deletion of exon 51. The range of this deletion was determined using aCGH. Primers located behind the deletion were selected and the resulting PCR product was sequenced, revealing the deletion of the last 60bp of exon 51 and a huge part of intron 51 (over 27kb). Thus the donor splice site is destroyed.
The investigation of the mRNA obtained from the muscle biopsy of the patient ascertained the occurrence of three transcription products, two of which changing the reading frame and subsequently leading to a premature stop codon, the third one lacking the last 46 codons of exon 51.
The diagnosis could have been determined thanks to the cooperation of several departments. A clinical geneticist and neurologist expressed suspicion of the disease based on elevated liver enzymes. The convincing clinical picture further developing led to deeper investigation and with the help of a molecular cytogeneticist and a pathologist to the precise diagnosis.
Supported by grant for conceptual development of research organization University Hospital Motol 00064203 from the Ministry of Health of the Czech Republic.

PM10.10

Survival in patients with Duchenne muscular dystrophy and cardiomyopathy in long-term follow-up.

M. Treneva, *O. Groznova;*
Research and Clinical Institute for Pediatrics at Pirogov Russian National Research Medical Universi, Moscow, Russian Federation.

Purpose: Duchenne muscular dystrophy (DMD) patients often have cardiomyopathy. Unsuccessful treatment of
congestive heart failure symptoms in DMD patients is a big problem.
Methods: in 68 patients follow-up was from 6 up to 18 years (all
with verified mutations of dystrophin gene). Cardiac examination was made.

Result: all the patients were found to have indications for the use of an ACE inhibitor and almost half of the children had those for the administration of beta-blocker. Patients were divided in two groups: group I (n=35) received long-term courses of an ACE inhibitor (captopril in a dose of 0,5 mg/kg/day)
and a beta-blocker (metoprolol by individually adjusting its dose). Despite recommendations, Group 2 (n=33) were not treated with the above drugs. Mortality
in group I during the follow-up period was 37% (13 patients), in group II - 60%
(20 patients). In group I mean death age was 21,15 years, in group II - 18,25 years (no significant difference were found). The part of survived patients to the age of 21 years was significantly higher in group I: related frequency 0,77 (95% CI 0,5983···0,94) versus 0,39 (95% CI 0,19···0,5974). Conclusion: early started long-term treatment by ACE
inhibitor
and a beta-blocker in patients with Duchenne muscular dystrophy significantly increased the part of survived patients to the age of 21 years.

PS10.11
Identification of a synonymous variant as disease causing mutation in a DMD carrier

J. Sanz[1], D. Niedrist[2], S. Gallati[1], **F. Joncourt**[1];
[1]Division of Human Genetics, University Hospital, Bern, Switzerland, [2]Institute for Medical Genetics, Zürich, Switzerland.

A fifty year old woman was referred to our laboratory for analysis of the dystrophin gene. Her brother had died from Duchenne muscular dystrophy with unknown molecular cause. Based on elevated CK-levels in 1988 she had been identified as probable DMD carrier. After exclusion of a large deletion/duplication sequencing of the *DMD* coding region revealed the novel heterozygous variant: c.1329C>T. The substitution is synonymous, but as it is located near the end of exon 11, an effect on splicing was suspected. In order to prove or exclude such an effect transcript analysis was essential. A muscle biopsy was not feasible and the possibility of creating a lymphoblastoid cell line was lacking. Therefore RNA extraction from buccal and nasal epithelial cells was attempted. Even though full length dystrophin is not expected to be expressed in these tissues, nasal epithelial cells, but not buccal cells, proved to be a good source of *DMD* mRNA for our purpose. An aberrant transcript not present in a normal control was identified, reamplified and sequenced. The aberrant transcript was found to lack the four last bases of exon 11, r.1328_1331delGCAA, thus leading to a frameshift and a premature stop codon, p.(Ser443Ilefs*5). The results were in accordance with several *in silico* analyses. Taken together our findings yield convincing evidence, that c.1329C>T indeed is a disease causing mutation. Furthermore, nasal epithelial cells, which in contrast to muscle biopsies and blood samples can be obtained in a non-invasive way, proved to be a good alternative material for transcript analysis.

PM10.12
Genetic confirmation of germline mosaicism in a Duchenne muscular dystrophy Tunisian family

M. Gribaa[1], *W. Manoubi[1,1], A. Mili[1], H. Ben Hamouda[2], S. Sassi[1], I. Ben Charfeddine[1], A. Amara[1], I. Chatti[1], D. Hmida[1], A. Chaieb[3], A. Saad[1];*
[1]Laboratory of Human Cytogenetics, Molecular Genetics and Reproductive Biology Farhat Hached University, Sousse, Tunisia, [2]Department of Pediatrics, Tahar Sfar University Hospital, Mahdia, Tunisia, [3]Department of Pediatrics, Farhat Hached University Hospital, Sousse, Tunisia.

Introduction: Duchenne muscular dystrophy (DMD) is an X-linked recessive genetic dystrophinopathy related to the absence of Dystrophin cytoskeletal protein. This disease affects generally boys; women are vectors.
Objective: In this context, we report a molecular study in a Tunisian family affected by DMD. Genetic analysis showed a particular transmission profile indicating a maternal germline mosaicism.
Patients and methods: Here we report a family composed by four boys and two girls. Genetic study was performed by MLPA and a modified fluorescent PCR (TP-PCR). MLPA allowed deletions and duplications analysis of different dystrophin's gene exons. Genotyping of six microsatellite markers, using the TP-PCR technique, helped to establish the haplotype of each individual and to follow its transmission in this family.
Result: MLPA showed, in both affected boys, a deletion of the exons 61 and 62 of the Dystrophin gene. However, the genotyping study revealed the presence of the disease associated haplotype in three boys in whom one is phenotypically healthy with no deletion responsible for the disease.
Discussion and Conclusion: Genetic analysis showed a particular transmission profile indicating a maternal germline mosaicism. She transmitted the same haplotype of the X chromosome to three of her sons, of which only two are sick and carrying the deletion of exons 61 and 62 of the Dystrphin gene. This can be explained by the presence of two cell populations in the germ cells of the mother: one carries the deletion and the other not, allowing a random transmission of the disease to her sons.

MuSK - a new target for lethal fetal akinesia deformation sequence (FADS)

M. Wilbe[1], *S. Ekvall[1], K. Eurenius[2], K. Ericson[1,3], O. Casar-Borota[1,3], J. Klar[1], N. Dahl[1], A. Ameur[1], G. Annerén[1], M. Bondeson[1];*
[1]Immunology, Genetics and Pathology and Science for Life Laboratory, Uppsala, Sweden, [2]Women's and Children's Health, Uppsala, Sweden, [3]Pathology and Cytology, Uppsala, Sweden.

Fetal akinesia is clinically and genetically heterogeneous disorders, with the common feature defined as reduced or loss of fetal movement. Several disease genes of fetal akinesia have been described, but the genetic etiology of majority of cases is still unknown.
We report on a family with recurrent fetal loss, where the parents had five affected fetuses with fetal akinesia deformation sequence (FADS [MIM 208150]) and one healthy child. The fetuses displayed no fetal movements from gestational age of 17 weeks, extended knee joints, flexed hips and elbows and clenched hands. There was polyhydramnion and no visible fetal stomach. Whole exome sequencing were performed on a family trio and only one candidate homozygous variant was identified in the fetus, c.40dupA (p.Thr14Asnfs*9), located in *MuSK* (muscle, skeletal, receptor tyrosine kinase). Segregation analysis revealed homozygosity for all affected fetuses, while the variant was not present in the healthy child. The c.40dupA variant leads to a frameshift in MuSK predicting a premature stop codon, but the mutated mRNA is not cleared by nonsense-mediated decay pathway, which is currently under investigation.
MuSK is an agrin-dependent receptor tyrosine kinase required for formation of the neuromuscular junction and missense mutations in this gene have previously been described in congenital myasthenic syndrome (CMS). Interestingly, MuSK is located in the same acetylcholine receptor pathway as several other genes reported to cause CMS and/or FADS.
Additional families with intra-uterine fetal death, fetal akinesia and FADS are under currently under investigation, aiming to increase knowledge of genetic etiology in unresolved cases.

PM10.14
GJB1 mutations in Croatian CMT patients

A. Merkler[1], *Z. Mitrovic[1], J. Sertic[1,2];*
[1]University Hospital Centre Zagreb, Zagreb, Croatia, [2]University of Zagreb School of Medicine, Zagreb, Croatia.

Introduction: In heterogeneous group of hereditary motor and sensory CMT neuropathies, GJB1 mutations causing M.Charcot-Marie-Tooth X type 1 (CMTX1) are considered to be second most common, following PMP22 variants. The disease is most often characterized by severe distal muscles weakness and atrophy, sensory loss and foot deformity. Female carriers can be mildly affected or asymptomatic. The diagnosis is suspected on NCV profile, featuring an intermediate velocity range. We report the results of GJB1 clinical and molecular study in the first series of Croatian CMT patients.
Objective: The detection and phenotypic characterization of GJB1 mutations in Croatian CMT patients.
Materials and methods: Following clinical and EMG examination, 22 suspected samples from 18 families, negative for PMP dupl/del, were analyzed for the mutations in GJB1 coding region. Applied Biosystems 3130xl Genetic analyzer and BigDye® Terminator v3.1 Cycle Sequencing Kit were used. The prediction of new variants pathogenicity was made with PolyPhen-2 software.
Results: GJB1 missense point mutations were found in 12 patients from 9 families (7 heterozygous, 5 hemizygous). In 3 unrelated families p.Val170Asp was found. In each of the remaining 6 families different mutations were found (p.Leu108Pro, p.Val13Met, p.Ser49Pro, p.Arg183His). Two mutations were not described previously: p.Phe141Ser (c.422T>C) and p.Val177Met (c.529G>A). Very severe phenotype was characteristic of novel p.Phe141Ser in hemizygous and also heterozygous state. Cardinal phenotypic features are compared.
Conclusions: GJB1 mutations were found in one half of CMTX1 suspected patients/families. In hemizygous and also heterozygous patients, phenotype is often severe, yet varies from mild/asymptomatic to devastating, with earliest distal sensory involvement.

PS10.15

GNE variants in a family with a complex neurological syndrome

E. Koschmidder[1], *I. Brænne*[2], *B. Arif*[3], *S. Naz*[3], *S. Hinderlich*[4], *C. Klein*[1], *K. Lohmann*[1]; [1]*Institute of Neurogenetics, Luebeck, Germany,* [2]*Institute for Integrative and Experimental Genomics, Luebeck, Germany,* [3]*School of Biological Sciences, Lahore, Pakistan,* [4]*Department of Life Sciences and Technology, Beuth University of Applied Sciences, Berlin, Germany.*

A consanguineous Pakistani family with a complex neurological syndrome including dystonia, pyramidal signs, limited speech, and hearing loss (Arif et al. Mov Disord 2011;26:2279-2283) was investigated. An autosomal recessive mode of inheritance was assumed in the five affected siblings. The ancestors and two siblings were healthy. In order to identify the genetic cause, genome sequencing was performed in two patients. Filtering for rare, shared, homozygous variants, predicted to alter the protein sequence revealed variants in six different genes (FER1L6, ABP1, DIAPH3, DUSP5, EMG1, MPP2). Since none of the variants segregated within the family, filtering for compound heterozygous variants identified eight candidate genes (SQLE, SPRED1, GNE, LEFTY1, MYH9, CDC42BPA, DHX57, STAB1). Only the two variants in GNE (p.R101C, p.L332F [NP_005467]) segregated with the disease in the family. While L332F was novel and not found in ethnically matched controls, R101C had a minor allele frequency of 0.3% in 190 Pakistani controls and of 0.002% among Europeans at http://exac.broadinstitute.org/gene/ENSG00000164116. Both variants are in-silico predicted to be pathogenic and are located in the epimerase domain of Glucosamine (UDP-N-acetyl)-2-epimerase/N-acetylmannosamine kinase (GNE). GNE encodes a bifunctional enzyme needed for the rate-limiting step in sialic acid synthesis. Experiments to access epimerase activity in the mutants are underway. Mutations in GNE are known to cause GNE-related myopathy and sialuria. A disease-causing effect of our GNE variants might suggest pleiotropy for mutations in GNE. However, results are based on a single family only. Thus, further research is warranted to elucidate the full phenotypic spectrum of GNE mutations.

This study was supported by the German Research Foundation (LO 1553/8-1).

PM10.16

Results of multigene panel testing for inherited peripheral neuropathy reveal a high prevalence of autosomal recessive genetic aetiology, not restricted to severe early onset disease

R. Whittington[1], *S. Burton-Jones*[1], *N. Forrester*[1], *D. Lim*[2], *T. Willis*[3], *G. Dennis*[1], *D. Smith*[1], *M. Williams*[1], *T. Antoniadi*[1];
[1]*Bristol Genetics Laboratory, North Bristol NHS Trust, Bristol, United Kingdom,* [2]*Clinical Genetics Unit, Birmingham Women's Hospital NHS Foundation Trust, Birmingham, United Kingdom,* [3]*The Muscle team, Robert Jones and Agnes Hunt Hospital, Oswestry, United Kingdom.*

Inherited peripheral neuropathy (IPN) is a clinically and genetically heterogeneous group of disorders involving more than 90 genes and various modes of inheritance. Since July 2013 we have provided a 56-gene IPN NGS panel assay as a specialist UK Genetic Testing Network service. This is a frontline diagnostic tool and has largely replaced single-gene Sanger sequencing. Of the 56 genes included, 26 are associated with an autosomal recessive form of the condition, and for the majority of those no diagnostic service was previously available.

During the first 18 months more than 500 patient results were issued following IPN gene panel testing. Of all the positive diagnostic results, up to one third involved recessive genes. We present the distribution of recessive cases, the genes and phenotypes involved, and highlight individual case studies.

Autosomal recessive inheritance might typically be expected in severe, early onset, progressive neuropathy; however in our cohort a large proportion of patients were over 18 upon genetic diagnosis, including some cases assumed to be sporadic. This broadens the spectrum of phenotypes associated with recessive genes.

Our data shows that gene panel testing is a powerful, unbiased approach for genetic diagnosis in IPN. It provides a higher diagnostic yield, faster and at a lower cost than sequential single-gene screening of the proband, allowing efficient clinical management and family follow-up.

PS10.17

IPS cells creation to generate iPSc-derived motor neurons: a new cellular model to progress in the understanding of the axonal Charcot-Marie-Tooth disease

P. Faye[1], *N. Vedrenne*[2], *L. Richard*[1,3], *S. Bourthoumieu*[1,4], *B. Funalot*[5], *F. Sturtz*[1,6], *A. Lia*[1,6]; [1]*EA6309 Myelinic Maintenance and Peripheral Neuropathies, Faculty of Medicine and Pharmacy, Limoges, France,* [2]*EA 3842 Cellular Homeostasis and Pathology, Faculty of Medicine and Pharmacy, Limoges, France,* [3]*Neurology Department , CHU of Limoges, Limoges, France,* [4]*Cytogenetic Department, CHU of Limoges, Limoges, France,* [5]*Genetic Department, Henri-Mondor's Hospital, Paris, France,* [6]*Biochemistry and Molecular Genetic Department, CHU of Limoges, Limoges, France.*

Induced pluripotent stem cells (iPSc) are a highly interesting solution to create and observe the behavior of specific and unattainable cells from a patient. Our team is interested in genetic peripheral nerves disease and in particular in Charcot-Marie-Tooth pathology (CMT). One of our objectives is the development of motoneurons models from patients using the iPSc strategy in order to better understand the pathophysiology of *GDAP1* gene. This gene was described in 1998 to be responsible for a CMT axonal form and it encodes a mitochondrial outer membrane protein, but its function is still unclear.

We first obtained dermal fibroblasts (DF) from skin biopsies of a healthy person and of a homozygous patient carrying *GDAP1* nonsense mutation. Then, we reprogrammed DFs into iPSc using non-integrative plasmids (Oct4, Sox2, Klf4 and cMyc). After amplification, all quality controls were performed to conclude that our iPSc had the same properties and capacities than embryonic stem cells and a normal karyotype. Finally, we optimized protocols to successfully differentiate these iPSc into rosettes (structures full of neural progenitors), then into neurons and finally into motoneurons for control and GDAP1 patients.

Generation of motoneurons using axonal CMT-patient-derived iPSc was a first crucial step to better understand the role of GDAP1 in this pathology. Dynamic study of these *in-vitro* motoneurons, like observing their mitochondria in real time, will be then possible. The endpoint of this study will be to perform screenings of various drugs, so as to restore the function of these cells.

PM10.18

Whole exome sequencing approach in genetic diagnosis of limb girdle muscular dystrophy.

J. P. Fichna[1], *A. Macias*[2], *M. Szymczyk*[2], *A. Kamińska*[2], *C. Żekanowski*[1];
[1]*Mossakowski Medical Research Centre, Warsaw, Poland,* [2]*Medical University of Warsaw, Warsaw, Poland.*

Limb-girdle muscular dystrophy (LGMD) is a heterogeneous group of genetically determined disorders, characterized by primary or predominantly proximal distribution of muscle weakness. So far over 25 different *loci* associated with the disease have been identified. However, a large overlap of phenotypic manifestations resulting from different gene mutations poses a challenge for determination of the exact type of the muscular disease. Moreover new genes are still to be discovered as up to 50% clinical LGMD cases are left without molecular diagnosis.

To accelerate molecular diagnosis and to find novel genes involved in the disease we have adapted Whole Exome Sequencing (WES) workflow. Variants prioritisation was based on predicted pathogenicity, dbSNP information, and affected molecular pathways.

So far we have analysed genomic DNA samples from 34 LGMD patients, and in 17 cases we found mutations in the genes already associated with the disease: *CAPN3*, *DYSF*, *FKRP*, *ANO5*, *PLEC1* and *SGCA*. Two patients had more than one known gene affected. Apart from causative mutations also additional variants in genes related to muscle diseases (*TTN*, *DES*, *COL6A2*, *COL6A3*, *LDB3/ZASP*, *RYR1*, *LMNA*, *LARGE*, *NEB*, *FLNC*) that might contribute to the clinical phenotype were found.

Genetic diagnosis was possible more often in a group clinically determined as dysferlinopathies and calpainopathies with 14 out of 20 patients harbouring pathological variants in known genes. In the group of 14 patients with less typical phenotype instant genetic diagnosis was made only in three cases. Genetic etiology of patients without mutations in already known LGMD genes is being further investigated.

The research was supported by the KNOW-MMRC project (JPF).

PM10.20

LMNA related Congenital Muscular Dystrophy (L-CMD) - clinical review of patients diagnosed at the Newcastle MRC centre for Neuromuscular Diseases in the last 10 years.

M. Bertoli, *J. Hudson, H. Lochmüller, V. Straub, K. Bushby;*
Newcastle University John Walton Centre for Muscular Dystrophy Research, MRC Centre for Neuromuscular Diseases Institute of Genetic Medicine, International Centre for Life, Newcastle upon Tyne, United Kingdom.

Lamin A/C related muscular dystrophies can present in adulthood as Limb-girdle muscular dystrophy 1B and an autosomal dominant form of Emery-Dreifuss muscular dystrophy, or at birth or in very early infancy. Because of the risk of a life threatening cardiac involvement early diagnosis is crucial.

We review the clinical presentation and medical history of a cohort of 10 patients with a laminopathy associated to an early onset muscular dystrophy

(L-CMD, Lamin-related Congenital Muscular Dystrophy). Age at last clinical assessment was 1 to 38 years (mean age 13 years).The severity of the muscular involvement is variable, presenting at birth with severe neonatal hypotonia or in early infancy with an abnormal gait. Contractures and rigid spine can be present at birth but most frequently develop during childhood. Onset of other complications is also variable: severe feeding difficulties were observed in two patients requiring PEG insertion at 4 and 8 years respectively; impaired respiratory function requiring non invasive nocturnal ventilation was observed in two patients at 4 and at 35 years. Symptomatic cardiac arrhythmias requiring defibrillator or pacemaker implantation were observed in two patients, and one patient had asymptomatic sinus tachycardia and diastolic dysfunction at 5 years.
Due to the variable severity of the phenotype an early clinical diagnosis can be challenging, and the interpretation of a novel genetic variants, which requires particular care due to the possible cardiac risk of family members, can even be more complex and requires active interaction between the clinician and the genetic laboratory.

PS10.21

Bilateral congenital lumbar hernias in a patient with central core disease - a case report

J. Lazier[1], *J. K. Mah*[2], *A. Nikolic*[3], *V. Samedi*[4], *X. C. Wei*[5], *C. Fajardo*[4], *M. Brindle*[6], *R. Perrier*[1,7], *M. A. Thomas*[1,7];
[1]*Department of Medical Genetics, Alberta Children's Hospital, Calgary, AB, Canada,* [2]*Section of Neurology, Department of Pediatrics, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada,* [3]*Division of Neuropathology, Department of Pathology and Laboratory Medicine, University of Calgary and Calgary Laboratory Services, Calgary, AB, Canada,* [4]*Division of Neonatology, Department of Pediatrics, University of Calgary, Calgary, AB, Canada,* [5]*Department of Radiology, Faculty of Medicine, University of Calgary, Calgary, AB, Canada,* [6]*Department of Surgery, Alberta Children's Hospital, University of Calgary, Calgary, AB, Canada,* [7]*Department of Pediatrics, University of Calgary, Calgary, AB, Canada.*

Congenital lumbar hernias are rare malformations caused by defects in the development of the posterior abdominal wall. A known association exists with lumbocostovertebral syndrome, however other associated anomalies have been previously reported, including one case with arthrogryposis, suggesting an association with myopathy. We present an infant girl with bilateral congenital lumbar hernias, multiple joint contractures, decreased muscle bulk and symptoms of malignant hyperthermia. Molecular testing revealed an R4186C mutation in the ryanodine receptor 1 (RYR1) gene, known to be associated with central core disease. This is the first reported case of a child with congenital lumbar hernias and central core disease.
Stromal interaction molecule 1 (STIM1), which modulates calcium flow through RYR1, plays an important role in skeletal muscle differentiation. Mutations in STIM1 have been previously shown to result in immunodeficiency and myopathy. It is possible that downstream RYR1 mutations may also impair store-operated calcium entry, leading to altered calcium-dependent signalling pathways that interrupt muscle differentiation and development. This case suggests an expansion of the central core disease phenotype to include congenital lumbar hernias.

PM10.22

Genetic diagnosis of the Myotonic Dystrophies by Molecular Combing

M. Larsen[1], *S. Rost*[1], *J. Komatsu*[2], *N. Frankenbach*[2], *A. Bensimon*[2], *C. R. Müller*[1];
[1]*Department of Human Genetics, University of Würzburg, Würzburg, Germany,* [2]*Genomic Vision, Paris, France.*

Myotonic Dystrophy type 1 and 2 (DM1, DM2) together represent the most common muscular dystrophies in adults with a frequency of 1:8000. Both diseases are associated with an expansion of a microsatellite repeat within the untranslated regions of two different genes, DMPK and ZNF9, respectively.
Currently, the gold standard for genetic DM diagnosis is Southern blotting by which the repeat sizes for DM1 can be determined accurately. This is not the case for DM2, due to the somatic instability of the expanded alleles. Therefore, we developed an alternative diagnostic technique for DM based on molecular combing in order to analyze both repeat loci in parallel and to quantify expanded DM2 alleles.
Molecular Combing is an *in situ* hybridization like technique where locus specific probes are hybridized to uniformly stretched genomic DNA. Different loci can be detected by individually designed probes. We designed a diagnostic protocol for assaying the DM1 and DM2 loci together in one approach. The two loci including the repeat itself are reliable detected by two different probe sets and repeat sizes can be measured directly with an accuracy of 0.8 kb (±0.4). For the first time, the Molecular Combing DM-test allows for a quantification of expanded DM2-alleles on single molecules. We demonstrate that there is a wide size range of repeats in the sample of an individual DM2 patient which is in accordance with previous speculations in the literature. In order to use this method in routine diagnosis, improvement of the detection limit is needed to distinguish normal alleles from short but pathogenic expansions.

Pediatrics department University Hospital Hassan II Fes

Progressive muscular dystrophies, term proposed by Erb in 1884, form a set of neuromuscular diseases of various etiologies and different severities. These are diseases characterized by progressive degeneration of muscle fibers with a histological formula necrosis refresh characteristic; they also show great phenotypic and genotypic heterogeneity.
In this present study, we were interested to take stock of the Sacroglycanoapthies due to their greater frequency in Morocco and their very close clinical characteristics, as well as the implementation of molecular diagnostics in the Laboratory Molecular Biology.
Based on the received clinical data, 24 patients with progressive muscular dystrophies were analyzed by PCR-SSCP screening SGCG the gene, more particularly by targeting c.del525T mutation in exon 6 of the gene, followed by sequencing of the disputed region.
Molecular tests we conducted showed that approximately 40% of patients had a deletion in the c.del525T SGCG gene in the homozygous state. This frequency clearly showed the molecular level the high frequency of these diseases in our country and stressed the importance of testing a priority in our patients.
The diagnostic approach that we used in our study seems well suited for driving in the first instance in our country, especially as it has the advantage of easily allowing a differential diagnosis.

PM10.24

MYH7 exon 31 mutations within the rod domain cause autosomal dominant muscular dystrophy in two un-related Jewish Moroccan families

M. Feinstein-Linial[1], *M. Buvoli*[2], *A. Buvoli*[2], *M. Sade*[3], *D. Dayan*[1], *L. A. Leinwand*[2], *O. S. Birk*[1];
[1]*Morris Kahn laboratory of human genetics at the national institute of biotechnology in the Negev, Beer-sheva, Israel,* [2]*Department of molecular, cellular and developmental biology, university of Colorado, Boulder, CO, United States,* [3]*Department of neuromuscular diseases , Wolfson medical center, Holon, Israel.*

Skeletal myofibers are characterized by the expression of particular myosin isoforms. In slow twitch, type I fibers, which display oxidative metabolism and high endurance, the predominant myosin is MYH7, encoding the slow/β-cardiac MYH. MYH7 mutations have been associated with at least 5 different clinical phenotypes, among them are Dilated Cardiomyopathy 1S/ Left Ventricular Noncompaction 5 (MIM613426), Familial Hypertrophic Cardiomyopathy 1 (MIM192600), Laing Distal Myopathy (MIM160500), Myosin Storage Myopathy (MIM608358) and Scapuloperoneal Syndrome, Myopathic Type (MIM181430). Two unrelated families of Jewish Moroccan ancestry presented with apparently autosomal dominant heredity with partial penetrance of a unique progressive muscular dystrophy somewhat reminiscent of Laing Distal Myopathy. Whole exome sequencing identified in both families two different heterozygous mutations within exon 31 of MYH7: c.4309G>C (p.Ala1437Pro) and c.4301G>C (p.Arg1434Pro). Each of the mutations impair myosin self-assembly properties and has dominant negative activity in nonmuscle cells, as was demonstrated in COS-7 cells transfected with β-myosin constructs carrying the mutations. Of MYH7 mutations, proline mutations within the Rod domain were shown to cause Laing distal myopathy and to be the most damaging to MYH7 Rod domain. Thus, our functional studies demonstrate that the Laing-like partly-penetrant myopathy stems from mutations affecting the myosin rod domain.

PS10.25

Healthy, premutation and mutation range myotonic dystrophy type 2 alleles - seeking the approximate borders between stable and unstable repeat motifs

J. Radvanszky[1,2], *E. Radvanska*[3], *E. Nagyova*[2], *P. Spalek*[4], *A. Valachova*[5], *T. Szemes*[2], *G. Minarik*[2,6], *L. Kadasi*[1,2];

[1]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [3]*Department of Neonatology, Faculty Hospital, Nove Zamky, Slovakia,* [4]*Centre for Neuromuscular Diseases, University Hospital, Bratislava, Slovakia,* [5]*Department of Clinical Genetics, Faculty Hospital, Trencin, Slovakia,* [6]*Institute of Molecular BioMedicine, Faculty of Medicine, Comenius University, Bratislava, Slovakia.*

Introduction: Myotonic dystrophy type 2 (DM2) is caused by expansion of a (CCTG)n repeat in the CNBP1 gene. In healthy-range alleles the repeat is generally interrupted by one or more GCTG, TCTG or ACTG motifs. Uninterrupted tracts were, however, described in expanded alleles as well as in larger healthy-range alleles which are generally considered as DM2 premutations. The threshold for pathogenicity is still poorly described in the literature, while the smallest reported pathogenic alleles had 55 and 75 CCTG repeats, respectively.

Materials and methods: For DNA analyses we used conventional PCR and bi-directional repeat-primed PCR complemented by Sanger sequencing and targeted massively parallel sequencing where needed.

Results: We identified wider range and higher frequency of uninterrupted alleles than it was previously reported, with 15 alleles characterised in total, spanning the whole spectrum of healthy-range alleles. We therefore further investigated the intergenerational stability of these alleles. Moreover, in two unrelated patients with symptoms of neuromuscular disorder we identified two ambiguous alleles, containing 31 and 34 uninterrupted CCTG repeats. Since further analyses revealed a full range DM1 expansion in the DMPK gene in the first patient and a homozygous CLCN1 stop mutation in the second patient we concluded that these "grey zone" alleles are most likely not pathogenic themselves, although, they represent unstable premutation alleles. Their possible modifying role, however, cannot be conclusively disclosed.

Conclusion: Our results suggest that uninterrupted alleles with up to ~30 CCTG repeats are likely stable during transmission, while instability gradually increases with increasing length of uninterrupted tracts above this approximate threshold (financial support: VEGA_2/0115/15).

PM10.26

A large deletion affecting *TPM3*, causing severe nemaline myopathy

K. Kiiski[1], *V. Lehtokari*[1], *A. Y. Manzur*[2], *C. Sewry*[2,3], *I. Zaharieva*[3], *F. Muntoni*[2,3], *K. Pelin*[1,4], *C. Wallgren-Pettersson*[1];

[1]*The Folkhälsan Institute of Genetics and the Department of Medical and Clinical Genetics, University of Helsinki, Haartman Institute, Helsinki, Finland,* [2]*Great Ormond Street Hospital, London, United Kingdom,* [3]*Dubowitz Neuromuscular Centre, UCL Institute of Child Health, London, United Kingdom,* [4]*Department of Biosciences, Division of Genetics, University of Helsinki, Helsinki, Finland.*

We present here the first large (17-21 kb) aberration in the α-tropomyosin$_{slow}$ gene (*TPM3*) identified using our self-designed nemaline myopathy (NM) CGH-array. The identified homozygous mutation deletes the promoter as well as the muscle-specific exons 1a and 2b of *TPM3*. The promoter and exon 1b of the non-muscle isoform seem to be intact. The homozygous deletion was identified also using whole-exome sequencing (WES). Previously, we identified one heterozygous nonsense mutation in *NEB* exon 42. We hypothesize that this nonsense mutation may have had a modifying impact on the severe phenotype of the patient. This female infant was born to first-cousin parents. Paucity of movement was noted from birth, and proximal and axial weakness was confirmed at 5 months. Best motor function achieved was rolling from side to side. Failure to thrive led to nasogastric tube feeding at ten and gastrostomy insertion at 13 months. The patient died at age 17.5 months. Muscle biopsy at 5 months showed marked variation in fibre size with several small fibres with slow myosin, some central nuclei, red-staining inclusions on trichrome stain in several fibres, which electron microscopy confirmed as rods, as well as central mitochondrial aggregates. We have screened 196 families with NM or a related disorder using the NM-CGH array. This *TPM3* deletion is the first large rearrangement outside the *NEB* gene, suggesting that large aberrations in the other NM genes are rare. They should, however, be taken into consideration. The NM-CGH microarray method is available for mutation analysis in our laboratory.

PS10.27

The importance of developing the Hellenic Neuromuscular Disorders (HNDR) Registry

K. Kosma, *K. Kekou, C. Sofokleous, S. Kitsiou-Tzeli, E. Kanavakis;*
Department of Medical Genetics, Medical School, University of Athens, Athens, Greece.

The Department of Medical Genetics of Athens University has been the reference centre for neuromuscular disorders in Greece since 1990, being the first lab to offer routine molecular diagnosis and prenatal testing for DMD/BMD (Duchenne / Becker Muscular Dystrophy), SMA (Spinal Muscular Atrophy) , Myotonic Dystrophy and FSHMD.

On 2012 the first national registry for neuromuscular disorders in Greece [Hellenic Neuromuscular Disorder Registry, HNDR)] was created, while on 2013 it has been connected with TREAT-NMD network. Currently the software is configured to register patients with DMD/BMD and SMA disorders and up to now we have included data on 155 patients, from which 18 have SMA and the rest DMD/BMD.

The HNDR has become a hub for information and awareness for the public and the means to link patients and their families with scientists in Greece and all over the world. This structure also enables patients to volunteer for research therapeutic protocols, opening the way for the creation of trial centers in our country. Beyond that, this database has been proven helpful in the research for neuromuscular disorders therapy, genotype-phenotype correlation, and population studies. The HNDR publicizes the extent of the problem in Greece, which additionally helps anyone interested in lobbying for the rights and needs of the patients with neuromuscular disorders.

PM10.28

Genetic testing of inherited muscular dystrophies and myopathies using Next Generation Sequencing

K. Stehlikova, *D. Skalova, L. Fajkusova;*
Centre of Molecular Biology and Gene Therapy, University Hospital Brno, Brno, Czech Republic.

The inherited muscular dystrophies and myopathies comprise a heterogeneous group of muscle diseases that share similar clinical features as progressive skeletal muscle weakness and wasting. Mutations in several genes that encode proteins of extracellular matrix, endoplasmic reticulum, nuclear envelope, sarcolemmal proteins and glycosyltransferases are known to be responsible for muscular dystrophies and myopathies. The large overlap of phenotypic manifestations resulting from different gene mutations poses a challenge for determination exact type muscular disease.

Fistly, we designed capture library to target the coding and all flanking intron regions of 42 genes associated with group of disease as muscular dystrophies, congenital muscular dystrophies, congenital myopathies, distal myopathies and other myopathies. We performed targeted capture combined with next-generation sequencing using NimbleGen SeqCap EZ Choice library in 140 Czech probands. Mutations associated with muscular dystrophies or myopathies were identified in 77 of them. For the rest of patients, we have to confirm detected variants and correlate them with clinical findings of patients. Mutations have been detected in *ACTA1, CAPN3, COL6A1, COL6A3, DMD, DNM2, DYSF, LAMA2,LMNA,RYR1, SGCG, SGCB* and *SEPN1* gene. To be able to offer complex diagnostics of neuromuscular disorders, we broaden our neuromuscular panel by adding of remaining genes from groups chosen in the first panel and by adding genes associated with other groups of diseases: myotonic syndromes, ion channel muscle diseases, metabolic myopathies, congenital myasthenic syndromes, motor neuron diseases and other neuromuscular disorders.

This work was supported by grant IGA MZ CR NT14574-3.

PS10.29

A novel mutation in LRRK2 influences risk for Parkinson disease in the Maltese Population

G. Camilleri[1], *S. Camilleri*[2], *S. Bezzina Wettinger*[1], *R. Farrugia*[1];

[1]*Deaprtment of Applied Biomedical Science, Faculty of Health Sciences, University of Malta, Msida, Malta,* [2]*Department of Physiology and Biochemistry, Faculty of Medicine and Surgery, University of Malta, Msida, Malta.*

Introduction: LRRK2 encodes Leucine-rich repeat kinase 2, one of the most common known autosomal dominant genetic causes of Parkinson disease (PD). Individuals with mutations in LRRK2 present with a phenotype and pathology similar to idiopathic, late onset PD. A number of mutations have been identified in this gene, however, the pathogenic nature of most mutations remains unclear.

Materials and Methods: Next generation sequencing data from healthy individuals was mined for LRRK2 mutations present in the Maltese. A novel mutation (N618S) was identified and genotyped by PCR and RFLP in a PD case-control collection; samples from Malta collected as part of the Geoparkinson

project. Odds Ratio (OR) with 95% confidence interval (CI) was determined using logistic regression.
Results: The novel mutation identified was in exon 16 of LRRK2. The A>G change at c.1853 gives rise to a missense mutation: N618S. Preliminary analysis on part of the Maltese collection gave a minor allele frequency of 0.03 in controls (n=136) and 0.06 in cases (n=73), giving an OR of 2.17 (95%CI: 0.82 - 5.74).
Conclusion: The novel N618S mutation appears to increase risk for PD in the Maltese.

Genetic studies of patients with Parkinson's disease in Ukraine

O. Koliada;
Gerontology Institute, Kiev, Ukraine.

Parkinson's disease is the second most frequently occurring neurodegenerative disorder. The frequency of the disease in a population of people over 60 years is 2%. Diagnosis of the disease is very complicated at the young age, as the first symptoms appear, on average, at the age of 50-60 years. In this regard, especially promising are studies in the field of molecular genetics, results of which can be used in early diagnosis of the disease. The objective of this work was to find genetic markers for Parkinson's disease in populations in Ukraine. 350 patients with PD (210 men and 140 women) were examined after a mean disease duration of 7,6 ± 0,33 years (mean age was 63,1 ± 1,3 years).
Genotyping was performed by PCR-RFLP method and methods based on real-time PCR. For the first time in Ukraine, major mutations in the genes PARK2, LRRK2, SNCA and GBA responsible for hereditary forms of Parkinson's disease were genotyped. Frequencies of mutations in patients that had various peculiarities of the disease and were at different age of manifestation were analyzed. Comparison of telomere length in buccal cells and leukocytes of patients with PD and control group was carried out. Significant differences were revealed in the length of telomeres in buccal epithelium cells in patients and in controls, while in blood cells telomere length did not differ. In addition, a significant correlation between telomere length in blood cells and in buccal epithelial cells was found in patients, but not in control group.

PS10.31
Imbalance of excitatory/inhibitory synaptic expression in Rett syndrome iPSC-based neuronal models

I. Meloni[1], S. Amabile[1], E. Landucci[1], T. Patriarchi[1,2], E. Frullanti[1], A. M. Pinto[1], C. Lo Rizzo[1], F. Ariani[1,3], **F. Mari**[1,3]*, M. A. Mencarelli[3], J. W. Hell[2], A. Renieri[1,3];*
[1]Medical Genetics, University of Siena, Siena, Italy, [2]Department of Pharmacology, University of California, Davis, CA, United States, [3]Genetica Medica, Azienda Ospedaliera Universitaria Senese, Siena, Italy.

Introduction: Rett syndrome is a neurodevelopmental disorder due to de novo mutations in MECP2, CDKL5 or FOXG1 genes. MeCP2 and FoxG1 are transcriptional regulators; CDKL5 is a kinase involved in multiple cellular processes. In spite of their involvement in the same disease, a functional interaction between the three proteins has not been proven and disease mechanisms remain elusive. We reported recently that expression of GluD1 is increased in iPSCs-derived neurons from patients with mutations in *MECP2* and *CDKL5* (Livide et al, Eur J Hum Genet 2015). GluD1 is a post-synaptic protein that induces preferentially inhibitory presynaptic differentiation of cortical neurons.
Methods: We established a human neuronal model based on patients-specific iPSCs and we characterized their expression profile to test the hypothesis that common alterations occur in cells mutated in the three genes.
Results: We identified an over-expression of GluD1 also in FOXG1-mutated cells. Since GluD1 induces inhibitory presynaptic differentiation and an excitation/inhibition imbalance has been suggested in MECP2-related Rett syndrome, we tested the expression of a panel of excitatory and inhibitory markers. Our results demonstrated an excitation/inhibition imbalance in neurons mutated in all three genes. A consistent imbalance was also observed in embryonic FOXG1+/- mouse brain. However, a reduction of both excitatory and inhibitory markers is observed in post-natal mouse models.
Conclusions: Our data provide further evidence in favor of an excitation/inhibition imbalance as an important contributor to the pathogenesis of Rett due to MECP2 mutations and suggest a similar mechanism for CDKL5- and FOXG1-mutated patients.

PM10.32
Performance of SMN1 and SMN2 copy number assays using ddPCR

S. Marrs, *D. Skvortsov, M. Patil, J. Regan;*
Digital Biology Center, Bio-Rad Laboratories, Pleasanton, CA, United States.

Introduction: Spinal muscular atrophy (SMA) is the most common autosomal recessive disease causing death in infants. The disease is caused by the lack of SMN1. The copy number of a highly similar gene, SMN2, determines disease severity. It is difficult to measure SMN1 and SMN2 copy number accurately since these two genes only differ by a single functional nucleotide. Although no therapies currently exist for SMA, five different pharmaceutical companies have therapies in clinical trials. To assess the efficacy of these therapies, it is necessary to measure the number of SMN2 copies accurately in each trial participant.
Materials and Methods: 16 Coriell samples and 93 Kenyan, 70 Mexican, and 96 British HapMap samples were screened for SMN1 and SMN2 copy number using droplet digital PCR (ddPCR).
Results: 99.2% of the samples measured within 10% of the integer for SMN1 and SMN2 copy number, and 100% were within 15% of the integer. In total: 5, 1, 204, 45, and 20 samples had 0, 1, 2, 3, and 4 copies of SMN1, respectively. Likewise, 43, 109, 108, 14, and 1 samples had 0, 1, 2, 3, and 5 copies of SMN2, respectively. None of the 275 samples had 4 copies of SMN2.
Conclusions: ddPCR provides unambiguous copy number calls for SMN1 and SMN2 when ≤3 copies are present. We did not have sufficient number of samples with ≥4 copies to determine the accuracy of this technology for higher-order copy number states.

PS10.33
A comprehensive analysis of SMN2 target re-sequencing in a cohort of Italian and Spanish patients affected by Spinal Muscular atrophy.

G. Dubsky de Wittenau[1], S. Radovic[2], A. Alias[3], E. Tizzano Ferrari[4], F. Cesca[1], A. Poz[1,5], F. Curcio[1,5], **R. Lonigro**[1,5]*;*
[1]University, Department of Medical and Biological Sciences, Udine, Italy, [2]IGA Technology Services, Parco Tecnologico L. Danieli, Udine, Italy, [3]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [4]Hospital de la Santa Creu i Sant Pau, barcelona, Spain, [5]Azienda Ospedaliero Universitaria, Udine, Italy.

Homozygous deletion of *SMN1* results in a spinal muscular atrophy (SMA) phenotype. Severity of the disease partially relies on the individual copy numbers and variants of the phenotypic modulator *SMN2*. We used a NGS strategy of „pooled indexing" for gene re-sequencing of 41 SMA patients belonging from Italian and Spanish population. All subjects carry 3 copies of *SMN2*, 0 copies of *SMN1*. We report a total of 115 SNPs, among which 60 never previously identified, and 5 indels among which only one previously described. All indels and most of SNPs are intronic, except than two conservative SNPs in exon2a and exon3 respectively. The main intriguing results are: i. Variants distribution is not homogenous but rather clustered along the *SMN2* sequence. The highest variant rate have been found in intron 7 (1:112bp), in intron 8 and 3'UTR (1:152bp). These findings suggest that exon 7, which undergoes alternative splicing and is involved in modulating SMA phenotype, is flanked by hotspot of hyper-mutable regions. ii. Only two individuals present the exon2a variant (c.C84T), while 33 out of 41 individuals present the exon3 variant (c.A462G). It will be intriguing to test the last variant as an hallmark of deletion-prone chromosome 5. iii. In one patient we have a variants frequency sustaining 4 copies of *SMN2* along the 5' of the gene and 3 copies of *SMN2* along the 3'. This last result sustains quantitative re-sequencing of *SMN* as a tool to improve diagnosis/prognosis by identifying partially deleted and non-functional genes.

PM10.34
A natural variant (c.863G>T) in exon 7 of SMN1 disrupt the inclusion of Exon 7 into mRNA and is responsible for spinal muscular atrophy

Y. Qu, *F. Song, J. Bai, Y. Cao, W. Zhang, H. Wang, Y. Jin;*
Capital Institute of Pediatrics, Beijing, China.

Proximal spinal muscular atrophy (SMA) is an autosome recessive genetic neuromuscular disorder, which is caused by deletion or mutation of *SMN1* (survival motor neuron1) gene. *SMN* exon 7 splicing is regulated by a number of exonic and intronic splicing regulatory sequences and the trans-factors that bind them. Here we identified a natural variant c.863G>T (p.Arg288Met) in exon 7 of SMN1 gene in three patients affected with type Ior typeII SMA .The in vivo assay showed that most of the *SMN1* transcripts loss the entire exon 7. The ex vivo splicing assay had demonstrated that this variant disrupt inclusion of exon 7 (about 85%) into *SMN1* mRNA and different bases replacement showed different splicing effect in both *SMN1* and *SMN2* pre-mRNA. The variant c.863G>T is located in the region that inclu-

des multiple splicing factors and is specially adjacent to the binding site of Tra2β1. Our results showed that this variant disrupts the binding of Tra2β1 not promote the binding of hnRNP A1. This present research about this natural occurrence variation influence the pre-mRNA splicing of SMN should be contributed to interpretation of the pathogenic mechanism in SMA patients.

STIM1 mutations at a common amino acid residue (p.340) identified in two individuals with a predominant muscle disease phenotype

E. A. Harris[1], *J. Hudson*[2], *M. Neri*[3], *A. Ferlini*[3], *K. Bushby*[1], *H. Lochmüller*[1], *V. Straub*[1], *R. Barresi*[1,4];

[1]*Newcastle University John Walton Muscular Dystrophy Research Centre, Newcastle upon Tyne, United Kingdom,* [2]*Northern Genetics Service, Newcastle upon Tyne, United Kingdom,* [3]*Section of Medical Genetics and Microbiology, Department of Medical Sciences, University of Ferrara, Ferrara, Italy,* [4]*Rare Diseases Advisory Group Service for Neuromuscular Diseases, Muscle Immunoanalysis Unit, Newcastle upon Tyne, United Kingdom.*

Background: Dominant mutations in STIM1 have been identified in the complex phenotype Stormorken Syndrome (SS) and in non-syndromic tubular aggregate myopathy (TAM). All reported individuals with SS have a common p.R304W gain of function mutation in the coiled coil domain 1 of STIM1. In contrast mutations in TAM are restricted to the EF hand domain.

Methods and Patients: We performed exome sequencing on patient 1 and identified a de novo STIM1 mutation. We subsequently selected 4 patients with tubular aggregates, and 4 patients selected by phenotype, and performed immunostaining for STIM1 and direct sequencing of the STIM1 gene. Patients with STIM1 mutations were deep phenotyped.

Results: Two patients with STIM1 mutations were identified. Patient 1 has the common SS mutation (p.R304W), and exhibits features in keeping with this (thrombocytopaenia, miosis, aspenia, hypocalcaemia). Tubular aggregates were present in muscle biopsy and showed accumulation of STIM1. Patient 2 has a novel mutation at the same amino acid residue (p.R304G), and presents with a strikingly similar pattern of neuromuscular phenotype but aside from miosis no additional features of SS. The neuromuscular phenotype in both patients comprises myalgia, muscle stiffness, and reduction in range of joint movement, with mild weakness on examination.

Conclusion: The use of STIM1 immunoananlysis in patients with tubular aggregates was successfully applied to screen for patients with STIM1 mutations. We report a novel mutation at the common SS amino acid residue in a patient with TAM and miosis, in addition to further characterisation of a new patient with SS.

We developed a massively parallel sequencing approach in order to optimize clinical diagnosis of myopathies at La Timone Hospital (Marseille), which is a reference center for a number of neuromuscular disorders in France. In a pilot project, we selected 298 genes implicated in neuromuscular diseases and cardiomyopathies listed in the Gene Table of Neuromuscular Disorders as well as differential diagnosis genes. Targeted exome approach was developed using HaloPlex target enrichment system adapted for Ion Torrent Next Generation Sequencing technology. This initial study had 92% sequence coverage at 20x and resulted in 47% diagnostic yield in a cohort of 37 distal myopathy patients. Detailed analysis of the technical characteristics of the study allowed us to pinpoint the aspects that could be further optimized. For example, we observed that longer HaloPlex probes were lost at the emulsion PCR step. Moreover, results for several target genes were not interpretable due to high rate of off-target read alignment. Based on these results, an optimized set of HaloPlex probes for 306 genes was designed for Illumina sequencing technology. Forty six myopathy patients were screened for mutations using this improved targeted exome approach. We believe that the diagnostic pipeline described in this study could be useful for other groups studying neuromuscular diseases. Moreover, the targeted exome approach used here could be applied to other genetic disorders.

Transthyretin (TTR) mutations in the turkish familial amyloid polyneuropathy (FAP) patients.

M. Poda[1], *H. Durmuş*[2], *M. M. Atmaca*[3], *Y. G. Parman*[2];

[1]*Istanbul university, DETAE, Genetics Dept., Istanbul, Turkey,* [2]*Istanbul University, Istanbul Medical Faculty, Neurology Dept., Neuromuscular Disorders Unit,, Istanbul, Turkey,* [3]*Istanbul University, Istanbul Medical Faculty, Neurology Dept., Neuromuscular Disorders Unit, Istanbul, Turkey.*

- Introduction

Familial amyloid polyneuropathy (FAP) is an clinically heterogeneous autosomal dominant trait. Mutations in the TTR gene are most commonly observed. TTR is synthesized mainly in the liver and mutations in the gene result in misfolding and depositions of mutated TTR protein, cousing a life-threatening nerve length-dependent polyneuropathy. Until now, over 100 mutations are described that are reflected in the protein structure.

- Materials and Methods

Blood for DNA extraction was drawn after the patients signed an informed consent. DNA was isolated from 10ml whole blood using a commercially aviable kit (QIAamp DNA Blood Maxi Kit- Qiagene). For the detection of variants in *TTR* gene, coding region of the TTR gene was amplified and for the PCR fragments Sanger sequencing was performed (Macrogene). The obtained chromatograms were analysed with the aid of Chromas and CLC Main Workbench 5.5 programs. The obtained sequences were alined with the human reference sequence NG_009490. Detected variants were searched and confirmed in public databases such as *dbSNP* (http://www.ncbi.nlm.nih.gov/SNP/) and *Mutations in Hereditary Amyloidosis* (http://amyloidosismutations.com/cdna-attr.html).

- Results

Six different variants in theTTR gene were observed (n=48) (rs1800458, rs28933979, rs121918090 , rs121918097, rs121918082 , rs36204272) in our patient population . Four of the variations were described as pathogenic mutations in the databases [n=3, p.Val50Met (rs28933979); n=2, p.Gly67Glu (rs121918090); n=1, p.Gly73Glu (rs121918097); n=1, p.Glu109Gln (rs121918082).

- Conclusions

As a mere reflection the clinical and genetic heterogeneity of the disease, DNA testing helped
resolve the diagnosis of the 14.5% of the patients.

Targeted next-generation sequencing reveals novel TTN mutations causing recessive distal titinopathy

A. Evilä[1], *S. Penttilä*[2], *P. Hackman*[1], *B. Udd*[1,2,3];

[1]*Folkhälsan Institute of Genetics and Department of Medical Genetics, Haartman Institute, University of Helsinki, Helsinki, Finland,* [2]*Neuromuscular Research Center, University of Tampere and Tampere University Hospital, Tampere, Finland,* [3]*Neurology Department, Vaasa Central Hospital, Vaasa, Finland.*

Tibial muscular dystrophy (TMD) is the first described human titinopathy. It is caused by mutations in the last two exons, Mex5 and Mex6, of titin gene (*TTN*). The first reported TMD mutations were dominant and the Finnish founder mutation, an 11-bp insertion/deletion in Mex6, caused a severe early-onset limb-girdle muscular dystrophy 2J (LGMD2J) when homozygous. Later we reported that not all TMD mutations cause LGMD when homozygous, but some rather cause a more severe TMD. We have now performed a targeted next-generation sequencing assay of myopathy related genes on six families with recessive distal titinopathy. Two novel TMD mutations in *TTN* were identified, which both seem to be recessive. Three of the families, Italian, Bosnian and Iranian, had a novel nonsense TMD mutation in *TTN* Mex5 in homozygous state or in combination with another nonsense mutation on the other allele. One Hungarian family had a novel missense TMD mutation in *TTN* Mex6 in combination with a frameshift mutation on the other allele. In addition one Spanish family had a previously reported Iberian TMD mutation in combination with a frameshift mutation and another Spanish family had a novel missense mutation in *TTN* A-band in combination with a nonsense mutation and a novel titinopathy phenotype. Family members with only one *TTN* mutation were healthy. According to our previous results the frameshift and nonsense mutations located upstream of the last exons of *TTN* cause degradation of mRNA through nonsense-mediated decay and mainly the other mutated *TTN* allele is expressed. This study was supported by a grant from the Jane and Aatos Erkko Foundation.

Objective: Spinal muscular atrophy (SMA) is caused by homozygous inactivation of the SMN1 gene. The SMN2 copy number modulates the severity of SMA. The 0SMN1/1SMN2 genotype, the most severe genotype compatible with life, is expected to be associated with the most severe form of the disease, called type 0 SMA, characterized by severe neurologic impairment from birth. The aim of the study was to review clinical features and prenatal manifestations in this rare SMA subtype.

Methods: SMA patients with the 0SMN1/1SMN2 genotype were retrospectively collected using the UMD-SMN1 France database. Data from 16 patients were reviewed.

Results: These 16 patients displayed type 0 SMA. Most patients, at birth, had profound hypotonia, severe muscle weakness, severe respiratory distress, and cranial nerves involvement (inability to suck/swallow, facial muscles weakness). They also showed characteristics of fetal akinesia deformation sequence (FADS) and congenital heart defects (CHD). Recurrent episodes of bradycardia were observed. Death occurred within the first month. At prenatal stage, decreased fetal movements were frequently reported, mostly only by mothers, in late stages of pregnancy; increased nuchal translucency was reported in about half of the cases; CHD, abnormal amniotic fluid volume, or joint contractures were occasionally reported.

Interpretation: Despite a prenatal onset attested by severity at birth and signs of FADS, prenatal manifestations of type 0 SMA are not specific and not constant. Finally, as illustrated by the frequent association with CHD, type 0 SMA physiopathology is not restricted to motor neuron, highlighting that SMN function is critical for organogenesis during development.

[1]Department of Clinical Genetics, Aarhus University Hospital, Aarhus N, Denmark, [2]Department of Biomedicine, Aarhus University, Aarhus C, Denmark, [3]BGI-Shenzhen, Shenzhen 518083, China, [4]Department of Cardiology, Aarhus University Hospital, Aarhus N, Denmark, [5]Department of Clinical Medicine, Aarhus University, Aarhus C, Denmark, [6]Department of Neurology, Aarhus University Hospital, Aarhus N, Denmark, [7]Department of Pathology, Aarhus University Hospital, Aarhus N, Denmark, [8]Department of Pediatrics, Aarhus University Hospital, Aarhus N, Denmark, [9]Department of Dermatology, Aarhus University Hospital, Aarhus N, Denmark, [10]Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands.

We describe a Danish family with an, until recently, unknown X-linked disease with muscular dystrophy (MD), facial dysmorphology and pulmonary artery hypoplasia. One patient died suddenly before age 20 and another was resurrected from cardiac arrest at the age of 28. Linkage analysis pointed to a region of 25 Mb from 123.6 Mb to 148.4 Mb on chromosome X containing over 100 genes. Exome sequencing identified a single nucleotide splice site mutation c.502-2A>T, which is located 5' to exon 6 in the gene encoding four and a half LIM domain 1 (FHL1) protein. FHL1 expresses three main splice variants, known as FHL1A, FHL1B and FHL1C. In healthy individuals, FHL1A is the predominant splice variant and is mainly found in skeletal and cardiac muscle. The FHL1 transcript profiles from two affected individuals were investigated in skin fibroblasts with quantitative real-time PCR. This demonstrated loss of isoform A and B, and an almost 200-fold overexpression of isoform C confirming that lack of FHL1A and overexpression of FLH1C results in an extended phenotype of EDMD as recently shown by Tiffin et al. (2013)

Chromosome 18p deletion syndrome: clinical, developmental and cytogenomic characterization of six Brazilian patients

V. A. Meloni[1], *R. S. Guilherme[1], M. Moysés-Oliveira[1], S. S. Takeno[1], C. B. de Mello[2], B. C. Costa-Tavares[3], M. I. Melaragno[1];*

[1]Genetics Division-Universidade Federal de São Paulo, São Paulo, Brazil, [2]Núcleo de Atendimento Neuropsicológico Infantil Interdisciplinar, São Paulo, Brazil, [3]Allergy and Immunology Division-Universidade Federal de São Paulo, São Paulo, Brazil.

Introduction: Chromosome 18p deletion syndrome [del(18p)] (OMIM 146390) has been well described in literature with over 150 patients reported on, but few of them were evaluated by cytomolecular techniques.

Materials and Methods: We studied six Brazilian patients with 18p deletion based on clinical, developmental and cytogenomic findings. The patients were evaluated by a specific clinical protocol, including immunological, endocrinological and neuropsychological assessments. The cytogenetic study was performed by G-banding karyotype, SNP-array (Genome-Wide Human SNP Array 6.0, Affymetrix) and FISH-BAC techniques.

Results: The results showed four *de novo* pure deletions and two deletions caused by derivative chromosomes, one of them *de novo* and the other inherited from a paternal translocation. Although literature indicates 18p11.11 as the most frequent breakpoint, our patients presented different breakpoints: 18p11.21 (4/6, four out of six) and 18p11.23 (2/6). The main clinical findings were: short stature (5/6); microcephaly (2/6); ectopic pituitary (1/6); growth hormone deficiency (1/6); hypothyroidism (3/6); intellectual disability (5/6); cardiac anomalies (2/6); scoliosis (3/5); and *keratosis pilaris* (4/6). The distinguished facial dysmorphic features were similar among the patients: ocular hypertelorism (6/6); ptosis (3/6) and strabismus (6/6). The neuropsychological assessments showed IQ scores from borderline intellectual functioning to moderate intellectual disability.

Conclusions: Some genes located in the 18p deleted segment seem to play an important role in the patient's phenotype, such as *TGIF1, GNAL, LAMA1* and *LPIN2* genes. The SNP-array technique permitted a better chromosome breakpoint definition and, associated to the specific clinical protocol, provided a better genotype-phenotype correlation revealing genes that might influence the patient's phenotype.

Three new cases with atypical deletions in the 22q11.2 region

A. M. Cueto-González[1,2], *T. Vendrell-Bayona[1], M. Del Campo[1,3], M. Borregan[1], N. Castells[1,4], N. Jariod[1], A. Plaja[1], E. Tizzano[1,3];*

[1]Hospital Vall d'Hebron, Barcelona, Spain, [2]Facultat de Medicina. Departament de Ciències Morfològiques. Universitat Autònoma de Barcelona., Barcelona, Spain, [3]CIBERER, Spain, Spain, [4]Universitat Autònoma de Barcelona, Barcelona, Spain.

22q11.2 deletion syndrome (22q11.2DS) is mainly characterized by conotruncal congenital heart defects, velopharyngeal insufficiency, hypocalcemia and a characteristic craniofacial appearance. The etiology in the majority of patients is a 3-Mb recurrent deletion in 22q11.2 region. However, rare cases with proximal, central and distal deletions in 22q11 region have been reported with different phenotypes.

We report three cases with atypical deletions diagnosed in a total of 119 patients with deletions in 22q11.2 region attended in our 22q11DS Multidisciplinary Clinics.

The first case, a girl with short stature, hirsutism and ventricular septal defect was found to have a distal 22q11DS deletion, arr[hg19] 22q11.21(20754422-21561514)x1, including the CRKL gene and with no overlap with the known critical region. The deletion was also present in her brother that only presents nasal voice and her asymptomatic father. A paternal uncle died around 3 months old of congenital heart disease sixty years ago.

The second and third cases are two boys that shared a de novo deletion in the centromeric end of the distal region of 22q11DS, arr[hg19] 22q11.21q11.22 (21505358/21808950-22905068)x1. One patient had global developmental delay and an Autism spectrum disorder (ASD) while the other patient had global developmental and learning delay, with particular phenotypic features.

Correlation of clinical and genetic data of atypical 22q11DS deletions is of

cardinal importance in dissecting the contribution of individual genes to DGS phenotype. In particular, nasal voice cosegregation with a partial deletion of 22q11DS region (case 1) may point to specific genes involved in palate formation or function.

Using chromosomal microarray testing we detected a 1.48 Mb *de novo* 2q11.1q11.2 duplication in a patient with developmental delay, microcephaly, plagiocephalus, torticollis, laryngomalacia and failure to thrive. This duplication contains about 26 genes (12 OMIM genes). One *de novo* duplication 2q11.2 with a minimum size of 1.47 Mb was described in the literature in a patient with moderate developmental delay, hypotonia with continued head lag at age 15 months, short stature, midface hypoplasia with hypoplastic nose, macrocephaly with frontal bossing and dolichocephaly and significant shortening of all segments of the extremities with significant brachydactyly. Five other patients with similar duplications and psychomotor retardation/ learning difficulties were found through the DECIPHER database. While head circumference seems to be variable, shared anomalies consist of frontal bossing/ large forehead (described in 4 of 7 patients), birth weight < P10 and failure to thrive (described in 2 patients), muscular hypotonia (described in 2 patients), sensorineural hearing impairment (described in 2 patients) and café-au-lait spots (described in 2 patients). In 3 cases the duplication was maternally inherited (in 2 cases from mothers with known learning difficulties), in 3 cases the duplication was *de novo* and in one case the inheritance was unknown because the father could not be tested. In one patient another *de novo* aberration was detected, which could have an impact on the phenotype. Our observations indicate that 2q11.1q11.2 duplication is a novel recurrent microduplication syndrome mediated by flanking low-copy repeats.

PM11.004

A 17 mb deletion in 2q31.3-q33.1 in a girl with central nervous system malformations and severe developmental delay

E. Caramaschi[1], *P. Bergonzini*[2], *G. Tediosi*[1], *M. Maretti*[3], *I. Stanghellini*[4], *L. Iughetti*[5], *A. Guerra*[2], *A. Percesepe*[4];

More than 30 cases with a deletion of the 2q31-q33 region have been reported. Deletions vary in size and location and are associated with variable clinical features including craniofacial dysmorphism, developmental delay, growth retardation and other anomalies. We report the case of a girl born from healthy unrelated parents after an uncomplicated pregnancy (birth weight 2660g). Perinatal history was unremarkable, apart from a congenital laryngeal stridor. Her motor development was delayed (sit position at the age of 3 years, walk at the age of 4 years). Dysmorphic features were evidenced: triangular face, high forehead, maxillary hypoplasia, small eyes, low set ears, short neck, small teeth, small hands. Ophthalmological examination showed alternating strabismus. The girl developed epilepsy from 6 month of age, resistant to drug treatment. Neuroradiological examination at the age of 9 and 10 years showed a diffused reduction of white matter with moderate ventriculomegaly, gracile posterior body and splenium of corpus callosum and gracile hippocampus. Neurological examination evidenced based enlarged deambulation, chaotic movement and dysmetria, no other anomalies. She developed motor stereotypies of the hands, severe intellectual disability (not able to speak), and aggressive behavior both self- and hetero-aggressive. In past clinical history reported frequent respiratory, skin and oral infection (no specific immunological deficit). Array CGH analysis has evidenced a 17 Mb deletion in chromosome in 2q31.3-q33.1. Our case shows phenotypic similarities with previously described cases with overlapping deletions; in addition we report the presence of a drug resistant epilepsy, reported also by Mencarelli (2007) and Mitter (2010), and of previously unreported brain anomalies, behavior problem and recurrent infections.

2q33.1q34 microdeletion syndrome: a case report

C. Pidone, *I. Loddo, M. C. Cutrupi, V. Procopio, M. I. S. Crapanzano, E. Moschella, M. R. Pizzino, S. Briuglia;*
UOC Genetics and Pediatric Immunology, University of Messina, Messina, Italy.

We describe a case of a girl, the second child of healthy non-consanguineous parents. Pregnancy was complicated by threats of preterm birth, but she was born full term. Birth weight was 3,120 kg and length 50 cm. At birth she had anterior anus with rectum perineal fistula, left hip dysplasia and several dysmorphic features: bilateral blepharophimosis, up-slanting palpebral fissures, epicanthus inversus, low-set ears, micrognathia, mild macroglossia, long hands and fingers (+2DS). She presented feeding difficulties, failure to threat and mild psychomotor delay. Brain MRI performed at 2 months of age was normal. She had also bicuspid aortic valve and selective IgA deficiency with recurrent respiratory and gastrointestinal infection. Array-CGH showed a *de novo* microdeletion of 8,3 Mbp in 2q33.1q34 (201,315,087-209,635,377). This region contains some interesting genes, such as CD28, CTLA4 and ICOS, that are important regulators of the immune system.
This microdeletion can explain the clinical features of our patient, outlining the characteristics of this syndrome.

Cerebral white matter abnormalities in 6p25 deletion syndrome

I. M. Bader[1], *G. Sander*[1], *G. Kronberger*[1], *I. Vlasak*[1], *I. Reindl*[2], *C. Rauscher*[2], *J. Koch*[2], *J. Atzwanger*[2], *E. Haschke-Becher*[3], *W. Sperl*[2], *O. Rittinger*[1];
[1]*Clinical Genetics Unit, Department of Pediatrics, Paracelsus Medical University, Salzburg, Austria, Salzburg, Austria,* [2]*Department of Pediatrics; Paracelsus Medical University, Salzburg, Austria, Salzburg, Austria,* [3]*University Institute of Medical and Chemical Laboratory Diagnostics, Salzburg, Austria, Salzburg, Austria.*

We report the phenotype and genotype of a 4 years and 11 months old boy who was transferred to hospital after an accident. CT-scan and cMRI showed a cranial fracture as a result of the accident and two incidental findings: 1) large bifronto-temporal arachnoidal cysts and 2) multifocal white-matter-lesions involving the periventricular, deep, and subcortical cerebral white matter.
The clinical phenotype of the boy included mild developmental delay, strabism, slightly dysmorphic features and mild hearing impairment.
Molecular karyotype from peripheral blood detected a ~ 3,9 Mb heterozygous microdeletion in 6p25.3 - 6p25.2 deleting 34 genes, 18 of which were OMIM annotated including the transcription factor FOXC1.
Microdeletions in 6p25 are thought to be associated with a distinctive clinical phenotype - the 6p subtelomeric deletion syndrome - that includes sensorineural hearing loss, anterior chamber eye defects, cardiac defects, developmental delay and other developmental and behavioral abnormalities, hypotonia, hip dysplasia, cerebellar abnormalities and a characteristic facial appearance. Few reports exist that describe multifocal T2-weighted and FLAIR abnormalities involving the periventricular, deep, and subcortical cerebral white matter associated with the 6p25 deletion in young children and in adults.
From our case and from the review of the literature we conclude that a microdeletion in 6p25 should be considered as the cause for unclear multifocal cerebral white matter abnormalities in patients that in addition have dysmorphic features and multiple congenital anomalies even when intellectual abilities are within the normal range (Vernon et al. 2013).

PS11.007

9q34.3 microdeletion in three patients characterized by array-CGH

K. T. Abe, *I. M. P. O. Rizzo, L. L. Roese, M. F. Pereira, L. M. Formigli, M. Schneider, M. D. V. Oliveira, N. Sakai Jr, D. R. Carvalho, C. E. Speck-Martins;*
SARAH Network of Rehabilitation Hospitals, Brasília – DF, Brazil, BRASILIA, Brazil.

Submicroscopic deletion del(9)(q34.3) is a newly described genomic disorder that has been reported as a clinically recognizable 9q Subtelomeric Deletion Syndrome (9qSTDS) also known as 9q34.3 Microdeletion Syndrome and Kleefstra Syndrome. That microdeletion affects fetal development and results in intellectual disability, childhood hypotonia and facial feature. In addition, congenital heart and renal defects, microcephaly, epilepsy, obesity, behavioral problems and absence of expressive speech are frequently present. Structural brain and/or subcortical white matter abnormalities may also occur. Microdeletions of the 9q34.3 region, like other terminal deletions, have breakpoints occurring in multiple sites of the distal chromosome end. There is no evidence for phenotype-genotype correlation between size of the deletions or type of mutations and severity of clinical features. Studies confirm the *EHMT1* gene to be the major determinant of the 9qSTDS phenotype. In addition, *EHMT1* haploinsufficiency is associated with neurodegeneration and neurodevelopmental defect. We report the molecular

characterization and phenotype of three patients, 3-years-7-months-old, 1-year-7-months-old, and 2-years-old, with respectively 374 Kb, 867 Kb and 1,750 Kb terminal deletions at 9p34.3 chromosome region detected by array-CGH. Although they had different deletion size and OMIM Genes deleted, they present similar and recognizable phenotype of 9q34.3 microdeletion syndrome. The first patient has only *EHMT1* and *CACNA1B* genes deleted, but all they have a submicroscopic deletion that share an overlapping region encompassing those genes. It reinforces that haploinsufficiency of both genes *CACNA1B* and *EHMT1* are dosage-sensitive and contribute to core phenotype of 9qSTDS.

PM11.008

Microdeletion of 9q34.11: an emerging contiguous gene syndrome?

R. E. Keelagher[1], *F. S. Togneri*[1], *N. S. Cooper*[2], *N. K. Ragge*[2], *D. J. McMullan*[1];
[1]*West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom,* [2]*West Midlands Regional Genetics Service, Birmingham, United Kingdom.*

Interstitial microdeletions within 9q34.11 have been described in a relatively small number of patients to date. Recurrent clinical features reported in these individuals include intellectual disability, hypotonia and seizures amongst others. Deletions including the STXBP1 gene have been associated with an increased risk of epilepsy. However, further genotype-phenotype correlations remain poorly defined. Here we describe two previously unreported patients with interstitial deletions of this region. In patient 1, a de novo deletion of ~1.8 Mb was detected at 9q33.3q34.11. Although this deletion is proximal to the Kleefstra syndrome region at 9q34.3, it appears to result in a strikingly similar phenotype including progressive microcephaly, hypotonia, severe developmental delay and facial dysmorphism. In patient 2, a deletion of ~2.1 Mb of 9q34.11 was detected. Clinical features noted in this patient overlap those described in patient 1 and include speech and language delay, microcephaly, hypotonia and facial dysmorphism. Importantly, absence seizures were reported in patient 2, despite the STXBP1 gene not being deleted in this individual. A common region of ~885 kb containing approximately 28 genes was deleted in both patients. These case reports provide further evidence for an emerging 9q34.11 contiguous gene deletion syndrome characterised by developmental delay, microcephaly and hypotonia and may assist in refining genotype-phenotype correlations associated with deletions of this region.

PS11.009

Mutation analysis in patients with Adams-Oliver syndrome using a targeted resequencing strategy.

J. Meester[1], *M. Zenker*[2], *M. Sukalo*[2], *B. Loeys*[1,3], *L. Van Laer*[1], *L. Southgate*[4], **W. Wuyts**[1,3];
[1]*University of Antwerp, Antwerp, Belgium,* [2]*Otto von Guericke Universität Magdeburg, Magdeburg, Germany,* [3]*Antwerp University Hospital, Antwerp, Belgium,* [4]*Queen Mary University of London, London, United Kingdom.*

Adams-Oliver syndrome (AOS) is a rare developmental disorder typically characterized by congenital cutis aplasia of the scalp and vertex with transverse terminal limb defects. In addition, vascular anomalies, comprising pulmonary and portal hypertension, retinal hypovascularisation and congenital cutis marmorata telangiectasia, as well as congenital heart defects, such as ventricular septal defects, tetralogy of Fallot and valve anomalies have been observed.

To date, five causal genes have been described: EOGT and DOCK6 for recessive AOS and ARHGAP31, RBPJ and NOTCH1 in dominant AOS and sporadic cases.

Using a targeted resequencing strategy with HaloPlex Targeted Enrichment (Agilent) and sequencing by synthesis on MiSeq (Illumina), the five known AOS genes were analyzed in 66 patients and families with an AOS phenotype or isolated aplasia cutis.

Possible causative variants were identified in 17 families. The majority of mutation positive families harboured a NOTCH1 mutation (7 families), followed by DOCK6 (5 families), EOGT (3 families) and RBPJ (2 families). No ARHGAP31 mutations were deteceted.

In conclusion, a mutation in circa 25% of the aplasia cutis/AOS families was detected with a next-generation based targeted resequencing approach of five known AOS causing genes. This confirms the genetic heterogeneity of AOS/aplasia cutis, and highlights a large proportion of patients with still unexplained etiology.

PM11.010

Webb-Dattani Syndrome (WEDAS), Report of a Saudi Arab Family with a Novel Homozygous Mutation in the *ARNT2* Gene

S. I. Al-SMajed[1], *S. Biskup*[2], *N. A. Al-Sannaa*[1], *H. Y. Al-Abdulwahed*[1], *M. Menzel*[3], *S. Kelkenberg*[3];
[1]*Johns Hopkins Aramco Healthcare, Dhahran, Saudi Arabia,* [2]*CeGaT GmbH, Hertie Institute for Clinical Brain Research, German Center for Neurodegenerative Diseases, Tuebingen, Germany,* [3]*CeGaT GmbH, Tuebingen, Germany.*

Webb-Dattani syndrome (#615926) is an autosomal recessive disorder characterized by frontotemporal hypoplasia, pituitary and hypothalamic insufficiency due to hypoplastic development of these brain regions. The condition was described in 6 siblings from highly consanguineous Saudi Arabian kindred with congenital brain malformation, panhypopitutrism, acquired microcephaly, seizures, severe global developmental delay, spastic cerebral palsy, and post-retinal blindness. A homozygous truncating mutation was identified in the *ARNT2* gene by a combination of homozygosity mapping and whole exome sequencing.

Here we describe another family with three affected siblings born to a healthy Saudi Arab first cousins couple. The index patients were identical male twins presented at three months of age with congenital central hypotonia and hypoventilation precipitated by an acute bronchiolitis. They had a similar clinical manifestation that was characterized by diabetes insipidus, central hypothyroidism, adrenocortical insufficiency, severe developmental delay, acquired microcephaly, cortical blindness with normal retinal examination, seizures, and gastroesophageal reflux. Brain MRI showed hypothalamic, infundibular, and pituitary axis insufficiency, small sella with absent posterior pituitary bright spot. Family history is significant for an older affected deceased female sibling at 18 months of age, and four miscarriages of undetermined etiology. Whole exome sequencing detected a homozygous unclear variant (c.378C>Tp.G126G) in ARNT2 gene of both of the affected twins. According to splice prediction programs, this variant creates a new donor splice site, possibly leading to a loss of function. Both of the parents were found to be heterozygous and none of the unaffected siblings were homozygous for this variant.

Introduction: High resolution microarray comparative genomic hybridization (aCGH) is a powerful genetic tool implemented as a first-tier test for diagnosis of genomic imbalances in individuals with intellectual disability, autistic disorders and congenital malformations.it also has been proven to be successful in characterizing the growing list of microdeletion/duplication syndromes. Using this experimental approach, we and others recently described new microdeletion/microduplication syndromes.

Methods: A "genotype first" approach, using aCGH, in which patients are characterized by a similar genomic rearrangement before a common clinical presentation has been used.

Results: We report 13 new patients with proximal 19p13.3 submicroscopic rearrangements and review patients from the literature and public genomic databases such as DECIPHER and ISCA Consortium for a total of 37 cases. We describe the phenotypic findings and suggest these patients represent a new microdeletion/duplication syndrome at 19p13.3 band, with a 113.5 Kb critical region as Small Region of Overlapping harboring three genes. Common features consist of abnormal head circumference in most patients (macrocephaly with the deletions and microcephaly with the duplications), intellectual disability (ID) with developmental delay, hypotonia, speech delay and common dysmorphic features.

Discussion: This study provides detailed clinical information for geneticists to assist in the evaluation, diagnosis and management of individuals with similar genomic interstitial rearrangements at 19p13.3 band.

PM11.012

Genetic diagnosis of chromosomal anomalies in pediatric patients by array CGH.

M. Perez Sanchez[1], *A. Gonzalez Ramirez*[2], *S. Roldan.*[1], *A. Mora Guijosa*[1], *J. Barrionuevo*[1];
[1]*Servicio Andaluz de Salud (SAS)., Granada, Spain,* [2]*FIBAO., Granada, Spain.*

Laboratory evaluation of patients with developmental delay/intellectual disability, congenital anomalies and dismorphic features has changed significantly in the last years with the introduction of microarray technologies. With these techniques, a patient`s genome is examined for detection of gains or loses of genetic material that typically are too small to be detectable by standard G-banded chromosome studies.

In our laboratory this technology has been implanted as the first tier test for genetics studies for developmental delay/ mental retardation/ autistic disorder and/or multiple congenital anomalies (DD/MR/ASD/MCA).
In this study we present the results of array CGH obtained in 548 patients with clinical diagnosis of DD/MR/ASD/MCA. The Nimblegen CGX Cytogenetic Microarrays platform, suplied by PerkinElmer, was performed.
From the total of 548 patients, the 57,1% were men and 42,9% women. Patologic result was obtained in 13,1% of patients, without stadistical diferences between sexs.The genetics diagnostic yield obtained were 12,5 % for developmental delay, 10,1% for mental retardation, 10,7 for autistic disorder and 16,8 for multiple congenital anomalies.
Previous studies suggest that when array-CGH is performed, the diagnostic yield reached 8 to 20 % of total patients. Our results are in concordance wiht these previous results with an average of 13,1% detected from the total of patients, with a range from 10,1% in the case of mental delay to 16,8 for multiple congenital anomalies.
Our results are in concordance with the results previously obtained in other laboratories and they are improved significantly the genetics diagnosis for DD/MR/ASD/MCA patientes in our laboratory.

PS11.013

Progressive cerebral striatal arteriopathy in ichthyosis prematurity syndrome; is it eosinophilia-related?

M. E. C. Meuwissen[1], *J. Lambert*[2], *V. Siozopoulou*[3], *L. Mahieu*[4], *G. Delanghe*[5], *F. Kooy*[1], *P. Govaert*[5];
[1]*Dept. of Medical Genetics, University Hospital Antwerp, Antwerp, Belgium,* [2]*Dept. of Dermatology, University Hospital Antwerp, Antwerp, Belgium,* [3]*Dept. of Pathology, University Hospital Antwerp, Antwerp, Belgium,* [4]*Dept. of Neonatology, University Hospital Antwerp, Antwerp, Belgium,* [5]*Dept. of Neonatology, ZNA Koningin Paola Children's Hospital, Antwerp, Belgium.*

BACKGROUND Ichthyosis Prematurity Syndrome (IPS) is characterized by premature birth, thick caseous desquamating epidermis, respiratory complications and transient eosinophilia. Although respiratory problems can be severe, outcome after the first months is reported to be favorable. Mutations in FATP4 have been identified in this rare autosomal recessive disorder.
METHODS We report on non-identical twin brothers with consanguineous parents born prematurely at 30+4 gestational weeks, both with congenital skin lesions affecting the thorax, back and extremities, but most prominently the scalp. After birth, CPAP was needed for two days due to respiratory distress. At 6 weeks of age, intubation was necessary for 4 days in one boy due to apnea and desaturation. Serial brain ultrasound in both boys showed progressive striatal arteriopathy. Blood eosinophilia was demonstrated in both patients. At 2 months, the skin lesions improved tremendously, leaving only a reddish discoloration and dryness of the skin.
RESULTS Initial skin pathology showed a verrucous epidermis and hyperkeratosis with corneal desquamation. Targeted genetic analysis revealed the presence of the homozygous c.469A>G change leading to the p.Asn157Asp amino acid substitution in the FATP4 gene, confirming the diagnosis of IPS in both boys.
DISCUSSION Progressive striatal arteriopathy has not been described in IPS. Both boys showed eosinophilia, which can induce brain damage. In addition, encephalopathy is a known feature in eosinophilia-associated conditions, i.e. Idiopathic Hypereosinophilia syndrome (OMIM 607685), Incontinentia Pigmenti (OMIM 308300) and autosomal recessive Hyper-IgE syndrome (OMIM 243700). We hypothesize that hypereosinophilia may have been a causative factor for the striatal arteriopathy, which may be an underrecognized finding in IPS.

PM11.014

A 60Kb deletion in the AUTS2 gene in a patient with cardiopathy, facial dysmorphism and autistic traits

M. J. García-Barcina, *E. Santamaría, E. Sarasola, M. A. Fernández-Cuesta, C. Ruiz-Espinoza, B. Barreña;*
Hospital Universitario de Basurto, Bilbao, Spain.

We present the case of a child referred to the Dismorphology consultation at the age of 3 months. Born after normal pregnancy and instrumental delivery at 36+5 w. Birth weight: 2690g and Apgar 7/9. At 4 hours of life he presented an episode of choking while sucking that needs stimulation for recovery. Progressively acquires suck-swallow coordination and no significant symptoms associated were observed. An atrial septal defect (ASD) (ostium secundum) was diagnosed by echocardiography and the patient was discharged for control in external consultations.
On the exploration at 3m slightly decreased axial, lower limbs on flexion (without arthrogryposis), increased tendon reflexes, and peculiar phenotypic traits (hypertelorism and almond shaped palpebral fissures, short philtrum, thin upper lip and microstomia) were observed.
