At 15 months, the ASD was repared. He presented a convergent not paretic strabismus, the muscle tone was improved in general but the lower limb tone was increased when excited, the reflexes were symmetrical but exalted and the CPR was extensor bilateral. We observed a limitation of joints extension which improved in subsequent controls. Now, at 41momths, he presented a global developmental delay with autistic traits.
The aCGH (Nimblegen, 720K) performed defined a 60Kb deletion on 7q11.22, not seen in the aCGH (qChip [R], 60K), and confirmed by MLPA in the AUTS2 gene.
Balanced genomic rearrangements disrupting AUTS2 gene have been identified implicating AUTS2 in neurodevelopmental disorders. More recent descriptions suggest that the AUTS2 syndrome could be a single gene disorder and our case support this hypothesis.

Familial translocation t(1;12)(q43;q21.1) truncates a CHRM3 GENCODE isoform in a family with specific learning difficulties, ataxic symptoms, and stroke

T. Luukkonen[1,2], *M. Pöyhönen*[3,4], *L. Kuuluvainen*[3,4], *P. Ellonen*[1], *A. Palotie*[1,5], *J. Terwilliger*[2,6,7], *R. Salonen*[8], *T. Varilo*[3,2];
[1]*FIMM Institute for Molecular Medicine Finland, Helsinki, Finland,* [2]*National Institute for Health and Welfare, Helsinki, Finland,* [3]*Dept. of Medical Genetics, University of Helsinki, Helsinki, Finland,* [4]*Dept. of Clinical Genetics, Helsinki University Central Hospital, Helsinki, Finland,* [5]*Broad Institute of Harvard and MIT, Cambridge, MA, United States,* [6]*Columbia Genome Center, Columbia University, New York, NY, United States,* [7]*New York State Psychiatric Institute, New York, NY, United States,* [8]*Dept. of Medical Genetics, Norio-centre, Rinnekoti Foundation, Helsinki, Finland.*

We have established a National Registry of Balanced Chromosomal Rearrangements in Finland by ascertaining all known Finnish carriers (n=2575). The registry contains medical records of all available carriers including family members carrying the same rearrangement identical-by-descent. From this resource, we have drawn families with apparent correlating phenotype to the balanced translocation. In our gene-mapping pilot we identified a potential positional candidate gene for intracranial and aortic aneurysm (Luukkonen et al. 2013, JMG).
Here, we describe the clinical and genetic findings in a family where carriers (n=6) of t(1;12)(q43;q21.1) are affected first by specific learning difficulties, chronic headache, balance problems, tremor, fatigue, and later with stroke without known predisposing factors. By next-generation mate-pair sequencing, we fine-mapped the specific chromosomal breakpoints, which do not truncate any protein coding genes. On chromosome 1, *CHRM3* locates 62 kb distal to the breakpoint, and a *CHRM3* GENCODE isoform spans the breakpoint. Significant linkage for episodic ataxia type 3 has been previously identified in 1q42.3. On chromosome 12, *ATXN7L3B* locates 550 kb and *KCNC2* 1.2 Mb distal to the breakpoint. Both genes were within a 670 kb deletion in a recently published family with a complex neurodevelopmental and ataxic phenotype.
This study has brought into focus three genes - *CHRM3*, *ATXN7L3B* and *KCNC2* in a family with an early retirement because of complex neurological phenotype leading to stroke, and perfectly co-segregating translocation t(1;12)(q43;q21.1). We propose that disruption of the *CHRM3* GENCODE isoform may play a role in the pathogenesis and lead to the observed complex phenotype.

PM11.016

Is Bardet-Biedl syndrome more frequent in Europeans than current estimates?

J. L. Mandel[1,2,3], *C. Redin*[1,4], *J. Muller*[1,2];
[1]*Translational medicine and neurogenetics dpt. IGBMC, INSERM U964, CNRS UMR7104, University of Strasbourg, Illkirch, CU Strasbourg, France,* [2]*Genetic diagnostic laboratory, CHU Strasbourg, Strasbourg, France,* [3]*Collège de France, Paris, France,* [4]*Center for Human Genetics Research, Mass General Hospital, Harvard Medical School, Boston, MA, United States.*

It is generally quite difficult to have reliable estimates of the prevalence of rare genetic diseases as they may be often underdiagnosed and there are few efforts to have systematic data collection on a scale large enough to obtain significant numbers. Often numerical values are quoted either from rare ancient studies or even unreferenced. In the case of Bardet-Biedl syndrome, a genetically heterogeneous disease, the numbers usually quoted are 1:125 000 to 1:160 000 for European populations. While Bardet- Biedl syndrome can be caused by mutations in 19 currently identified genes (OMIM February 2015), two genes (BBS1 and BBS10) account for almost half the cases in European populations, and each of them have a major mutation, p.Met390Arg for BBS1 and p.Cys91LeufsTer5 in BBS10. We have looked for the frequency of these two mutations in the ExAC database, and for the cu-

mulated frequency of other rarer known mutations in these genes. Based on this analysis, we estimate that the frequency of BBS in Europeans is likely to be about 1:50 000, ie 3 times more than previous estimates, and this suggests that this severe and pleiotropic disease was underdiagnosed.
Using the same strategy of using a recurrent mutation whose contribution to a genetically heterogeneous disease has been well established, we estimated the incidence of Aicardi-Goutières syndrome (that was quoted as unknown in the most recent update of the cognate GeneReviews) at about 1:50 000 to 1:65 000, using ExAC data for the p.Ala177Thr mutation in the RNASEH2B gene.

Introduction: Bardet-Biedl Syndrome (BBS; MIM 209900) is a recessive and genetically heterogeneous ciliopathy characterized by postaxial polydactyly, retinitis pigmentosa, obesity, hypogonadism, cognitive impairment and kidney dysfunction. So far, 20 BBS genes have been identified, with the last ones reported being found in one or few families.
Materials and Methods: Exome sequencing was performed in a consanguineous family in which two affected children presented typical BBS features (retinitis pigmentosa, postaxial polydactyly, obesity, hypogonadism and cognitive impairment). *BBS1* to *BBS18* were sequenced by New Generation Sequencing (*BBS1* to *BBS16*) and Sanger Sequencing (*BBS17* and *BBS18*).
Results: A missense mutation in *IFT172* gene (NM_015662.2: c. 2857C>T, p. Arg953Cys) was identified at the homozygous state in the two patients and found at the heterozygote state in both parents and their 3 healthy children. *IFT172* mutations have been initially reported in Jeune and Mainzer-Saldino syndromes (Halbritter et al., 2014). Recently, mutations have also been found in isolated retinitis pigmentosa and Bardet-Biedl- like ciliopathy (Bujakowska and al., 2014). This is the second report of *IFT172* mutations in BBS patients confirming *IFT172* as a BBS gene. Moreover, another *IFT* gene, *IFT127*, was already associated with Bardet-Biedl syndrome (Aldahmesh et al., 2014) and this report confirmed the implication of IFT genes in the pathogenesis of BBS.
Conclusions: In this report we validate *IFT172* as the 20th BBS gene (BBS20) and confirm intraflagellar transport defects in BBS.

Introduction: Bardet-Biedl syndrome (BBS, #209900) is a rare genetic disorder considered a member of the group of ciliopathies. In recent years, zebrafish (*Danio rerio*) has been extensively used as a genetic model for the study of human disorders given the high homology that exists between human and zebrafish genomes (>80%). Here, we report an *in vivo* assay to analyse the functionality of three *BBS5* variants, predicted to be pathogenic, which have been detected by WES or direct sequencing.
Materials and Methods: Functional modelling of *BBS5* variants was carried out using 8-10 somite stage embryos, previously microinjected with bbs5-MO at one- to two-cell stage. Non-injected embryos were used as controls. We therefore performed rescue experiments with full-length human mRNA (wild-type and mutant, separately). Thus, affected embryos were classified according to severity of observed phenotypes.
Results: As previously reported, zebrafish embryos injected with bbs5-MO manifested several gastrulation defects, such as curved body axis, kinked notochord, longer somites or partial loss of somite definition. These phenotypes, ranging from mild to more severe, seem to be rescued by using wild-type human BBS5 mRNA, but not with mRNA carrying the detected mutations.
Conclusions: Our preliminary results indicate that these mutations could cause defects that lead to an abnormal planar cell polarity (PCP) signalling, which is known to underlie certain clinical phenotypes in BBS patients. These findings need to be confirmed by whole mount in situ hybridization (ongoing).

Characterization of the total ciliopathy variant load dissolves the enigma of oligogenic inheritance in Bardet-Biedl syndrome

N. Bachmann[1], *E. Decker*[1], *M. Hiersche*[1], *C. Decker*[1], *H. J. Bolz*[1], *A. Bohring*[2], *D. Mitter*[3], *G. Borck*[4], *S. Al Khatani*[5], *A. O. Khan*[6], *M. Cetiner*[7], *C. Bergmann*[1,8];
[1]*Bioscientia Center for Human Genetics, Ingelheim, Germany,* [2]*University of Münster, Institute for Human Genetics, Münster, Germany,* [3]*University of Leipzig, Institute for Human Genetics, Leipzig, Germany,* [4]*University of Ulm, Institute for Human Genetics, Ingelheim, Germany,* [5]*Armed Forces Hospital, Khamis Mushayt, Saudi Arabia,* [6]*King Khaled Eye Specialist Hospital, Division of Pediatric Ophthalmology, Riyadh, Saudi Arabia,* [7]*University Hospital of Essen, Department of Pediatrics, Essen, Germany,* [8]*University of Freiburg, Department of Medicine, Freiburg, Germany.*

Bardet-Biedl syndrome (BBS) is clinically and genetically heterogeneous and overlaps with other ciliopathies. Mutations in about 20 genes are described. BBS was among the first Mendelian disorders for which triallelic inheritance has been proposed which still causes uncertainty for genetic counselling and prenatal diagnostics. We performed genetic testing in 145 unrelated BBS patients, the most comprehensive sequencing-based study to date. Initially, we tested for the *BBS1* and *BBS10* hotspot mutations. NGS using our panel for ciliopathies (currently targeting 381 genes) was performed in 81 patients. In all but three families who fulfilled the diagnostic criteria, we identified homozygous or compound heterozygous mutations in a single *BBS* gene or *ALMS1*. Most mutations were private, 50 were novel and not described so far. High-coverage NGS enabled the detection of causative CNVs which were key to the diagnosis in hitherto unsolved constellations. As no MLPA kit is available for any of the *BBS* genes, all deletions would have been most probably missed by conventional techniques. Most patients carried additional mutations at other loci. However, in contrast to published data, our findings are in accordance with a recessive disease model. While modifiers may play a role for variable expressivity, our study widely resolves the long-standing enigma of triallelic or oligogenic inheritance in BBS. More than 95% of typical BBS patients harbour pathogenic mutations in one of the known disease genes why we conclude that further genetic heterogeneity is limited. Our data is of major importance for genetic counselling, clinical management and prenatal diagnostic testing.

PM11.020

Beals-Hecht syndrome: expanding the clinical phenotype

C. Machado, *J. Dupont, A. Sousa;*
Hospital de Santa Maria, Lisboa, Portugal.

Introduction: Beals-Hecht syndrome (BHS) or Congenital ContracturalArachnodactyly (CCA) is a rare autosomal dominant connective tissue disorder characterized by dolichostenomelia, crumpled ears, arachnodactyly, muscle hypoplasia andmultiple joint contractures. Heterozygous mutations in FBN2, which codes for fibrillin-2, are identified in about 27-75% of patients.In animal models,FBN2 is a key regulator of bone formation during embryogenesis.
Case presentation: We describe a 2 year-old boy, who is the second child of healthy non-consanguineous parents. At birth,micrognathia, crumpled helices, pectuscarinatum, arachnodactyly and campodactyly of both hands and feet, flexion contractures of wrists, elbows and knees, and generalized muscle weakness were noticed. Cardiac evaluation identified total anomalous pulmonary venous return and patent ductus arteriosus. Chest x-ray showed bilateral fusion of multiple ribs.
ArrayCGH did not identify pathogenic CNVs. Sequencing of FBN2 revealed two novel heterozygous variants: c.7138+1G>A,at a donor splice site, and a missense variant of unknown significance, c.2934T>A(p.Phe978Leu). Segregation analysis is ongoing.
Conclusion:Our case is within the most severe clinical spectrum of BHS/CCA.To our knowledge, apart from an infant with partial fusion of C2-C3 vertebral bodies, no other bone fusions were described in affected humans [1]. We propose the fused ribs present in our patientcould be an additional clinical finding in relation to BBS/CCA. Bioinformatic evaluation indicated that the c.7138+1G>A variant affects splicing of exon 56, and is thus probably pathogenic. Nonetheless, functional studies and results from segregation

analysis are needed to better clarify the pathogenicity of the FBN2variants identified in this patient.

PS11.021

Relation between assisted reproduction techniques and genomic imprinting defects

J. A. Tenorio, *V. Romanelli, L. Fernández García-Moya, P. Arias, G. Gordo, I. Dapía, J. Nevado, SOGRI Consortium, P. Lapunzina;*
INGEMM, Madrid, Spain.

Introduction: Beckwith-Wiedemann (BWS) is an overgrowth syndrome characterized by an unusual growth, macroglossia, hemihyperplasia, and other features as abdominal wall defects, major frequency of tumors compared with general population. Other clinical features are embryonic tumors, adrenocortical cytomegaly, ear anomalies, visceromegaly, renal abnormalities, neonatal hypoglycemia and polydactyly.
The molecular basis of this syndrome is multifactorial, but the most common alterations are imprinting defects at 11p15.5 locus, which represents about 70% of the cases.
Material and Methods: In this study, we analyzed KvDMR and H19DMR methylation levels in 121 patients with BWS, 16 born by assisted reproductive techniques (ART) and 105 by natural conception.
In 25 patients (15 from ART and 10 from Natural conception) we also analyzed several methylation imprinting loci: SRNPN, PEG1, ZAC, and GNAS. MS-MLPA and pyrosequencing were applied to performed molecular analysis of the imprinting regions.
Results: We found alterations in the locus 11p15.5 in 15 of 16 patients born by ART and 61 of 105 of patients born by natural conception. In addition, several patients born by assisted reproductive techniques presented defects in other imprinting loci.
Conclusions: Imprinting defects in patients born after assisted reproductive techniques are nine times more frequent than patients born after natural conception. This defects may include more than one imprinting loci and the dysregulation of the epigenetic pattern are related to the development of imprinting disorders such as Beckwick Wiedemann. Thus, ART is related to the disruption of DNA methylation pattern.

Beckwith-Wiedemann syndrome (BWS) is a disorder characterized by pre- and postnatal overgrowth in children, abdominal wall defects, macroglossia and a high risk of tumors. It is caused by different epigenetic and genetic defects of the 11p15 region containing imprinted genes which are localized in two domains controlled by the imprinting control region IC1 and IC2.
The aim of the study was to establish the molecular background of BWS in a group of 77 Polish patients. Molecular analyses were performed on leukocyte DNA and comprised methylation sensitive multiplex ligation-dependent probe amplification (MS-MLPA), microsatellite analyses, *CDKN1C* gene sequencing, and arrayCGH. The presence of 11p15 defects in 60 BWS patients, including a pair of monozygotic twins, was revealed. Hypomethylation at IC2 in 36 patients, hipermethylation at IC1 in 3 patients, and paternal UPD of 11p15 in 12 patients were identified. In other 7 patients aberrant methylation was associated with the presence of CNVs: duplications, a triplication or deletions involving both or one of the imprinted domains. In two patients novel frameshift mutations in *CDKN1C* gene were found. In the majority of cases genetic defects (CNVs, *CDKN1C* mutations) were inherited and their effects depended on their size, localization and the parental inheritance. Overall, the study revealed the presence of epigenetic or genetic defects in 77% of investigated patients. The pattern of our molecular findings is comparable with other populations. The study provides detailed data concerning mutational spectrum of a significant group of BWS patients.
The study was financed by National Science Centre project 1149/B/P01/2011/40 (NN407114940).

PS11.023

Brain-thyroid-lung syndrome in a child caused by a deletion on chromosome 14 proximal of the NKX2.1 gene locus

M. Kharbanda[1], *S. Khadouma*[2], *J. Jones*[3], *M. Donaldson*[3], *J. Pohlenz*[2], *P. Hermanns*[2], *C. Longman*[1];
[1]*Southern General Hospital, Glasgow, United Kingdom,* [2]*Children´s Hospital, Mainz, Germany,* [3]*Royal Hospital for Sick Children, Glasgow, United Kingdom.*

Brain-lung-thyroid syndrome (BLTS) is a rare disorder characterized by congenital hypothyroidism (CH), infant respiratory distress syndrome (IRDS) and benign hereditary chorea (BHC). BLTS is caused by mutations in the *NKX2.1* gene, a transcription factor which is involved in the development of the thyroid, lung and central nervous system.
In previously documented and published cases of patients with brain-thyroid-lung syndrome a mutation or deletion of *NKX2.1* has always been present. Here we present one patient with the clinical features of brain-thyroid-lung syndrome without a mutation in *NKX2.1*. Using *array comparative genomic hybridization*, we identified a heterozygous 1 Mb deletion on chromosome 14, which is approximately 195,000 bp proximal to *NKX2.1*. The deleted region encompasses 3 genes: *MBIP*, *BRMS1L* and *RALGAPA1*. Currently, we are trying to determine whether NKX2.1 directly interacts with one of these 3 proteins or whether one of the three proteins directly binds to the *NKX2.1* gene promoter.
Recently, a heterozygous deletion 200 kb proximal to the *NKX2.1* gene has been identified in another patient with a choreiform movement disorder. The smallest common deleted region of our patient and the described patient encompasses just the *MBIP* gene (MUK-binding inhibitory protein). MBIP is expressed in the thyroid, lung and forebrain. Our current aim is to clarify whether MBIP is involved directly or indirectly in *NKX2.1* gene expression or regulation. This finding will help to identify completely new mechanisms of NKX2.1 regulation and provide a deeper understanding of the thyroid development and the possible cause of thyroid disorders.

PM11.024

Exome sequencing reveals Camptosynpolydactyly and Mesoaxial synostotic syndactyly with phalangeal reduction to be allelic disorders

A. Dalal[1], *A. Kar*[1], *A. Das Bhowmik*[1], *S. R. Phadke*[2];
[1]*Centre for DNA Fingerprinting and Diagnostics, Hyderabad, India,* [2]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.*

Camptosynpolydactyly is a rare and complex type of hand malformation that was first reported in a child and subsequently in fetus from Muslim family in India. The proband had disorganized hands consisting of polydactyly with 2 digits arising from the dorsum of the hands. In addition there was syn- and camptodactyly of some fingers, syndactyly of toes and nails were dysplastic. There were no other anomalies present. Subsequent fetus showed similar anomaly and was terminated.
Homozygosity mapping and exome sequencing was done in proband after obtaining informed consent. The sequencing reads were mapped, annotated and filtered for known polymorphisms and synonymous variants. The patient revealed two consequent homozygous substitution mutations (c.[220G>T;221A>T]) in Basic Helix Loop Helix (BHLHA9) gene. These mutations result in substitution of Glutamic acid at 74 position with Leucine (p.E74L). The mutation was confirmed by sanger sequencing in parents and sibling and was predicted to be 'disease causing' by mutation prediction software.
BHLHA9 has already been reported to be involved in embryonic limb development. Duplications of 17p13.3 region involving BHLHA9 gene are known to be associated with Split hand/foot malformation with long bone deficiency (SHFLD3;612676). Recently missense mutations in BHLHA9 gene were identified in Mesoaxial synostotic syndactyly with phalangeal reduction (MSSD;609432). The phenotype of patients with MSSD is much milder compared to our patient. Mutations in MSSD have been reported at amino acid numbers 71, 73 and 75. Our patient had mutation at position 74. The reason for the difference in phenotype is not clear but it appears that both MSSD and camptosynpolydactyly are allelic disorders.

Clinical Genetics in the Dutch West Indies: 5-years' experience of clinical and molecular analysis of 350 patients with congenital malformation disorders and intellectual deficit.

T. De Vries[1], *S. Lo-A-Njoe*[2], *L. van der Veken*[1], *P. Caribbean genetic pediatricians*[3], *H. Ploos van Amstel*[1], *G. van Haaften*[1], *N. Knoers*[1], **M. M. van Haelst**[1];
[1]*Dept. of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Pediatric cardiology, Dept.of Pediatrics, Dr. Horacio Oduber Hospital, Aruba,*

Netherlands Antilles, [3]Dept. of Pediatrics, Dr. Horacio Oduber Hospital, Aruba, Fundasion Mariadal, Bonaire, St. Elisabeh Hospital, Curaçao, St. Maarten Medical Center, St. Maarten, Aruba, Bonaire, Curacao, St. Maarten, Netherlands Antilles.

The islands Curacao, Aruba, St. Maarten and the three BES-islands (Bonaire, St. Eustatius, and Saba) are part of the Kingdom of the Netherlands. Their total population of approximately 300.000 consists of a mixture of different races, which makes them very interesting for genetic analysis. Until recently Clinical Genetics was not part of regular pediatric care on these Dutch Caribbean Islands. Since 2010, clinical genetic outpatient clinics have been established at the pediatric departments of St. Elisabeth Hospital, Curaçao, Dr. Horacio Oduber Hospital, Aruba, Fundashon Mariadal, Bonaire, and St.Maarten Medical Center, St. Maarten.

Here we present the clinical and molecular genetic results of the first 350 consultations. The majority of cases presented with intellectual deficit and/or congenital malformations. A clinical and molecular diagnosis could be established in approximately 40% of the cases.

The first results of an Aruban cardio-genetics cohort showed a high incidence of 12.3/1000 live births with congenital heart diseases. Genome wide analysis revealed copy number variations (CNVs) that might be associated with the clinical phenotypes. In addition we found a significant number of patients with at least one region of homozygosity larger than 10Mb, suggestive for identity by descent or consanguinity. Analysis of homozygous regions is currently pending to identify candidate genes that might explain the congenital heart disease phenotype in patients without a molecular diagnosis.

Since the incidence of certain congenital anomalies is higher than the global incidence, and patients come from relatively closed island communities with very detailed phenotype description, these cohorts are very interesting for future genetics studies.

PM11.026

Novel mutations in IGF1R and SYNM cause reccessive congenital diaphragmtic hernia and mental retardation

R. Kadir, *N. Fluhr, M. Guri, O. S. Birk;*
Human Genetics and the Genetics Institute, Soroka Medical Center, Ben-Gurion University, Beer Sheva, Israel.

Autosomal recessive congenital diaphragmatic hernia (CDH) with mental retardation, IUGR, hearing loss, short stature, failure to thrive (FTT) and dysmorphism was diagnosed in three individuals of an Arab Israeli family. MRI demonstrated hypomyelination with narrowing of corpus callosum. Homozygosity mapping yielded 4 homozygous regions and whole exome sequencing of an affected individual identified only two mutations in these regions, both of which within the same 15q26.3 locus: IGF1R (NM_000857.3:c.1915G>A, p.639G>S) and SYNM (NM_145728.2:c.1859G>T, p.620L>F). None of the mutations were found in 100 ethnically matched controls and both mutations fully segregated as expected within the studied family.

Deletion mutations in this chromosomal locus, harboring both IGF1R and SYNM, have been previously linked with CDH. Mutations in IGF1R have been demonstrated to cause hearing loss, IUGR, short stature and FTT. Interestingly, null mutation of DESMIN, direct interactor of SYNM, leads to diaphragmatic hernia in adult mice. We thus present a complex phenotype, presumably caused by homozygous mutations in two genes which are in linkage disequilibrium. We speculate that the IGF1R mutation is the cause for FTT, IUGR, hearing loss and short stature and that the SYNM mutation results in the CDH.

Cornelia de Lange syndrome (CdLS) is an inherited disorder characterized by facial dysmorphism, growth and cognitive impairment, limb malformations and multiple organ involvement. Mutations in five genes, encoding subunits of the cohesin complex (SMC1A, SMC3, RAD21) and its regulators (NIPBL, HDAC8), account for 70% of patients with CdLS or overlapping phenotype.

Here, we present clinical description of seventeen patients with CdLS-like features caused by mutations in SMC3 and assess the degree of overlap with typical CdLS phenotype. Of these, ten probands are novel and seven individuals have been previously reported. Furthermore, we mapped all mutations to the known structure of the SMC complex to predict functional consequences.

All patients exhibited clinical findings of overlap with typical CdLS patients, in particular harboring SMC1A mutations. Although SMC3-associated phenotypes are also characterized by postnatal microcephaly but with a less distinctive craniofacial appearance, a milder prenatal growth retardation that worsens in childhood, few congenital heart defects and an absence of limb deficiencies.

Likewise some functional indications previously reported, our modelling of the mutation effects support the hypothesis that the mechanism of pathogenicity in SMC1A and SMC3 related CdLS might be due to a dominant negative effect of the altered protein resulting from missense or in-frame mutations. Nevertheless, the finding of one truncating SMC3 mutation, leads us to consider haploinsufficiency as additional potential cause of pathogenesis.

This work confirms that SMC3 mutations account for ~1-2% of CdLS-like phenotypes and emphasizes the importance of SMC3 mutation screening, which will allow us to better assess for genotype-phenotype correlation.

PS11.029

FISHing for a tissue-specific mosaic monosomy of chromosome 21

A. D. Kolotii[1,2], *Y. B. Yurov[1,2,3], I. Y. Iourov[1,2,4], S. G. Vorsanova[1,2,3];*
[1]Mental Health Research Center, RAMS, Moscow, Russian Federation, [2]Research and Clinical Institute for Pediatrics at the Pirogov Russian National Research Medical University, Moscow, Russian Federation, [3]Moscow City University of Psychology and Education, Moscow, Russian Federation, [4]Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.

Non-mosaic chromosome 21 monosomy is considered incompatible with life. Here, we present an exception, which turned out to be an example of tissue-specific mosaic monosomy of chromosome 21. In a 9-month-old girl with severe congenital malformations, cytogenetic analysis of blood revealed monosomy of chromosome 21. Array CGH (molecular karyotyping) has confirmed the loss of chromosome 21. To determine the background of viability in the index case, FISH analysis of different tissues (blood and buccal cells) was done using DNA probes for 21q22.13q22.2 and D13Z1/D21Z1 (pericentromeric DNA) loci and multicoulor banding. In buccal cells, we have detected ring chromosome 21 was detected in 80% of cells. The region of chromosome 21 lost through the ring chromosome formation was estimated as 21q22.11qter. The patient presented with microcephaly, large low-set ears, glaucoma, perforated corneal ulcer, protruding frontal suture, skull asymmetry, short neck, arachnodactyly, pectus excavatum, ventriculomegaly and thrombocytopenia. The present case appear to be one of few cases of mosaic chromosome 21 monosomy and probably one of the first case of tissue-specific mosaicism for chromosome 21 loss more-or-less well documented. One can speculate that this case is the result of intercellular natural selection between normal and abnormal cells as proposed earlier (Yurov et al., 2007, 2009, 2010). Interestingly, it is the FISH-based techniques that have helped to rule out the presence of normal cells. Thus, FISH and array CGH should be applied to analyze different tissues to diagnose similar cases.

Supported by Russian Scientific Fund (Grant #14-15-00411).

The ciliopathy protein CC2D2A associates with NINL and plays a role in RAB8A-MICAL3 regulated vesicle trafficking

R. Bachmann-Gagescu[1,2], *M. Dona[3], M. Ueffing[4], R. Roepman[3], K. Boldt[4], D. Doherty[5], C. B. Moens[6], S. C. F. Neuhauss[7], H. Kremer[3], E. Van Wijk[3];*
[1]University of Zurich- Medical Genetics, Zürich, Switzerland, [2]Institute for Molecular Life Sciences, Zurich, Switzerland, [3]Radboud University Medical Center, Nijmegen, Netherlands, [4]Eberhard Karls University, Tuebingen, Germany, [5]University of Washington-Dept of Pediatrics, Seattle, WA, United States, [6]Fred Hutchinson Cancer Research Center, Seattle, WA, United States, [7]University of Zurich- Molecular Life Sciences, Zürich, Switzerland.

Ciliopathies are a genetically and phenotypically heterogeneous group of human developmental disorders caused by dysfunction of primary cilia. Joubert syndrome (JS) is characterized by a distinctive hindbrain malformation variably associated with retinal dystrophy and other ciliopathy phenotypes. Mutations in CC2D2A, encoding a protein localized at the ciliary transition

zone, are found in ~10% of patients with JS. The ciliary transition zone plays an important role in controlling the ciliary protein content, but the precise mechanism remains unclear. Previous studies in the zebrafish demonstrated a role for Cc2d2a in Rab8a-dependent vesicle trafficking in photoreceptor cells. In this work, we identify the centrosomal protein NINL as a physical interaction partner of CC2D2A through a yeast-2-hybrid screen. NINL partially co-localizes with CC2D2A at the base of cilia and ninl knockdown in zebrafish leads to photoreceptor outer segment loss, mislocalization of opsins and vesicle accumulation, similar to cc2d2a-/- phenotypes. Moreover, partial ninl knockdown in cc2d2a-/- embryos enhances the retinal phenotype of the mutants, indicating a genetic interaction in vivo, for which an illustration is found in patients from a JS cohort. Similar to zebrafish cc2d2a mutants, ninl morphants display altered Rab8a localization. Further exploration of the NINL-associated interactome identifies MICAL3, a protein known to interact with Rab8a and to play an important role in vesicle docking and fusion. Together, these data support a model where CC2D2A associates with NINL to provide a docking point for cilia-directed cargo vesicles, providing a mechanism by which transition zone proteins can control the protein content of the ciliary compartment.

PS11.031

A specific R391X mutation in the RUNX2 gene may be associated with hearing loss in the Cleidocranial Dysplasia: Analysis of four families

F. Kul, A. Koparır, E. Fenercioglu, M. Seven, M. Ozen, **H. Ulucan**;
Istanbul university cerrahpasa medical school, Istanbul, Turkey.

Cleidocranial dysplasia (CCD, MIM119600) is an autosomal dominant skeletal dysplasia characterized by delayed closure of the cranial sutures, aplasia or hypoplasia of the clavicles and dental abnormalities. These findings accompanied by mobility of droopy shoulders, frontal and parietal bossing, hypertelorism, brachycephaly, presence of multiple wormian bones, wide pubic symphysis, supernumerary, late erupting teeth and short stature. CCD can be diagnosed by clinical and radiological evaluation and validated by molecular studies. Heterozygous loss of function RUNX2 gene, which plays an important role in osteogenesis and differentiation of precursor cells, causes CCD phenotype.

We report six cases from four unrelated families with CCD phenotype. First family had a classic CCD phenotype and, IVS4+4delAAGT mutation was detected. Second family had also similar clinical findings with first family and molecular analysis of RUNX2 is not completed yet. Third family also had classic CCD phenotype and accompanied by hypothyroidism and mixed type hearing loss. Her father was presented CCD phenotype and mild sensorineural deafness. Mutation analysis of third family revealed R391X in the RUNX2 gene. Last case had also classic CCD phenotype and molecular analysis of RUNX2 isn't completed yet. In CCD patients, though hearing loss was identified in the literature, previously, there is no comprehensive data about auditory capacity of patients who had R391X mutation in the RUNX2. Our data suggest that these specific mutation may cause conductive and/or sensorineural hearing loss in CCD. To elucidate this hypothesis further functional analysis should be performed.

PM11.032

Clinical exome sequencing emerges as an effective diagnostic tool in Saudi pediatric patients with suspected genetic etiology: a King Fahad Medical City (KFMC) experience

A. Peer Zada, *E. Faqeih, A. AlAsmari, T. Wani;*
King Fahad Medical City, Riyadh, Saudi Arabia.

We present here, for the first time, an observational study of 69 Saudi patients seen by clinical geneticists who ordered the clinical exome sequencing (CES) tests at KFMC. All the patients were pediatric; 33 females (48%), 36 males (52%); mean age for females, 5.6±0.6 and for males 4.6±0.5 years. The patients presented with diverse clinical indications; intellectual disability (ID: 65%, 45/69), mitochondrial disease (10%, 7/69), multiple congenital anomalies (MCA: ~6%, 4/69), metabolic disorders (~4%, 3/69) and others comprising of individual cases (~15%, 10/69). We analyzed the CES data with respect to the phenotypic indications at initial diagnoses, overall diagnostic yield, mode of inheritance, the spectrum of genetic mutations, consanguinity and the incidental findings reported. We observed an overall diagnostic rate of 42% (29 of 69 cases; 95% CI-40%-44%) with 48% (14 of 29) of the mutations reported as variants of unknown clinical significance but likely pathogenic and 52% (15 of 29) as known disease causing genetic alterations. The rate of molecular diagnosis was 44% (20/45) for ID, 57% (4/7) for mitochondrial disorders, 33% (1/3) for metabolic disorders, 25% (1/4) for MCA. Mendelian inheritance patterns included 85% (23/29) autosomal recessive (AR), 3.7% (1/29) autosomal dominant (AD) and 7.4% (2/29) X-linked. Interestingly, the rate of consanguinity among positive cases was around 80%. One patient with MCA without ID and one with movement disorder (2/29, 6.8%) received molecular diagnoses of two overlapping AR genetic disorders.

In summary, clinical exome sequencing is emerging as a potential molecular diagnosis tool in Saudi pediatric patients suspected with genetic etiology with a diagnostic rate of 42%.

PS11.033

A case of Cockayne syndrome detected by chromosomal microarray analysis

G. E. Rudenskaya, **I. V. Kanivetz**, *S. A. Korostelev, T. A. Adyan, A. V. Polyakov;*
Medical Genetics Research Centre, Moscow, Russian Federation.

Chromosomal microarray analysis (CMA) is widely used for search of chromosomal microdeletions/microduplications but in some instances is helpful for detection of monogenic disorders. Our case of Cockayne syndrome, type A (CSA), rare autosomal recessive disorder produced by ERCC8 mutations, is an interesting example. The 8-year-old girl, an only child of non-consanguineous Russian parents originating from different regions, had pronounced delay of motor and especially of mental development, growth deficiency (100 cm, 13 kg), microcephaly (42 cm), typical face with deep-set eyes, early hypohidrosis, ataxia, demyelinating polyneuropathy with feet deformity, atrophy and multiple small calcinates on brain MRI, and optic atrophy but no skin photosensitivity, deafness, retinal degeneration or cataract. Mutations in ERCC6 gene responsible for more severe CSB were not found. DNA test for CSA, which is not performed in our centre routinely, was planned. Meanwhile, CMA (Affymetrix CytoScan HD Array) was carried out in search of other possible diagnoses, and homozygous deletion of 5q12.1 was detected. Molecular karyotype: arr[hg19] 5q12.1(60,131,474-60,192,457) x0. The deletion had size 60983 bp and encompassed two genes, ELOVL7 (of no clinical significance) and ERCC8. Moreover, an increased number of long contiguous stretch of homozygosity (LCSH) - 14% of genome - was found. Both CMA findings are also strongly unusual for apparently non-inbred family. Homozygous deletion was confirmed by ALFP analysis of ERCC8 exon 12. Verified CSA diagnosis permits prenatal or preimplantation testing in the family and proper supportive medical care for the patient minding risk of immunological and other complications.

PM11.034

Cervical spinal cord compression caused by calcification of the yellow ligament in Coffin-Lowry syndrome

K. Kurosawa, *Y. Enomoto, C. Hatano, T. Yokoi, N. Nakamura;*
Kanagawa Children's Medical Center, Yokohama, Japan.

Coffin-Lowry syndrome (CLS) is an X-linked mental retardation syndrome characterized by severe to profound intellectual disability and musculoskeletal manifestations. Calcification of the yellow ligament (CYL) in early adulthood, resulting in myelopathy by spinal cord compression, had been previously reported in 3 CLS patients of Japanese origin. Here, we report on an additional 3 CLS patients with CYL: a 12-year-old boy and a pair of 17-year-old monozygotic twins. Ossification of the posterior longitudinal ligament and of the yellow ligament both represents ectopic ossification in the cervical and thoracic spine region. This ossification is a common disorder among Japanese and other Asian populations, resulting in compressive meylopathy and/radiculopathy in patients. Loss-of-function mutations in RSK2, a protein required for osteoblast differentiation and function, lead to CLS and are responsible for the skeletal abnormalities observed in CLS patients. Together with these results, the condition of CLS is likely accelerating the development of calcification in the ligaments and fascicles in our patients. Early detection and survey of this serious complication should be considered in the management of CLS, especially for patients of Oriental origin.

Insulin response dysregulation explains abnormal fat storage and high risks of diabetes mellitus type 2 in Cohen Syndrome

L. Floriane[1], L. Faivre[1,2], T. Gautier[3], J. Petit[4], E. Gautier[1,2], D. Masson[3], G. Jego[3], S. El Chehadeh-Djebbar[1,2], N. Marle[1,2], V. Carmignac[1], V. Deckert[3], M. Brindisi[5], L. Lagrost[3], C. Thauvin-Robinet[1,2], **L. Duplomb**[1];
[1]GAD, Dijon, France, [2]FHU TRANSLAD, Département de Génétique, Dijon, France, [3]Université de Bourgogne, Inserm UMR 866, Dijon, France, [4]Service d'endocrinologie, CHU Bocage, Dijon, France, [5]Service d'Endocrinologie, CHU Bocage, Dijon, France.

Cohen Syndrome (CS) is a rare autosomal recessive disorder, with glycosylation defect secondary to mutations in VPS13B gene, which encodes a protein of the Golgi apparatus. Besides congenital neutropenia, retinopathy and intellectual deficiency, CS patients are faced to obesity. Metabolism investigati-

ons show abnormal glucose tolerance tests and HDL values in some patients that should be risk factors for the development of diabetes mellitus and/or cardiovascular complications. To understand the mechanisms involved in CS fat storage, we used two models of adipogenesis differentiation: (i) SGBS preadipocytes with VPS13B invalidation thanks to siRNA delivery and (ii) CS primary fibroblasts. In both models, VPS13B invalidation leads to an accelerated differentiation into fat cells, which is confirmed by an earlier and an increased expression of specific adipogenic genes, consequently to an increase response of cells to insulin stimulation. At the end of the differentiation protocol, these fat cells exhibit a decreased in AKT2 phosphorylation after insulin stimulation, in favor of insulin resistance. Thus, in association with the in-depth analysis of the metabolic status of the patients, this study allowed us to recommend an appropriate nutrition education in order to prevent the occurrence of diabetes mellitus as well as recommendation for follow-up of CS patients, in particular for metabolic syndrome development. We also preconize not to use the term obesity in CS, but abnormal fat repartition, which should limit the number of patients whom are addressed for CS diagnosis only on the basis of intellectual deficiency associated with obesity.

PM11.036

Complex chromosomal rearrangement - trisomy 9p24.3q21.11, duplication 17q25.3, deletion 19p12 - in a child with severe hypotonia, facial dysmorphism and genital hypoplasia

D. Wahl[1], **U. Heinrich**[2]*, E. Krimmel[2], C. Uebler[3], I. Rost[2];*
[1]Praxis für Humangenetische Beratung und Psychotherapie, Augsburg, Germany, [2]Centre for Human Genetics and Laboratory Medicine, Martinsried, Germany, [3]Josefinum Kinderklinik, Augsburg, Germany.

The male child was born spontaneously as the second child of healthy non-consanguineous parents after 38 weeks of gestation after an uneventful pregnancy. Postpartal hypotonia, reduced muscle reflexes and weak crying were the first suspicious symptoms. Further clinical investigations revealed rhizomelia, craniofacial dysmorphism such as frontal bossing, flat occiput, flat nasal bridge, hypertelorism, epicantal folds, deep-set, simple-shaped ears and micro-retrognatia. Furthermore a simian crease, deep set thumbs, absent distal crease of the fifth digits, sacral dimple, skintag in the middle of the thorax and genital hypoplasia with cryptorchidism were evident. In the neonatal period a non-alloimmun-thrombopenia appeared that revovered spontaneously.
In the age of 5 months, the suckling was presented to the genetic counceller for the first time. Muscle hypotonia was still evident and presented as poor headcontrol and reduced spontaneous movement. However the baby could laugh and was alert. There was a tendency for infections. The family history was unremarkable, without evidence of abortions and disabilities.
Conventional chromosomal analysis revealed an additional derivative chromosome 9. Comparative genomic hybridization showed a complex chromosomal rearrangement with a terminal duplication 17q25.3 as well as a deletion 19p12 in addition to the trisomy 9p24.3q21.11. Using FISH analysis, the derivative chromosome 9 could be characterized as a product of a reciprocal translocation 9 and 17 with the correct karyotype 47,XY,+der(9)t(9;17)(q21.11;q25.3).
According to literature the patient's main symptoms are in compliance with trisomy 9 syndrome. This case again demonstrates that array CGH can reveal a complex chromosomal aberration even after a clear-cut conventional cytogenetic result.

Complex chromosome imbalances in form of monosomies 6p12.3-p21.1 and 18p11.21pter together with trisomy 19q13.41qter

A. T. Midro[1]*, B. Panasiuk[1], J. Kiśluk[2], A. Sawicka[1], J. Żurawska[2], S. Falkowski[1], O. Kowalczuk[2], J. Nikliński[2];*
[1]Department of Clinical Genetic Medical University Bialystok Poland, Bialystok, Poland, [2]Department of Clinical Molecular Biology, Medical University Bialystok Poland, Bialystok, Poland.

Introduction: A combination of several different approaches, including routine karyotype, FISH, and CGH studies are useful in identifying genes and regions responsible for phenotype modifications.
Material and Methods: In 23-years-old male using GTG and RBG techniques a monosomy of the short arm of chromosome 18p11.21→pter has been found in his karyotype. Array comparative genomic hybridization, was prepared using **SurePrint G3 Human CGH Microarray Kit, 8x60K. Results were analysed using Agilent CytoGenomics 2.7 Software.** All of the rearrangements were confirmed by FISH studies.
Results: We detected loss of 6449 kb at short arm of chromosome 6, loss of 13 687 kb at short arm of chromosome 18 and gain of 7138 kb at long arm of chromosome 19. Morphological phenotype of boy consist of short stature, long, lumpy head, slightly sunken temples area, sloping forehead, high, diffuse frontal hairline, triangular face, prominent eyebrows, ptosis, hypertelorism, flat nasal bridge, the long ridge and thick tip of the nose, big, raised to the top nostrils, flanged out lower lip, short nasolabial distance, broad mouth fissure, ear lobes obliquely backward, crowded, misaligned teeth. In addition the dystonia and hearing problems, intellectual disability and delay of speech development were observed.
Conclusion: Two additional sub-microscopic changes in form microdeletion 6p12.3-p21.1 and microduplication 19q13.41→qter as a highly complex chromosomal rearrangement involving three chromosomes together with deletion 18p11.21→pter resulted in complex phenotype in boy with previously diagnosed like de Grouchy syndrome.
The study was sponsored by Polish grant of Medical University Bialystok - No 113-06825L.

PM11.038

Associated malformations in cases with congenital diaphragmatic hernia

C. Stoll, *Y. Alembik, B. Dott, M. Roth;*
Genetique medicale, Strasbourg, France.

The etiology of congenital diaphragmatic hernia (CDH) is unclear and its pathogenesis is controversial. Because previous reports have inconsistently noted the type and frequency of malformations associated with CDH, we assessed these associated malformations ascertained between 1979 and 2007 in 386,088 consecutive births. Of the 139 patients with the most common type of CDH , the posterolateral, or Bochdalek-type hernia , 85 (61.2%) had associated malformations. These included: chromosomal abnormalities (n=25, 18.0%including 12 cases with trisomy 18); non-chromosomal syndromes (Fryns syndrome, fetal alcohol syndrome, De Lange syndrome, CHARGE syndrome, Fraser syndrome, Goldenhar syndrome, Smith-Lemli-Opitz syndrome, multiple pterygium syndrome, Noonan syndrome, spondylocostal dysostosis, and Beckwith-Wiedemann syndrome); malformation sequences (laterality sequence, ectopia cordis); malformation complexes (limb body wall complex) and non syndromic multiple congenital anomalies (MCA) (n=36, 25.9%). Malformations of the cardiovascular system (n=53, 27.5%), urogenital system (n=34, 17.6%), musculoskeletal system (n=29, 15.0%), and central nervous system (n=19, 9.8%) were the most common other congenital malformations. We observed specific patterns of malformations associated with CDH which emphasizes the need to evaluate all patients with CDH for possible associated malformations. Geneticists and pediatricians should be aware that the malformations associated with CDH can often be classified into a recognizable malformation syndrome or pattern (35.3%).

PS11.039

Unusual form of congenital ichthyosiform erythroderma (CIE) in two siblings of an Austrian family. Attempts to unravel genetic basis of this disorder.

P. M. Kroisel, *M. R. Speicher, C. Windpassinger;*
Institute of Human Genetics, Graz, Austria.

Congenital ichthyosis is a rare disease and particular subtypes like lamellar ichthyosis (LI) have a very low incidence of less than 1:500.000. In a couple of Austrian origin where a distant relationship of both parents was likely because their grandparents were born in the same small village, two of their four offsprings were affected by CIE/LI. The so-called collodium baby phenotype was present in one daughter and one son, whereas the other two offsprings are healthy. The affected girl died with 3 month due to disease related complications and the affected son is now 28 years old. He showed early onset of rickets not recognized before an age of 16. Because sufficient vitamin D treatments started late, he suffered from multiple fractures and developed bowing of upper and lower limbs. Growth retardation (150 cm length) and microcephaly (OFC 49 cm) but normal mental development and hearing were found. Some of his progeroid features and light sensitivity resemble similarities with Trichthiodystrophy, another heterogenic autosomal recessive disorder, caused by helicase subunits of transcription/repair-vector-gene mutations. Homozygosity mapping was performed by SNP array analysis using Affymetrix CytoScan 750 with analysis suite 2.1.0.16. Results obtained with patients DNA clearly support parental consanguinity. Just 3 homozygous segments ranging from 18,4 Mb at 5q23.2 from PHAX- to FGF1-gene and 4.7 Mb at 1q21.1 and 3.4 Mb at 12q24.11 were identified. Since none of thus far reported genes for CIE or LI map to these genomic segments, focused NGS approaches to identified potential candidate genes are now implemented.

PM11.040

Exome Sequencing As A Useful Tool To Correctly Diagnose A Congenital Myopathy In Two Sibs With An Unclear Phenotype And A Tentative Diagnosis Of Opitz-C Syndrome

R. Urreizti[1], S. Mort-Farre[1], N. Roca-Ayats[1], F. Munell[2], A. Sanchez-Montañez[2], F. Garcia-Garcia[3,4], J. Dopazo[3,4], B. Cormand[1], L. Vilageliu[1], S. Balcells[1], **D. R. Grinberg**[1]*;*
[1]1Department of Genetics, Faculty of Biology, Universitat de Barcelona, CIBERER, IBUB., Barcelona, Spain, [2]Neuropaediatrics Department, Hospital Vall d'Hebron, Barcelona, Spain, [3]Department of Computational Genomics, Centro Investigación Príncipe Felipe, Valencia, Spain, [4]BIER, CIBERER, Valencia, Spain.

Opitz C Syndrome (OTCS) is an ultra-rare disease with less than 60 patients diagnosed worldwide and a broad range of affectation, making its diagnosis very challenging. The OTCS gene/s has not been identified, yet. We recruited a cohort of 14 patients diagnosed as OTCS or C-like syndrome, some with a "tentative" diagnosis. To search for the OTCS gene, 4 patients and their parents, including two brothers with an unclear phenotype, were subjected to whole-exome sequencing (WES). While the WES sequences were being analyzed, a thorough clinical study of the older brother, including a muscle NMR, strongly suggested a congenital myopathy, rather than OTCS.
The WES analysis revealed that the 2 brothers bore 2 mutations in the RYR1 gene, inherited in an autosomal recessive manner. The maternal mutation was a missense change (p.Cys489Phe), while the paternal was a nonsense mutation (p.Arg2241STOP) previously associated with congenital myopathy and atypical periodic paralysis. The p.Cys489Phe mutation is predicted to be severely damaging by SIFT, PROVEAN and PolyPhen2. In addition, the Cysteine 489 residue is conserved among 33 vertebrate species and the nature of the amino acidic change and its position in a well-defined alpha helix suggest that the correct folding of the RYR1 protein may be affected. However, further functional studies need to be performed to demonstrate its pathogenicity.
WES is becoming a powerful tool in the molecular diagnosis of patients with unclear phenotypes, pathologies with an unknown molecular basis or in which very large genes (such as RYR1 with 106 exons) are involved.

S.Gerardo, Monza, Italy, Monza, Italy, [6]Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany, Essen, Germany, [7]Institute of Human Genetics, University of Cologne, Cologne, Germany, Cologne, Germany, [8]Unit of Clinical Genetics and Functional Genomics, Departments of Pharmacology-Physiology and Pediatrics, Medical School, University of Zaragoza, CIBERER-GCV and ISS-Aragon, Zaragoza, Spain, Zaragoza, Spain, [9]Institut für Humangenetik Lübeck, Universität zu Lübeck, Germany, Lübeck, Germany, [10]Divisions of Genetics and Metabolism, Children's Hospital of Philadelphia, Philadelphia, PA, 19104, USA., Philadelphia, PA, United States, [11]Department of Pediatrics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, 19104, USA, Philadelphia, PA, United States.

Cornelia de Lange syndrome (CdLS) is a genetically heterogeneous disorder manifesting extensive phenotypic variability. Mutations in NIPBL, SMC1A, SMC3, RAD21 and HDAC8, encoding subunits or regulators of cohesin, are found in about 70% of the patients.
Next generation sequencing approaches have allowed us to identify heterozygous de-novo mutations in five patients with CdLS phenotypes who were previously negative for mutations in the CdLS genes.
All five mutations alter chromatin-associated factors and each is predicted to result in a loss of function. Two mutations, one nonsense and one 4-bp frame-shift deletion, were found in the ANKRD11 gene, that is associated with KBG syndrome. The three other mutations disrupt components of the SWI/SNF chromatin-remodeling complex, previously associated with Coffin-Siris and Nicolaides-Baraitser syndromes. These mutations include a missense substitution in SMARCB1, a frame-shift deletion in ARID1A and a chromosome microdeletion including the ARID1B gene.
Our results support recent molecular findings that describe an intimate link between cohesin and the SWI/SNF complex in regulating transcription. Furthermore, ANKRD11 associates with histone deacetylases to enable its role in transcriptional regulation. These findings add to the growing body of work supporting the hypothesis that CdLS and overlapping phenotypes result from alterations in specific gene expression patterns.
In summary, mutations in ANKRD11 and components of the SWI/SNF complex can result in clinical pictures that are difficult to distinguish from CdLS and related disorders. Thus, sequence analysis of these genes should be strongly considered for those patients with suspected clinical diagnoses of CdLS who were negative for CdLS-associated genes.

PM11.042

Acute Megakaryoblastic leukemia in a patient with Cornelia de Lange syndrome. Could germline mutations in cohesin predispose to cancer ?

S. DRUNAT[1]*, J. Lachenaud[2], C. Baumann[1], O. Feneteau[3], E. Lainey[3], A. Marceau-Renaut[4], C. Preudhomme[4], A. Baruchel[2], H. Cavé[1];*
[1]Department of Genetics-Robert Debré Hospital, Paris, France, [2]Paediatric Hematology-Robert Debré Hospital, Paris, France, [3]Biological Hematology-Robert Debré Hospital, Paris, France, [4]Hematology Laboratory-CHRU Lille, Lille, France.

Cornelia de Lange Syndrome (CdLS) is a rare disorder characterized by a distinctive facial dysmorphism associated with growth delay, microcephaly, mental retardation and limb anomalies. CdLS is caused by heterozygous mutations in genes encoding the core proteins of the cohesin complex or its regulators. Cancer genomics analyses have discovered a very high mutation rate in Down syndrome-associated acute megakaryoblastic leukemia (DS-AMKL) suggesting that cohesin mutations may be the third genetic hit responsible for AMKL. Despite the potential role of cohesin in malignancy, increased tumor incidence in CdLS patients has not been described.
We report the occurrence of AMKL in a 3 years boy with a clinical diagnosis of CdLS. Leukemic cells displayed the same morphologic and immunophenotypic characteristics found in DS-AMKL blasts. Molecular and cytogenetic analysis revealed a frameshift mutation in *GATA1* and trisomy 21 in the bone marrow blast cells. Analysis of a blood sample of the patient at the age of 3 weeks by exome sequencing identified a *NIPBL* mutation responsible for the CdLS but also revealed the presence, at a mosaic level, of the *GATA1* mutation and trisomy 21 confirming that these defects which are primary events in DS-AMKL are here, secondary events.
This is the first report of leukemia in a patient with CdLS. The clinical implication of this observation needs further investigations to determine whether cohesin mutations in CdLS patients may predispose them to cancer. Our findings suggest that cohesin defects, in addition to their known role in leukemic progression, may also represent the first genetic hit to initiate leukaemogenesis by inducing aneuploïdy.

PS11.043

A series of 38 novel germline and somatic mutations of NIPBL in Cornelia de Lange syndrome.

Introduction: Cornelia de Lange syndrome is a rare and severe multisystemic developmental disorder. Five genes have been identified so far, all involved in the cohesin complex. NIPBL represents about 60% of identified heterozygous mutations. The majority of cases results from a de novo event. Recently, NIPBL somatic mosaicism has been highlighted through buccal cell DNA study in some patients with a negative molecular analysis on leukocyte DNA.
Materials and Methods: Here, we present a series of 38 patients with a Cornelia de Lange syndrome related to an heterozygous NIPBL mutation identified by Sanger sequencing. The diagnosis was based on the following criteria: 1) intrauterine growth retardation and postnatal short stature, 2) feeding difficulties and/or gastro-oesophageal reflux, 3) microcephaly, 4) intellectual disability and 5) characteristic facial features.
Results: We identified 37 novel NIPBL mutations including 34 in leukocy-

tes and three in buccal cells only. All mutations shown to have arisen de novo when parent blood samples were available. As previously reported, the present series confirms the difficulty in predicting the phenotype according to the NIPBL mutation. Until now, somatic mosaicism has been observed for thirteen cases which does not seem to be consistently associated with a milder phenotype. Besides, several reports support a postzygotic event for those cases.<

Conclusion: Considering these elements, we recommend a first-line buccal cell DNA analysis in order to improve gene testing sensitivity in Cornelia de Lange syndrome and genetic counseling.

Corpus callosum (CC) is the major brain commissure connecting the homologous areas of both hemispheres at the midline. CC malformations (CCM) are the most frequent brain malformations with an incidence of 1/4000 newborn often associated with chromosomal anomalies or mendelian syndromes with recessive and dominant inheritance. Recurrence is observed in 5 % of cases. Children with CCM have an uncertain neuro-developmental outcome. Therefore, counseling remains challenging, especially prenatally.

We systematically reviewed the data of 142 fetuses with CCM as isolated or associated autopsy findings in our center. We first completed the cytogenetic analysis by a CGH array when the underlying etiology was not found: 108 (76%) of cases remained unsolved.

In our effort to identify the disease causing gene of CCM antenatally, we used exome sequencing in 10 trios and a targeted high throughput sequencing strategy including 423 genes in 64 fetuses and 32 are ongoing. NGS allowed several diagnosis, such as a PDH deficiency (PDHA1), PCH with ACC (AMPD2), genitopatelar (KAT6B), Primrose (ZBTB20), Coffin-Siris (ARID1A and ARID1B) or Chudley Mac Cullough syndrome (GPSM2). Interestingly some diagnosis were not possible antenatally due to the absence of specific signs, but reevaluation of fetalpathological data (reverse phenotyping) allowed to support NGS findings. These situations will be illustrated.

All together, to date, as analysis are still ongoing, combined fetal imaging, fetal necropsy, cytogenetic and molecular analysis allowed the identification of the cause in at least 30 % of fetuses: 15% chromosomal anomaly and 15 % of mendelian disorder. The necessary reverse phenotyping underlines the importance of fetal necropsy following pregnancy terminations for CCM.

PS11.045

Whole exome sequencing for craniofacial anomalies: the NIjmegen experience

C. W. Ockeloen, *R. Pfundt, S. de Munnik, C. E. L. Carels, T. Kleefstra; Radboud University Medical Center, Nijmegen, Netherlands.*

Introduction: Whole exome sequencing (WES) is a successful genomewide approach to identify genetic causes of heterogeneous diseases. Our department was among the first to implement exome sequencing in clinical genetic diagnostics. We show the results of WES for diagnosis of craniofacial anomalies. Methods: Twenty patients with craniofacial anomalies (familial or syndromic cleft lip/palate, oligodontia and craniosynostosis) were investigated by means of WES. WES was performed on an Illumina HiSeq2000TM platform after enrichment with the Agilent SureSelect XT Human All Exon 50 Mb kit. A two-step analysis was used in which a CFA gene panel containing 94 genes, based on the OMIM database and recent publications, was analysed first before opening the whole exome. Results: In the first step analysis, a genetic diagnosis was made in 5/20 index patients (25%). These comprised mutations in *COL11A2* causing Stickler syndrome, in *GLHR3* causing van der Woude syndrome type 2, and *WNT10A* mutations in oligodontia patients. Whole exome analysis in 11/15 patients diagnosed Kallmann syndrome, caused by a *FGF8* mutation, in a family presenting with cleft lip/palate. Conclusion: With a diagnostic yield of 25% in the first analysis these results of the WES based CFA gene panel in a small patient cohort are promising. Having a genetic diagnosis allows optimal management and adequate genetic counselling. Therefore we recommend that diagnostic WES should be offered to all patients with syndromic or familial forms of orofacial clefting and oligodontia.

PM11.046

Partial monosomy 5p and partial trisomy 13q in a patient with cat-like cry and postaxial polidactily detected by SNP array - a case report

T. Tkemaladze[1], *K. Oexle*[2], *G. Melikishvili*[3], *E. Kvaratskhelia*[1], *S. Tchankvetadze*[4], *E. Abzianidze*[1];

[1]Tbilisi State Medical University, Tbilisi, Georgia, [2]Institute of Human Genetics, Krankenhaus rechts der Isar, Technische Universität, Munchen, Germany, [3]MediClubGeorgia Hospital, Tbilisi, Georgia, [4]Gudushauri National Medical Perinatal Center, Tbilisi, Georgia.

Here we present a case of a chromosomal rearrangement in a 7-month old boy from Georgia with partial deletion of 5p and partial duplication of 13q with features of both Cri-du-Cat (CdC) and trisomy 13. The patient was born from a second pregnancy of non-consanguineous parents on the 37th weeks of gestation. The first pregnancy was terminated due to multiple congenital anomalies. At birth the patient weighted 2450 gr, his lenght was 46 sm, OFC - 33 sm and presented with cat-like cry. He also has hypotonia, stridor, failure to thrive, postaxial polydactily, unilateral inguinal hernia, epilepsy/seizures and dysmorphic face: micrognatia, scaphocepaly, malformed low-set ears with posterior rotation, low nasal bridge, hypertelorism, thin upper and thin lower lips, long philtrum, high-arched palate. The SNP array revealed a deletion of 23Mb in 5pter (del 5p15.33-p14.3) and a duplication of 54Mb genetic materials in 13qter (dup 13q21.2-q34), that was inherited from a balanced translocation carrier mother. Only several cases of his type of chromosomal rearrangement have been so far. Our case further confirms the involvement of critical region 5p15.2 for cat-like-cry and involvement of GPC5 and GPC6 genes located on chromosome 13 (13q31.3q32.1 region) for postaxial polydactily.

PS11.047

Reverse phenotyping of a patient with CRIPT gene mutation and further delineation of the associated phenotype

B. Demeer[1,2], *A. Dadban*[3], *P. Vabres*[4,5], *G. Morin*[1], *B. Aral*[4,6], *A. Varenterghem*[7], *J. Thevenon*[4,8], *D. Bremond-Gignac*[9], *J. St-Onge*[10,6], *J. Rivière*[4,6], *J. Courcet*[4], *C. Thauvin*[4,8], *L. Faivre*[4,8];

[1]genetics department, CHU Amiens-Picardie, amiens, France, [2]EA 4666, Université de Picardie Jules Verne, Amiens, France, [3]dermatology department, CHU Amiens-Picardie, amiens, France, [4]Equipe d'Accueil 4271 Génétique des Anomalies du Développement, Fédération Hospitalo-Universitaire, Université de Bourgogne, Dijon, France, [5]Service de Dermatologie, CHU Le Bocage, Dijon, France, [6]Laboratoire de Génétique moléculaire, FHU-TRANSLAD, Plateau technique de Biologie, CHU, Dijon, France, [7]Pediatric gastroenterology department, CHU Amiens-Picardie, amiens, France, [8]Centre de Référence Maladies Rares „Anomalies du Développement et Syndromes Malformatifs" de l'Est, Centre de Génétique et Pédiatrie 1, Hôpital d'Enfants, Dijon, France, [9]Ophtalmology department, CHU Amiens-Picardie, amiens, France, [10]Equipe d'Accueil 4271 Génétique des Anomalies du Développement, Fédération Hospitalo-Universitaire, Université de Bourgogne, dijon, France.

We report on a 3 ½ year old boy, with prenatal onset growth deficiency (height:-4SD), microcephaly (OFC:-3.5 SD), transient neonatal pancytopenia, facial dysmorphism, feeding difficulties, developmental and speech delay, global hyperlaxity, significant sleep disturbance, and genital, ocular and extremities anomalies. He also presents with generalized pigmentation anomalies, and signs of ectodermal dysplasia. Array CGH (Agilent 60k), cytogenetic diagnosis of chromosomal breakage syndrome and metabolic screening are negative. The whole exome sequencing performed revealed a homozygous frame-shift mutation of the CRIPT gene, recently described as a novel primordial dwarfism gene (Shaheen et al, 2014). The mutation (c.132delA), described as probably pathogenic, was confirmed in the homozygous state by Sanger sequencing. Both healthy consanguineous parents were proven to be carrier in the heterozygous state.

Few available clinical data of the 2 described patients show very similar clinical appearance with strikingly facial dysmorphism, growth deficiency, microcephaly, psychomotor delay, and ocular and extremities anomalies. Mottled hypopigmentation is also described in the older patient.

This report is an example of "reverse phenotyping". The first description of the CRIPT gene by Shaheen et al helped us to reach a diagnosis in our patient. Nevertheless the term of primordial dwarfism and its broad definition used by the authors can be confusing; and can prevent some clinicians from suggesting this diagnosis. Cutaneous signs seem also to be very specific, and need to be precisely looked at in additional patients presenting with this unique syndrome.

PM11.048

Exome sequencing of sporadic patients with Currarino syndrome

I. Holm[1], B. Stadheim[1], P. S. Samarakoon[1], **K. L. Eiklid**[1,2];
[1]Deparment of medical genetics, Oslo, Norway, [2]Oslo University Hospital, Oslo, Norway.

Currarino syndrome (CS) is a complex of congenital caudal anomalies including anorectal malformations, sacral defects and a presacral mass. CS is associated with mutations in the MNX1 gene in familial cases, but in sporadic cases less than one third of the patients have detectable MNX1 mutations. We looked for genetic causes of CS in sporadic patients by Whole Exome Sequencing.

3 trios were included in the study. In addition we included DNA extracted from the presacral mass from one patient, both directly from the biopsy and from cultivated fibroblasts derived from the sample. The library was sequenced on a HiSeq 2000 (Illumina) with 100 bp paired end reads. Exome capture was performed with the SureSelect XT Custom Human All Exon v5 Plus library (Agilent Technologies). In addition we added a custom made 6 MB whole genome regions around MNX1 on chromosome 7 to look for variations in regulatory elements.

The data were filtered with an in-house developed program (FILTUS) and registered variants from an in-house database were used to filter out normal variation. We looked especially for sequence variants in genes involved in proliferation, differentiation and embryogenesis. All models of inheritance were applied for candidate gene identification. The first approach was to filter the data through a candidate gene list. Second a de novo analysis was done. When no relevant genes were found, the next approach was to analyze the samples through other inheritance models. Some candidate genes will to be discussed and further investigated.

PS11.049

Cytogenomic investigation in 162 patients with multiple congenital abnormalities and developmental delay: Brazilian experience

É. A. Zanardo[1], *G. M. Novo-Filho[1], R. L. Dutra[1], F. B. Piazzon[1], F. A. R. Madia[1], M. M. Montenegro[1], T. V. M. M. Costa[1], A. M. Nascimento[1], A. T. Dias[1], M. Rocha[1,2], C. Milani[1], A. F. de Carvalho[3], M. I. Melaragno[4], C. A. Kim[5], L. D. Kulikowski[1,2];*
[1]Laboratório de Citogenômica, Departamento de Patologia, Faculdade de Medicina da USP, São Paulo, Brazil, [2]Centro de Reprodução Humana e Genética, Departamento de Saúde Coletiva, Faculdade de Medicina do ABC, Santo André, Brazil, [3]Laboratório de Genética Humana e Mutagêneses, Departamento de Biologia Geral, Universidade Federal da Bahia, Salvador, Brazil, [4]Departamento de Morfologia e Genética, Universidade Federal de São Paulo, São Paulo, Brazil, [5]Unidade de Genética Médica, Departamento de Pediatria, Instituto da Criança - HC/FMUSP, São Paulo, Brazil.

The genomic imbalances are the most common cause of multiple congenital abnormalities (MCA) and developmental delay (DD), however the etiology of these imbalances are not well understood, making difficult the counseling genetics and the treatment. Currently, the improvement of cytogenomics diagnostic techniques, such as the screening by arrays, is fundamental to set an unequivocal molecular diagnosis and a more suitable genotype-phenotype correlation for patients with MCA/DD.

We report our experience with the implementation of several array platforms (Affymetrix, Agilent and Illumina) and probe densities in clinical diagnostic and scientific research of patients without conclusive diagnostic. The results were confirmed by MLPA and/or FISH techniques.

Thus this study evaluated the genome of 162 patients with MCA/DD. All patients were previously assessed by conventional cytogenetic analysis. We identified several different genomic alterations in 137/162 (~84.6%) patients, including deletion, duplication and loss of heterozygosity. Some patients 41/137 (~30%) showed only one copy number variation in the genome, others 41/137 (~30%) presented two abnormalities and 55/137 (~40%) revealed three or more alterations on different chromosomes, maybe due to a complex rearrangements.

Our findings showed that the interpretation of genotype-phenotype correlations in patients with complex genomic rearrangements is a very difficult task but the results can directly contributes to the elucidation of new syndromes. The array is a powerful tool to identification and characterization of genomic abnormalities and provides accurate diagnosis of unidentified or unexplained diseases suspected to have a genetic cause, contributing to appropriate clinical management of the patients.

PM11.050

Interstitial 1p32.3p32.1 deletion in a patient with multiple congenital anomalies

M. Kehrer[1], K. Schäferhoff[1], M. Bonin[1,2], A. Jauch[3], A. Bevot[4], **A. Tzschach**[5,1];
[1]Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tübingen, Germany, [2]IMGM Laboratories GmbH, Martinsried, Germany, [3]Institute of Human Genetics, University of Heidelberg, Heidelberg, Germany, [4]University Children's Hospital, University of Tübingen, Tübingen, Germany, [5]Technische Universität Dresden, Institute of Clinical Genetics, Dresden, Germany.

Interstitial deletions of chromosome bands 1p32.3p32.1 are rare. Only nine unrelated patients with partially overlapping 1p32.3p32.1 deletions of variable size and position have been reported to date. We report on a 17-months-old boy with choanal atresia, hearing loss, urogenital anomalies and microcephaly in whom an interstitial deletion of 6.4 Mb was detected in 1p32.3p32.1 (genomic position chr1:54,668,618-61,113,264 according to GRCh37/hg19). The deleted region harbors 31 RefSeq genes. Notable genes are *PCSK9*, haploinsufficiency of which caused low LDL cholesterol plasma levels in the patient, and *DAB1*, which is a candidate gene for cognitive deficits and microcephaly. The patient broadens our knowledge of the clinical consequences of 1p32 deletions and facilitates karyotype-phenotype correlations. Additional patients with overlapping deletions and/or point mutations in genes of this region need to be identified to elucidate the role of individual genes for the complex clinical manifestations.

PS11.051

Deletion 2q31: clinical and molecular analysis based on a four new cases

J. Pilch[1], *K. Matuszewska[2], P. Skiba[3], J. Gil[3], E. Gutmajster[4], A. Latos-Bieleńska[5,6];*
[1]Department of Paediatrics and Developmental Age Neurology, Medical University of Silesia, Katowice, Poland, [2]Center for Medical Genetics GENESIS, Poznań, Poland, [3]Department of Genetics, Wroclaw Medical University, Wroclaw, Poland, [4]Department of Medical Genetics, Medical University of Silesia, Katowice, Poland, [5]Department of Medical Genetics, University of Medical Sciences, Poznań, Poland, [6]Center for Medical Genetics GENESIS,, Poznań, Poland.

There are only few publications about interstitial deletions in long arm of 2 chromosome and only a few confirmed by array-CGH. Microarray technique allows to precisely define breakpoints which permits a more accurate phenotype-genotype correlation. On the one hand the phenotype of patients with 2q31 deletions seems to be well characterized but on the other hand the critical region for the phenotype is still unknown. The clinical manifestations are highly variable but the most common features include frequently observed fail to thrive, facial dysmorphism, developmental delay and mental retardation.

In our report we presents four new patients with de novo deletions overlapping 2q31. In all patients the breakpoints were characterized by a-CGH. The deletions ranged in size from 13 to 16Mb. In all patients microcephaly, high forehead, narrow mouth, small mandible, partial syndactyly of toes and sandal gap was stated. Additionally blepharophimosis, down slanting palpebral fissures, down-turned corners of the mouth and tapering fingers were present. One of the patients has an increased number of creases on the soles and palms which is one of the known features of wrinkly skin syndrome. In our report we try to delineate the phenotype of 2q interstitial deletions. We compare the phenotype of our patients with the ones presented in recent reports. We also suggest some genes candidates for the most common clinical manifestations of deletion in long arm of 2 chromosome.

PM11.052

A de novo 432 kb deletion in the 17q22 region: a case report and review of the literature

M. Kugaudo[1,2], *B. Nowakowska[3], D. Gieruszczak-Białek[1,4], K. H. Chrzanowska[1], M. Krajewska-Walasek[1];*
[1]The Children's Memorial Health Institute, Warsaw, Poland, [2]Department of Child and Adolescent Psychiatry, Medical University of Warsaw, Warsaw, Poland, [3]Department of Medical Genetics, Institute of Mother and Child, Warsaw, Poland, [4]Department of Pediatrics, Medical University of Warsaw, Warsaw, Poland.

Deletions involving the 17q22 region have been reported in the literature in nine patients. The size of the deletions reported to date is 8.18-1.98 Mb and a significant role of NOG and TBX has been suggested. Here we describe a girl with a 432 kb deletion in the 17q22 band without deletion of these genes. To our knowledge, this is the smallest reported deletion.

The patient was born at term by cesarean section because of breech position, birth measurements were normal. On physical examination at the age of 3 y, hypertelorism, upslanting and narrow palpebral fissures, epicanthal folds, short bulbous nose, long philtrum, tapered, short fingers, mild 5th finger clinodactyly, and proximally placed thumbs were observed. Developmental milestones were significantly delayed, and marked hypotonia was present. She had an atrial septal aneurysm, visual problems (astigmatism, hyperopia), and sensory processing disorder with a propensity for mutistic and aggressive behavior. Hypercalcemia with a tendency for lithiasis was diagnosed. A 432 kb deletion encompassing 12 genes in the 17q22 band was detected by aCGH analysis. The aberration was confirmed by FISH analysis as a de novo deletion.

Here we demonstrate the phenotype differences between our patient and the data from the literature and the possible influence of the deletion. The patients share some facial features and developmental delay. We suggest that in our patient, SUPT4H1 played an important role in development.
The molecular study was financed by Fundacja na Rzecz Nauki Polskiej, Homing Plus/2012-5/9 „Identification of novel genes causing DiGeorge Syndrome".

PS11.053

Additional patient report with Delleman syndrome and lipoma: Oculo cerebro cutaneous syndrome (OCCS) or Encephalo cranio cutaneous lipomatosis (ECCL)?

L. Coppin[1], N. Sannikoff[2], E. Heylen[3], **Y. Sznajer**[1]*;*
[1]Center for Human Genetic, Cliniques universitaires St Luc, U.C.L, Brussels, Belgium, [2]Dept of Pediatrics, Clinique Ottignies, Ottignies, Belgium, [3]Pediatric neurology, Dept of Pediatric, Clinique d'Ottignies, Ottignies, Belgium.

Delleman syndrome (or OCCS) is a very rare condition that has been reported in 30 unrelated patients t date. The diagnosis is based on triad of ocular (cyst, anophthalmia, microphthalmia, coloboma), cerebral (cerebral cysts, hydrocephaly, cortical atrophy or corpus callosum agnesis) and skin (focal dermal hypo- or aplasia, periorbital protruding outgrowths) anomaly. The differential diagnosis has to be made with ECCS and oculo-auriculo-vertebral spectrum (Goldenhar association). We report on the natural history of a full term boy, second child from caucasian unrelated healthy parents. Prenatal ultrasound diagnosed isolated ventricular dilation. Birth parameters include relative macrocephaly (weight P50, height: P50, OFC: P95). He presented tumour-like lesion on the right eyelid, bilateral periorbital skin appendages and skin hypoplasia with alopecia. Brain MRI showed left ventricular dilation, posterior midline shift to the right, cortical atrophy and extramedullary lipoma leading to spinal cord compression. Ophthalmology examination showed epibulbar dermoid, non-reactive pupils with bilateral pale optic disk. SNP array was normal (Agilent 44k). The patient was hospitalized at week 9 of life. He developed progressive neurologic demise and eventually died.
Phenotype in patients with OCCS may be highly variable. Some authors postulated on a continuum from ECCL to OCCS. In absence of any diagnostic marker, Alastair developed diagnostic criteria. In our patient, both syndromes fit as 'definite diagnosis'. The aetiology of OCCS remains so far unknown. Next generation sequencing (exome sequencing) could be the coming step to identify aetiology.

PM11.054

autosomal recessive developmental disorders

N. Akawi[1]*, J. McRae[1], W. Jones[1], D. King[1], J. Barrett[1], H. Firth[2], D. FitzPatrick[3], M. Hurles[1], The Deciphering Developmental Disorders Study;*
[1]The Welcome Trust Sanger, Cambridge, United Kingdom, [2]The Welcome Trust Sanger, Cambridge University Hospitals Foundation Trust, Addenbrooke's Hospital, Cambridge, United Kingdom, [3]MRC Human Genetics Unit, MRC IGMM, University of Edinburgh, WGH, Edinburgh, United Kingdom.

Developmental disorders are a clinically and genetically heterogenous group of childhood conditions that involve serious impairment in specific developmental areas. To date, many types of developmental disorders have been recognised with a wide range of clinical manifestations and variable severities. Next-generation sequencing technologies have uncovered the genetic bases for a substantial number of these disorders yet many still of unknown causes.
In the DDD study, thousands of children exhibiting developmental disorders were recruited and investigated using the latest molecular testing methods to identify the underlying genetic defects. Among the first 1000 trios investigated in the study, two third of the diagnoses made were from de novo mutations. However, increasing the number of investigated trios has increased the power to detect and diagnose inherited conditions, including autosomal recessive disorders. The anticipated power of such big data is: 1) to enable the discovery of novel recessive genes, 2) to confirm the pathogenicity of new recessive genes with slight evidence in the literature, 3) to expand the phenotypic spectrum of known disease-causing genes, 4) to shed light on pathways that are disrupted in a group of affected children. For example, several unrelated patients in our dataset were carrying rare loss-of-function and non-synonymous biallelic-mutations in different genes encoding Glycosylphosphatidylinositol-anchored proteins. Two of these genes were recently identified and few patients have been reported in the literature. Therefore, our data endorse their pathogenicity and expand their clinical spectrums.
All this expected knowledge could most likely create new opportunities for genetic counselling, prevention, management and treatment of the disorders for the affected children and/or their families.

PS11.055

The Frequency Of Disorders Of Sex Development (DSD) And Novel Genetic Associations In Children With Neurodevelopment Disorders - Insights From The DDD Study

G. E. Gazdagh[1]*, D. DD Study[2], E. Tobias[3], S. Ahmed[4], R. McGowan[1];*
[1]West of Scotland Genetics Service, Laboratory Medicine Building Southern General Hospital, Glasgow, United Kingdom, [2]Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, United Kingdom, [3]School of Medicine, College of Medical Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom, [4]Developmental Endocrinology Research Group, Royal Hospital For Sick Children, University of Glasgow, Glasgow, United Kingdom.

Context: Collaborative project to review the phenotypic and genotypic data from children recruited to the UK wide DDD study.
Objective: To report the frequency and range of DSD phenotypes observed in DDD participants who have one or more associated 'neurodevelopmental delay' diagnostic Human Phenotype Ontology (HPO) term.
Methods: Retrospective review of anonymized data from participants in the DDD study.
Results: Of 7439 DDD participants recruited, 603 (8%) had at least one HPO term in the 'abnormalities of the genital system'. Of these 603 children, 370 (61%) had at least one 'neurodevelopmental delay' diagnosis with a total of 436 DSD phenotypes, the majority, 420 (94%) abnormalities of the external genitalia. Of the male external genitalia abnormalities, 212 (54%) were testicular, 74 (19%) were hypospadias, 57 (15%) were penile and 47 (12%) were other abnormalities. Testicular abnormalities included: unilateral cryptorchidism, bilateral cryptorchidisms, hydrocele and other phenotypes. Causative mutations were found in 14 DDG2P genes (https://decipher.sanger.ac.uk/), confirming a range of syndromic diagnoses with associated DSD, including: KBG syndrome, Meier-Gorlin syndrome, Alpha- thalassemia/mental retardation syndrome, Kabuki syndrome and Donnai-Barrow syndrome. Of these likely pathogenic mutations, 6 of 14 (43%) were found in DDG2P genes not previously associated with DSD.
Conclusions: A range of DSD phenotypes are found in patients with neurodevelopmental delay. Recognition of these associations should not be overlooked in the management of patients with complex conditions. Exomic sequencing through projects like DDD increases diagnostic yield whilst the identification of mutations in developmental genes may improve understanding about the pathogenesis of DSD.

PM11.056

A case of developmental delay and dysmorphic features with duplication 15q11q13 inherited from the mother

S. Bertok*;*
Univ. Children's Hospital Ljubljana, Department of Endocrinology, Diabates and Metabolic Diseases, 1000 Ljubljana, Slovenia.

A 10-year old boy with speech delay, dysmorphic features, short stature, joint hyperlaxity, muscular hypotony and conductive deafness is presented. His father was diagnosed with X-linked spondilopehyseal dysplasia tarda.
Birth parameters were normal. In the first months he developed motor developmental delay with muscular hypotony. At one year short stature was diagnosed. Repeatedly he has been treated for mild middle ear infections and a conductive hearing loss was diagnosed at 10 years. At this age (height 130,67 cm (-1.793 SDS); weight 28,25 kg (-1.194 SDS); head circumference 55,5 cm (0.478 SDS)) he presented with two cafe au lait spots. Several dysmorphic features were observed: long face, high vaulted palate, wide, retroverted nostrils, low set ears, tag on the lobule, deep philtrum, tented upper lip, joint hyperlaxity, proximal placed thumbs, wide spaced nipples and 2-3 toe syndactily of the both feet. The boy had difficulties in fine motor skills, concentration, attention and social skills. At the age of 11,5 years suspect of autism spectrum disorder was made.
aCGH detected interstitial duplication of approximately 6.1Mb at 15q11.2q13.1 (arr[hg19] 15q11.2q13.1(22,765,628-28,940,098)×3 mat), subsequently confirmed by FISH. Parental analyses identified the mother as a carrier of the same duplication.
Several reports have suggested that maternally transmitted 15q duplications were associated with autistic features with variable degrees of developmental delay, while paternally derived cases presented with no major medical problems. Genetic counseling is vital to discuss the recurrence risks and options for prenatal and preimplantation genetic diagnosis in familial cases of 15q11q13 duplication.

Unique familial 16q12.1-q22.1 duplication: clinical manifestations and cytogenetic analyses

A. Pietrzyk[1]*, M. Dera[1], E. Studniak[1], A. Ziemniarska[1], N. Wujak[2], M. Piechota[2], S.*

Zajaczek[1];
[1]Cytogenetic Unit, Pomeranian Medical University, Szczecin, Poland, [2]Centre for Medical Genetics Genesis, Poznan, Poland.

Background: Pure 16q duplications are rare chromosomal abnormality associated with dysmorphic features, intellectual disability, behavioral disorder and congenital anomalies. Even though the number of described cases is small, three main groups have been proposed: proximal (16q11-q13), proximal- intermediate (16q21-16q22), intermediate- distal (16.q23-q24) aberration, depending on the covered region of chromosme 16. Only 4 cases of the proximal- intermediate 16q duplication have been reported so far, with no familial cases described.
Report: We present a family of mother and two daughters, carrying duplication 16q12.1- q.22.1. Two-year-old girl was evaluated due to mild facial features and delayed milestones. Her one-year-old sister manifesting distinct dysmorphic phenotype, evident developmental delay, hypotonia and obesity was operated because of hypertrophic pyloric stenosis. Their mother displayed neither dysmorphia nor congenital defects but had moderate intellectual disability. High resolution karyotype of peripheral blood lymphocytes showed additional material on the long arm of chromosome 10. Array CGH analysis revealed duplication of 16q12.1- q22.1, estimated to be 16.54 Mb in size. Additional FISH analysis confirmed that duplicated material was of chromosome 16 origin in both sisters and mother.
Conclusion: The involved region contains 208 genes, some of which are known neurotransmitters, receptors or cell cycle regulators what is consistent with clinical findings. Limited available data and varying size of duplicated region does not allow for reliable genotype-phenotype correlation. Every newly described patient and family is a valuable contribution for a further delineation of phenotypic spectrum for those particular chromosomal regions.

PM11.058
Triallelic and epigenetic-like inheritance in human disorders of telomerase

L. C. Collopy*;*
Barts and the London School of Medicine and Dentistry, London, United Kingdom.

*Genetic variants in TERT and TERC are known to cause d*yskeratosis congenita (DC) and related diseases. These patients have impaired telomere elongation causing stem cells to enter premature replicative senescence and/or apoptosis as telomeres become critically short. This explains the major impact of the disease on highly proliferative tissues such as the bone marrow and skin. However, variants in *TERC* and *TERT* are not always fully penetrant and in some DC families disease causing variants are seen in asymptomatic family members. It is therefore challenging to determine whether a new variant is pathogenic or not. Over the last three years we have identified 19 telomerase variants in patients with DC and related disorders. Analysis of these variants, taking into account familial segregation and functional studies, enabled us to categorise them into three groups; (a) disease causing, (b) bystanders and (c) status uncertain. Remarkably, these investigations identified families with disease causing variants where the mechanism of disease inheritance is novel; one family has triallelic mutations in both telomerase genes and in two families an epigenetic-like mechanism is at play. We have constructed a diagnostic algorithm which may be useful for the categorisation of uncharacterised telomerase variants in the future. This study therefore highlights that telomerase variants have highly variable functional and clinical manifestations and require thorough investigation to assess their pathogenic contribution.

PS11.059
Phenotypic overlap of dyskeratosis congenita with other syndromes identified through exome sequencing

A. Walne*, T. Vulliamy, I. Dokal;*
Barts and the London school of medicine and dentistry, London, United Kingdom.

The clinical presentation of dyskeratosis congenita (DC) and its allelic variants encompass a wide range of features including abnormal skin pigmentation, nail dystrophy, leukoplakia and bone marrow failure. Pathologically DC is characterized by selective exhaustion of highly proliferative cells that have critically shortened telomeres. To date causal mutations in ten telomere biology genes have been identified.
Through whole exome sequencing on uncharacterized DC patients, we identified biallelic variants in four families in the genes *DNAJC3, GRHL2, LIG4* that have been associated with other diseases (APCHD, Ectodermal dysplasia, Ligase IV syndrome, respectively) which have overlapping clinical phenotypes with DC. This raises the question, if these variants are disease-causing as we believe, then how wide is the phenotype of dyskeratosis congenita?
The table emphasises the large degree of clinical overlap seen in these patients with the diagnostic spectrum of phenotypes seen in DC as well as the diseases associated with the causal variants. These patients were referred with a suspected diagnosis of DC but based on the identified mutation, an alternative diagnosis should be considered. Telomere length tends to be short in most DC patients but is normal in these individuals. The outcome from this exome sequencing project highlights the difficulty in assigning a clinical label to a highly variable disease phenotype. It also suggests potential biological overlap of DC with other syndromes.

Dysmorphology Services: a snapshot of current practices and a vision for the future.

S. Douzgou[1], *E. Chervinsky*[2,3], *Y. Gyftodimou*[4], *S. Kitsiou-Tzeli*[5], *S. Shalev*[2,3], *E. Kanavakis*[5], *D. Donnai*[1], *J. Clayton-Smith*[1];

[1]*Manchester Centre for Genomic Medicine, Institute of Human Development, University of Manchester and Central Manchester University Hospitals NHS Foundation Trust as part of the Manchester Academic Health Science Centre, Manchester, United Kingdom,* [2]*Genetics' Institute, Ha'Emek Medical Center, Afula, Israel,* [3]*The Rapapport Faculty of Medicine, Technion, Haifa, Israel,* [4]*Department of Genetics, Institute of Child Health, Athens, Greece,* [5]*Department of Medical Genetics, Athens University School of Medicine, Athens, Greece.*

Dysmorphology concerns the recognition and management of rare, multiple anomaly syndromes. Genomic technologies and software for gestalt recognition will re-shape dysmorphology services. In order to reflect on a model of the service in the post-Genomic era, we compared the utility of dysmorphology consultations in two Mediterranean cities, Athens, Greece and Afula, Israel (MDS), the Manchester Centre for Genomic Medicine, a UK service with dysmorphology expertise (UKDS) and the DYSCERNE, digital service (DDS). We show that it is more likely that Chromosome Microarray Analysis will be performed if suggested in the UKDS rather than in the MDS; this most probably reflects the difference of access to genetic testing following funding limitations in the MDS. We also demonstrate that in terms of achieved diagnosis, the first visit to a dysmorphology clinic is more significant than a follow-up. We show that a confirmed syndrome diagnosis significantly decreases the requests for other, non genetic, laboratory investigations. Conversely, it increases the requests for reviews by other specialists and, most significantly (t-test 8.244), it increases further requests for screening for possible associated complications. This is the first demonstration of the demands, on a health service, following the diagnosis of a dysmorphic condition.

This study was supported by the Daniel Turnberg UK/Middle East Travel Fellowship. The DYSCERNE project was funded by grants from the European Commission Public Health Executive Agency, the European Society of Human Genetics and the Manchester Biomedical Research Centre.

Severe scoliosis in a girl with Temple syndrome due to isolated imprinting defect on human chromosome 14q32.2

F. Jobic[1], *R. Gouron*[2], *L. Cuisset*[3], *B. Demeer*[1];

[1]*Departement of Genetics, Amiens University Hospital, Amiens, France,* [2]*Department of Pediatric Orthopaedic Surgery, Amiens University Hospital, University Of Picardie-Jules Verne, Amiens, France,* [3]*Laboratory of Biochemistry and Molecular Genetics APHP-Cochin Hospital, Faculty of Medicine Paris Descartes University and Institut Cochin INSERM U567, Paris, France.*

ABSTRACT

Human chromosome 14q32.2 contains an imprinted gene cluster. Maternal uniparental disomy of chromosome 14, paternal deletions and loss of methylation at the intergenic differentially methylated region (IGDMR) result in a distinct human phenotype known as "maternal uniparental disomy 14 phenotype" also referred to as "Temple syndrome". The condition was first described in 1991 and is characterized by pre- and postnatal growth retardation, hypotonia, early-onset puberty, truncal obesity, small hands and feet and feeding difficulty.

To date, only seven patients with a primary epigenetic aberration confined to the 14q32.2 IGDMR have been described. The present report concerns a 13-year-old girl with a maternal uniparental disomy 14 phenotype who displayed an isolated imprinting defect at the maternally expressed gene 3 (*MEG3*) locus and developed rapidly-progressing scoliosis that required surgical treatment. We also review published reports on patients with an epimutation.

PM11.062

Whole-exome sequencing in two sisters with severe hypotonia and hyporeflexia, cognitive deficit, and epilepsy

P. De Nittis[1], *L. Gueneau*[2], *D. Cocciadiferro*[1], *A. Alfaiz*[2], *V. Napolioni*[3], *B. Augello*[1], *M. Pellico*[1], *L. Zelante*[1], *A. Reymond*[2], *G. Merla*[1];

[1]*IRCSS Casa Sollevo della Sofferenza, San Giovanni Rotondo, Italy,* [2]*Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland,* [3]*Department of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, CA, CA, United States.*

We identified two Italian sisters with severe cognitive and psychomotor delay, language defects, epilepsy, nystagmus, generalized hypotonia, heart rhythm abnormalities, osteotendinous hyporeflexia. Exome sequencing of the two affected siblings and their non-consanguineous healthy parents allowed circumscribing five genes with potentially causative variants. These rare and predicted to be deleterious variants were found either as homozygote within the MEOX2 gene or as compound heterozygote in exons of the GNB5, PHLDB3, SLC22A1 and RRN3 genes. The validation of these findings through identification of more patients with mutations in these genes, in vivo complementation, as well as engineering of animal models is warranted.

Among these candidate genes, we are currently focusing on the variant identified in GNB5 gene. The paternal allele carries a missense variant positioned in the last nucleotide of the second exon of this gene. This variant alters splicing accuracy, as determined by RT-PCR followed by direct sequencing of the amplified products. The maternal allele variant is a stop gain that targets transcripts to nonsense-mediated mRNA-decay. GNB5 is the fifth member of the heterotrimeric G-protein β-subunit family, involved in signal transduction receptors and effectors. Mice lacking Gnb5 exhibit markedly abnormal neurological phenotype including impaired development, tiptoe-walking, motor learning and coordination deficiencies, and hyperactivity. Further, it controls the deactivation of retinal phototransduction and the proper functioning of retinal bipolar cells in KO mice. Thus, Gnb5 may regulate dendritic arborization and/or synapse formation. These findings bear a resemblance to some of the reported symptoms in the examined patients.

PS11.063

Clinical utility of exome sequencing as a first-tier molecular test in infants suspected of having a monogenic disorder

Z. Stark[1], *T. Tan*[1,2], *B. Chong*[1], *G. Brett*[1], *P. Yap*[1], *M. Walsh*[1], *D. Amor*[1,3], *R. Savarirayan*[1,2], *G. McGillivray*[1], *A. Yeung*[1], *P. Ekert*[4,2], *C. Theda*[5], *S. Single-gene disorders are a common cause of morbidity and mortality in infants. Diagnosis can be challenging as the clinical presentation is frequently undifferentiated or incomplete in the early stages. Individual disorders are rare, and often genetically heterogenous. This commonly results in extensive, protracted, costly and invasive diagnostic investigations in this patient group.

We prospectively evaluated exome sequencing as a first-tier molecular test in 37 infants suspected of having a monogenic disorder. All participants were less than 2 years of age, and 40% were less than 3 months of age. Infants with pathogenic CNVs and those who had previously undergone singe gene sequencing were excluded. Exome sequencing with targeted phenotype-driven analysis occurred in parallel with standard investigations, including single gene Sanger sequencing when clinically indicated. The most common indication for testing was the presence of multiple congenital abnormalities and dysmorphic features (54%), followed by suspicion of a neurometabolic disorder (20%). Exome sequencing resulted in a molecular diagnosis of 21 genetic conditions in 20 infants, giving a diagnostic rate of 54%. Four relatives received a genetic diagnosis following cascade testing, and 10 couples were identified as being at high risk (25% or 50%) of recurrence in future pregnancies. By contrast, a molecular genetic diagnosis was reached in 20% using standard approaches in the same patient group.

Employing exome sequencing as a first-line molecular test in selected infants has the potential to considerably shorten the diagnostic process, improve diagnostic yield, guide management, and enable accurate recurrence risk counselling in a timely manner.

PM11.064

Eyebrow abnormalities as a suggestive feature for the diagnosis of multiple congenital anomalies syndromes

C. Rusu[1], *A. Sireteanu*[2], *M. Panzaru*[1], *E. Braha*[1], *L. Butnariu*[1], *M. Gramescu*[1], *R. Popescu*[1];

[1]*University of Medicine and Pharmacy, Iasi, Romania,* [2]*Regional Institute of Oncology, Molecular Genetics Lab, Iasi, Romania.*

Eyebrow abnormalities are relatively rare birth defects that could be highly suggestive for the diagnosis of multiple congenital anomalies (MCA) syndromes. To confirm this hypothesis, we have selected 84 cases from our own experience with marked eyebrow abnormalities. All patients had a specific diagnosis confirmed with genetic tests in most of the cases. We have identified different types of eyebrows based on specific criteria like facial distribution, sparseness, thickness or uniformity. The most common abnormalities in our group were diamond-shaped eyebrows (32% of cases), synophris (18% of cases) and sparse eyebrows (17%), whereas the least common

ones were linear and lowset, as well as thick eyebrows (4% each) and bushy eyebrows (1% of cases). Each eyebrow pattern has been associated with specific syndromes and based on our own experience and literature data we have identified for every pattern the most commonly associated clinical features, making the association highly suggestive for the diagnosis. Clinical data will be illustrated with pictures.
In conclusion, we appreciate that Clinical Genetics still has a place within the Genomic Era, the recognition of suggestive clinical features being very useful for MCA diagnosis in developing countries, where financial resources are limited and detailed molecular testing is not always available in daily practice. This leads to a more specific diagnosis and increases the cost-effectiveness of genetic testing.

PS11.065
Novel mutations in PIEZO1 cause an autosomal recessive form of Generalised Lymphatic Dysplasia

*S. Martin-Almedina[1], **E. Fotiou**[1], M. Simpson[2], S. Lin[3], K. Gordon[1], G. Brice[1], G. Atton[1], I. Jeffery[1], D. Rees[4], H. Jeffery[1], C. Mignot[5], J. Vogt[6], T. Homfray[1], M. Snyder[3], S. Rockson[3], S. Jeffery[1], P. Mortimer[1], S. Mansour[1], P. Ostergaard[1];*
[1]St George's University of London, London, United Kingdom, [2]King's College London School of Medicine, London, United Kingdom, [3]Stanford University, Stanford, CA, United States, [4]King's College Hospital, London, United Kingdom, [5]GH Pitié-Salpêtrière, Paris, France, [6]Birmingham Women's Hospital, Birmingham, United Kingdom.

We have identified *PIEZO1* mutations that cause a form of autosomal recessive GLD which is characterised by a high incidence of non-immune hydrops fetalis and chronic peripheral primary lymphedema. This may be lethal in utero or in the neonatal period. However, it may fully resolve and present later in childhood with four limb lymphoedema with facial oedema and a susceptibility to facial cellulitis with intermittent swelling. Some of the patients have intestinal lymphangiectasia or pleural effusions.
Whole exome sequencing was performed in three families and novel variants in only one gene, *PIEZO1*, were identified under the criteria of an autosomal recessive disease. The whole coding region of the gene was Sanger sequenced in 10 unrelated individuals of similar phenotype. In total, we have identified nine homozygous or compound heterozygous mutations in six unrelated GLD families; three nonsense, four missense, and two splice site mutations. The missense mutations were located in evolutionary conserved residues and predicted to have damaging effects on the protein. The splice variants caused exon skipping and the nonsense mutations affected PIEZO1 expression. RT-PCR and western blot were used to investigate the effect of the identified variants on gene and protein expression. A skin biopsy was investigated and lack of initial lymphatics was found.
Mutations in PIEZO1 have previously been reported to cause autosomal dominant DHS but our report suggests that biallelic mutations in this gene cause GLD. Therefore, it suggests that PIEZO1 has a role in the development of lymphatic structures. This work was supported by the BHF, the Newlife Foundation for Disabled Children and the NIH.

PM11.066
Identification of the first gene involved in Goldenhar syndrome

E. Lopez[1], *M. Bérenguer[1], S. Marlin[2], A. Tingaud-Sequeira[1], S. Charron[1], H. de Belvalet[1], G. Mathieu[1], F. FECLAD[3], P. Babin[1], B. Arveiler[1,4], D. Lacombe[1,4], C. Rooryck[1,4];*
[1]Laboratoire MRGM, EA4576, Université de Bordeaux, Bordeaux, France, [2]Centre de Référence des Surdités Génétiques, Département de Génétique, Hôpital Necker, Paris, France, [3]Fédération des Centres Labellisés pour les Anomalies du Développement, 8 centres, France, [4]Service de Génétique Médicale et Centre de Référence Anomalies du Développement et Syndromes Malformatifs, CHU de Bordeaux, Bordeaux, France.

The oculoauriculovertebral spectrum (OAVS, OMIM 164210) or Goldenhar syndrome is a developmental anomaly involving the first and second branchial arches. This pathology represents one of the most common congenital craniofacial disorder, with a prevalence around 1/26,000 births. Main features include facial asymetry resulting from maxillary and/or mandibular hypoplasia, hemifacial microsomia, unilateral or bilateral ear anomalies, ocular defects, and vertebral malformations. To date, although various chromosome abnormalities have been associated with OAVS and several candidate genes have been screened, the genetic etiology of this pathology remains largely unknown.
For the present study, a project with national recruitment established a cohort of 156 patients with OAV spectrum. In order to determine the molecular basis of Goldenhar syndrome, we performed exome sequencing in trios including selected patients with Goldenhar syndrome and their healthy parents. We identified a nonsense mutation in GOLD1 gene, a poorly characterized transcription factor known to be involved in ear development. Screening of the cohort identified a missense mutation in a second patient. Interestingly, GOLD1 belongs to a genetic environment within a paralogon that was already involved in another Copy Number Variant associated with OAVS. Functional studies by transient knockdown in zebrafish model evidenced gold1 as craniofacial cartilages architecture key factor.
In conclusion, we report GOLD1 as the first gene involved in Goldenhar syndrome. Future identification of others genes should allow a better understanding of molecular processes leading to OAVS.

PS11.067
Three siblings with non-immune hydrops fetalis with gracile bones and dysmorphic features: second report in the literature

M. B. Duz[1], *E. Koparir[2], M. Ozen[1,3,4], E. Fenercioglu[1], M. Seven[1], H. Ulucan[1];*
[1]Cerrahpasa Medical School, Department of Medical Genetics, Istanbul, Turkey, [2]Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey, [3]Biruni University, Istanbul, Turkey, [4]5Department of Pathology&Immunology,Baylor College of Medicine, Houston, TX, United States.

A brother and a sister from a consanguineous family was first described by Abbot et al. in 2008 (MIM 613124). They both had non-immune hydrops fetalis with gracile bones and dysmorphic features. They died after an hour from birth due to respiratory insufficiency.
We here report three female siblings from a consanguineous Turkish family, who had non-immune hydrops fetalis, dysmorphic facial appearance, and bone fractures. They were born at 36, 33 and 33+6 week gestation by caesarean section due to malpresentation, respectively. All of siblings had similar facial dysmorphism with down-slanting palpebral fissures, low-set ears, short and upturned nose, long and smooth philtrum, narrow and high palate, and short neck. Radiographic studies of the first child revealed fractures of bilateral humerus and right femur, second child had fractures of left humerus and left femur, whereas last child had only left humerus fractures. The siblings died after three days, forty-three days and nine days from birth, due to respiratory problems, respectively. We suggest that our patients are similar with those of Abbott et al. indicating a new autosomal recessive condition. To elucidate this phenotype, molecular studies are still in progress.

PM11.068
Multiple Congenital Anomalies in two Boys with Mutation in HCFC1 and Cobalamin Disorder

G. Morin[1], *M. Gérard[2], A. Bourillon[3], C. Colson[2], S. Mathieu[4], D. Rabier[5], T. Billette de Villemeur[4], H. Ogier de Baulny[6], J. Benoist[3];*
[1]Service de Génétique Clinique et Oncogénétique, Amiens, France, [2]Service de Génétique Clinique, Caen, France, [3]Laboratoire de Biochimie - Hôpital Robert Debré, Paris, France, [4]Service de Neuropédiatrie - Hôpital Trousseau, Paris, France, [5]Service de Biochimie - Hôpital Necker Enfants Malades, Paris, France, [6]Service de Neuropédiatrie - Hôpital Robert Debré, Paris, France.

The cobalamin type C deficiency is a rare condition that results from impaired biosynthesis of both methylcobalamin (MeCbl) and adenosylcobalamin (AdoCbl). Hemizygous mutations of the HCFC1 gene explain the majority of clinically and biologically compatible cblC patients without MMACHC mutations (OMIM 309541). We report a family with two maternal half-brothers with multiple congenital anomalies and HCFC1 gene mutation in the second Kelch domain. Both presented with dysmorphic features (flat profile, cleft lip for one), increased nuchal translucency, prenatal onset microcephaly and hypospadias. Additionally to early onset intractable epilepsy and profound neurocognitive impairment, this familial observation suggests that HCFC1 gene should be considered in boys with midline malformations, even without proven cobalamin C deficiency.

PS11.069
Diagnostic dilemma - Hidrolethalus syndrome

V. Belengeanu[1], *G. Furau[1], C. Popescu[1], L. Paiusan[1], M. Stoian[2,3], H. Viskari[4], D. Misceo[5];*
[1]University of West Vasile Godis Arad, Arad, Romania, [2]Discipline of Medical Genetics, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania, [3]Personal Genetics-Medical Genetics Center, Bucharest, Romania, [4]Institute for Molecular Medicine, Helsinki, Finland, [5]Department of Medical Genetics, Oslo University Hospital, University of Oslo, Oslo, Norway.

Hydrolethalus syndrome is a rare clinical entity including as main characteristics hydrocephalus, absent midline structures, polydactyly and lethality. The vast majority of the cases have been reported in Finland. We present two Romanian newborns with severe malformations. The first case is a male fetus. The fetus was delivered by caesarian section at 28 weeks of gestation, with hydrocephaly, microphtalmia, cheiloschisis, micrognathia, low set ears, bilateral postaxial poydactyly with six fingers of the hand, preaxial and postaxial polydactyly of the feet with seven toes and syndactyly of 5th and 6th. The fetus lived 20 minutes. Autopsy showed also laryngeal stenosis, palatoschisis, lissencephaly, agenesis of corpus callosum, classic open book appearance of the brain. The second case is a feminine fetus, delivered by caesarian section at 29 weeks of gestation. She lived the 10 minutes. She

showed severe dysmorphia with true anophthalmia, arhinia, median cleft upper jaw, very small lower jaw and small ears. She had right hand with polydactyly and bilateral syndactyly of 2th and 5th toes. Autopsy showed cerebral hemispheres open-book and the occipital keyhole images, agenesis of corpus callosum and lissencephaly. The right lung had two lobes, the left lung one lobe. Sequencing analysis of HYLS1 and KIF7 genes did not identify any pathogenic variants. The dilemma is the discordance between the presence of majority of the specific signs of the syndrome and absence the mutations in the so far causative genes. These cases with overlapping manifestations of the hydrolethalus syndrome might be in fact another hydrolethalus syndrome or the syndrome is etiologically heterogeneous.

PM11.070

A new homozygous *IGF1R* mutation defines an autosomal recessive form of SHORT syndrome characterized by developmental delay and marked progeroid appearance.

L. Micale[1], *V. Ottaviani[1], I. Isidori[2], C. Fusco[1], B. Augello[1], D. Rogaia[3], A. Mencarelli[3], C. Ardisia[3], G. Stangoni[3], G. Merla[1], P. Prontera[3];*
[1]IRCCS Casa Sollievo della Sofferenza Hospital, Medical Genetics Unit, San Giovanni Rotondo (FG), Italy, [2]INeurology Unit, University and Hospital of Perugia, Perugia, Italy, [3]Medical Genetics Unit, University and Hospital of Perugia, Perugia, Italy.

Insulin-like growth factors I (IGF-I) is essential for pre and post-natal somatic growth and cellular proliferation. The binding of IGF-I to IGF1R leads to receptor autophosphorylation resulting in recruitment of cytoplasmic components of multiple downstream signalling pathways, including the PI3K/Akt and MAPK/Erk pathways, which are important for cell survival and cell growth.
Here, using exome sequencing, we identified and characterized a new homozygous c.2201G>T mutation in the IGF1R gene in a female patient, born from consanguineous parents, showing very high IGF-I levels and clinical features of SHORT syndrome plus developmental delay, CNS defects, and marked progeroid appearance. This mutation cosegregated in the heterozygous state in the parents and other relatives, which show a milder phenotype.
Based on a bioinformatics analysis, the c.2201G>T mutation was predicted to cause an alternative splicing event that we confirmed by RT-PCR followed by direct sequencing of amplified products. This event causes an aberrant isoform that adds 25 aminoacids after the proline at codon 733, predicted to be damaging and causing dramatic structural changes of the protein.
Functional studies using primary dermal fibroblast cultures obtained from affected and healthy individuals revealed a lower IGF1R protein expression in both homozygous and heterozygous fibroblasts. Furthermore, decreased IGF-1R content affects IGF-I signalling, as showed by a reduction of IGF-I-dependent Akt phosphorylation and IGF-IR auto-phosphorylation.
This study provides valuable insights into the pathophysiological and phenotipical consequences caused by loss of IGF1R function.

PS11.071

A Germline mTOR Mutation in Aboriginal Australian Siblings with Intellectual Disability, Dysmorphism, Macrocephaly and Small Thoraces.

G. S. Baynam[1,2,3], *M. Davis[4], K. Mina[4], L. Schofield[2], R. Allcock[1], N. Laing[1], M. Cook[5], H. Dawkins[6], J. Goldblatt[7];*
[1]University of Western Australia, Perth, Australia, [2]Murdoch University, Perth, Australia, [3]Telethon Kids Institute, Perth, Australia, [4]PathWest, Perth, Australia, [5]Australian National University, Canberra, Australia, [6]Office of Population Health Genomics, Public Health and Clinical Services Division, WA Department of Health, Perth, Australia, [7]Genetic Services of Western Australia, Perth, Australia.

The Australian Desert, a new familial phenotype and a global search for functional studies to support potential drug repurposing. We report 3 Aboriginal Australian siblings with a unique phenotype which overlaps with known megalencephaly syndromes and RASopathies, including Costello syndrome. A gain of function mutation in mTOR was identified and represents the first reported human condition due to a germline, familial mTOR mutation. We describe the findings in this family to highlight i) that the path to determination of pathogenicity was confounded by the lack of genomic reference data for Australian Aboriginals and that ii) the disease biology, functional analyses in this family and studies on the Tuberous Sclerosis Complex support consideration of an mTOR inhibitor as a therapeutic agent

PM11.072

Oligonucleotide array CGH analysis of a cohort of 220 patients with intellectual diability, developmental delay and multiple congenital anomalies

A. Saberi[1,2], *g. Shariati[1,2], H. Galehdari[3,2], M. Hamid[4,2], N. Abdorasuli[2];*
[1]Ahvaz Jundishpour university of medical sciences, Ahvaz, Iran, Islamic Republic of, [2]Narges genetic lab, Ahvaz, Iran, Islamic Republic of, [3]Ahvaz shahid chamran university, Ahvaz, Iran, Islamic Republic of, [4]Pasteur Institute of Iran, Ahvaz, Iran, Islamic Republic of.

Array CGH (aCGH) enables genome wide investigation of copy number changes at high resolution and have recently been implemented as a clinical diagnostic tool. In this study, a high resolution oligonucleotide chromosomal microarray was applied in an Iranian cohort of 220 patients with DD/ID and multiple congenital anomalies: male;114, female:116, aged 7days- 20 years. DNA extracted from peripheral blood cells were analyzed with CytoChip_ISCA_4x180 oligo array. The imbalances were confirmed by FISH or MLPA. We considered copy number variants (CNVs) as pathogenic if the variant was responsible for a known syndrome, encompassed gene/s of known function, occurred de novo or, if inherited, the parents was variably affected and/or the involved gene/s had been reported with DD/ID and multiple congenital anomalies. aCGH identified 39 clinically significant microdeletions and 18 microduplications in 23.6% (52/220) patients, with size of aberrant regions ranging from 39kb to 24.2Mb. 26.3% (15/57) of the copy number variant (CNV) detected corresponded to well-known microdeletion and microduplication syndrome (Williams, Digeorge, prder-Willi, kabuki, WolfHirschhorn, Tar, Reiger, Potoki-lupski and Mitochondrial complex deficiency IV syndrome). 61% (35/57) of the detected CNVs were de novo, 26% (15/57) inherited and 12% (7/57) unknown. We also identified two novel CNVs, one at 9p11.2-p13.1 and the other at 10p12.1 as a pathogenic submicroscopic CNV. Our study provides further evidence of the high diagnostic yield of aCGH for genetic testing of patients with DD/ID and unexplained multiple congenital anomalies.

2q22.1q22.3 deletion, upstream ZEB2, causes intellectual disability, myoclonic epilepsy, omphalocele, genital anomalies and facial similarities with Mowat-Wilson syndrome

N. Revencu[1], *M. Ravoet[1], F. Christiaens[2], A. Beleza-Meireles[1];*
[1]Center for Human Genetics, Cliniques Universitaires Saint-Luc, Université catholique de Louvain, Brussels, Belgium, [2]Pediatric Neurology, Cliniques Universitaires Saint-Luc, Université catholique de Louvain, Brussels, Belgium.

BACKGROUND
Array-CGH has improved the diagnostic yield in patients with intellectual disability (ID) and/or multiple congenital anomalies (MCA), allowing the definition of novel microdeletion and microduplication syndromes.
CASE REPORT We report a boy with severe ID, dysmorphisms, myoclonic epilepsy, thin corpus callosum, omphalocele and chordee. He presents distinctive facial features comprising large, prominent forehead, thick eyebrows, deep-set eyes, strabismus, wide nasal bridge, bilateral epicanthus, large ear lobes, prominent, rounded nasal tip, deep philtrum, open, large mouth with M-shaped upper lip, small teeth and pointed chin, which were somewhat evocative of Mowat-Wilson syndrome. He has wide-spaced nipples and prominent finger pads in hands and feet.
RESULTS
Array-CGH identified a de novo 2q22.1q22.3 (140,509,156-144,980,623) deletion, comprising the LRP1B, KYNU, ARHGAP15 genes and partially the GTDC1 gene. Interestingly, the ZEB2 gene, responsible for Mowat-Wilson syndrome, is located about 150Kb downstream the deletion.
DISCUSSION
Two other patients have been previously reported with de novo similar deletion and no other genomic rearrangement:
- in DECIPHER, patient 1607 (del 139,813,180-145,063,389), who presents ID, craniofacial dysmorphism, strabismus, absent nipples, and prominent fingertip pads
- in the literature, Mulatinho et al describe a Brazilian patient (del 138,750.000-144.750.000) presenting ID, lack of speech, craniofacial dysmorphism, omphalocele, hypospadias and cryptorchidism.
CONCLUSION
A novel case of 2q22.1q22.3 deletion is documented, defining a rare, but recognizable, ID/MCA syndrome, bringing the total number of known cases to 3. Omphalocele and genital anomalies are present in 2 of the 3 patients. Patients present similar craniofacial features, somewhat evocative of Mowat-Wilson syndrome, suggesting a possible positional effect over ZEB2.

PM11.074

Effectiveness and costs of whole exome sequencing compared to traditional diagnostic investigations in children with complex neurological disorders

G. R. Monroe[1], *G. W. Frederix*[2], *S. Savelberg*[1], *K. Duran*[1], *T. de Vries*[1], *N. Verhoeven-Duif*[1], *J. J. van der Smagt*[1], *P. Terhal*[1], *P. van Hasselt*[3], *M. M. van Haelst*[1], *G. Visser*[3], *A. Hövels*[2], *G. van Haaften*[1];

[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Utrecht University Pharmacoepidemiology and Clinical Pharmacology, Utrecht, Netherlands,* [3]*Division of Pediatrics, Department of Metabolic Diseases, Wilhelmina Children's Hospital, Utrecht, Netherlands.*

Introduction: A systematic evaluation of whole exome sequencing (WES) diagnostic yield and assessment of the costs associated with implementing WES in the clinic is currently lacking. We determine the increased diagnostic yield and provide a thorough cost analysis of the clinical care prospectively with WES compared retrospectively to care without WES.

Materials and Methods: Seventeen children of healthy, unrelated parents were randomly selected from the 2011 patient population at the Sylvia Toth Center (STC; Utrecht, the Netherlands), a specialized center for children with complex neurological disorders and diverse phenotypes. WES was performed on Illumina HiSeq 2500. In parallel, the clinical records of patients were obtained and a comprehensive cost summary of medical treatments, hospital visits, and all other resource use was compiled per patient. This cost was then compared to the cost of care using WES, assessed prospectively.

Results: The diagnostic yield in this patient cohort is 18%, confirming past studies' diagnostic yields on intellectual disability cohorts. The three mutations detected are in genes recently associated with intellectual disability (ANKRD11, CTNNB1, ANDP), and the mutations are all heterozygous de novo frame-shift deletions resulting in protein truncation. In addition, strong candidate genes (HNRNPU, CHD4) have been identified.

Conclusions: The increased diagnostic yield and fractional increase in total overall price in the cost of care for these patients suggests that WES should be implemented early in patient care for similar centers that have patient populations for whom providing a diagnosis is both difficult and expensive.

PS11.075

Interstitial deletion 6p21.2-p21.1: characterization by array-CGH and phenotype description

I. M. P. O. Rizzo, *K. T. Abe, L. L. Roese, D. R. Carvalho, C. E. Speck-Martins;*
SARAH Network of Rehabilitation Hospitals, Brasília – DF, Brazil, BRASÍLIA, Brazil.

Deletions in the short arm of chromosome 6 represent a rare genetic alteration and small number of cases was described, frequently about telomeric region. The number of patients identified with microdeletion syndrome has been increasing significantly with widespread application of high-resolution genome analysis technologies such as array comparative genomic hybridization (array-CGH).

We identify a 6,295Mb interstitial deletion at 6p21.2-p21.1 by array-CGH. This region encompasses fifty-seven genes cataloged at OMIM.

The patient was a seven years old girl with mental retardation, neurosensory deafness, facial dymorphism, obesity beginning in infancy and atopic dermatitis.

The comparison genotype/phenotype has been done and six genes whose function is known and correlated have been identified. The consequences of haploinsufficiency of GLP1R, MOCS1, TREM2, GNMT, PEX6 and CUL7 in this case have been debated.

Individually, none of the identified genes encompasses all findings in patient, however could be contributing in the phenotype.

PM11.076

Two cases with a rare chromosomal abnormality: isochromosome 18p

V. Cejnova[1], *L. Liskova*[1], *V. Harmas*[1], *M. Tothova*[2], *A. Klimova*[1], *M. Soukupova*[1], *J. Lastuvkova*[1];

[1]*Regional Health Corporation, Usti nad Labem, Czech Republic,* [2]*GENVIA, Prague, Czech Republic.*

Tetrasomy 18p, one of the most commonly observed isochromosomes, consists of two copies of the p arms on chromosome 18[i(18p)]. It has a prevalence of 1/140,000-180,000 live births and affects both genders equally. Tetrasomy 18p syndrome is characterized by nonspecific morfologic features; low birth weight, microcephaly, low-set ears, strabismus, abnormalities in muscle tone and deep tendon reflex. Feeding difficulties and developmental delays are also followed.

We present two cases with *de novo* tetrasomy 18p. In the first case we report a *de novo* tetrasomy 18p in a female dysmorphic child with delayed psychomotor development and hypotonia. The physical examination showed: microcephaly, strabismus, low-set ears, bilateral epicanthic folds, broad nasal bridge and tented mouth with slightly everted upper lip. The small metacentric marker chromosome was identified by conventional cytogenetic analysis and fluorescence *in situ* hybridization (FISH) as i(18p) in the proband with the karyotype 47,XX,+i(18)(p10). In the second case we present a prenatally detected mosaic isochromosome 18p with the karyotype 47,XY,+i(18)(p10)[30]/46,XY[29] by amniocentesis. Interphase FISH analysis of stimulated cultured cord blood lymphocytes showed 2% (6/306) mosaicism for tetrasomy 18p. The pregnancy was terminated.

Array comparative genomic hybridization (aCGH) confirmed the diagnosis of tetrasomy 18p molecularly and revealed a 14 Mb triplication at 18p11.32p11.21 in the first case. In the second case a 14 Mb duplication at 18p11.32p11.21 was characterized by aCGH. The parental origin of the isochromosome was determined based on a variety of short tandem repeats and was found to be maternal in both cases.

PS11.077

Growth and growth hormone in 15 children with Kabuki syndrome

M. Klaassens, *E. Janssens, D. A. Schott, W. J. M. Gerver, L. J. Zimmerman, C. T. R. M. Stumpel;*
Maastricht University Medical Center+, Maastricht, Netherlands.

Introduction

Kabuki Syndrome (KS; OMIM 147920) is a congenital anomaly/intellectual disability syndrome caused by a mutation in the KMT2D or KDM6A gene. Children with KS have a spectrum of clinical features, one of the key features is postnatal growth deficiency.

Mutations in KMT2D gene, encoding an H3K4 histone methyl transferase, act as an epigenetic transcriptional activator during growth and development. As for the KDM6A mutation, no molecular cause for growth retardation has been described.

GH deficiency has been reported in KS but in the majority of children with KS no cause for small stature has been found. We studied the growth hormone and IGF-I pattern in order to learn more about a possible mechanism involved in this postnatal growth retardation.

Methods

Currently, we have assessed 15 KS children (age 3-10 years old, 6.44±2.29) with a known KMT2D or KDM6A mutation. Height was variable, with a mean height SDS of -2.38 ±1.41. Both clonidine (CLO) and arginine (ARG) were used for stimulation. GH and IGF-1 were measured according to international standard.

Results and Conclusion

Growth hormone deficiency was present in 4 of 15 (26.67%) children. Apparently growth hormone deficiency is not the only cause for small height in KS patients. In addition, in 2 children the GH tests showed a tendency to GH resistance, although no one actually met the defined criteria. Further research is necessary to determine the underlying cause of growth retardation in the majority of KS patients.

Currently we are performing a clinical study with growth hormone in children with Kabuki syndrome; the results are pending but promising.

PM11.078

Kapur-Toriello Syndrome: a further case report and expansion of the phenotype

H. Lefroy, *U. Kini;*
Department of Clinical Genetics, Oxford University Hospitals NHS Trust, Oxford, United Kingdom.

Kapur-Toriello syndrome (KTS) is a rare multiple congenital abnormalities syndrome first described by Kapur and Toriello in 1991. We present a new case, taking the total number reported in the literature to six.

With gradual expansion of the cohort, evidence is emerging for several key features including bilateral cleft lip / palate, a distinctive nose, low set ears, ocular, cardiac, intestinal and brain malformations. Other features seen less commonly in previous cases, but which our case adds evidence for, include growth retardation, digital abnormalities, short stature and a short, wide neck.

Structural pituitary abnormalities associated with growth hormone deficiency have not been previously reported in patients with KTS, although short stature and growth retardation have been frequently noted. To our knowledge, our patient is the first with KTS to receive growth hormone therapy. It would therefore seem appropriate to monitor growth hormone levels in patients with KTS presenting with short stature.

Autosomal recessive inheritance has previously been suggested. As this is the fourth case with a single affected individual born to non-consanguineous parents, it raises the possibility of autosomal dominant inheritance.

With so few documented cases of KTS, it is important for new cases to be

reported so that the clinical phenotype may be better delineated. As whole genome sequencing becomes increasingly available, we hope that a molecular cause for this rare syndrome may soon be identified.

Mutations and deletions of the *ANKRD11* gene are known to cause KBG syndrome. We report a series of 20 French patients with KBG syndrome including 3 families. Molecular anomalies consisted of 9 mutations and 8 deletions involving at least part of the *ANKRD11* gene. The 9 mutations were identified by targeted sequencing of the gene, following clinical diagnosis of KBG syndrome. The age at diagnosis ranged from birth to 65 years. All mutations were loss of function and were clustered in the largest exon. The size of deletions ranged from 127kb to 1.2Mb. There were no significant clinical differences between mutated and deleted cases. Facial gestalt was characteristic in all cases, and allowed the diagnosis even in young children. Deafness was present in 25%, short stature in 55%. Interestingly, the teeth were considered as normal in 3 adult patients and two patients exhibited a caudal appendage. In most patients, intellectual level ranged from borderline intelligence to mild/moderate intellectual deficiency. A single patient had severe ID. Two had epilepsy and behavioral problems were noted in 20%. From an epidemiological point of view, our study confirms the high rate of familial cases. All cases with a mutation were recruited from two French centers, whereas the 8 16q24.3 deletions identified by array-CGH deletions were recruited through a national network. We postulate that mutations are probably more frequent than deletions but remain undiagnosed. Diagnosis is clinical on the basis of typical facial features and similarities with Cornelia de Lange syndrome may be striking.

Microcephaly with or without chorioretinopathy, lymphoedema, or mental retardation (MCLMR) (MIM #152950) is a rare autosomal dominant condition. The causative gene, kinesin family member 11 (KIF11) was identified in 2012. KIF11 mutations were found in individuals with and without lymphoedema. To further delineate this condition, we collected the clinical details of thirty seven individuals from twenty two families, all with KIF11 mutations.

The condition arose de novo in 40% of cases where parental results were available. In our cohort, 86% had microcephaly, 78% had an ocular abnormality consistent with the diagnosis, 46% had lymphoedema, 73% had mild-moderate learning difficulties, 8% had epilepsy and 8% had a cardiac anomaly. We identified three individuals with KIF11 mutations, but no clinical features of MCLMR demonstrating reduced penetrance. The variable expression of the phenotype and presence of mildly affected individuals indicates that the prevalence may be higher than expected, and we would therefore recommend a low threshold for genetic testing.

Our data suggests that mutations in KIF11 cause a variable spectrum of clinical features. Not only is the microcephaly variable, the ocular abnormalities are also variable with chorioretinopathy being the most prevalent. Recently a series of cases with retinal detachment mimicking FEVR have been reported suggesting a broader spectrum of ocular manifestation than originally suggested. Our review will explore and summarise the relationship between the KIF11 genotype and some of the major, phenotypic characteristics of MCLMR identified to date. This work was funded by BHF.

PS11.081

New insights and broader spectrum of lissencephaly including a definition of a novel subtype.

N. Di Donato[1,2], S. Chiari[3], C. Adams[1], S. Collins[1], R. Guerrini[3], W. B. Dobyns[1], **G. Mirzaa**[1];

[1]Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA, United States, [2]Institut für Klinische Genetik, TU Dresden, Dresden, Germany, [3]Pediatric Neurology Unit, Children's Hospital A. Meyer, University of Firenze, Florence, Italy.

Introduction: Lissencephaly (LIS), the most severe malformation of neuronal migration, is characterized by broad or absent gyri and abnormally thick (12-20 mm) cortex. Several patterns and syndromes are known including the less severe variant subcortical band heterotopia (SBH), but rapidly increasing knowledge requires revision of the current classification.

Materials and Methods: We reviewed brain scans, clinical and molecular findings for 129 LIS patients ascertained from 2009-2014 and grouped them by severity (LIS grade 1-6), gradient (diffuse vs. anterior or posterior), and presence of other malformations.

Results: Posterior predominant LIS grade 3 (27%) followed by diffuse LIS or SBH (17%) due to mutations of LIS1 and DCX were the most common forms. All other LIS patterns were less frequent (2-9%) with anterior predominant forms significantly less frequent than posterior predominant forms. Recognizable tubulinopathies accounted for 10% of patients (grade 4 LIS with atypical mixed pachygyria-microgyria). This is the only group lacking the consistent anterior or posterior gradient characteristic of LIS. In addition, we recognized a novel anterior predominant "thin" LIS (cortex 5-7 mm; normal is 3-4 mm) with reduced number of gyri and shallow sulci. When combined with severe cerebellar hypoplasia this variant is caused by mutations in RELN or VLDLR. However, 8 patients had "thin" LIS with a normal cerebellum. None had mutations in the known LIS genes. Based on high percentage of homozygosity in SNP arrays in several of these patients, we strongly suspect autosomal recessive inheritance. We will present more detailed diagnostic criteria and updated results of molecular testing.

PM11.082

Diagnostic yield of targeted next generation sequencing panel for cortical malformations

G. M. Mancini[1], *M. Wilke[1], R. Oegema[1], R. Schot[1], M. Wijgerde[1], W. B. Dobyns[2], D. J. J. Halley[1], M. A. van Slegtenhorst[1];*

[1]ErasmusMC, Department of Clinical Genetics, Rotterdam, Netherlands, [2]Children's Research Institute, Seattle, WA, United States.

Malformations of the brain cortex development (MCD) are rare diseases diagnosed by MRI scan and are classified into proliferation disorders(microcephalies and megalencephalies), disorders of neuronal migration (lissencephaly, cobblestone malformation and heterotopia) and disorders of cortical organization (polymicrogyria and schizencephaly). Identification of many genes has improved etiological diagnosis, but genetic heterogeneity makes testing of individual genes unpractical. In Rotterdam a diagnostic custom-made panel for high throughput sequencing of 103 genes involved in MCD, belonging to all three ategories has been developed. About 168 patients have been tested in two years. Most of the patients had no mutation in one or more candidate genes (e.g. *LIS1, DCX, FLNA, ARX, GPR56*), previously tested by Sanger sequencing. The diagnostic yield of the panle

was about 6%. Most diagnoses have been achieved in the group of primary microcephalies, and the least in the group of polymicrogyria, although the latter was the most common indication for the test. Expert post-test clinical and radiological re-phenotyping has led to reclassification of the disease, broadening the phenotypic spectrum of known disorders, as for mutations in the small nuclear RNA coding *RNU4atac*, for *ACTB*, *KIAA1279*, *CENPJ and RELN*. Diagnoses also included cases with insufficient radiological data for appropriate classification. Low-abundance mosaic mutations, e.g. *TUBB2B* and *PIK3R2* that we observed, remain a challenge to detect. When applied as first-tier test, targeted NGS panels can be cost-effective for the diagnosis of MCD, without the drawbacks of unsolicited findings. However these preliminary data underpin the etiological heterogeneity of MCD and the need for collaborative research efforts.

PS11.083

Skeletal dysplasia may be a feature of Meckel syndrome type 9 (MKS9), a rare entity caused by *B9D1* mutations

G. A. Gradek[1], *K. Bakke*[2], *E. B. Budal*[3], *K. Rosendahl*[4], *G. Houge*[1], *P. M. Knappskog*[1], *S. Johansson*[1];
[1]*Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, N-Bergen, Norway,* [2]*Department of Obstetrics and Gynaecology, Haukeland University Hospital, N-Bergen, Norway,* [3]*Department of Pathology, Haukeland University Hospital, N-Bergen, Norway,* [4]*Department of Radiology, Haukeland University Hospital, N-Bergen, Norway.*

INTRODUCTION: Meckel Syndrome (MKS) is a genetically heterogeneous recessive ciliopathy presenting in fetal life with multiple malformations, of which occipital encephalocele is the most characteristic. MKS type 9, caused by *B9D1* mutations, is a rare entity with only two published cases so far, and none of them had a skeletal phenotype.
MATERIALS AND METHODS: An unrelated couple lost four fetuses due to malformations consistent with MKS. Fetal DNA was collected from CVS or spleen and subjected to 6.0 SNP-array-based copy number analysis, haplotype analysis, and finally whole-exome sequencing (WES) analysis of a ciliopathy-related gene panel. Whole body X-ray was performed on fetus 4.
RESULTS: 6.0 SNP-array and Sanger sequencing of the *MKS1*-gene were normal. Fetus 1 and 2 shared haplotypes around *NPHP3, TMEM67, B9D1,* and *B9D2.* Only in *B9D1* compound heterozygosity for pathogenic variants were detected by the ciliopathy panel and later verified by Sanger sequencing. Ultrasound and X-ray examination of fetus 4 displayed angulated tibiae and radii and a large calvarium.
CONCLUSION: Only four patients with a ciliopathy due to *B9D1* mutations have so far been described, two with MKS and two with Joubert syndrome (JS). Here we expand the severe end of the phenotypic spectrum of *B9D1* mutations, adding skeletal dysplasia to the list of possible manifestations.

PM11.084

X-linked microcephalic primordial dwarfism syndrome in two siblings

[1]*CHU Liège, Liège, Belgium,* [2]*Clinique de l'Espérance, Liège, Belgium,* [3]*APHP-Robert Debré university hospital, Paris, France.*

A boy was born at term from non-consanguineous parents with a birth weight of 2130 gr (-3 SD), length of 45 cm (-2.5 SD) and OFC of 30.5 cm (-4 SD). Pregnancy was complicated by oligohydramnios and IUGR. Facial dysmorphism was noted at birth including blepharophimosis, stubby nose and thick columella, mild retrognathia, and posterior cleft palate. Cerebral imaging showed bilateral cysts of the choroid plexus and mild enlargement of the cerebral ventricle. Auditory evoked potentials suggested sensorineural deafness. He had subsequent developmental delay and growth retardation. Hypsarythmia occurred at age 9 months. He died from status epilepticus. His young brother, born at term with a birth weight of 3090 gr (-0.8 SD) and OFC of 31.5 cm (-3.5 SD) had similar dysmorphism, including blepharophimosis and cleft soft palate. Subsequently, he presented severe developmental delay, feeding difficulties and gastro-esophageal reflux. Seizures appeared at the age of 1 year. Aged 13.8 year, his weight is 15.0 kg (-4 SD), height 111 cm (-6 SD) and OFC 44.5 cm (-7 SD). He is unable to walk or speak. Clinically, these patients, originally reported as blepharophimosis-MR syndromes, share similarities with Juberg-Marsidi syndrome. Array CGH was normal. Whole exome sequencing identified a hemizygous mutation in a gene located in Xp11.22, affecting a highly conserved amino-acid, and predicted, in silico, to be pathogenic. This mutation was present in both siblings, the mother and maternal grand-mother but absent in another male maternal relative. X chromosome inactivation and functional studies are currently underway.
This work was supported by a FIRS grant from the CHU Liège, Belgium.

PS11.085

A review of the spectrum of KIF11 mutations causing Microcephaly with or without chorioretinopathy, lymphoedema, or mental retardation (MCLMR)

E. Fotiou[1], **H. Jeffery**[1], *G. Jones*[1], *D. Williams*[2], *K. Karaer*[3], *G. Brice*[1], *K. Gordon*[1], *P. Mortimer*[1], *S. Jeffery*[1], *P. Vasudevan*[2], *S. Mansour*[1], *P. Ostergaard*[1];
[1]*St George's University of London, London, United Kingdom,* [2]*University Hospital Leicester NHS Trust, Leicester, United Kingdom,* [3]*Dr Ersin Arslan State Hospital, Gaziantep, Turkey.*

Mutations in *KIF11* cause microcephaly with or without chorioretinopathy, lymphoedema, or mental retardation (MCLMR, MIM #152950) which is a rare autosomal dominant condition. MCLMR can be de novo or inherited. The phenotype is variable, often displaying mild-to-severe microcephaly plus any of the following: ocular abnormalities, lymphoedema, and learning difficulties. This report further expands the molecular spectrum of *KIF11* variations.
Previous investigations have identified and reported a total of 50 cases. We have screened another cohort of 28 unreported, unrelated MCLMR subjects for mutations in *KIF11* by Sanger sequencing. We found 15 mutations in 17 subjects; one variant had previously been reported. A variety of mutations were identified including a synonymous mutation (c.2922G>A) in two unrelated subjects, which we show has an impact on splicing. This is the first report of a synonymous mutation in *KIF11* being responsible for causing disease.
Identifying further mutations in this gene supports the role of *KIF11* as contributory to MCLMR. A review of the spectrum of mutations in the *KIF11* mutation positive subjects in this cohort and all published cases (i.e. a total of 67 cases under review) shows that nonsense mutations were most common (33%), followed by frameshift mutations (27%), missense and splice-site mutations (20% each). The mutations are distributed evenly throughout the *KIF11* gene. No mutations were identified in 11 unrelated individuals with clinical features consistent with MCLMR, suggesting genetic heterogeneity associated with this condition. This work was funded by BHF and Newlife Foundation for Disabled Children.

PM11.086

Clinical phenotype of 5q31.1 - q31.2 microdeletion

A. Cieślikowska, *M. Kucharczyk, M. Kugaudo, M. Krajewska-Walasek, K. Chrzanowska; Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland, Warsaw, Poland.*

Interstitial deletions of chromosome band 5q31 are rather uncommon, only several patients have been reported to date. We report on a case of a 12-year-old girl patient with a de novo 4.19Mb interstitial deletion of chromosome bands 5q31.1-q31.2 detected by whole-genome oligonucleotide microarray analysis. Clinical manifestations in this patient included: failure to thrive, psychomotor retardation, short stature, muscular hypotonia, skeletal anomalies, microcephaly, cleft palate, hand and foot anomalies and dysmorphic features.
Overlapping microdeletions have been previously reported [Rosenfeld et al., 2011: DECIPHER 249028; Kleffman et al. 2012].In these patients microdeletions were rather larger (5.0 - 8.1Mb) and extend distally into 5q31.3. Carriers of larger microdeletions which include subbands 5q31.1 and/or 5q31.3 seem to be more severely affected with congenital malformations, growth anomalies, and severe encephalopathies. No common occurrence of the smallest region of overlap has been observed. Compared to the previously reported patients, severe feeding difficulties, weakness and fatigue of calf muscle and unusual tiredness are unique features only to our patient, which might be due to different sizes and positions of the individual deletions.
In conclusion, this case increases our knowledge of phenotypic consequences of interstitial 5q31 deletions. There has been considerable interest in mapping the smallest region of overlap for this syndrome in order to identify the critical pathogenic genes and establish genotype-phenotype correlations.
This study was supported by the MNiSW Grant No. 0193/IP1/2013/72.

Heterozygous ACTG2 mutations impair binding to actin filaments and cause megacystis microcolon intestinal hypoperistalsis syndrome

D. Halim[1], *L. Signorile*[2], *R. Verdijk*[3], *F. Muller*[4], *J. Kerner*[5], *J. B. Verheij*[6], *C. S. van der Werf*[6], *R. M. H. Wijnen*[7], *D. Tibboel*[7], *Y. van Bever*[1], *R. M. W. Hofstra*[1], *A. Brooks*[1], *M. M. Alves*[1];

States, [6]Department of Genetics, Groningen University Medical Center, Groningen, Netherlands, [7]Department of Pediatrics Surgery, Erasmus University Medical Center, Rotterdam, Netherlands.

Introduction: Megacystis microcolon intestinal hypoperistalsis syndrome (MMIHS) is a rare congenital disease characterised by severe dysfunctions of the bladder and the intestine. Recently, mutations in the enteric smooth muscle actin γ-2 (*ACTG2*) have been associated with MMIHS. ACTG2, one of the six actin isoforms, is specifically expressed in smooth muscle cells of the enteric organs.
Materials and Methods: In order to confirm the involvement of *ACTG2* in MMIHS development, we sanger sequenced a cohort of sporadic MMIHS patients to determine mutation frequency, and further investigated the molecular pathogenesis associated with *ACTG2* mutations by performing a series of *in vitro* assays and molecular modelling analyses. We also investigated whether these mutations lead to histopathologic abnormalities, and for that we performed immunohistochemistry on intestinal tissue from patients and controls.
Results: Our results showed that heterozygous *ACTG2* mutations were present in all MMIHS patients included in this study. We also determined that the identified mutations inhibited ACTG2 incorporation into the actin filaments, and contributed to reduce contractility. Molecular modelling of ACTG2 mutants confirmed our results, and showed significant changes in the protein structure that likely affect polymerization of ACTG2. Finally, by immunohistochemistry we detected ACTG2 expression in all intestinal layers formed by smooth muscle cells in different stages of human embryonic development. Interestingly, no histopathologic abnormalities were found in patients.
Conclusions: Taken together, our data confirmed that *ACTG2* mutations cause MMIHS and showed that reduced incorporation of ACTG2 into actin filaments affect contractility, and therefore underlies the pathogenesis of MMIHS.

10q26.1 Microdeletion: a New Case Redefines the Critical Regions for Microcephaly and Genital Anomalies

N. Choucair Alam[1,2,3], J. Abou Ghoch[1], A. Fawaz[4], **A. Mégarbané**[5,6]*, E. Chouery[1];*
[1]University of Saint Joseph, Beirut, Lebanon, [2]Aix-Marseille University, Marseille, France, [3]Institut National de la Santé et de la Recherche Médicale, UMR_S910, Marseille, France, [4]Neuropediatrics Department, Lebanese University, Beirut, Lebanon, [5]University of Saint Joseph, University of Saint Joseph, Lebanon, [6]Institut Jérôme Lejeune, Beirut, Lebanon.

Distal 10q deletion syndrome is a well characterized chromosomal disorder consisting of neurodevelopmental impairment, facial dysmorphism, cardiac malformations, genital and urinary tract defects as well as digital anomalies. Patients with interstitial deletions involving band 10q26.1 present a phenotype similar to the ones with the distal 10q deletion syndrome, which led to the definition of a causal 600 kb smallest region of overlap (SRO).
In this report, we describe a male patient with an interstitial 4.5 Mb deletion involving exclusively the 10q26.1 segment. He had growth and psychomotor retardation, microcephaly, flat feet, micropenis, and cryptorchidism. The patient's deleted region does not overlap the 10q SRO. We reviewed the clinical phenotype of patients with similar deletions and suggest the presence of two new SROs, one associated with microcephaly, growth and psychomotor retardation, and the other associated to genital anomalies. Interestingly, we narrowed those regions to segments encompassing five and two genes respectively. FGFR2, NSMCE4A, and ATE1 were suggested as candidates for facial dysmorphism, growth cessation, and heart defects respectively. WDR11 was linked to idiopathic hypogonadotropic hypogonadism and Kallmann syndrome. Its haploinsufficiency could play a crucial role in the genital anomalies of these patients.

PS11.089
The first female patient with Myhre syndrome and rare R496C mutation in *SMAD4* gene.

A. Skórka[1,2]*, D. Gieruszczak-Białek[1], A. Pollak[3], M. Krajewska-Walasek[2], R. Płoski[4];*
[1]Department of Pediatrics Medical University of Warsaw, Warsaw, Poland, [2]Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland, [3]Department of Genetics, Institute of Physiology and Pathology of Hearing, Warsaw, Poland, [4]Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.

Myhre syndrome (MYHRS, OMIM 139210) is an autosomal dominant disorder characterized by developmental and growth delay, athletic muscular built, cognitive deficits, skeletal anomalies, stiffness of joints, distinctive facial dysmorphism and deafness. Recently, *SMAD4* (OMIM 600993) was identified by exome sequencing as the disease gene mutated in MYHRS. Previously only three missense mutations affecting Ile[500] (p.Ile500Thr, p.Ile500Val, and p.Ile500Met) have been described in several unrelated subjects with MYHRS. Here we report on a 10-year-old girl with a heterozygous *SMAD4* missense mutation affecting residue Arg[496]. So far this mutation have been described in only three male patients. Our patient presented with striking dysmorphic features and precocious puberty with normal hormonal studies. Her radiological survey shows typical abnormalities including: narrow pelvic, thickened calvarium, flattened vertebrae with enlarged pedicles. But apart from this she had normal psychomotor development and her intelligence is within normal limits. She attends regular school without any learning problems. She has normal soft skin, no stiffness of joints and no muscle hypertrophy. She also has no heart defect, no arterial hypertension nor deafness. She also has no growth delay. Our findings provide further information about the *SMAD4* mutation spectrum in MYHRS and we present the clinical case with rather milder phenotype in comparison to patients with mutations affecting Ile[500].

PM11.090
Exome sequencing resolves a case of myoclonic epilepsy and Fanconi syndrome

E. G. Seaby[1]*, R. D. Gilbert[1], R. J. Pengelly[1], G. Andreoletti[1], A. Clarke[2], S. Ennis[1];*
[1]University of Southampton, Southampton, United Kingdom, [2]St George's Hospital, London, United Kingdom.

Progressive myoclonic epilepsy encompasses a syndrome of myoclonic seizures and progressive neurological decline caused by a group of rare genetic disorders including lysosomal storage and mitochondrial diseases. The associated aetiological heterogeneity of progressive myoclonic epilepsy poses a diagnostic challenge, yet the application of high throughput sequencing technologies has allowed the identification of rare causal variants in Mendelian diseases such as these. Sodium valproate is a common anticonvulsant drug that is used therapeutically in epileptic disorders, but has been associated with Fanconi syndrome, particularly in severely disabled individuals who are tube fed. We discuss the case of an 8 year old Pakistani boy, with a complex phenotype of myoclonic epilepsy with severe myopathy, severe developmental disability, Fanconi syndrome, pyrexia of unknown origin and a family history of Leigh syndrome. An initial clinical diagnosis of a mitochondrial disorder was made and supported by a marginally decreased level of complex V within the electron transport chain on muscle biopsy. Mitochondrial DNA tests revealed no mutations in m3243A>G or m8344A>G, yet mitochondrial DNA depletion showed an intermediate result of 44% of mean normal levels. Genomic DNA was extracted and sent off for whole exome sequencing and was analysed using an in-house pipeline. Despite a prior hypothesis that our patient had a mitochondrial disorder, we identified a causal variant in KCTD7 (p.Leu108Met) which provided a diagnosis of progressive myoclonic epilepsy type 3. This enabled us to reflect on our prior hypothesis and infer the cause of his Fanconi syndrome to be secondary to valproate therapy.

PS11.091
Congenital diaphragmatic hernia: a rare association with Nager syndrome due to SF3B4 mutation?

H. Linden[1]*, J. Taylor[2], M. Anthony[3], E. Adams[3], E. Blair[1];*
[1]Clinical Genetics Department, Churchill Hospital, Oxford, United Kingdom, [2]Molecular Genetics Laboratory, Churchill Hospital, Oxford, United Kingdom, [3]Department of Neonatal Medicine, John Radcliffe Hospital,, Oxford, United Kingdom.

Nager syndrome is a rare congenital malformation syndrome resulting from hypoplasia of the first and second branchial arches. It is a form of acrofacial dysostosis characterized by craniofacial and limb anomalies. Mutations in the SF3B4 gene have been confirmed as the cause of this condition in most affected individuals.
We report the case of a female neonate with an antenatal diagnosis of diaphragmatic hernia, severe micrognathia and polyhydramnios. At birth additional features of cleft palate and ventricular septal defect were noted. The severe micrognathia was associated with temporomandibular joint ankylosis requiring a tracheostomy. Other salient craniofacial features included low set ears with bilaterally small external auditory meatus and down slanting palpebral fissures. No significant upper limb abnormalities were detected.
A previously unreported heterozygous frameshift mutation (c.1175dupC) in exon 6 of the SF3B4 gene was identified by exome sequencing, confirming a diagnosis of Nager syndrome.
Diaphragmatic hernia has been described in only three previous cases of Nager syndrome, two of which had a confirmed molecular diagnosis. Therefore, this case adds evidence to suggest that diaphragmatic hernia should be considered to be a rare feature of the condition. In addition, our case is unusual in exhibiting no significant upper limb anomalies. To date the majority of cases of Nager syndrome have been reported with thumb hypoplasia/

aplasia. Therefore, this case highlights a milder upper limb phenotype. This case contributes to the understanding of the fetal and neonatal phenotype of Nager syndrome.

PM11.092

Clinical, immunological and genetic characteristics in a family with Nijmegen breakage syndrome

D. Avdjieva-Tzavella[1], *R. Emilova*[2], *S. Mihailova*[3], *I. Boneva*[4], *H. Kathom*[1], *E. Naumova*[3], *R. Tincheva*[1];

[1]Department of Clinical Genetics, University Pediatrics Hospital, Medical University, Sofia, Bulgaria, Sofia, Bulgaria, [2]Cytogenetic laboratory, University Pediatric Hospital, Medical University, Sofia, Bulgaria, [3]Department of Clinical Immunology, University Hospital Alexandovska, Sofia, Bulgaria, [4]Cytogenetic laboratory, University Pediatric Hospital, Medical University,, Sofia, Bulgaria.

Nijmegen breakage syndrome (NBS) is an autosomal recessive disease caused by mutations in the NBS 1 gene, located on chromosome 8q21. The gene product, nibrin is involved in DNA double strand break repair. The vast majority of NBS patients are of Slavic origin and share the founder NBS1 mutation (657D5). Essential features found in NBS were microcephaly, typical face, immunodeficiency, chromosomal instability, and a highly increased risk for malignancies.

We report three siblings with NBS, born to nonconsanguineous parents. The patients presented with obvious microcephaly, bird-like face, café au lait spots and normal intelligence. Cytogenetic analysis of children and healthy parents showed increased spontaneous chromosome breakage. The majority of the breaks involved four fragile sites on chromosomes 7 and 14 - 7p15, 7q36, 14q12, and 14q32. Immunological studies demonstrated a marked decrease in both B and T cell number and function. Mutation screening of the NBS1 gene revealed that children were homozygous for the 657del5 allele in exon 6, their parents are heterozygous for the same mutation.

First child died at 8 years of age from pneumonia. Second child had no history of recurrent infections. Third child had recurrent gastrointestinal and pulmonary infections since birth.

In conclusion patients with the same NBS1 genotype may show a variety of phenotypes. Other gene/epigenetic factors seem to play a role in phenotype presentation.

PS11.093

p.Arg1809Cys substitution in neurofibromin is associated with a distinctive NF1 phenotype without neurofibromas

Analysis of 786 NF1 mutation-positive subjects with clinical diagnosis of neurofibromatosis type 1 (NF1) allowed to identify the heterozygous c.5425C4T missense variant (p.Arg1809Cys) in six (0.7%) unrelated probands (three familial and three sporadic cases), all exhibiting a mild form of disease. Detailed clinical characterization of these subjects and other eight affected relatives showed that all individuals had multiple cafè-au-lait spots, frequently associated with skinfold freckling, but absence of discrete cutaneous or plexiform neurofibromas, Lisch nodules, typical NF1 osseous lesions or symptomatic optic gliomas. Facial features in half of the individuals were suggestive of Noonan syndrome. Our finding and revision of the literature consistently indicate that the c.5425C4T change is associated with a distinctive, mild form of NF1, providing new data with direct impact on genetic counseling and patient management.

PM11.094

Clinical variability in a family with a novel SOS1 variant correlating with Noonan syndrome phenotype

K. H. Chrzanowska[1], *M. Pelc*[1], *M. Kugaudo*[1], *E. Ciara*[1], *W. K. Wiszniewski*[2], *M. Krajewska-Walasek*[1];

[1]The Children's Memorial Health Institute, Warsaw, Poland, [2]Baylor College of Medicine, Houston, TX, United States.

Noonan syndrome (NS) is a relatively common RASopathy caused by activating mutations in 14 genes associated with the Ras/MAPK signal transduction cascade. *SOS1* is one of the major NS-related genes, underlying the disease in about 10-13% of affected individuals.

We present a familial case of a NS patient, her affected brother and father with a novel heterozygous variant c.2013T>A (p.Ser671Arg) identified in exon 12 of *SOS1*, located in the RAS-exchange motif (REM) domain. The Mutation Taster prediction algorithm defined this variant as probably damaging, additionally, substitution segregated with the disease in the family.

The female patient was assessed by a clinical geneticist at the age of 5.5 years due to a 'peculiar' facial appearance in a child with a heart murmur. Her height and OFC were at the 25th centile and she presented with a distinctive phenotype suggesting NS: high and broad forehead, hypertelorism, sparse eyebrows, posteriorly rotated ears, curly scalp hair, broad chest, and hyperkeratotic palmar skin. No congenital cardiac anomalies were found on echocardiography. Additionally, electrocardiography did not show arrhythmia or hypertrophy, however heart enlargement was documented on a chest X-ray (index 0.55). Her affected father and brother exhibited anthropometric characteristics similar to the probant, however the boy was discordant for facial features and had straight hair.

Members of the reported family did not display clinical manifestations frequently observed in *SOS1* mutation-positive individuals (i.e. congenital heart defects, macrocephaly), but all three had mild cognitive deficits, which are a feature less commonly correlated with this gene.

The research was supported by projects: NCN-UMO-2011/03/N/NZ2/00516, CMHI-S140/2014.

Oculo auriculo vertebral spectrum (OAVS) is a rare congenital disease characterized by aural, oral, mandibular and vertebral defects often associated with cardiac, pulmonary, renal, skeletal, and central nervous systems anomalies. The etiology of OAVS is still unknown. A number of chromosomal abnormalities containing genes potentially involved in the disease pathogenesis has been described. In the current study, we used a high-density Affymetrix SNP 6.0 array platform to evaluate the contribution to OAVS of rare submicroscopic chromosomal anomalies. Minimal diagnostic criteria for inclusion in the study were the presence of at least three of the following clinical characteristics: hemifacial microsomia, ear anomalies and preauricular pits or tags. A total of 60 subjects (34 females and 26 males) including 55 sporadic and 5 familial cases were studied. Thirty rare copy number variants (CNVs), ranging from 100 Kb to 1 Mb, were identified in 27/60 individuals. Of these, four had de novo origin in sporadic patients, whereas thirteen had been inherited from an unaffected parent. None of detected CNVs was listed in the database of genomic variants as well as in 80 ethnically matched Caucasian control subjects. Despite none of the identified CNV was recurrent, three independent chromosomal aberrations contained genes involved in the Pax-Six-Eya-Dach regulatory network. Current results suggest that individually rare CNVs are collectively significant contributors to the genetics of OAVS. Moreover, the CNVs detected in the present study suggest a number of OAVS candidate genes that warrant further investigation.

Haaften[1], M. M. van Haelst[1];
[1]Dept. of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands, [2]Centrum Gezond Gewicht, Erasmus Medical Center, Rotterdam, Netherlands, [3]Dept. of Surgery, Rijnstate Hospital, Arnhem, Netherlands.

Syndromic obesity is defined by obesity in association with intellectual deficit and/or other congenital anomalies. An underlying genetic cause has not been identified in the majority of affected patients.
The recent developments of Next-Generation-Sequencing techniques provide a time- and cost efficient method to identify new obesity genes. We developed a custom NGS enrichment probe set, the 'Obesitome kit V1', aimed at enrichment and sequencing of 582 obesity related genes. Genes were selected on (presumed) obesity relevance, based on information from multiple publically available databases, pathway resources and scientific publications.
Based on the initial results of 55 morbid obese syndromal cases, we subsequently refined our enrichment to include the 255 most interesting obesity related genes ('Obesitome kit V2'). Of these 255 genes, 53 are routinely offered for NGS analysis in our DNA diagnostics section, the remaining genes can be used for extended research analysis.
Here we present clinical, molecular and functional follow-up study results of the first cohort (n=450) of (syndromal) morbid obesity patients. We identified known and novel pathogenic obesity gene mutations in approximately 15% of the investigated patients. These results will increase our understanding of the pathophysiological mechanisms of obesity and ultimately lead to personalized medicine of morbid obesity.

PS11.097
Identification of a novel truncating mutation in the distal part of KAT6B exon 18 in a girl with a typical Say-Barber-Biesecker-Young-Simpson phenotype

M. Krajewska-Walasek[1], *M. Pelc[1], D. Jurkiewicz[1], M. Kucharczyk[1], A. Jezela-Stanek[1], R. Płoski[2], E. Ciara[1];*
[1]The Children's Memorial Health Institute, Warsaw, Poland, [2]Warsaw Medical University, Warsaw, Poland.

Among a group of disorders collectively known as the blepharophimosis-mental retardation syndromes, the most distinctive phenotype is presented by patients with Say-Barber-Biesecker-Young-Simpson syndrome (SBBYSS).
SBBYSS is a rare multiple congenital anomaly syndrome characterized by a distinctive facial appearance (severe blepharophimosis, immobile mask-like face, bulbous nasal tip, small mouth with a thin upper lip), skeletal problems (joint laxity, long thumbs and great toes, dislocated or hypoplastic patellae), hypothyroidism, and global developmental delay. Recent studies demonstrate that *de novo KAT6B* mutations causing SBBYSS occur either throughout the gene, or cluster in a more distal (3') region of exon 18.
We present a 16-year-old girl with the typical, clinically recognizable pattern of SBBYSS features and a novel c.5819delA (p.Gln1940Argfs*11) molecular variant of *de novo* origin. The deletion is within the highly conserved C-terminal region of *KAT6B* and causes frameshift and occurrence of premature stop codon.
Our patient with moderate psychomotor delay, hypotonia, hypothyroidism, dislocated patellae and long thumbs also presents all of the facial features described so far in SBBYSS.
Our data contribute to the current knowledge on allelic heterogeneity observed at the *KAT6B* locus in classical SBBYSS and provide further evidence on the genotype–phenotype correlation in this rare disorder, expanding the locus-specific mutation database established so far. Dysmorphologists should keep this syndrome in mind during evaluation of patients with blepharophimosis and mild mental retardation, as the likelihood of identifying a *KAT6B* mutation in individuals with typical SBBYSS is high.
The study was financed by NCN Project Harmonia 4 No. UMO-2013/08/M/NZ5/00978

PM11.098
An atypical presentation of OFD1 syndrome

A. Accogli[1,2], *M. Pacetti[3,2], P. Fiaschi[3,2], A. Consales[1], M. Pavanello[1], V. Capra[1];*
[1]Istituto Giannina Gaslini, Genova, Italy, [2]Università degli Studi di Genova, Genova, Italy, [3]Ospedale San Martino-IST, Genova, Italy.

Introduction: Morning glory disc anomaly (MGDA) is a congenital abnormality of the optic disc reported as an isolated condition or associated with various anomalies including basal encephalocele and moyamoya disease. However the co-occurrence of these three entities is rare and the pathogenesis is still poorly understood. On the contrary Oral-Facial-Digital Syndrome type 1 (OFD1; OMIM 311200) is a well recognized X-linked-dominant developmental disorder belonging to ciliopathies. Among brain structural anomalies in OFD1, both sphenoidal encephalocele and moyamoya disease have never been reported.
Materials and Methods: The only child showed bilateral MGDA and coloboma, sphenoidal encephalocele, moyamoya disease and mild clinical features of OFD1.
Results: Sequence analysis of *OFD1* gene detected a *novel* hemizygous missense variant, c.1081T>C, resulting in p.Tyr361His mutation change.
Conclusions: Similarly to other ciliopathies, inactivation of *Ofd1* transcript is associated with defective Sonic hedgehog (Shh) pathway. *Ofd1* inactivation in zebrafish produces several malformations including retinal coloboma, whereas in mutant mouse it exerts a crucial role in developing of forebrain through the regulation of Shh signaling. On the other hand Shh is a critical pathway yielding a pleiotropic effects in many developmental processes such as in modulating the closure of the buccohypophyseal canal and the vessel formation. Here we report the first case of bilateral MGDA and coloboma, sphenoidal encephalocele and moyamoya disease due to a *novel* missense mutation in *OFD1* gene contributing to expand the phenotype of OFD1. Moreover we speculate on a possible pathogenic role of *OFD1* gene in patients with moyamoya disease, basal encephalocele and MGDA.

PS11.099
Haploinsufficiency of PCSK1 in a father and a son without obesity

D. Niedrist, *B. Oneda, R. Baldinger, R. Asadollahi, A. Rauch;*
Institute of Medical Genetics, University of Zurich, Zürich-Schlieren, Switzerland.

The PCSK1 gene was within the first genes implicated in the literature in severe early-onset obesity. Autosomal recessive congenital PCSK1 deficiency was shown to cause neonatal diarrhea and midchildhood severe obesity. Recently Philippe et al. (2014) also reported nonsense mutations in PCSK1 likely causing dominantly inherited human obesity.
We now report on a father and son with haploinsuffiency of PCSK1 without obesity. The 2 year-old boy was referred to our outpatient clinic because of psychomotor developmental delay. In the boy and his father we detected the microscopically balanced translocation : 46,XY, t(5;12)(q15;p13.1). By chromosomal microarray analyses (CMA) there was a deletion of about 157kb in the chromosomal band 5q15 encompassing the PCSK1 gene. The translocation was de novo in the father with behavioural problems in school and epileptic seizures in childhood until puberty. When we saw the boy at the age of 17 months his measurements were within the normal percentiles. The paternal grandmother reported the psychomotor development of the boy as comparable with the one his father had. The BMI of the father at the age of 40 was 25.2 kg/m^2.
The only gene deleted by CMA in this family was PCSK1. This gene is up to now not reported to be involved in developmental delay. The breakpoint on chromosome 12p13, however, may be responsible for the borderline developmental delay in this family: possibly involved gene: GRIN2B (12p13.1, mental retardation, autosomal dominant 6).
In our family there was a haploinsufficiency of PCSK1 and definitively no obesity supporting recessive inheritance of obesity in PCSK1 defects.

PM11.100
Penta X syndrome diagnosed in a newborn girl

S. Markholt[1], *S. E. B. Thim[1], B. Høst[1], J. Graakjaer[2], A. Skytte[1];*
[1]Aarhus University Hospital, Aarhus, Denmark, [2]Vejle Hospital, Vejle, Denmark.

We present a detailed prenatal and postnatal clinical description and extended DNA analyses in a case of Penta X syndrome diagnosed in a newborn girl.
The pregnancy was uneventful until gestational age (GA) week 28, there were normal fetal ultrasonographic examination at GA 13+1 weeks, and no abnormalities diagnosed at the 20 weeks prenatal anomaly scan. At week 28 polyhydramnios was suspected leading to extra prenatal scans. Which revealed polyhydramnios, dilated intestines, suggesting possible intestinal atresia, IUGR with -23,1% to -30,7% weight deviation and short femora (-2,8 SD). Because of suspected brain sparing the birth was initiated at GA 38+3 weeks and the girl was born with a birth weight of 2,484 g.
She had hypertelorism, abnormal configuration of the ears, cleft palate (in the soft palate), bilateral single transverse palmar creases, bilateral clinodactyly, short lower limbs compared to the rest of the body, mild hypotonia and a shrill animal like cry. Echocardiography showed mild stenosis of the right pulmonary artery and mild coarctation of aorta, none of which were thought to have clinical significance.
Quantitative fluorescent polymerase chain reaction (QF-PCR) was performed on DNA extracted from a peripheral blood sample and showed a diallelic pentasomic pattern in 2 of 3 markers on the X-chromosome. The third marker was borderline within normal range. Chromosome analysis with Q-

banding was performed on cultured peripheral blood lymphocytes from the patient and revealed the karyotype 49,XXXXX in all examined metaphases. Results of the extensive molecular analyses including parental analyses and SNP-array will be presented.

PS11.101

Clinical and molecular characterisation of Pierre Robin Sequence with additional anomalies ("PRS-Plus")

J. Xu[1], N. Baker[1], S. Raj[1], N. Kilpatrick[1], T. Penington[1,2], P. G. Farlie[1], **T. Y. Tan**[3,2]*;*
[1]Murdoch Children's Research Institute, Parkville, Melbourne, Australia, [2]Royal Children's Hospital, Parkville, Melbourne, Australia, [3]Victorian Clinical Genetics Services, Parkville, Melbourne, Australia.

Pierre Robin Sequence (PRS) comprises micrognathia, cleft palate, glossoptosis and upper airway obstruction affecting 1 in 6000 neonates, often resulting in airway and feeding difficulties. Although syndromic forms of Pierre Robin Sequence are well known, the full phenotypic spectrum of non-syndromic PRS is less defined. We sought to provide an accurate phenotypic characterisation of a large cohort of 141 non-syndromic Pierre Robin Sequence patients managed at the Royal Children's Hospital in Melbourne from 1985 to 2012. We categorised patients into either "Isolated PRS" (n=83) or "PRS-Plus" (n=58) groups. Patients in the PRS-Plus group had additional anomalies beyond the craniofacial system, with the musculoskeletal and ocular systems most commonly involved. Choanal stenosis/atresia was the single most common co-existing craniofacial malformation. Compared to those with isolated PRS, PRS-Plus patients had worse outcomes at birth and during the neonatal period, with a higher proportion being born small-for-gestational-age, have failure to thrive and require surgical intervention for airway and feeding. A subset of patients with a family history of cleft and/or a musculoskeletal anomaly was selected for targeted DNA sequencing of the SOX9 conserved non-coding elements (CNEs) at chromosome 17q24. In one patient with PRS, talipes equinovarus and pectus excavatum, a single nucleotide substitution was identified in CNE1, at a consensus GATA1 transcription factor binding site; however the functional significance of this variant is currently being investigated.

PM11.102

Somatic mosaicism for the mutation in PIK3CA and significant activation of Akt/mTOR signaling in a girl with segmental overgrowth; Clinical report of PROS

S. MIZUNO[1]*, Y. Enokido[2], T. Morishita[3], N. Hanada[4], Y. Muramatsu[1], N. Wakamatsu[5];*
[1]Central Hospital, Aichi Human Service Center, Kasugai, Aichi, Japan, [2]Institute of developmental research, Aichi Human Service Center, Kasugai, Aichi, Japan, [3]Aichi Children's Health and Medical Center, Obu, Aichi, Japan, [4]Hanada children's clinic, Okazaki, Aichi, Japan, [5]Institute of Developmental Research, Aichi Human Service Center, Kasugai, Aichi, Japan.

Here, we report the case of a girl who presented with hyperplasia of the lower extremities, macrodactyly, and multiple lipomatosis. We made a clinical diagnosis of PIK3CA-related overgrowth, which was subsequently confirmed by direct gene sequencing. The patient was born to healthy unrelated parents at 39 weeks of gestation. At birth, she presented with enlarged syndactyl toes, a broad foot, and a mass in her inguinal region. Her feet rapidly increased in size to almost twice the average size, and more so for her left foot. Adipose tissue was reduced in her upper extremities and torso. She underwent surgery several times to reduce adipose tissue in order to manage overgrowth. The patient's phenotype differed from that of Proteus syndrome, Klippel-Trénaunay-Weber syndrome, and CLOVES syndrome as follows. Her facial appearance was symmetric and nondysmorphic, overgrowth was limited to the lower extremities, her skin showed no nevi or hemangiomas, and no cerebriform skin was observed on hypertrophic regions (characteristic of Proteus syndrome). Histological analysis of the resected tissue revealed mature adipose tissue of normal morphology. We identified the patient as having the recently proposed clinical entity PROS (PIK3CA-related overgrowth spectrum). Using direct sequencing, a PIK3CA mutation (p.His1047Arg) was identified in DNA obtained from dissected hyperplasic adipose tissue; this was absent in DNA obtained from her blood lymphocytes. Significant activation of Akt/mTOR signaling was also observed in the patient's adipose tissue. This report contributes to the dysmorphological diagnosis of the phenotypic spectrum of mosaic PIK3CA mutations.

PS11.103

Testing strategies for PIK3CA-associated overgrowth disorders.

A. Tanska, *P. Rehal, J. Bell;*
West Midlands Regional Genetics Service, Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom.

Mutations in the PIK3CA gene have been found to cause several conditions related to overgrowth of tissues. These conditions include disorders of the brain such as Megalencephaly-Capillary malformation syndrome (MCAP) and hemimegalencephaly as well as segmental body overgrowth disorders like fibroadipose hyperplasia or Congenital, Lipomatous, Overgrowth, Vascular Malformations, Epidermal Nevi and Spinal/Skeletal Anomalies and/or Scoliosis syndrome (CLOVE). PIK3CA-associated disorders are caused by postzygotic activating mutations which are present in the mosaic form primarily in affected tissues of the body. The most frequent somatic mutations in PIK3CA identified in overgrowth syndromes occur in exons 9 and 20 (occasionally referred to as exons 10 and 21).
We routinely sequence exons 9 and 20 of PIK3CA using both Sanger and Next Generation Sequencing (NGS) methodologies. Here, we present our diagnostic strategy for a patient referred with clinical features suggestive of MCAP syndrome. Molecular analysis performed on DNA extracted from blood of the MCAP patient has produced results which required subsequent evaluation. Identification of a low-level somatic mutation is challenging and may require more than one tissue to be tested. Moreover lack of detection of a mutation in PIK3CA gene does not exclude the clinical diagnosis of PIK3CA-associated disorders due to limitations in detecting mosaicism from different tissue samples.
Results of further investigation of this case together with the potential role of NGS technologies in a diagnostic strategy for mosaic disorders will be presented.

PS11.105

Trisomy of 14q32 in a patient with Prader-Willi Syndrome-like phenotype

I. Garin[1], I. Llano[2], N. Olabarrieta[3], C. Hernando[4], I. Lesende[5], O. Villar[4], **B. Gener**[2]*, G. Perez de Nanclares[1];*
[1]Molecular (Epi)Genetics Lab, Research Unit, Hospital Universitario Araba, Vitoria-Gasteiz, Spain, [2]Servicio de Genética, BioCruces Health Research Institute, Hospital Universitario Cruces, Barakaldo, Spain, [3]Servicio Neuropediatria, Hospital Universitario Cruces, Barakaldo, Spain, [4]Qgenomics, Quantitative Genomic Medicine Laboratories, Barcelona, Spain, [5]Health in Code, Hospital Marítimo de Oza, A Coruña, Spain.

Introduction: The main clinical features of Prader-Willi Syndrome (PWS) are hypotonia, hyperphagia, obsesity, hypogonadism, short stature, small hands and feet, mental disabilities, and behavioral problems. Signs and symptoms of PWS could also be found in patients who show other types of chromosomal abnormalities, among others Temple Syndrome (mat14UPD).
Materials and Methods: We report a case referred for genetic study with clinical suspicious of PWS due to the presence of hypotonia, hyperphagia, mood fluctuations, temper tantrums and developemental delay. 15q11 MS-MLPA test was normal so 14q32 MS-MLPA was carried out. Microsatellites of 14q32 region, CGH array and FISH study were analysed. Finally, deep genome sequencing of the 14q32 region was performed.
Results: The patient showed a gain of methylation and copy at MEG3-DMR. The microsatellites study revealed that the patient presented both paternal and one maternal chromosomes. FISH study of the patient pointed out that added copy could have been incorporated in tandem. CGH array and deep sequencing of the region revealed the exact boundaries of the insertion of the genomic extra material. Parents showed no (epi)genetics alterations of this region, so de novo origin was inferred.
Conclusions: We report a patient with an interstitial trisomy of 14q resulting from the insertion of part of 14q32 region of the paternal allele. It seems that the rearranged genomic segment was flanked by homologous low copy repeat (LCR) structures. These LCR could have acted as recombination substrates for non-allelic homologous recombination, leading to the gain of dosage of the region analyzed.
Grants:[PI13/00467;CP03/0064;SIVI 1395/09 to GPdN]

PM11.106

Primary amenorrhea, visual impairment and intellectual disability in a girl with a complex rearrangement involving 5q33.3 and 9q21.2 microdeletions

G. Kayhan[1]*, M. A. Ergun[1], T. Liehr[2], M. Yirmibes Karaoguz[1], E. F. Percin[1];*
[1]Medical Genetics Department, Gazi University Hospital, Ankara, Turkey, [2]Institute of Human Genetics, Jena University Hospital, Jena, Germany.

Case: We report a 21 year-old girl with primary amenorrhea, speech delay, mild intellectual disability, visual impairment, clinodactyly and low hairline. Total testosterone and 17 OH-progesteron levels were slightly increased. The other hormonal profile, brain MRI and pelvic USG were normal.
Methods and results: A cytogenetically balanced de novo complex chromosome rearrangement between chromosome 5 and 9 was detected by GTG and multicolor banding (MCB) techniques: 46,XX,der(5)(5pter->5q13.3::5q33-

>5q13.3::9q22.3->9q21.2::5q33->5qter),der(9)
(pter->q21.2::q22.3->qter) dn. Affymetrix 2.7K SNP array revealed 0.98 Mb and 0.94 Mb deletions on two of the breakpoint regions 5q33.3 and 9q21.2, respectively: arr 5q33.3(158,709,846-159,688,769)x1,9q21.2(79,573,426-80,513,997)x1. Completely deleted genes were IL12B, ADRA1B, TTC1, PWWP2A, FABP6, FOXB2, VPS13A, GNA14 and the disrupted genes were UBLCP1, CCNJL and GNAQ in these regions.
Conclusions: Somatic mosaic mutations of GNAQ cause Sturge-Weber Syndrome which may include intellectual disability. In DECIPHER, intellectual disability and speech delay have been reported in many patients with larger deletions on 9q21 overlapping with FOXB2, VPS13A, GNA14, GNAQ and in a patient with a deletion involving last exon of GNA14 and first two exons of GNAQ. Thus, disruption or haploinsufficiency of GNAQ and GNA14 may be related to intellectual disability. In addition, these changes may also be associated with primary amenorrhea and visual loss, because GNAQ and GNA14 play role in GnRH, estrogen, relaxin, androgen, serotonin and visual signaling pathways. However, it should be considered that the other breakpoints may also contribute to the phenotype.

PS11.107

Efficient clearance of progerin through autophagy induction and SRSF-1 downregulation under MG132 treatment in Hutchinson-Gilford progeria syndrome

K. Harhouri[1], *C. Navarro[1], D. Depetris[1], M. Mattei[1], X. Nissan[2], P. Cau[1,3], A. De Sandre-Giovannoli[1,4], N. Lévy[1,4];*
[1]Aix Marseille Université, Inserm UMR_S 910 - GMGF, Marseille, France, [2]CECS, I-STEM, AFM, Institut des cellules Souches pour le Traitement et l'Etude des maladies Monogéniques, Evry, France, [3]APHM, Hôpital d'Enfants de la Timone, Service de Biologie Cellulaire, Marseille, France, [4]APHM, Hôpital d'Enfants de la Timone, Département de Génétique Médicale, Marseille, France.

Hutchinson-Gilford progeria syndrome (HGPS; OMIM #176670) is an extremely rare premature and accelerated aging disease which affects 1 in 4-8 million children with symptoms resembling normal adult aging, including growth impairment, thin skin, loss of subcutaneous fat, alopecia, osteoporosis and cardiovascular disease leading to shortened lifespan and death at a mean age of 13.5 years. HGPS is caused by a de novo point mutation (c.1824 C>T, p.G608G) within exon 11 of the LMNA gene encoding A-type lamins. This mutation activates a cryptic donor splice site in exon 11 that leads to the deletion of 50 amino acids at its carboxy-terminal domain, resulting in a truncated and permanently farnesylated prelamin A called progerin. Accumulation of progerin is a hallmark of HGPS that affects the integrity of the nuclear scaffold, leading to nuclear blebbing and functional defects in cultured cells. We show that progerin is sequestered, together with other proteins (lamins B1/B2, emerin), into abnormally shaped Promyelocytic-Nuclear Bodies (PML-NB), identified as novel biomarkers in Progeria. MG132, inhibiting proteasome activity, induces progerin nucleocytoplasmic translocation after a transition through the nucleolus, and progerin degradation through macroautophagy. MG132 also strongly reduces progerin production through caspase-linked cleavage of SRSF-1 controlling prelamin A mRNA splicing. In vivo, through MG132 treatment, progerin expression decreases in skeletal muscle from LmnaG609G/G609G mice. Altogether, we demonstrate progerin clearance based on MG132 dual action and shed the light on a promising class of molecules towards an encouraging therapy for Progeria and related diseases.

PM11.108

Clinical manifestations of germline PTEN pathogenic mutations: A review of published cases with emphasis on phenotypic traits

K. Danielsson, *N. Larsson;*
Lund University, Lund, Sweden.

Background: Cowden syndrome is an autosomal dominantly inherited tumour predisposition syndrome with a prevalence around 1/200 000 in the European/USA population. It is associated with increased risk of developing malignant tumors including breast, thyroid and endometrial cancer. Germline mutations in PTEN gene are considered an underlying cause of the disease. However, 37% of mutation carriers do not fulfill clinical diagnostic criteria for any defined syndrome, and therefore a wider phenotype could be associated with pathologic mutations in PTEN.
Purpose: This study aimed to describe the comprehensive clinical phenotype associated with PTEN mutations, to examine potential genotype/phenotype correlations, and to evaluate the relevance of currently used clinical diagnostic criteria.
Method: A systematic review of published cases and observational articles was undertaken and clinical characteristics of described cases were compiled.
Results: 297 articles and abstracts describing 682 presumably unique individuals were identified in the study. Clinical traits included in established criteria for PTEN related syndromes occurred with high frequency. Patients with germline PTEN mutation displayed mixed polyposis as well as vascular malformations, and several novel traits were noted similar to observations seen in mouse models of PTEN deficiency. Germ cell/gonadal malignancies were significantly more prevalent among the study population compared to general population. Further, Cowden syndrome appeared to be diagnosed more frequently among females, and Bannayan-Riley-Ruvalcaba syndrome more frequently among males, potentially resulting from gender weighting in the diagnostic criteria.
Conclusion: The phenotype associated with PTEN mutations seem to be wider than believed, and further study is needed for understanding the prevalence of novel clinical characteristics among mutation carriers and their ramifications.

PS11.109

New mutations associated with Rasopathies identified by Sanger and next generation sequencing in a Central European population

M. Čižmárová[1], *K. Hlinková[1], L. Košťálová[2], Z. Pribilincová[2], S. Bertok[3], R. Bertalan[4], K. Poločková[5], H. Duba[6], L. Kovács[2], A. Hlavatá[2], D. Ilenčíková[2,6];*
[1]Laboratory of clinical and molecular genetics, 2nd Department of Pediatrics, University Children´s Hospital, Bratislava, Slovakia, Bratislava, Slovakia, [2]2nd Department of Pediatrics, University Children´s Hospital, Bratislava, Slovakia, Bratislava, Slovakia, [3]3Department of Endocrinology, Diabetes and Metabolic Diseases, University Children´s Hospital, Ljubljana, Slovenia, [4]2nd Department of Medicine, Faculty of Medicine, Semmelweis University, Budapest, Hungary, [5]Department of Pediatrics, Hospital with policlinic, Karviná, Czech Republic, [6]Department of Human Genetics, General Women´s and Children´s Hospital, Linz, Austria.

Introduction
Rasopathies represent a group of dysmorphic syndromes caused by mutations in RAS/MAPK signaling pathway, such as Noonan syndrome, Noonan syndrome with multiple lentigo, Costello, cardio-facio-cutaneous and neurofibromatosis-Noonan syndrome. These syndromes share clinical features including mainly short stature, specific cranio-facial features and heart defects. Therefor the diagnosis of Rasopathies is a difficult task.
Aim
Determination of genetic cause and description of genotype-phenotype correlation in patients with Rasopathy phenotype by Sanger and next generation sequencing.
Patients and methods
Mutation analysis of 14 genes associated with Rasopathies (PTPN11, SOS1, RAF1, BRAF, KRAS, HRAS, NRAS, MAP2K1, MAP2K2, SHOC2, CBL, NF1, RIT1 and SPRED1) was performed by Sanger and target sequencing using the HaloPlexTM Target Enrichment System on MiSeq sequencing platform in 48 patients from Central Europe - Slovakia (18), Slovenia (20), Hungary (3), Czech republic (2) and Austria (5). Patients were selected according to the scoring questionnaires oriented to the main clinical features of Rasopathies. Data were analyzed by ChromasPro and SureCall softwares.
Results
We identified mutations in 60% of examined patients (29/48) including 3 new variants (c.87+2T>C in SOS1, c.1175G>A in BRAF, c.490C>A in MAP2K1 genes) with potentially pathogenic effect on patient´s phenotype.
Conclusion
We contributed to enlargement of the mutation spectrum occuring in patients with Rasopathies and described the possible mutation effect on the phenotype.
This work was supported by Ministry of Health of the Slovak Republic under the project registration number
2012/21-UKBA-21.

PM11.110

Molecular findings in Spanish patient with RASopathies. Extending the analysis with prioritization methods

P. Carrasco Salas[1], J. M. Lezana Rosales[1], S. Carmona Tamajón[1], S. Franco Freire[2], C. Benito López[2], M. Martínez Atienza[3], S. Pedrinaci[3], C. Vázquez[4], **J. López Siles**[1];
[1]MGC Genetaq, Málaga, Spain, [2]Department of Genetics, Maternal-Fetal Hospital, Málaga, Spain, [3]Department of Genetics, Virgen de las Nieves Hospital, Granada, Spain, [4]Department of Genetics, Maternal-Fetal Insular Hospital, Las Palmas de Gran Canaria, Spain.

Introduction: RASopathies are caused by germline mutations in genes encoding protein components of the Ras-MAPK pathway.
Material and methods: First, 12 genes (*PTPN11, SOS1, RAF1, KRAS, SHOC2, NRAS, BRAF, MAP2K1, MAP2K2, HRAS, LRP1, CBL*) associated with the Ras-MAPK pathway were studied by next-generation sequencing (NGS) in 14 Spanish patients with clinical suspicion of RASopathies. A segregation test

was performanced in the patients' parents when they were available. Additional candidate genes were selected with an R custom script using PSIQUIQ library (Shannon P, 2015).

Results: In 3 patients, clinical diagnosis was molecularly confirmed in the first screening. Two cases are waiting for segregation study.

Using the script, more than 1000 candidate genes were obtained, based on several molecular interaction databases, using as query the previous 12 genes. Twenty-three genes with more than 5 interactions with query genes and/or more than 25 interaction methods reported, and availability in NGS capture kit used, were selected for the second screening. This additional screening revealed some variants of uncertain clinical significance (VUCS) in 8 patients.

Table 1. Heterozygous changes identified in patients samples.

Patient	Phenotype	1st screening*	Mutation origin	Clinical significance	2nd screening*
1	NS	*RAF1*: c.785A>G	No data	VUCS. Novel	*JAK3*: c.2164G>A *ERBB2*: c.1157C>A
2	NS	*PTPN11*: c.236A>G	No data	Pathogenic	*PIK3CG*: c.1076G>A *PIK3CG*: c.2496T>G

13	NS	Negative	-	-	Negative
14	NS	Negative	-	-	*JAK3*: c.452C>G

NS- Noonan syndrome.
CFC- Cardiofaciocutaneous syndrome.
* Transcripts according to HGMD.

Conclusion: Multi-gene analysis by NGS has improved the molecular diagnosis of RASopathies, but many cases still remain undiagnosed. Bioinformatics tools can propose new candidate genes related to these disorders as shown, but further studies are needed to confirm their causal effect.

PS11.111

Ring chromosome 22 in patients with multiple congenital anomalies

J. Vukajlovic[1], *S. Cirkovic*[1], *D. Radivojevic*[1], *T. Liehr*[2], *B. Dobric*[1], *N. Ilic*[1], *M. Miskovic*[1], *T. Lalic*[1], *M. Djurisic*[1];
[1]*Mother and Child Health Care Institute of Serbia, Belgrade, Serbia,* [2]*Institute of Human Genetics, Universitatsklinikum, Jena, Germany.*

Introduction: Ring 22 chromosome is a rare chromosomal aberration, with only ~100 cases reported and no consistent clinical picture. We present 3 cases with variable clinical phenotypes: RPM, microcephaly, hypotonia, ataxia.

Materials and Methods: Chromosomal analysis was done from cultured cells of PHA-stimulated lymphocytes from blood and cultured skin fibroblasts using GTG banding. Specific characterization of marker chromosome was done using multicolor fluorescent in situ hybridization (M-FISH).

Results: Two patients had aberrant karyotypes: 46,XX,r(22)(p12q13) and 46,XY,r(22)(p12q13), respectively. Third patient had aberrant mosaic karyotype: mos 46,XY,r(22)(p12q13)[44]/46,XY,dic r(22)(p12q13[6]). Cytogenetic analysis from this patient's skin fibroblasts showed presence of only one clone: 46,XY,r(22)(p12q13)[52]. Clinical features in patients with ring22 can be associated with 22q13.3 syndrome (Phelan McDermid syndrome) since the formation of ring22 is followed by terminal deletion of p and q arms. The last described patient had cells with dic r(22) causing presence of three copies of 22p12-22q13.2 region in minority (6/50) of peripheral blood lymphocytes. This aberration still might account for the CES (cat eye syndrome) features since it may have been present at a much higher frequency early in development and then subsequently lost.

Conclusion: Our report emphasizes the importance of cytogenetic and molecular-cytogenetic approach in order to better understand the spectrum of abnormalities in each case, and assess genotype-phenotype correlation.

PM11.112

The significance of RIT1 mutations in the etiology of Noonan syndrome: phenotype-genotype correlations in Polish patients

M. Pelc[1], *E. Ciara*[1], *M. Kugaudo*[1,2], *D. Jurkiewicz*[1], *D. Piekutowska-Abramczuk*[1], *J. Trubicka*[1], *K. Chrzanowska*[1], *M. Krajewska-Walasek*[1];
[1]*Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland,* [2]*Department of Child and Adolescent Psychiatry, The Medical University of Warsaw, Warsaw, Poland.*

Noonan syndrome (NS), a RASopathy which exhibits genetic and phenotypic heterogeneity, has been associated with germline mutations in 14 genes related to the RAS/MAPK signaling pathway, including recently discovered *RIT1* gene encoding a small GTPase from the RAS superfamily.

We present 6 new unrelated NS patients of Polish origin with 5 different pathogenic substitutions in conserved domains of RIT1: p.Ser35Thr, p.Ala57Gly, p.Ala77Ser, p.Phe82Leu, p.Gly95Ala. *De novo* occurrence has been confirmed in 4 cases, whereas p.Ala77Ser was identified in the patient's father, who also presented with NS phenotype. In our molecularly defined group of NS patients *RIT1* mutations constitute ~8% (6/76).

The clinical findings of our study largely agree with the literature, as the patients exhibited typical NS features, however, without intellectual disability, additionally, only 2/7 had short stature. It is worth noting that 4/6 patients suffered from postnatal lymphedema and other lymphatic disorders. Cardiac anomalies occurred in 4/7 individuals. The patient with p.Phe82Leu mutation died early due to the severe hypertrophic cardiomyopathy. In the affected father with p.Ala77Ser substitution teratoma maturum testis has been identified.

Our results, together with the recently published data concerning 4 other Polish individuals, introduce the largest group of NS patients of Caucasian origin with *RIT1* mutations. They contribute to the further delineation of molecular and clinical profile of *RIT1*-related NS and underline that *RIT1*, as the third most frequently affected gene in NS, should certainly be included into the diagnostic panels screening for RASopathy disorders.

The research was supported by projects: NCN UMO-2011/03/N/NZ2/00516, CMHI S140/2014.

PM11.114

Expanding EP300 mutational spectrum of Rubinstein-Taybi syndrome and literature overview

G. Negri[1], *P. Colapietro*[1], *D. Rusconi*[1], *D. Milani*[2], *M. T. Bonati*[3], *M. Priolo*[4], *L. Mazzanti*[5], **L. Larizza**[1,3], *C. Gervasini*[1];
[1]*Genetica Medica - Dipartimento di Scienze della Salute - Università degli Studi di Milano, Milano, Italy,* [2]*Unità di Pediatria ad alta intensità - Fondazione IRCCS Ca' Granda, Milano, Italy,* [3]*IRCCS Istituto Auxologico Italiano, Milano, Italy,* [4]*UOC Genetica Medica - Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy,* [5]*UO Pediatria - Dipartimento Scienze Medico Chirurgiche Policlinico - Ospedaliero Universitario S.Orsola Malpigh, Bologna, Italy.*

Rubinstein-Taybi syndrome (RSTS, #180849, #613684) is a rare congenital neurodevelopmental disorder characterized by postnatal growth deficiency, typical skeletal abnormalities, dysmorphic features and intellectual disability. Mutations in two genes, CREBBP (16p13.3) and EP300 (22q13.2), encoding two homologous transcriptional co-activators, have been identified in ~55% and ~8% of affected individuals, respectively.

To date, only 14 EP300-mutated RSTS patients have been described, six in our laboratory, and 12 additional mutations are reported in the LOVD database, summing up to 26 different alterations.

EP300 analysis of CREBBP-negative RSTS patients led to the identification of five novel further inactivating de novo mutations: an exons 17-19 deletion and two stop mutations in exons 23 and 28 respectively (c.3829A>T/p.K1276* and c.4585C>T/p.R1528*), a duplication in exon 29 (c.4640dupA/p.N1547Kfs*3) and a IVS9 splicing mutation (c.1878-12A>G).

RNA analysis on patients carrying the c.4585C>T/p.R1528* and c.4640dupA/p.N1547Kfs*3 mutations, which affect the KAT domain, revealed the presence of both the WT and the aberrant transcript.

All EP300-mutated patients show a convincing, although mild, RSTS phenotype including typical broad thumb and big toes, craniofacial dysmorphisms, prenatal and postnatal growth delay with a moderate to mild intellectual disability. Organ malformations were rare and, when present, always isolated.

This study, expanding the RSTS EP300 mutational spectrum to 31 alterations and providing a clinical description of five additional patients, will enhance RSTS-EP300 mutated patients hallmarks identification and improve the clinical practice allowing a better genotype-phenotype correlation doing.

DOCK4 mutated in Seckel syndrome

R. Oegema, *R. Schot, D. Heijsman, L. van Unen, F. W. Verheijen, G. M. S. Mancini; Erasmus MC, Rotterdam, Netherlands.*

Seckel syndrome is a genetic heterogenic disorder caused by mutations in several genes involved in the regulation of the cell cycle and DNA repair. Mutations in each gene are extremely rare and only account for the diagnosis in single or a small number of families.
Two sisters from a Turkish consanguineous family presented with primary microcephaly (-8 SD), short stature of prenatal onset (-5 SD), behavioral issues, and intellectual disability.
Their facial features were suggestive of Seckel syndrome. Homozygosity mapping (using Affymetrix 6.0 SNP arrays) identified 5 regions; 1p34.2, 2q22.2-2q22.3, 3p24.1-p24.2, 7q31.1-q32.3 and 18q21.33q22.3. No known Seckel genes are located within these regions. With whole-genome sequencing (Complete Genomics) the homozygous *DOCK4* c.3470G>A variant was identified, leading to a putatively deleterious amino acid substitution (p.R1157H).
The variant was absent from dbSNP and 414 Mediterranean control chromosomes. *DOCK4, dedicator of cytokinesis 4,* encodes a Rac1 guanine exchange factor (GEF), which is involved in the PDGF-dependent cell migration through modeling of the actin cytoskeleton. DOCK4 is highly expressed in brain and during embryonic development and it has been proposed to play in role in neurite differentiation and extension. We stimulated fibroblasts from one of the affected individuals with PDGF-BB, and stained the fixated cells with the F- actin marker rhodamine phallodoidin. This showed a poorly organized actin network in patient fibroblasts compared to control cells. A PDGF-responsive migration assay on patient cells is pending. Confirmation of our data in additional families will encourage further studies on the role of this gene in human growth and brain development.

PM11.116

‚Serpentine-like syndrome' - a very rare multiple malformation syndrome characterised by brachioesophagus and vertebral anomalies

A. Beleza-Meireles[1], *P. Steenhaut*[2], *L. Peetermans*[3], *P. Clapuyt*[4], *P. Bernard*[2], *C. Debauche*[5], *Y. Sznajer*[1];
[1]*Centre de Génétique Humaine, Cliniques universitaires St. Luc, Tour R. Franklin (niv. 0), Belgium,* [2]*Obstetrics Department, Cliniques universitaires St. Luc, Avenue Hippocrate 10, Woluwe-Saint-Lambert, Belgium,* [3]*Neonatalogy Unit, Department of Paediatrics, Cliniques universitaires St. Luc, Avenue Hippocrate 10, Woluwe-Saint-Lambert, Belgium,* [4]*Radiology Department, Cliniques universitaires St. Luc, Avenue Hippocrate 10, Woluwe-Saint-Lambert, Belgium,* [5]*Neonatalogy Unit, Department of Paediatrics, Cliniques universitaires St. Luc, Avenue Hippocrate 10, 1200 Woluwe-Saint-Lambert, Belgium.*

"Serpentine-like syndrome" is a severe and rare multiple malformation syndrome characterised by brachioesophagus with secondary intrathoracic stomac associated with cervical (sometimes more extensive) congenital vertebral anomalies (failure of fusion, segmentation and formation, or combinations of these). Other associated anomalies have been described such as malposition and herniation of other abdominal organs.
We report the case of a baby girl born prematurely (29wog) due to polyhydramnios. She presented IUGR, craniofacial dysmorphism, median cleft lip and short neck. She had a midline diaphragmatic hernia, a very short oesophagus. The stomach, spleen and part of the pancreas were located in the thorax. She was also diagnosed with a large rachischisis from cervical to thoracic spine, with major defect of the anterior arches and a cyst of the spinal cord. The lobulation of the lungs was abnormal. Both the echocardiogram and the transfontanellar ultrasound were normal. Most of these malformations have been observed prenatally. SNP array was normal. She died at age 12 days. No relevant family history was registered.
To our knowledge, our patient represents the 7th report of a patient with "Serpentine-like syndrome". Brachioesophagus and congenital vertebral anomalies (in particular rachischisis) are the cardinal features of this multiple congenital malformations syndrome. All cases have been sporadic so far and the cause was not found in any of them. It is likely that this condition originates during early embryonic development. We believe that the specificity of the presentation as well as the similarities between cases suggests a common, yet to identify, genetic cause, probably involving developmental „toolkit" genes or related pathways.

PS11.117

Novel myopathy in a newborn with severe thoracic dysplasia caused by mutations in the SBDS-gene. Further delineation of the phenotypic spectrum of Shwachman-Diamond syndrome

A. Topa[1], *M. Tulinius*[2,3], *A. Oldfors*[4], *C. Hedberg Oldfors*[4];
[1]*Department of Clinical Pathology and Genetics, Sahlgrenska University Hospital, Gothenburg, Sweden,* [2]*The Queen Silvia Children's Hospital, Gothenburg, Sweden,* [3]*Department of Paediatrics, University of Gothenburg, Gothenburg, Sweden,* [4]*Department of Pathology, University of Gothenburg, Gothenburg, Sweden.*

Shwachman-Diamond-Bodian syndrome (SDS) is a pleiotropic disease, in which the main features are bone marrow dysfunction and pancreatic insufficiency. Skeletal changes can occur in a variable degree and in rare cases as severe congenital thoracic dystrophy. We report on a new-born baby boy with asphyxia, narrow thorax and severe hypotonia initially suggesting a neuromuscular disease. The muscle biopsy showed myopathic changes with prominent variability in muscle fibre size and abnormal expression of developmental isoforms of myosin. The myofibrils showed focal loss and disorganization of myofilaments and thickening of the Z-discs including some abortive nemaline rods. The boy became permanently dependent on assisted ventilation. Pancreatic insufficiency has subsequently been evidenced explaining the malabsorption and failure to thrive. Except transitory thrombocytopenia and leukopenia, no other major hematologic abnormalities were noted. He had bilateral nephrocalcinosis with preserved renal function. Transitory liver dysfunction with increased transaminases and parenchymal changes on ultrasound were registered. The clinical diagnosis was molecularly confirmed by detection of compound heterozygous mutations in the SBDS gene using whole-exome sequencing: a recurrent intronic mutation causing aberrant splicing (c.258+2T>C) and a novel missense variant in a highly conserved codon (c.41A>G, p.Asn14Ser) considered to be damaging for the protein structure by in silico prediction programs. The parental carrier status has been confirmed. This case illustrates the challenges in differential diagnosis of pronounced neonatal hypotonia with asphyxia and highlights the muscular involvement in SDS. To our knowledge, this is the first report of evidenced myopathy in a patient with clinically and molecularly confirmed SDS.

PM11.118

Molecular analysis of a novel intragenic deletion in GPC3 in three cousins with Simpson-Golabi-Behmel syndrome

R. Hollstein[1], *J. Schmidt*[2], *G. Gillessen-Kaesbach*[2], *F. J. Kaiser*[1];
[1]*Sektion für Funktionelle Genetik am Institut für Humangenetik, Universität zu Lübeck, Lübeck, Germany,* [2]*Institut für Humangenetik, Universität zu Lübeck, Lübeck, Germany.*

Simpson-Golabi-Behmel syndrome (SGBS) is an X-linked recessive overgrowth syndrome, characterized by pre/postnatal overgrowth, distinctive craniofacial features, a broad spectrum of congenital malformations, intellectual disability (ID) of variable degree and an increased risk for embryonal tumors. SGBS is caused by deletions, duplications and point mutations in *GPC3*, encoding a membrane associated cell surface heparan sulfate proteoglycan named glypican 3. GPC3 plays essential roles in regulation of cell growth signaling and cell division. Several large intragenic deletions of *GPC3* detected by array-CGH and PCR analysis of genomic DNA but so far not on mRNA level have been reported. Here we report on a family with three affected cousins who display typical clinical features of SGBS, such as overgrowth, accessory nipples, hypertelorism and ID. By initial microarray-CGH we identified a deletion of approximately 30-50 kb that includes at least one exon of *GPC3*. By subsequent Sanger sequencing of genomic DNA we could map the chromosomal breaking points to define a deletion of 43,617 bp including exons 6 and 7 of the *GPC3* gene. RT-PCR analysis on RNA derived from whole blood could further confirm the deletion of both exons on transcript level. This loss of two exons results in a frameshift and a premature stop.
Based on our results we have established a breakpoint spanning PCR that could also identify the mutation in the mothers and grandmother of the patients. Thus we provide a molecular test that allows accurate genetic counselling and prenatal diagnosis for this family.

An unexpected diagnosis of Troyer syndrome in two brothers with a Silver-Russell syndrome-like phenotype

A. Wischmeijer[1,2], *A. Tranchina*[1], *E. Scarano*[3], *F. Tamburrino*[3], *A. Perri*[3], *D. M. Cordelli*[4], *R. Bergamaschi*[5], *M. Seri*[1], *C. Graziano*[1], *R. Zuntini*[1], *E. Bonora*[1], *L. Mazzanti*[3];
[1]*Medical Genetics Unit, Policlinico S.Orsola-Malpighi, University of Bologna, Bologna, Italy,* [2]*Clinical Genetics Unit, Arcispedale S. Maria Nuova - Istituto di Ricovero e Cura a Carattere Scientifico, Reggio Emilia, Italy,* [3]*S.S. di Malattie Rare e Sindromologia, Dipartimento della Donna, del Bambino e delle Malattie urologiche, Policlinico S.Orsola-Malpighi, University of Bologna, Bologna, Italy,* [4]*Pediatric Neurology Unit, Policlinico S. Orsola-Malpighi, University of Bologna, Bologna, Italy,* [5]*Pediatric Emergency Unit, Policlinico S.Orsola-Malpighi, Bologna, Italy.*

Our laboratory received independent requests for UPD7 testing in two boys with clinical suspicion of Silver-Russell syndrome (SRS), a normal ICR1 methylation pattern of chromosome 11p15, normal karyotype; UPD7 was not

confirmed. The patients turned out to be brothers, sons of first-degree cousins from Morocco with irrelevant family history.
The sibs, 3 and 5 years-old, presented pre- and postnatal growth retardation, developmental delay with predominant speech impairment, hypotonia and joint hyperlaxity, happy demeanor but no clear walking difficulties. Physical evaluation showed relative macrocrania, prominent maxilla, pectus excavatum, flat feet.
Considering parental consanguinity and a difficult differential diagnosis, whole exome sequencing was performed, which led to the identification of a novel homozygous variant c.892dupA in the SPG20 gene in both affected sibs. This variant causes a premature stop codon in spartin, the protein encoded by SPG20. Parents are heterozygous carriers of this variant, that is absent from large control databases (ESP, ExAc).
Mutations in SPG20 have been reported in Troyer syndrome, an autosomal recessive disorder, mainly characterized by progressive spastic paraparesis, pseudobulbar palsy, distal amyotrophy, developmental delay, and short stature, with onset in early childhood.
A neurologic examination, performed after this finding, showed lower limb muscular hypotrophy with mild distal hypertonus and intra-rotated feet when running in both sibs.
The mutation therefore seems causative of the patients' phenotype.
Even if it is a rare condition, Troyer syndrome should be considered in patients with syndromic short stature (SRS-like) and developmental delay, for prognostic and counseling issues.

PM11.120

Potocki-Lupski syndrome due to a small supernumerary marker chromosome derived from chromosome 17

O. S. Kurinnaia[1,2,3], *S. G. Vorsanova*[1,2,3], *M. A. Zelenova*[1,2,3], *V. O. Sharonin*[1], *Y. B. Yurov*[1,2,3], *I. Y. Iourov*[1,2,4];
[1]*Mental Health Research Center, RAMS, Moscow, Russian Federation,* [2]*Research and Clinical Institute for Pediatrics at the Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*The State Educational Institution of Professional Training under the Federal Agency of Health Care and Social Development, Moscow, Russian Federation.*

Potocki-Lupski syndrome (PLS) is usually caused by the chromosome 17 duplications at 17p11.2. However, there are rare cases of this syndrome originating from chromosome rearrangements producing partial trisomy 17p encompassing the critical region. Here, we present a 4-year-old girl with a developmental delay, language impairment, symptomatic epilepsy, behavioral problems, congenital corneal opacity of the right eye, and dysmorphic features mimic PLS facial appearance. Cytogenetic analysis has revealed a supernumerary marker chromosome. Molecular cytogenetic analysis by SNP array molecular karyotyping and FISH has indicated this marker chromosome to be derived from chromosome 17. This small supernumerary marker chromosome (sSMC) was detected in about 60% of cells. SNP array and FISH showed approximately the same percentages of abnormal cells. Molecular karyotyping has shown that sSMC was composed of a genomic region corresponding to 17p11.2q11.1 (8.5 Mb) and affected 164 genes. sSMC was larger than commonly reported duplications (3.7 Mb). In the available literature, there have been only 3 reports describing supernumerary "marker" chromosomes 17 in PLS. Interestingly, the present case exhibited a derivative chromosome affecting larger genomic region as to those previously reported. The latter seems to be key explanation of clinical manifestations additional to PLS phenotype. Finally, this case exemplifies that sSMCs addressed through SNP array and FISH represent an attractive perspective for genotype-phenotype correlations. Supported by a grant from the Russian Science Foundation (#14-15-00411).

PS11.121

Supernumerary ring chromosome 7 in mosaic. Molecular cytogenetic analysis and clinical findings.

E. Margarit[1], *M. Obón*[2], *L. Rodríguez*[1], *A. Soler*[1], *Y. Viedma*[1], *A. Sánchez*[1];
[1]*1Biochemistry and Molecular Genetics.and IDIBAPS, Hospital Clínic, Barcelona, Spain,* [2]*Universitary Hospital Dr Josep Trueta, Girona, Spain.*

Supernumerary ring chromosomes cause genomic imbalance and can be associated to an abnormal phenotype depending on the gene content. It is important to identify and characterize the extra chromosome composition in order to perform phenotype-genotype correlations. Only thirteen patients with a supernumerary pericentromeric ring (7) chromosome have been reported to date. Among them, language delay and poor expressive speech performance are frequently reported. We report a patient with a de novo supernumerary r(7) chromosome present in 56% of lymphocytes, found by conventional cytogenetic analysis in a 19 years-old girl referred for low IQ, disturbed behaviour and a peculiar facial phenotype. Subsequent array-CGH analysis detected a 25 MB duplication encompassing the pericentromeric region 7p11.2-7q21.11. Based on the array-CGH results, the gene content of the r(7) chromosome was determined. The 7q11.23 region included in the ring chromosome has been associated to the Williams-Beuren syndrome when deleted (OMIM #194050) and to the duplication 7q11.23 syndrome (OMIM #609757). This duplication causes a recognizable phenotype characterized by language delay and mild craniofacial anomalies, showing variable expressivity. In some cases, the genetic imbalance is inherited from one of the normal parents. Clinical assessment of our patient showed some minor facial dysmorphisms, such as a narrow flat front, almond-shaped palpebral fissures, small mouth, thin lips and pointed chin, besides a central obesity. Psychological tests disclosed an IQ in the low limit of normality, showing variable performances in different areas. Aggressive behaviour and low social skills were also noted. Phenotype-genotype associations are discussed.

Genetic Susceptibility of Thalidomide Teratogenesis: study of variants in developmental genes in humans

L. R. Fraga[1,2], *T. W. Kowalski*[1], *L. T. Rodrigues*[1], *M. H. Hutz*[1], *M. T. V. Sanseverino*[1,3], *L. Schuler-Faccini*[1,3], *F. S. L. Vianna*[1,3,4];
[1]*Post-graduation program of Genetics and Molecular Biology – Federal University of Rio Grande do Sul, Porto Alegre, Brazil,* [2]*Current address: PhD student in School of Medical Sciences, Institute of Medical Sciences. University of Aberdeen. Scotland, Aberdeen, United Kingdom,* [3]*Teratogen Information Service, Medical Genetics Service, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil,* [4]*Post-graduation Program in Epidemiology – Federal University of Rio Grande do Sul, Porto Alegre, Brazil.*

Introduction: Thalidomide remains infamous for being a teratogen, causing severe damage to embryos exposed during early pregnancy. Remarkably Thalidomide is currently used to successfully treat conditions like Leprosy complications and Multiple Myeloma worldwide. Yet, surprisingly, how thalidomide caused teratogenesis is still not fully resolved. Many theories have been put forward, some of the widely accepted ones include induction of oxidative stress, angiogenesis inhibition and disruption of Cereblon E3 ubiquitin ligase complex which may alter molecular pathways involving developmental genes resulting in thalidomide embryopathy (TE). **Objective:** To identify if genetic variants of susceptibility to TE in developmental genes can be detected in subjects with TE. **Methods:** We compared the allelic and genotypic frequencies of single nucleotide polymorphisms (SNPs) in several important signalling molecules that have multiple roles in embryogenesis, specifically, *FGF8, FGF10, BMP4, SHH* and *TP53* genes in 28 TE subjects to 68 non-TE subjects from the Brazilian population without congenital malformations. All DNA samples were genotyped by Real-Time PCR and all the necessary ethical consents were obtained. **Results:** For the genes looked at in this study we did not identify differences in genetic frequencies between the TE and control group. **Conclusions:** We did not, at this time, identify genetic susceptibility to TE for the evaluated variants. However, we have only used a small sample size and a limited number of gene targets, to validate this approach. We are looking at other potential targets using the same methodology to help in understanding of molecular mechanism of teratogenesis. **Funding:** CNPq, CAPES and FIPE-HCPA.

Macrothrombocytopenia and developmental delay with a de novo CDC42 mutation: Yet another locus for thrombocytopenia and developmental delay

K. Kosaki[1], *R. Kosaki*[2], *T. Takenouchi*[1];
[1]*Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan,* [2]*Division of Medical Genetics, National Center for Child Health and Development, Tokyo, Japan.*

The combinatory phenotype of thrombocytopenia and developmental delay has been described for two genetic conditions: a chromosome 11q deletion that is referred to as Jacobsen syndrome, and a 21q22 microdeletion syndrome. Herein, we report a young girl who presented with persistent macrothrombocytopenia and a developmental delay. A physical examination showed distinctive facial features with microcephaly. She communicated with simple words. She was able to identify colors and to name objects. She had an intention tremor and fell while attempting a tandem gait. Whole exome sequencing identified a de novo mutation in CDC42 (NM_001039802), i.e., c.191A>G, p.Tyr64Cys as the sole candidate in an autosomal dominant de novo mutation model or an autosomal recessive model. The mutation was confirmed using Sanger sequencing. CDC42 is a critical regulator of the cytoskeleton. While the observation may be coincidental, the strong degree of similarity between the phenotype of the proposita and that of mice lacking Cdc42 suggests a probable causal relationship. The conditional knock-out of Cdc42 in mice results in central nervous system defects and macrothrombo-

cytopenia. This pattern of hematologic indices was exactly the same as that which was observed in the proposita. We suggest that this CDC42 mutation may represent yet another mechanism leading to the combinatory phenotype of persistent macrothrombocytopenia and developmental delay.

The ciliary transition zone (TZ) is thought to control ciliary formation, composition and signaling by facilitating a protein diffusion barrier at the ciliary base, and TZ defects are associated with ciliopathies such as Meckel-Gruber syndrome (MKS), Nephronophthisis (NPHP) and Joubert syndrome (JBTS). Here, using a co-expression/evolution profiling approach to uncover candidate TZ genes, TMEM107 was identified as a new TZ protein mutated in patients with oral-facial-digital syndrome type VI (OFD VI) and JBTS. Mechanistic studies in C. elegans roundworms reveal TMEM-107 functions redundantly with NPHP-4 to regulate cilium integrity, TZ docking and the assembly of TZ membrane-microtubule Y-link connectors. Consistent with evolutionary and mammalian biochemical analyses, TMEM-107 occupies an intermediate layer of the nematode TZ-localised MKS functional module and organises the TZ recruitment of a distinct transmembrane submodule including TMEM-17, TMEM-231 and JBTS-14/TMEM237. Furthermore, transmembrane MKS module proteins including TMEM-107 are immobile within the TZ membrane and display ring-like super resolution localisation patterns reminiscent of the ciliary necklace. Thus, TMEM107 is a ciliopathy constituent of an anchored ring-like domain of the TZ membrane and organises a discrete transmembrane component of the C. elegans MKS module.

PS11.125

Trisomy of the short arm of chromosome 10: description of three new cases

D. A. Ochiana, *V. Plaiasu, G. Motei, F. Brezan, I. Anca;*
Mother and Child Care Institute, Bucharest, Romania.

Trisomy 10p is a rare, complex syndrome of mental retardation and multiple congenital malformations caused by the partial or total duplication of the short arm of chromosome 10. This abnormality may be a de novo occurrence or may be inherited from a carrier parent. Most cases appear because of an unbalanced segregation of famililal chromosomal translocations that result in trisomy 10p associated with other additional segmental imbalaces.
We describe three cases of non-mosaic trisomy 10p resulting from familial translocations: two sisters with a complex cytogenetic anomaly consisting in 10p trisomy and a rare subtelomeric 2p25.1 deletion and one other unrelated girl with 10p trisomy, without any apparent additional genomic imbalance (46,XX,der(2)t(2;10)(p25.1;p11.1)mat and, respectively, 46,XX,der(14)t(10;14)(p11.1;p11.1)mat). The inheritance and identity of the translocations were ascertained by extensive familial cytogenetic and FISH studies.
The few tens of patients with trisomy of the short arm of chromosome 10 reported to date have shown variable clinical manifestations. The clinical presentation for the girl with der(14) (10 days old) is very similar to that found for pure trisomy 10p reported in the literature, with facial dysmorphism, congenital abnormalities, hypotonia and severe developmental delay.
For the two sisters with der(2) (ages 1y 4mo and 8y 1mo), the phenotypic features slightly overlap those previously described for trisomy 10p, with additional clinical characteristics, probably due to the accompanying monosomy.
Acknowledgments: This work was supported by Objective 3.3 of Romanian Ministry of Health Program VI and by PN-II-PT-PCCA-2013-4-133 grant

PM11.126

Management of Children with Trisomy 13: Clinical Details of 22 Patients Receiving Intensive Treatment.

E. Nishi[1,2], *T. Hiroma*[3], *M. Arakawa*[1], *T. Nakamura*[3], *Y. Fukushima*[2], *T. Kosho*[1,2];
[1]*Division of Medical Genetics,Nagano children's hospital, Azunimo city, Japan,* [2]*Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan,* [3]*Division of Neonatology, Nagano children's hospital, Azunimo city, Japan.*

Trisomy 13 (T13) is characterized by multiple congenital anomalies, severe developmental delay, and a short life span with the 1-year survival rate as 5-10 % and the median survival time as 7 days through population-based studies. Management of T13 is controversial, supposedly due to the lack of precise clinical information of this syndrome especially on efficacy of treatment. To delineate the natural history of T13 managed under intensive treatment, we reviewed detailed clinical data of 22 patients with full T13 admitted to Nagano Children's Hospital from 1994 to 2014.
Major clinical findings included congenital heart defects (91%), cleft lip or cleft palate (68%), polydactyly (59%), and cryptorchidism (50% of male). 19 patients received resuscitation by intubation and required Mechanical ventilation. Of these, six were extubated and 11 needed tracheostomy. A total of 29 surgical interventions except for cardiac surgery were performed on 15 patients. Enteral feeding was accomplished in 19, six of whom were fed orally. Eight patients could be discharged home. The survival rate at age 1 week, 1 month, and 1 year was 100%, 95%, and 41%, respectively. Median survival time was 271 days (range, 22–3987). Common final modes of death were congenital heart defects and heart failure (50 %). These data were similar to those obtained in patients with trisomy 18 in our hospital [Kosho et al., 2006].This study has demonstrated improved prognosis through intensive treatment, which would be helpful for clinicians to offer the best information on treatment options to families of patients with T13.

PS11.127

Discordant prenatal and postnatal cytogenetic findings in a case of de novo complete trisomy 5p

E. Krimmel[1], *D. Wahl*[2], *A. Ovens-Raeder*[3], *U. Heinrich*[1], *I. Rost*[1];
[1]*Center for Human Genetics and Laboratory Diagnostics (MVZ), Martinsried, Germany,* [2]*Practice for genetic counselling and psychotherapy, Augsburg, Germany,* [3]*Genetic counselling and diagnostics, München, Germany.*

Isolated trisomy of the complete short arm of chromosome 5 is a very rare constitutional chromosomal finding. We report a case of a meanwhile 6 month old dysmorphic girl with a prenatally not detected *de novo* trisomy of the complete short arm of chromosome 5.
Prenatal ultrasonography at 12th week of gestation revealed a dorsonuchal edema of 7.00 mm. Subsequently, chorionic villus sampling (CVS) was performed for conventional chromosomal analysis. After direct preparation the CV trophoblast cells showed a numerically normal female karyotype (46,XX), whereas after long-term culture all analysed CV mesenchymal core cells showed a numerically abnormal female karyotype with tetraploidy (92,XXXX).
Fetal ultrasonography at 17th week of gestation revealed persistent nuchal edema, bilateral clubfeet and a generally petite developed fetus. Parents rejected a recommended amniocentesis. Molecular analysis for Noonan-Syndrome and high-resolution array-CGH performed with DNA of the cultured tetraploide cells showed negative results.
Five weeks after birth the child was presented to a geneticist because of several dysmorphic features and a severe failure to thrive. Chromosomal analysis of peripheral blood showed an aberrant female karyotype with an additional marker chromosome segregating in all cells. The marker could be identified as an isolated complete short arm of chromosome 5 confirmed by molecular-cytogenetic analysis: 47,XX,+del(5)(q11.1).ish del(5)(wcp5+). The report will discuss the discordance of the results, describe the established dysmorphism and emphasize the importance for additional cytogenetic testing of a second fetal tissue, if abnormal prenatal ultrasound findings persist and cytogenetic analysis of one fetal tissue show negative or unclear results.

PM11.128

Molecular diagnosis of Czech tuberous sclerosis complex patients in the period 2009-2013

H. Filipova, **R. Vrtel**;
University Hospital and Palacky University Olomouc, Olomouc, Czech Republic.

AD inherited tuberose sclerosis complex, caused by TSC1 or TSC2 gene mutation, is characterised by hamartomatous growths in many organs (brain, heart, kidney etc.). Molecular diagnostics for Czech TSC patients is performed at Institute of Medical Genetics, University Hospital Olomouc since 1995. Previously used methods for unknown mutations detection (DGGE

and SSCP) have been replaced from 2009 by MLPA and Sanger sequencing of all TSC coding sequence, with the aim to increase the efficiency of causal mutations detection.
In the period from 2009 to 2014 the following file of patients has been investigated by our laboratory for the TSC genes analysis: 124 new cases of TSC (7 prenatal samples) and 37 patients indicated before the year 2009. The file also included family members (127 postnatal examinations and 14 prenatal samples) and confirmatory samples (45 examinations).
For the period a complete analysis of TSC genes was carried out in 98 index cases. 87 causal mutations were uncovered, 29 of them not previously published in TSC1/TSC2-LOVD database. 64 cases were related to the TSC2 gene mutation, 23 patients have TSC1 gene mutation, for 5 persons (3 prenatal samples from fetuses with rhabdomyoma) no mutation was found. In 6 individuals sequential change of unknown significance was found, to clarify its possible causality it is necessary to investigate the parents' DNA, or other members of the family.
Since 2014, we are implementing massive parallel sequencing (MPS, MiSeq) of both TSC genes in order to speed up the passage of the samples through the laboratory. Preliminary MPS results will be discussed.

PS11.129

A paternal isodisomy of chromosome 12 causes two different disorders in a developmentally delayed girl with mild dysmorphic features and sideroblastic anaemia

M. Alders[1], *P. Lakeman*[1], *M. Peters*[2], *T. W. Kuijpers*[2];
[1]*Department of Clinical Genetics, Academic Medical Center, Amsterdam, Netherlands,* [2]*Department of Paediatric Haematology - Immunology, Academic Medical Center, Amsterdam, Netherlands.*

History: 5 year old girl (no sibs) of non-consanguineous parents with psychomotor developmental delay (IQ ~80), sideroblastic anaemia, microcephaly (<- 2,5 SD) and short stature (4 cm < -3 SD), hypotonia, exercise intolerance, myopia, immunological problems an recurrent infections.
Clinical examination showed mild facial dysmorfisms with an upslant of palpebral fissures, hypertelorism (mum too), hypoplastic alae nasi, a smooth philtrum, small chin, and cup-shaped and low implanted ears. Furthermore, there was a tapering of the fingers, clinodactyly of the fifth digits, vitiligo and eczema.
Biochemical and Molecular investigations: a slightly elevated lactate was shown in blood with no amnio acid abnormalities and a (probably secondary) growth hormone deficiency. There were no abnormalities in karyotyping (46,XX); microarray CGH analysis, Mitomycin C (Fanconi anaemia), mtDNA (including Pearson), RPS19 and RPS14 (Blackfan Diamond), SHOX, FGFR3, NBN (Nijmegen Immunodeficiency syndrome) and several sideroblastic anaemia genes (SLC25A38; GLR5, STEAP3, ABCB7, ALAS2. NGS (WES) identified homozygosity for: 1) a pathogenic nonsense mutation in PUS1 which is associated mitochondrial myopathy with lactic acidosis and ringed sideroblasts (MLASA); and a pathogenic splice site mutation in 2) PFKM, which is associated with Glycogen Storage disease VII (Tarui disease). Her clinical phenotype is predominantly explained by MLASA, but both disorders fit with her clinical problems. The father was a heterozygous carrier, but the mother was not.
Conclusion: This girls' phenotype was explained by an extraordinary genotype. She had (at least) two rare recessive disorders based on a proven paternal isodisomy of chromosome 12 resulting in homozygous pathogenic mutations in PUS1 and PFKM.

PM11.130

Velocardiofacial Syndrome: Review of the Five Years Experience

E. Yilmaz Gulec[1], *A. Gezdirici*[1], *Z. Ocak*[1], *E. Koparir*[1], *H. Bornaun*[2], *K. Oztarhan*[2], *A. Guzeltas*[3], *F. Cipe*[4], *M. Cetinkaya*[5], *H. Aslan*[6];

Introduction: Chromosome 22q11.2 deletion syndrome, also known as velocardiofacial syndrome / DiGeorge syndrome is one of the most common microdeletion syndromes . Its incidence is 1/4000 in live births. Common manifestations are conotruncal heart defects, palatal abnormalities, hypocalcemia, immune deficiency, velopharyngeal incompetence and intellectual /behavioral problems. We aim to document the most common features of our patients diagnosed during the antenatal period and childhood.
Materials and Methods: A total of 27 cases diagnosed at our hospital between years 2010-2014 were analyzed retrospectively. The variables analyzed were sex, age at diagnosis, presenting manifestation, type of heart defect, other features and positive family history.
Results: From total of 24 children 15 (63 %) were female, 9 (37 %) were male, 3 were antenatal cases. The youngest patients were 1 month old (8), 16 were younger than 1 year, the oldest was 11 years old. The prenatal cases were diagnosed between 25th and 32nd weeks of gestation. Heart defects were the most common presenting manifestation (23/27). Hypocalcemia, immune deficiency, velopharyngeal incompetence and dysmorphic features were the other features in the rest (4/27). The most common cardiac defect was co-existence of VSD and ASD (6), the others were Tetralogy of Fallot (4), truncus arteriosus (4), interrupted aortic arch (3) and VSD (3). Families were tested in 10 cases; 4 of them were found affected.
Conclusions: In the light of these results, we planned to develop a guideline for the diagnosis of velocardiofacial syndrome in high risk pregnancies and newborns in our clinic.

Waardenburg syndrome (WS) is one of the most common forms of syndromic deafness, characterized by the clinical association with pigmentation abnormalities of the eye, skin and hair. Four subtypes are described (WS1-4), type 1 and 2 being the most frequent and 3 the rarest. WS1 is caused by heterozygous mutations in PAX3, a transcription factor playing a key role in neural crest cells and muscle development. More than one hundred mutations have been published. Two homozygous mutations in PAX3, leading to hindlimb defects (WS3), were also described.
Here we document 2 consecutive severe cases of WS with fetal presentation. Ultrasound found increased nuchal translucency, lack of active movements, club hands and feet, and neural abnormalities. Both pregnancies were medically interrupted due to the severity of the phenotype.We identified in both fetuses a homozygous missense mutation within PAX3 homeodomain, shedding light on the molecular basis of this very rare form of WS. The consanguineous parents are heterozygous for the mutation and present with a classical form of WS1.
In vitro experiments were carried out to confirm the deleterious effect of this mutation. We found that PAX3 activation ability on the MITF promoter, alone or together with SOX10, was crippled by the mutation. While the cellular localization of the protein was not affected, the mutation clearly interferes with the trans-acting activity of PAX3 and thus inhibits it from activating downstream targets in the neural crest pathway.

Our lab was the first to publish that constitutional mutations in the epigenetic regulator *EZH2* cause Weaver Syndrome (WS). WS is characterized by overgrowth, increased height, large head, intellectual disability and susceptibility to various cancers. We found pathogenic mutations in *EZH2* among 7 out of 45 individuals with Weaver-like features, of which two had developed malignancies prior to referral. Our efforts focus on determining characteristics that will help predict the likelihood of WS patients developing cancer, through phenotype/genotype correlations and functional studies.
Given that *EZH2* is a histone-modifying enzyme known to be mutated in various somatic cancers, we hypothesized that constitutional mutations in other epigenetic regulators could explain the overgrowth features seen in our undiagnosed patients. To investigate this, we carried out whole exome sequencing for a subset of patients in our cohort.
In one patient, we identified a novel *de novo* mutation in a key epigenetic regulator. Based on the similarities of the patient's phenotype to WS and other

lines of evidence including animal models, we characterized this mutation as probably pathogenic. This is the first report of overgrowth associated with a constitutional mutation in this gene, which is mutated somatically in various cancers. Further investigations are needed to make a definitive link between mutations in this epigenetic regulator, Weaver-like syndromes, and cancer development. We intend to present the identity of this gene and results of further studies at this meeting.

This work was supported by the CIHR Operating Grants PCN102990, PCN110794, MOP119595. ASAC holds a Doctoral Grant from the Fundação para a Ciência e a Tecnologia (Portugal/EU).

Heterozygosity of ELN can cause tortuous cerebral artery in Williams syndome

Y. Muramatsu[1,2], *S. Mizuno[1], H. Kakizawa[3], K. Shimizu[4], H. Ohashi[4], S. Hayashi[5], J. Inazawa[5], K. Itomi[3];*
[1]Department of Clinical Genetics, Central Hospital, Aichi Human Service Center, Kasugai, Japan, [2]Department of Pediatrics, Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Division of Neurology, Aichi Children's Health and Medical Center, Obu, Japan, [4]Division of Medical Genetics, Saitama Children's Medical Center, Saitama, Japan, [5]Department of Molecular Cytogenetics, Medical Research Institute and School of Biomedical Science, Tokyo Medical and Dental University, Tokyo, Japan.

Introduction: Williams syndrome (WS) is a contiguous gene syndrome commonly caused by a 1.5-Mb deletion involving ELN located at 7q11.23. Elastin arteriopathy plays a key role in WS. Although cardiovascular diseases such as supravalvar aortic stenosis and peripheral pulmonic stenosis are the most significant features, there were some reports of cerebral vessel stenoses, which cause cerebral infarction or moyamoya disease. Neurovascular abnormalities have still not fully been studied in patients with WS.
Materials and Methods: In this study, we investigated magnetic resonance imaging and angiography findings of the brain and intracranial vessels in WS. Four patients were included in this study. Three were typical WS (age range, 1-2 years) diagnosed by fluorescence in situ hybridisation, and the fourth was a 7-year-old girl with an interstitial 7.92Mb deletion of 7q11.21-q11.23 containing the whole ELN gene and a part of the LIMK1 gene. She had a history of peripheral pulmonary stenosis, rectal prolapse, and skeletal features similar to those seen in WS.
Results: Bilateral tortuosity of middle cerebral artery and vertebrobasilar artery were observed in all four cases. Neither constriction of vessels nor infarction was detected.
Conclusions: Tortuosity of the intracranial artery is one of the clinical manifestations in WS. ELN may play an important role in pathogenesis.

PM11.134

Williams-Beuren syndrome: phenotypic, biologic and molecular characteristics

S. Popa[1,2], *A. Grozavu[1], R. Popescu[1,2], M. Panzaru[1,2], L. Butnariu[1,2], E. Braha[1,2], C. Rusu[1,2];*
[1]University of Medicine and Pharmacy "Grigore T. Popa", Iasi, Romania, [2]"St. Mary" Children's Hospital, Iasi, Romania.

Introduction: Williams-Beuren syndrome (WBS) is known as a multisystem disorder caused by the deletion of several genes on chromosome 7 (7q11.23). We have used specific facial anomalies, intellectual disability, cardiac abnormalities, and hypercalcemia as diagnostic selection criteria, and used multiple ligation-dependent probe amplification (MLPA - MRC Holland) analysis to confirm the diagnosis.
Materials and Methods: We have analyzed 24 patients confirmed with WBS, and identified 5 cases related to a familial disorder and 19 isolated cases. We have analyzed the clinical and biological characteristics of the above-cited individuals and correlated them with the deletions identified using MLPA P064 kit. Deletion size was further characterized using MLPA follow-up kit P-029-A1.
Results: The data show that 21 of the patients had a hemizygous deletion of ELN, STX1A, FZD9, CYLN2, and LIMK1 genes, whereas three individuals had an atypical deletion (a smaller one that does not extend telometically futher than LIMK1 gene) with an incomplete phenotype (mild dysmorphic face, supravalvular aortic stenosis and learning difficulties). The dysmorphic face was present in all individuals, but the frequency of different features varied. 71% of subjects associated congenital heart defects, whereas hypercalcemia was found only in 19% of the patients with WBS. All subjects had mild to moderate intellectual disability.
Conclusions: For countries with limited financial resources, the use of a combination of MLPA kits allows both confirmation and estimation of the deletion size in WBS patients. A comprehensive phenotype-genotype correlation is provided, with detailed illustration of particular cases.

PS11.135

A partial deletion of the Williams-Beuren syndrome (WBS) region in a child with classic Williams facial features: further delineation of genotype-phenotype correlations in the WBS region

A. C. Foster[1], *F. S. Togneri[2], M. Drozniewska[2], L. Reali[2], N. S. Cooper[1];*
[1]Birmingham Women's Hospital NHS Foundation Trust, Birmingham, United Kingdom, [2]West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom.

This patient was referred to clinical genetics following investigations for trisomy 21 and Beckwith-Wiedemann syndrome due to dysmorphic features, mild motor delay and relatively large size. On examination she was noted to have facial features typical of Williams-Beuren syndrome (WBS) and a systolic murmur. Cardiac investigations identified mild left ventricular hypertrophy, mild mitral valve prolapse with regurgitation, and hypertension requiring treatment with amlodipine. Microarray analysis detected an atypical deletion of 1.6Mb at 7q11.23 partially overlapping the WBS region. Imbalance of this region has not previously been reported in the literature.
WBS is a microdeletion syndrome caused by a recurrent deletion of 1.5-1.8 Mb at 7q11.23. The syndrome is characterised by a specific phenotype that includes cardiac, facial, cognitive, endocrine, growth, and connective tissue features. The microdeletion typically encompasses 26 to 28 genes. While deletion of ELN is established as responsible for the cardiovascular phenotype, the exact phenotypic impact of the other genes in the region is not yet clear. Overlapping deletions provide an important insight into genotype-phenotype correlations. It has been suggested that BAZ1B is a candidate for craniofacial development and thus the facial features of WBS. However, our patient has typical facial features and preservation of BAZ1B. Our patient's atypical feature of height velocity along the upper centiles is also of great interest. Here we present a review of atypical deletions reported in the literature, including our new case, and summarise the current knowledge of genotype-phenotype correlations in WBS.

PM11.136

Genotype-phenotype correlation in three patients with Wolf-Hirschhorn syndrome

H. Gurkan[1], *U. Vatansever[2], E. I. Atlı[1], D. Eker[1], S. Ulusal[1], N. A. Çiftdemir[2], H. Tozkır[1];*
[1]Trakya University, Medical Faculty, Department of Medical Genetics, Edirne, Turkey, [2]Trakya University, Medical Faculty, Department of Pediatrics, Edirne, Turkey.

Wolf-Hirschhorn syndrome (WHS) (OMIM 194190) is a multiple congenital anomalies/mental retardation (MCA/MR) syndrome caused by partial 4p deletion that was first described independently by Wolf et al. and by Hirschhorn et al. in 1965.
Clinical signs and symptpms include typical facial appearance, resembling the ''Greek warrior helmet'' profile, mental retardation, severe growth delay, hypotonia, congenital heart malformations, midline defects, such as cleft palate and hypospadias, ocular colobomas, renal abnormalities and seizures. Different phenotypes and clinical findings are caused by the number of genes deleted on the 4p16.3 locus.
Here we represent the clinical findings of three patients who have deletion on 4p16.3 chromosomal locus. Size of the deletions were different from each other.
The first patient is a 3,5- year-old female who has afebrile convulsion, hearing loss and speech delay. Submicroscobic heterozygous deletion including PIGG, GAK, FGFRL1, SPON2 genes on 4p16.3 was determined by MLPA method performed with P373-A1 MLPA probemix.
The second patient is a 2-day-old female patient. She has a dysmorphic face appearence, preauricular pit, PDA? and sacral dimple. She has a 46,XX,del(4)(p15.?3) karyotype. A 19 Mb heterozygous deletion between 4p16.3-4p15.3 regions was determined by arrayCGH [CytoScan750K_Array, Affymetrix] method. Deleted region includes 88 genes described in OMIM.
Third patient is a 9-year-old male who has microcephaly, dysmorphic face appearence, iris coloboma, exophtalmus, ASD+PDA+ pulmonary stenosis, gastroesophageal reflux, scoliosis and seizures. He has a 46,XY, der(4)t(4;18)(p16.3;p11.2) karyotype.
Differential expressivity and incomplete penetrance in WHS cause difficulties in clinical diagnosis and problems in understanding the genotype/phenotype correlations.

PS11.137

Cytogenetic approach of girls with short stature: unrelated 6 cases with structural X chromosome abnormalities

V. PLAIASU, *D. Ochiana, G. Motei, F. Brezan, I. Anca;*
IOMC Prof.dr.Alfred Rusescu, Bucharest, Romania.

There are various genetic causes of short stature. It has been known that short stature is associated with several disorders including wide variations

of chromosomal abnormalities. A detailed clinical evaluation is essential to suspect and diagnose the underlying cause, especially in patients with overlapping phenotypes.
This work presents the cytogenetics results found in Romanian female patients with short stature as a main clinical feature for referral to Genetics Department. G-banding and metaphase FISH techniques were performed and showed various X chromosome abnormalities: Xp and Xq deletions [46,X,del(X)(p11.2), 46,X,del(X)(q22)], isochromosome X [mos 45,X/46,X,i(X)(q10)], 46,X,idic(X)(p22.1)], ring chromosomes [mos 45,X/46,X,r(X)].
Phenotypic expression of Turner syndrome patients is largely dependent on the patient's karyotype and is most commonly associated with a 45,X karyotype, with a wide spectrum of clinical features. In some patients with Turner syndrome the karyotype shows mosaicism, including cell lines with monosomy X along with X structural anomalies, with possible imbalance of gene content of the X chromosome. A ring X chromosome with loss of XIST gene function and certain X-autosomes translocations are the only sex chromosome structural abnormalities likely to cause mental retardation. Haploinsufficiency of SHOX gene, located on the short arm of the X chromosome, is responsible for height deficit in Turner syndrome patients.
Genetic evaluation of X chromosome rearrangements is important for an accurate diagnosis and to provide information regarding natural history, prognosis, available treatment, recurrence risk.
Acknowledgments: This work was supported by objective 3.3 of Romanian Ministry of Health Program VI and by PN-II-PT-PCCA-2013-4-133 grant

Zimmermann-Laband syndrome (ZLS) is a developmental disorder characterized by facial dysmorphism with early onset gingival enlargement, intellectual disability, hypo/aplasia of nails and terminal phalanges of hands and feet, and hypertrichosis. We report that heterozygous missense mutations in KCNH1 account for a significant proportion of ZLS. KCNH1 encodes Eag1/Kv10.1, a member of the ether-à-go-go family of voltage-gated K+ channels. Patch-clamp recordings in cells expressing homomeric KCNH1 mutant channels revealed a shift in the threshold for K+ current activation to more negative potentials for all but one mutant. For the latter, co-expression experiments demonstrated a dominant action over the wild-type channel, with reduced K+ conductance of the heterotetrameric channels at depolarizing potentials but a pronounced conductance at negative potentials. These data support a gain-of-function effect of all KCNH1 mutants. We also report that a single missense change in ATP6V1B2 underlie a small fraction of ZLS. ATP6V1B2 encodes the B2 subunit of the vacuolar H+-ATPase, a multimeric enzyme that mediates acidification in organelles by pumping protons against an electrochemical gradient. Structural analysis indicated a possible perturbing effect of the introduced residue on complex assembly. Our findings provide evidence that disturbances in voltage-dependent K+ currents cause the clinically recognizable ZLS phenotype, and document genetic heterogeneity for this disorder.

PS12.001
Detection of extensive driver mutation heterogeneity in 5 Bulgarian patients with adenosquamous carcinoma of the lung

L. T. Balabanski[1], *N. Chilingirova[2], S. Ivanov[1], R. Vazharova[1], D. Toncheva[1], G. Kurteva[2];*
[1]Genomics Laboratory, Malinov Clinic, Sofia, Bulgaria, [2]Medical Oncology Clinic, Specialized Hospital for Active Treatment in Oncology, Sofia, Bulgaria.

Background: Lung cancer remains amongst the leading causes of death worldwide. Adenosquamous carcinoma of the lung is a relatively rare subtype of non-small cell lung cancer accounting for approximately 1-4% of all cases. The genetic mechanisms underlying the onset and progression of this type of cancer are still not clear. The aim of this study was to gain an insight into the mutational profile of tumour tissue from 5 Bulgarian patients with adenosquamous carcinoma of the lung.
Materials and Methods: DNA was extracted from formalin-fixed, paraffin-embedded tumour tissue. Libraries were prepared for sequencing using a TruSight Cancer Panel and included the exons of 94 cancer genes and 284 SNPs associated with cancer. Sequencing was performed on an Illumina MiSeq platform. The BWA pipeline was used for alignment and variant calling.
Results: In each of the patients we identified at least one clear-cut driver mutation leading to a loss of function of a haploinsufficient gene. The genes affected were *APC* (p.Ser2497Ter; p.Gly857Ter; c.730-1G>T), *TP53* (p.Arg196Ter; p.Val197Met), *BRCA2* (c.9089_9090insA), *ATM* (p.Tyr313Ter) and *NF1* (p.Arg304Ter). Each patient also carried other somatic and germline potential driver mutations such as heterozygous nonsense mutations in the haplosufficient FANC family genes (*FANCA*, *FANCC*, *FANCG*, *FANCI*, *FANCM*), as well as many novel missense mutations in other genes predicted as pathogenic by the RadialSVM algorithm.
Conclusion: We observed great heterogeneity in all patients, which highlights the need for a personalised approach in designing a therapeutic strategy for lung cancer patients in order to maximise their chances for successful treatment.

PM12.002
Next-generation sequencing as a tool for assessing minimal residual disease in AML patients with CEBPA mutations

*L. Zejskova[1], R. Plachy[1], **L. Sedlackova**[1], O. Mazal[1], A. Zavrelova[2], P. Zak[2], V. Petecukova[3], J. Novak[3], T. Kozak[3], S. Pekova[1];*
[1]synlab genetics s.r.o., Laboratory for Molecular Diagnostics, Prague, Czech Republic, [2]Department of Clinical Hematology, Faculty Hospital Hradec Kralove, Hradec Kralove, Czech Republic, [3]Department of Clinical Hematology, Faculty Hospital Kralovske Vinohrady, Prague, Czech Republic.

Introduction: Mutations in the CCAAT/enhancer binding protein alpha (*CEBPA*) gene occur approximately in 5 – 10 % of acute myeloid leukemia (AML) patients and can be used as molecular markers for monitoring of minimal residual disease (MRD). However, detection of MRD using quantitative real-time PCR (RT-qPCR) is complicated due to GC-rich regions and thus validation of leukemia-specific and sensitive MRD assay can be technically difficult. The goal of our work was the application of next-generation amplicon-based deep sequencing (NGS) as a quantitative detection method for MRD monitoring.
Materials and methods: Since 2010, we have performed mutational analysis of the *CEBPA* gene coding region in 411 AML patients at initial diagnosis using Sanger sequencing. In patients with the *CEBPA* mutation as the only detected mutation, we designed leukemia-specific assay using RT-qPCR. However, in 5 patients the assay did not provide sufficient sensitive and specific detection of residual leukemic cells. In these cases MRD was monitored by NGS technology.
Results: From January 2013 we examined 38 samples from 5 AML patients. The assay detection sensitivity achieved the threshold of 10^{-4} to 10^{-5} (1 leukemic cell in 10 000 to 1 leukemic cell in 100 000 cells). Dynamics of residual leukemic cells correlated with clinical outcome of the patients. In patients with relapse, the occurrence of the *CEBPA* mutation was also confirmed by conventional Sanger sequencing.
Conclusion: Quantitative assessment of *CEBPA* mutations using NGS offers a promising way for the detection of MRD level necessary for individualized monitoring of disease status and treatment efficacy.

PS12.003
Polymorphisms of DNA repair genes in the susceptibility of acute myeloid leukemia (AML)

A. Daraki[1,2], *D. Koumbi[1], P. Masoura[2], S. Samara[2], C. Sambani[1], K. Manola[1], P. Kollia[2], V. Aleporou-Marinou[2];*
[1]Laboratory of Health Physics, Radiobiology & Cytogenetics, NCSR "Demokritos", Athens, Greece, [2]Department of Genetics & Biotechnology, Faculty of Biology, National and Kapodistrian University, Athens, Greece.

Alterations in the polymorphisms of DNA repair genes have been associated with the pathogenesis of leukemia. DNA double-strand break repair pathway represents the main pathway in maintaining genome stability which is distinguished into two pathways: homologous recombination (HR) and non-homologous end-joining (NHEJ). The Rad51 proteins are essential components of the HR, whereas Lig4 proteins represent central components of the NHEJ. In this study, we investigated possible implications of the G135C and C26T germline polymorphisms of RAD51 and LIG4 genes, respectively, in AML development and its specific chromosomal abnormalities. Genotyping was performed in 83 patients and 91 controls by PCR-RFLPs. The polymorphic site G135C of RAD51 gene showed the same allelic and genotypic frequency between patients and controls. The genotypic distribution of

C26T polymorphism of LIG4 gene revealed a statistically higher frequency of the variant genotypes in patients compared to controls (C/T: 50.6% vs 30.8%, T/T: 10.8% vs 6.6%, respectively, p=0.006). Allele frequency distribution analysis for LIG4 gene, showed that patients exhibited an almost 2-fold increased risk of carrying at least one mutant allele (T) compared to controls (p=0.004). No statistically significant associations were found for both polymorphisms after stratification of patients according to karyotypic findings. However, an increased frequency of variant genotypes of C26T polymorphism of LIG4 gene was observed in patients with -7/del(7q), -5/del(5q) and +8, compared to controls. Our results showed that the AML risk was not associated with RAD51 gene polymorphism; however, our data provide evidence for an important role of the C26T polymorphic site of the LIG4 gene in AML development.

PM12.004

Principal clinical features of acute myeloid leukemia with mutations DNMT3A R882

E. Petrova, *I. Martynkevich, L. Polushkina, L. Martynenko, M. Ivanova, N. Cybakova, E. Kleina, E. Shabanova, A. Chechetkin, K. Abdulkadyrov;*
Russian Research Institute of Haemotology and Transfusiolofy, St.-Petersburg, Russian Federation.

The aim of the research was to analyse frequency of DNMT3A mutations in AML patients, their association with clinico-hematologic parameters and prognostic significance. The investigation group included 143 AML patients. Mutations DNMT3A R882 were identified in 23 (16,1%) patients: R882H - 16, R882C - 6, R882S - 1.
Patients with DNMT3A R882 had higher WBC (p=0,001) and platelets (p=0,020) count at diagnosis and more frequently belonged to FAB groups M5 (p=0,003) and M4 (p=0,012), as compared with DNMT3Awt. Of 23 patients who had AML with DNMT3A mutations, 17 (24,3%) had tumors with normal cytogenetic profiles (of a total of 70 cytogenetically normal samples) (p=0,009). Patients with isolated DNMT3A mutations were seen in 4 cases, whereas in the rest of patients they were detected simultaneously with mutations in genes FLT3, NPM1, NRAS and CKIT. DNTM3A mutations were significantly more prevalent in NPM1mut (p=0,005) and FLT3-ITD (p=0,005) positive cases than wild type. DNMT3A mutations associated with negative influence on patients overall survival (OS) and risk of relapse, compared with DNMT3Awt (Me of OS and RFS: 5,2 and 13,0; 4,8 and 10,0 months; p = 0,031 and p = 0,045, respectively).
Summary. AML with DNMT3A mutations represent the group, homogeneous on a number of clinical and laboratory parameters. DNMT3A mutations are highly recurrent in patients with de novo AML with an intermediate-risk cytogenetic profile. The presence of DNMT3A mutations can be considered as an independent adverse prognostic factor for survival, suggesting that testing of DNMT3A mutations can help further improve risk stratification in AML patients.

PS12.005

Bioinformatics analysis of mature mi-RNA motifs distribution in tumor suppressor genes surroundings

E. V. Butenko, *D. E. Romanov, E. A. Pshenichniy, T. P. Shkurat;*
Southern Federal University, Rostov-on-Don, Russian Federation.

Every human tumor type has its own unique mi-RNA expression profile. MiRNA can be located in intergenic spaces, in antisense strain, in introns and exons. Such genome organization can determine the mechanism of coordination between RNA and protein expression, but also represents the value of mi-RNA motifs in human evolution. Based on the findings that genome functioning is connected with its structure we have conducted the bioinformatics analysis of mature mi-RNA motifs distribution in tumor suppressor genes surroundings.
We analyzed the intergene spaces located in surroundings of the tumor suppressor genes (APC; BRCA1; BRCA2; CDKN2A; DCC; MEN1; NF1; NF2; PTEN; RB1; TP53; VHL; WT1). Sequences were obtained from NCBI data base and miRBase release 21 using E-utilities API. Motif search was carried out with MEME Suite program package. The results were filtered to yield only those matches with 85% identical nucleotides.
The entire set of non-coding DNA sequences contained 755 motifs of 19-23 nucleotides, homologous to 261 mature mi-RNA sequences. About 60% of all motifs were homologous to miR-5585, miR-1273g, miR-619, miR-5196, miR-5095, miR-709 and miR-1285. These motifs can be considered as non-specific and widely spread in human genome. We have found that tumor suppressor genes have specific patterns of mi-RNA homologous motifs distribution. Prevalent motif type and the density of motif distribution varied from gene to gene. Results can be discussed as a background to the search of new targets for tumor diagnostics and therapy.

Research was supported by grants 6.703.2014/K and RFMEFI59414X0002.

PURPOSE: To present a patient with familial adenomatous polyposis (FAP) caused by adenomatous polyposis coli (APC) somatic mosaicism; Description: we report of a twenty-one year old female presented with rectal bleeding and abdominal pain. Colonoscopy and esophagogastroduodenoscopy revealed extensive polyposis of the recto-sigmoid junction, distal sigmoid, proximal right colon and cecum. The rectum was essentially spared aside from two small pedunculated polyps. The stomach and duodenum, including the papilla, were normal. In preparation for recto-sigmoid sparing surgery, more than sixty polyps were removed. The patient had no extracolonic signs of FAP. Her maternal grandmother was diagnosed with colon cancer at age seventy-six, but there was no other family history of polyps or colon cancer. Methodology: Next-generation sequencing (NGS) analysis was performed using the ColoSeq™ panel* on DNA extracted from both peripheral blood lymphocytes and colonic polyps. RESULTS: Molecular analysis detected the p.E1408X deleterious mutation in the APC gene in 12 of 276 (4%) reads of the DNA in the peripheral blood and in 30% of the DNA from colonic polyps. CONCLUSIONS: In this patient, 4% APC mosaicism of the peripheral blood lead to florid polyposis. Somatic mosaicism has been reported to cause cancer syndromes in a few cases, but has been underestimated. This case should reinforce the need for NGS analysis in all patients with a personal history of polyposis, no family history of colon polyps/cancer, and no identified germline mutation by traditional less sensitive approaches.

Analysis of BCR-ABL mutations in chronic myeloid leukemia patients treated with tyrosine kinase inhibitors

G. Cardos[1], *S. Dinu*[1], *P. Apostol*[1], *M. Stoian*[1], *C. Ionescu*[1], *P. Gurban*[1], *F. Iordache*[1], *S. Spandole*[1], *R. Manolache*[2], *D. Duta*[3], *A. Rodewald*[1,4];
[1]*Personal Genetics, Bucharest, Romania,* [2]*Hematology Clinic, Coltea Hospital, Bucharest, Romania,* [3]*Filantropia Municipal Hospital, Craiova, Romania,* [4]*Human Biology Institute, University of Hamburg, Hamburg, Germany.*

Mutations in the BCR-ABL tirozin-kinase (TK) domain represent the most common mechanism of resistance to personalized therapy with TK inhibitors (TKI) in patients with chronic myeloid leukemia (CML).
Mutational status of the BCR-ABL gene corresponding to the TK domain was analyzed by capillary sequencing in 45 CML patients with suboptimal response/failure to TKI, in order to tailor their therapy. The response of the patients to TKI therapy was monitored at molecular and cytogenetic level.
Mutations in the BCR-ABL gene were identified in 18 (40%) patients: a single mutation in 15 patients and 2 mutations in 3 patients. Mutations identified corresponded to several regions of the BCR-ABL oncoprotein, such as: the P-loop (M244V, G250E, Q252H), the ATP-binding region (L298V, V299L, T315I, F317L), the SH2-contact region (M351T) and the substrate-binding region (F359V). The T315I mutation, conferring resistance to almost all known TKI, was detected both as single mutation (in 7 patients) and in combination with M351T (1 patient).
The 2 mutations detected in the BCR-ABL TK domain in case of 2 patients represented different clones; during dasatinib therapy, the resistant clones were selected (M351T and T315 respective), while the clones sensitive to this drug have disappeared.
Different chromosomal abnormalities associated with clonal evolution were identified in 3 patients, which may be the major cause of secondary resistance to TKI.
Conclusions:
- Mutational status of the BCR-ABL TK domain is valuable information for the best therapeutic decision and management of patients with CML;
- Additional TKI resistance mechanisms can be detected by a combined molecular and cytogenetic monitoring of the CML patients.

Changes in the gene expression and copy number aberrations in non-invasive and muscle-invasive bladder tumors

O. S. Antonova[1], *S. Hadjidekova*[1], *Z. Hammoudeh*[1], *R. Staneva Tsvetkova*[1], **B. Rukova**[1], *S.*

Karachanak-Yankova[1], D. Nesheva[1], V. Sabriev[2], E. Popov[2], G. Stamenov[3], R. Cherneva[4], C. Slavov[2], D. Damyanov[5], D. Toncheva[1];
[1]Department of Medical Genetics, Medical University- Sofia, Sofia, Bulgaria, [2]Department of urology, University Hospital Aleksandrovska, Sofia, Bulgaria, [3]MBAL Nadezhda, Sofia, Bulgaria, [4]Department of intenal medicine, University Hospital Aleksandrovska, Sofia, Bulgaria, [5]Bulgarian Academy of Sciences, Sofia, Bulgaria.

Background:
The aim of this study was evaluation and comparison of the copy number aberration and the expression of the genes, related to cancer drug resistance in non-invasive and muscle invasive bladder carcinomas.
Materials & Methods:
Bladder transitorial cell cancer samples from pTa, pT1, pT2, pT2a and pT2b stages were tested for gene expression levels and copy number aberrations. A gene expression analysis of the 84 genes from Cancer drug resistance and metabolism panel (Qiagene) of 30 tumours and CytoChip Oligo aCGH, 44K format (Bluegnome) of 12 tumours were performed.
Results:
The DNA copy number data shows gains, amplifications and loses in the bladder cancer genome, compared to the control. Tumours from pT2, pT2a and pT2b stages have higher numbers of chromosomal imbalances then non-invasive tumours.
The gene expression analysis of the bladder tumours revealed an up-regulation for CYP1A1, CYP3A5, AR, CLPTM1L, CCNE1, MVP, TOP2B, AHR and PPARG genes compared to the normal tissue. A statistically significant difference (p<0,0001) in the expression level in muscle invasive versus non-invasive bladder tumours of the EGFR, ERBB2, ERBB4, ABCC1, ABCC3, ARNT, CYP1A1, CYP3A5, EPHX1, MVP and PPARG genes is observed. These genes are involved in the multi-drug resistance and the metabolism of: steroid hormones, cyclosporine, polycyclic aromatic hydrocarbons, and anticancer drugs Vincristine, Thiopurine, and Taxol. This data confirms the significance of these genes as targets for further clinical trials.

Study of tumour recurence in superficial transitional cell carcinoma by microarrays

J. Mares[1], *M. Klabanova[2], V. Soukup[3], J. Dušková[4], A. Horinek[4], M. Babjuk[1];*
[1]2nd Faculty of Medicine Charles University, Prague, Czech Republic, [2]Diana Lucina, Prague, Czech Republic, [3]1st Faculty of Medicine Charles University, Prague, Czech Republic, [4]1st Faculty of Medicine Charles University, Prague, Czech Republic.

Treatment of bladder superficial tumours is dependent on the risk of recurrence and it is therefore clinically important to identify bladder cancers with a high risk of intravesical recurrence after transurethral bladder tumour resection. For the improvement of recurrence prognosis we applied gene expression microarray analysis to two groups of bladder tumours (superficial bladder tumours with no or late recurrence during the period of two years versus early recurrence ones). Data from microarrays containing 29,019 targets (Applied Biosystems) were subjected to a panel of statistical analyses to identify bladder cancer recurrence-associated gene expression changes. After validation 33 genes manifested significant differences between both groups. The significant expression was observed in the group of patients without recurrence by 30 genes of which the highest differences were detected by NINJ1, GNE, ANXA1, TNFSF15, WDR34, ARHGEF4, PRICKLE1, PSAT1, RNASE1, TM4SF1, TSPAN1, PLOD2 and WDR72. These genes code for signal transduction, vascular remodeling and vascular endothelial growth inhibition mainly. Specially, PRICKLE1 and TNFSF15 genes were described to be linked with WNT/β-catenin signaling and angiogenesis regulation and MTOR pathway. Loci of genes with significant changes of gene expression were on characteristic chromosomes for bladder cancer: 9q, 17q, 2q and 16p. On the basis of these findings we documented a number of expression changes of genes among which some seem to form clinically useful recurrence markers of superficial bladder tumours. Research was supported by MSM 0021620808 and Diana Lucina.

Routine and emergency BRCA1 and BRCA2 genetic testing using MASTRDx (Multiplicom®) kit, and MiSeq (Illumina®) sequencer: Description of two NGS-Workflows.

V. Guibert[1], *C. Delnatte[1,2], O. Ingster[3], M. Morin Meschin[3], I. Mortemousque[4], A. Lortholary[5], S. Audebert Bellanger[6], P. Parent[6], P. Gesta[7], H. Journel[8], D. Galliano[9], H. Lallaoui[10], S. Bézieau[1], C. Garrec[1];*
[1]CHU Nantes, Service de Génétique Médicale, Laboratoire de Génétique Moléculaire, Nantes, France, [2]CLCC René Gauducheau, Nantes, France, [3]CLCC Paul Papin, Angers, France, [4]CHRU, Tours, France, [5]Centre Catherine de Sienne, Nantes, France, [6]CHRU, Brest, France, [7]CHG, Niort, France, [8]CH Bretagne Atlantique, Vannes, France, [9]Pôle Santé Léonard de Vinci, Chambray les Tours, France, [10]SELARL Cylab, La Rochelle, France.

Background
BRCA1 and BRCA2 are major genes involved in hereditary breast and ovarian cancer (HBOC). Facing an increasing number of routine genetic tests and emergency indications such as eligibility to targeted therapies (anti-PARP) and surgery decision, we optimized our genetic testing strategy to reduce processing time. Based on high-throughput sequencing, our approach allowed the bi-monthly screening of 96 patients in routine diagnosis (RD), and the additional testing of 16 patients every three weeks as part of a fast track (FT) was performed.
Methods
96 DNA samples (RD) or 16 DNA samples (FT) were amplified using BRCA MASTRDx kit (Multiplicom®), based on five multiplex PCR covering coding regions and exon-intron junctions of BRCA1 and BRCA2 genes, followed by sequencing on MiSeq (Illumina®). Bioinformatic analysis was performed using SeqNext Software (JSI®). Large rearrangement were researched using MLPA (MRC Holland®).
Results
1154 patients were analysed in 2014 (1070 RD and 84 EI): 10.3% of them had germline deleterious mutations (CNV included), and 6.9% carried variants of unknown significance. The Next-Generation Sequencing (NGS)-based strategy amorced the shortening of analysis delay, which get closer to our target delay of 16 weeks maximum. The fast track process, including medical validation, last less than 8 weeks.
Conclusion
This NGS approach enabled to increase the throughput of genetic tests for BRCA1 and BRCA2, and to develop an efficient fast track in response to therapeutic emergency indications. The use of two MiSeq sequencer enables a technical capacity of 2500 patients a year. Furthermore, this technological resource allows us to consider HBOC genes panel sequencing.

PS12.011

Routine germline BRCA testing in serous ovarian cancer: The West of Scotland experience

P. Spiliopoulou[1], *S. Gibson[2], R. Davidson[2], R. Glasspool[1], I. McNeish[3];*
[1]Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom, [2]Clinical Genetics, Southern General Hospital, Glasgow, United Kingdom, [3]Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom.

Background: Germline mutations in BRCA1/2 (gBRCA) are strongly linked to non-mucinous ovarian cancer (OC), in particular high grade serous OC (HGSOC). Since Jul 13, all patients with non-mucinous OC in the West of Scotland (WoS) have been offered germline BRCA1/2 testing regardless of family history. All patients received counselling prior to testing. Methods: Sequencing results were collated with clinical data. Progression-free (PFS) and overall (OS) survivals in gBRCA mutation carriers and non-carriers were compared using Gehan-Breslow-Wilcoxon test. Results: 154 patients were referred to genetics and 120 accepted testing. gBRCA mutations were identified in 22/120 (18.3%) - 6 BRCA1, 16 BRCA2. An additional 4/120 (3.3%) had variants of unknown significance (VUS). In HGSOC, the mutation rate was 21/92 (22.8%) (6 BRCA1, 15 BRCA2). 50% mutations occurred in women with Manchester score (MS) ≤ 15: these would have been missed if family history alone determined decision to test. OS for gBRCA2 carriers with stage III/IV HGSOC was significantly better than gBRCA wild-type (HR: 2.25 95%CI 1.05-4.79, p = 0.02, gBRCA wild-type median 63.2m, BRCA2 carriers median undefined). Median PFS of gBRCA2 carriers was also significantly better than gBRCA wild-type (27.9m vs 15.1m, HR 1.8, 95%CI 1.08-3.26 p = 0.02). For gBRCA1carriers both PFS and OS did not differ significantly from non-carriers. Conclusions: Routine germline BRCA1/2 mutation testing is acceptable and feasible in women with OC. c.20% women with HGSOC carry a gBRCA mutation. In WoS, we observe higher prevalence of BRCA2 mutations (16.3%) than previously reported (6-8%). In our cohort, gBRCA2 mutation confers better PFS and OS than wild-type BRCA1/BRCA2 status.

PM12.012

BRCA1/2 Mutation Status Is an Independent Factor of Improved Survival for Advanced Stage Ovarian Cancer

R. Janavičius[1,2], *V. Rudaits[1], D. Janulynaitė[1], T. Žvirblis[1], L. Griškevičius[1];*
[1]Vilnius university Hospital Santariskiu Clinics, Vilnius, Lithuania, [2]State Research Institute Innovative Medicine Center, Vilnius, Lithuania.

The aim of this study was to evaluate BRCA1 and BRCA2 mutation impact on prognosis of advanced-stage (III-IV) ovarian cancer patients after standard treatment.
Methods: A total of 466 patients with advanced-stage (primary) epithelial ovarian cancer (EOC) were identified from a clinical database during year

1998-2013 and enrolled in a prospective, single-center study. All cases with available germline DNA (n=297) were screened for BRCA1 and BRCA2 gene mutations using combination of methods (HRM, Sanger/Next Generation Sequencing, MLPA). Progression-free survival (PFS) and overall survival (OS) was assessed between BRCA1/2 mutation carriers and BRCA1/2 wild-type patients. To eliminate survivorship bias, analysis was limited for cases with BRCA testing performed <36 month from the diagnosis. Various clinical risk factors for PFS and OS were assessed by univariate and multivariate Cox regression analysis with stepwise model selection process.
Results: Older age (hazard ratio [HR], 1.032; 95% confidence interval [CI], 1.010-1.055; P=0.0047), nonoptimal cytoreduction (HR, 3.170; 95% CI, 1.986-5.060; P=0.0001), and BRCA1/2 wild type (HR, 1.625 [1.003-2.632]; P=0.0486) were significantly associated with shorter PFS in multivariate Cox regression analysis. Nonoptimal cytoreduction (HR, 2.684; 95% CI, 1.264-5.701; P=0.0102) and BRCA1/2 wild type (HR = 1,612 (95% CI 1,16 - 2,23; P=0.0002) were statistically significant risk factors for shorter OS. The overall 5-year survival for the hereditary case patients was better than that of the nonhereditary patients, however after that time no survival advantage was apparent.
Conclusions: Advanced ovarian cancer patients harboring BRCA1/2 mutation treated with debulking surgery and platinum-based adjuvant chemotherapy have a longer PFS and OS not longer than 5-years.

[1]*University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom,* [2]*University of Cambridge, Cambridge, United Kingdom,* [3]*National Human Genome Research Institute, Bethesda, MD, United States,* [4]*Mayo Clinic, Rochester, MN, United States,* [5]*Leiden University Medical Center, Leiden, Netherlands,* [6]*University of Pennsylvania, Philadelphia, PA, United States,* [7]*McGill University, Quebec, QC, Canada,* [8]*Dana-Farber Cancer Institute, Boston, MA, United States,* [9]*Huntsman Cancer Institute, Salt Lake City, UT, United States,* [10]*University of California, San Francisco, CA, United States,* [11]*Memorial Sloan Kettering Cancer, New York, NY, United States,* [12]*Baylor College of Medicine, Houston, TX, United States,* [13]*Institute of Cancer Research, London, United Kingdom,* [14]*Harvard medical School, Boston, MA, United States,* [15]*National Institute of Health, Bethesda, MD, United States,* [16]*QIMR Berghofer Medical Research Institute, Herston, Australia,* [17]*Curie Institute, Paris, France,* [18]*Hunstman Cancer Institute, Salt Lake City, UT, United States,* [19]*National Cancer Institute, Rockville, MD, United States.*

Most people at risk of hereditary cancer remain unrecognized. Cost and complexity of interpreting sequenced data are significant barriers. As technical advances reduce the cost of sequencing, and new interventions offer real hope of cancer cure and prevention, the problem of variant interpretation has become more visible.
The BRCA Challenge calls on clinicians, clinical laboratories and researchers across the world to share their knowledge of variation in the BRCA 1 and 2 sequences. Existing databases; BIC, UMD, LOVD, ClinVar, HGMD are being linked to ensure a single point of access. The goal is to provide the community with a reliable record of those variants that can be interpreted as pathogenic for a high penetrance phenotype versus benign. An international interpretation community will include the existing ENIGMA project, which establishes clinical significance of variants in these genes. Meanwhile, an API suitable for the extraction of all relevant sequence variation is being developed, including co-occurrence data, from genomic datasets to better define non-pathogenic variants across population diversity.
Ultimately the database will facilitate exploration of the clinical significance of variants across pathogenicity, building on and contributing to the work of CIMBA (the Consortium of Investigators of Modifiers of BRCA1/2), focused on refining the estimates for penetrance of a subset of variants, as well as ClinGen (Clinical Genome Resource) which provides curated genomic knowledge to improve clinical care. Barriers to be overcome include concerns around the quality of phenotypic data, the reliability of sequences, confidentiality, the standardisation of data collection, and the attribution of credit to generate, collect the data and curate their collection.

PM12.014

Two new cases of double heterozygosity for BRCA1 and BRCA2 gene mutations detected during routine diagnostic screening at the SW Thames Regional Genetics Laboratory

A. Perez-Caballero, *L. Kiely, E. Fidanis, L. Collins, H. Gosrani, R. Norris, S. Cottrell, A. Haworth, J. Short, R. Taylor;*
SW Thames Regional Genetics Laboratory, London, United Kingdom.

Introduction: *BRCA1* and *BRCA2* are the two major genes associated with inherited breast and ovarian cancer. Double heterozygosity (DH) is an extremely rare event in which both *BRCA1* and *BRCA2* are mutated simultaneously in a patient. To date, most cases of DH reported are in Ashkenazi populations, but only a few cases have been reported to have more than one non-Ashkenazi BRCA mutation. Here, we have described two families with two different mutations, one in *BRCA1* and another in *BRCA2*. One case includes an Ashkenazi mutation and a non-Ashkenazi mutation while the other case includes two non-Ashkenazi mutations.
Method: MLPA and bidirectional Sanger sequencing analysis of the entire coding region of *BRCA1* and *BRCA2* were carried out.
Result:
Family 1. Family with early onset of breast cancer, our patient was diagnosed at the age of 33 and her mother at the age of 36. In the index case, the c.5266dupC frameshift mutation in *BRCA1* (common Ashkenazi mutation) and the c.9097_9098insT frameshift mutation in *BRCA2* were detected.
Family 2. The proband was diagnosed with breast cancer at the age of 36 and has a family history of breast cancer from the maternal side. Sequencing analysis showed that the patient was heterozygous for the c.3750delG frameshift mutation in *BRCA1* and the c.4447delA frameshift mutation in *BRCA2*.
Conclusions: These findings highlight that a second mutation could potentially be missed if a screen is not completed once a mutation is detected.

PS12.015

BRCA1/2 risk-reducing bilateral salpingo-oophorectomy audit

C. J. Compton[1], *S. J. Rose*[1], *C. Jacobs*[1], *A. Kulkarni*[1], *C. Hammond*[2], *S. Wells*[1], *L. Izatt*[1];
[1]*Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom,* [2]*Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom.*

Background: BRCA1/2 carriers have a lifetime risk of ovarian cancer of up to 30-50% and no evidence-based ovarian cancer screening is available. Therefore, most women opt for a risk-reducing bilateral salpingo-oophorectomy (RRBSO). Since 2007 the BRCA family service at Guy's Hospital has advised gynaecological surgeons to follow a protocol for RRBSO in BRCA1/2 carriers as standard practice. This evidence-based protocol, implemented after an audit in 2006, includes removal of fallopian tubes, serial sectioning, peritoneal washings, and HRT recommendations.
Methods: An audit of women who had RRBSO between February 2013 to May 2014 (37 women) was undertaken to measure compliance with this protocol and review the evidence for the protocol. Data was collected from the BRCA family service database and clinical notes were reviewed. Information about post-surgical use of HRT was collected from the patient.
Results: 84% (31 women) were between 40 and 59 years at the time of surgery. Removal of fallopian tubes was evident in 97% (36 women), sectioning was undertaken in 76% (28 women) and peritoneal washings was documented in 51% (19 women). This showed an improvement in compliance with the protocol compared to the 2006 audit (36%, 16% and 8% respectively). No pattern was identified between compliance and hospital where surgery was performed.
Conclusion: Compliance with recommendations has vastly improved since the implementation of the RRBSO protocol. Inconsistencies between and within hospitals highlights the need for further discussion with surgeons in our catchment area. Before disseminating the results widely, literature review and revision of protocol is planned.

PM12.016

An Audit of BRCA1 and BRCA2 genetic testing offered to unaffected individuals as part of the cancer genetics service at Guys Hospital

H. Eshika, *A. Kulkarni, C. Compton, J. Campbell, C. Rideout;*
Guys Hospital, London, United Kingdom.

Introduction
In keeping with recommendations made by NICE guidelines (2013), the cancer genetic services at Guys started offering genetic testing to unaffected individuals who have a combined BRCA1 and BRCA2 mutation carrier probability of 10% or more. Eligibility was determined by confirming ovarian cancers and cancers in first degree relative. In addition families had to have a Manchester score of 17 or over to be eligible. The aim of this audit was to review the data on unaffected individuals who underwent BRCA1 and BRCA2 testing.
Method
We obtained all diagnostic BRCA1 and BRCA2 results between the period of 30/08/2013 and 01/09/2014. These were separated into affected and unaffected individuals. The unaffected individuals were further separated into mutation, VUS or no mutation and their Manchester score was calculated.

Results
From a total of 359 individuals, a total of 29 unaffected individuals were identified. Of these 29, BRCA mutations were identified in 2 (6.9%), VUS were identified in 7 (24.2%) and 20 (68.9%) were negative for either BRCA1 or BRCA2.
Conclusions
We concluded that there was a 6.9% pick up rate for mutations which is lower than the 10% threshold. However, the small sample size may have contributed to this. The individuals in whom mutations were identified had a very high Manchester score (29 and 37 respectively). Interestingly, a very high number (24.2%) of VUSs were also identified. In light of the findings we may need to review our threshold for offering genetic testing to unaffected individuals based on mutation probability, cost implications and high variant rate.

PS12.017
Analytical validation of a CE marked companion diagnostic tumor test to detect BRCA1 and BRCA2 mutations in ovarian cancer for clinical use

S. Wehnelt[1], *K. Timms*[2], *K. Copeland*[3], *C. Hayward*[3], *B. Roa*[4], *D. Mancini-DiNardo*[4], *K. Bowles*[4], *N. Singh*[4], *L. Esterling*[4], *J. Mitchell*[2], *B. Wardell*[2], *B. Morris*[2], *M. Perry*[2], *M. Francis*[2], *L. Fitzgerald*[2], *J. Lanchbury*[2], *S. Bhatnagar*[2];
[1]*Myriad GmbH, Munich, Germany,* [2]*Myriad Genetics, Inc., Salt Lake City, UT, United States,* [3]*Myriad Genetics GmbH, Zurich, Switzerland,* [4]*Myriad Genetic Laboratories, Inc., Salt Lake City, UT, United States.*

Background: Somatic and germline mutations in the *BRCA1* and *BRCA2* genes may predict outcomes to ovarian cancer therapies such as platinum and PARP inhibitors. To identify patients that may benefit from these therapies, a companion diagnostic test has been developed to analyze tumor specimens for *BRCA1/2* mutations. The aim of this study is to validate the test's analytical performance.
Methods: Genomic DNA isolated from 42 anonymized ovarian tumor samples underwent full sequence and large rearrangement analysis using next generation sequencing (NGS). The criteria for calls required 99% of bases to have ≥ 100 reads. The reproducibility of this test was evaluated by sequencing 10 samples in triplicate across 6 batches. All samples underwent analysis by an independent laboratory to verify results.
Results: The analytical sensitivity was estimated to be >99.07% (lower bound of 0.95 C.I.), with an analytical specificity >99%. The average read depth was approximately 425X per base, with a minimum inclusion criterion of 50X per base. All samples that were previously identified by alternative methods as positive for deletions/duplications were correctly identified using NGS dosage analysis. This study also showed that the results were 100% concordant with independent laboratory analysis - both finding 319 sequence variants - and had 100% intra- and inter-run reproducibility.
Conclusions: Ovarian tumor testing for *BRCA1/2* mutations including sequence and large rearrangement variants using NGS has been validated with high sensitivity and specificity for companion diagnostic use. It may be used for identifying patients with somatic or germline mutations to help guide therapy decisions.

PM12.018
A significant proportion of Greek TNBC patients carry rare loss-of-function mutations in 15 breast cancer predisposing genes

A. Vratimos[1], *I. Konstanta*[1], *F. J. Couch*[2], *S. N. Hart*[2], *I. Konstantopoulou*[1], *G. Fountzilas*[3], *D. Yannoukakos*[1], **F. Fostira**[1];
[1]*NSCR Demokritos, Athens, Greece,* [2]*Mayo Clinic, Rochester, MN, United States,* [3]*Aristotle University of Thessaloniki, Thessaloniki, Greece.*

Triple-negative breast cancer (TNBC) is an aggressive breast cancer subtype which is generally characterized by poor overall survival, mainly attributed to inadequate therapeutic targets. Germline BRCA1 mutations have been strongly associated with TNBC, the prevalence of which can be as high as 29% in populations with strong founder effect. Mutations in other breast cancer predisposing genes can be associated with TNBC, but the contribution of these genes is still unclear.
TNBC patients (n=733; mean age 45.19 years) were recruited solely on their TNBC status, between years 1999-2014. Initially, the Greek founder BRCA1 mutations were tested; individuals who were wild type at these loci were then tested by next generation sequencing using a 27-breast cancer gene panel.
Loss-of-function mutations were identified in 25.3% (186/733) of the individuals tested. BRCA1 mutations were observed in 20.2% (148/733). The mean age of breast cancer diagnosis was 39.6 years. Another 38 deleterious mutations were detected in 14 additional genes. Interestingly, 3.1% of these mutations cluster in only three genes, namely BRCA2 (1.9%), RAD51C (0.68%) and BARD1 (0.54%).
TNBC status alone can be a significant predictive factor for germline mutations in predisposition genes, irrespective of family history and early onset of disease. Even with the application of improved DNA sequencing techniques, BRCA1 loss-of-function mutations are still the major players in TNBC. Mutations in additional genes, which are BRCA1 partners in the homologous recombination pathway, also seem to be overrepresented in TNBC patients. These observations might be beneficial in terms of developing targeted therapeutics, such as poly-ADP-ribose polymerase inhibitors.

PS12.019
Identification of a first large deletion of the BRCA1 gene in a Croatian patient

V. Musani[1], *I. Susac*[2], *P. Ozretic*[1], *D. Eljuga*[3], *S. Levanat*[1];
[1]*Rudjer Boskovic Institute, 10000 Zagreb, Croatia,* [2]*Eljuga Polyclinic, 10000 Zagreb, Croatia,* [3]*Clinic of Gynecology and Obstetrics, University Hospital Center, 10000 Zagreb, Croatia.*

Breast cancer is the most common cancer in women after non-melanoma skin cancer, and it is the leading cause of cancer related deaths in Croatia. Ovarian cancer is in the fifth place, both in incidence and mortality. About 5-10% of all breast and/or ovarian cancer cases are hereditary, and heterozygous germline *BRCA1* and *2* mutations are responsible for the majority of hereditary breast and/or ovarian cancers. In the most cases, the mutations are small nucleotide alterations leading to premature stop of translation. Large rearrangements of *BRCA1* gene and less often, *BRCA2* gene have been described in recent years, but haven't been found in Croatia so far.
Here we describe a case of a Croatian breast cancer patient with no apparent family history of cancer, who developed a triple negative breast cancer at the age of 29, with return of the disease at the age of 33. No mutation was found by HRM or sequencing, but the 5-7 exon deletion of the *BRCA1* gene was determined with a Quantitative Multiplex PCR method and confirmed with MLPA analysis.

Whole cDNA analysis of BRCA1 and BRCA2 genes in Spanish breast/ovarian cancer families

G. Montalban[1], *S. Bonache*[1], *A. Tenés*[1], *E. Carrasco*[2], *N. Gadea*[3], *J. Balmaña*[3,2], *O. Díez*[4,1], *S. Gutiérrez-Enríquez*[1];
[1]*Oncogenetics Group, Vall d'Hebron Institute of Oncology VHIO, Barcelona, Spain,* [2]*High Risk and Cancer Prevention Group, Vall d'Hebron Institute of Oncology VHIO, Barcelona, Spain,* [3]*Medical Oncology Department, Vall d'Hebron Hospital, Barcelona, Spain,* [4]*Molecular Genetics Unit, Vall d'Hebron Hospital, Barcelona, Spain.*

Introduction: Germline pathogenic variants in BRCA1 and BRCA2 genes are associated with inherited high-risk of breast (BC) and ovarian cancer (OC). The whole coding sequence and the flanking exon-intron junctions are routinely screened in genomic DNA. However, in only about 25% of the cases a clear deleterious variant is identified. The disease susceptibility may also be associated with alterations in gene expression due to variants located in splicing and/or transcription regulatory non coding regions, not included in the conventional analysis. To test this hypothesis, we analyze the whole BRCA1/2 cDNA in high-risk Spanish families testing negative for BRCA1/2.
Materials and Methods: Total RNA of 200 probands and 10 control individuals was isolated from peripheral blood leukocytes. PCR overlapping amplicons including the entire cDNA of both genes were generated. Full-length transcripts were qualitatively assessed by QIAXCEL and bidirectional Sanger sequencing, allowing the detection of aberrant transcripts and alterations in natural occurring isoforms. Single polymorphisms in coding regions were also identified to confirm biallelic expression.
Results: To date, one out of 60 patients analyzed presents an aberrant transcript consisting in a partial inclusion of intron 21 in BRCA1. This splicing alteration is yet to be confirmed by capillary electrophoresis of fluorescent amplicons. A potential allelic imbalance of BRCA1 expression has been also detected in another individual.
Conclusions: Although the frequency of splicing and expression alterations in high-risk families appears to be low, the analysis of RNA can provide a more comprehensive BRCA1/2 diagnostic.

NGS screening for BRCA1/2 in Portuguese high-risk breast/ovarian cancer families: initial results, advantages and challenges

P. Machado[1], *S. Fragoso*[1], *S. Santos*[1], *A. Opinião*[2], *S. Bento*[2], *A. Luis*[2], *A. Clara*[2], *P. Rodrigues*[2], *C. Simões*[2], *J. Parreira*[2], *F. Vaz*[2];
[1]*Molecular Biology Department, Portuguese Institute of Oncology of Lisbon, Lisbon,*

Portugal, [2]Breast Cancer Risk Evaluation Clinic, Portuguese Institute of Oncology of Lisbon, Lisbon, Portugal.

Introduction: *BRCA1* and *BRCA2* are the genes most frequently involved in hereditary breast/ovarian cancer (HBOC). These genes are very large and the genetic screening based on Sanger sequencing is laborious and time consuming. Last year our Lab acquires a Next Generation Sequencing (NGS) instrument and we change the *BRCA1/2* screening to NGS. **Patients and methods:** Review of all patients screened for *BRCA1/2* by NGS. All patients underwent pre and post-test counselling, were pre-screened for the *BRCA2* Portuguese founder mutation [Machado et al, 2007], analysed for *BRCA1/2* point mutations by NGS with *MASTR-BRCA* assay (*Multiplicom)* and for large rearrangements by MLPA. **Results:** The first stage of NGS implementation included the re-analysis of 11 patients previously positive for a *BRCA1/2* mutation and 100% concordance was obtained for all mutations and variants. Between September 2014 and January 2015, 290 patients were screened and 25 positive patients were detected (8*BRCA1*, 9*BRCA2, 1BRCA1+BRCA2, 2BRCA large* rearrangements, *1CHEK2 and 4* founder mutation), which corresponds to a 8.6% detection rate. **Conclusion:** NGS is a valuable methodology with high throughput and quality, allowing a rapid diagnostic result for more appropriate clinical/prophylactic attitudes. In 5 months, 290 high-risk families were screened and 25 presented deleterious mutations. As expected, several neutral or unknown variants were also detected, posing a significant challenge for counselling. Depending on pedigree reanalysis and multidisciplinary decision, BRCA1/2 negative families will be screened for a selected panel of other relevant genes.

Prostate-Specific Antigen velocity as a predictive biomarker in a prospective prostate cancer screening study of men with genetic predisposition

C. G. Selkirk*[1], *C. Mikropoulos**[2], *S. Saya*[2], *E. Bancroft*[3,2], *T. Dadaev*[2], *C. Brendler*[1], *E. Page*[2], *D. A. Leongamornlert*[2], *N. Taylor*[3], *E. J. Saunders*[2], *C. Cieza-Borrela*[2], *.. The IMPACT study collaborators*[2,3], *S. Moss*[4], *Z. Kote-Jarai*[2], *B. T. Helfand***[1], *R. A. Eeles***[2,3];*
[1]NorthShore University HealthSystem, Evanston, IL, United States, [2]The Institute of Cancer Research, Sutton, United Kingdom, [3]Royal Marsden NHS Foundation Trust, London, United Kingdom, [4]Queen Mary's University of London, London, United Kingdom.

Objectives: *BRCA2* mutation carriers are more likely to develop prostate cancer (PrCa) and aggressive disease. We assessed whether men in the IMPACT study (Identification of Men with a genetic predisposition to ProstAte Cancer: Targeted screening in men at higher genetic risk and controls) exhibit altered PSA kinetics prior to diagnosis.
Methods: We calculated PSA Velocity (PSAV) using validated methods: arithmetic mean(a), linear regression(b) and first and last readings(c) equations. Pearson chi-square test was used to compare PSAV between *BRCA1/2* carriers versus negative controls in those that underwent prostate biopsy (PB). Binary Logistic Regression was used to compare PSAV between carriers who were and were not diagnosed with cancer.
Results: PSAV was available for 191 men who underwent a PB; 57 PrCas were diagnosed. There was no difference in the median PSAV between *BRCA1* carriers and non-carriers who were diagnosed with cancer (0.24 vs. 0.37 ng/ml/yr, respectively). In comparison, *BRCA2* carriers with cancer showed a significantly higher PSAV when compared to non-carriers (1.36 vs. 0.50 ng/ml/yr, respectively, p=<0.05). *BRCA2* carriers with a PSAV over 0.75ng/ml/yr were 5 times more likely to be diagnosed with PrCa compared to non-carriers [95%CI=1.5-14; P value=0.003]. In addition, *BRCA2* carriers with cancer were 12 times more likely to have high-grade disease (Gleason score ≥7) phenotype compared to non-carriers with cancer [95%CI: 1.1-98; p=0.039].
Conclusions: This is the first study to document that *BRCA2* carriers have different PSA kinetics compared to non-carriers. This increased PSAV most likely reflects prior associations with disease susceptibility, aggressive disease and PrCa specific mortality.

PS12.023

Uptake of risk-reducing mastectomy in BRCA1 and BRCA2 gene mutation carriers at The Royal Marsden

K. Kohut[1], *J. Wiggins*[1], *A. George*[1,2], *Z. Kemp*[1], *N. Rahman*[1,2], *H. Hanson*[1,2];
[1]Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom, [2]Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom.

Background: Women with a BRCA1 or BRCA2 mutation may choose surveillance with MRI and mammography or risk-reducing mastectomy (RRM) to manage their breast cancer (BC) risk. The reported uptake of RRM in the UK has historically been low, with many women opting for surveillance. However, demand for RRM anecdotally is said to be increasing. Here we report uptake of RRM at the Royal Marsden (RM) Hospital.
Methods: A comprehensive list of female BRCA mutation carriers was obtained from the RM Genetics Unit database. The electronic patient record was interrogated to ascertain decision-making regarding breast surgery.
Results: 858 carriers were identified: 458 with BRCA1 mutations and 400 with BRCA2 mutations. Of the 458 BRCA1 carriers, 82 had therapeutic mastectomy for BC (14 unilateral, 23 bilateral, 45 unilateral with contralateral RRM). Of the remainder 124(33%) chose bilateral RRM and 252(67%) had no breast surgery. Of the 400 BRCA2 carriers, 90 had therapeutic mastectomy for BC (25 unilateral, 21 bilateral, 44 unilateral with contralateral RRM). Of the remainder 76(25%) chose bilateral RRM and 234(75%) had no breast surgery.
Conclusions: Uptake of bilateral RRM in BRCA carriers was slightly higher for BRCA1 vs BRCA2 mutation carriers (33% vs 25%), but this was not statistically significantly different. Rates of contralateral RRM with therapeutic mastectomy for BRCA mutation carriers with unilateral BC were similar for both genes (~50%). Further work is underway to investigate if RRM uptake has been constant or is increasing.
This work was funded by the RM/ICR NIHR BRC.

PM12.024

Emerging phenotype of BRCA2 mutations in South African patients with breast cancer and Fanconi anaemia

T. Wainstein[1], *C. Feben*[2], *R. Kerr*[1], *A. Krause*[2];
[1]Division of Human Genetics, University of the Witwatersrand, Johannesburg, South Africa, [2]Division of Human Genetics, NHLS/University of the Witwatersrand, Johannesburg, South Africa.

Introduction: Heterozygous mutations in *BRCA2* predispose to Hereditary Breast and Ovarian Cancer syndrome (HBOCS). Further, a rare subtype of Fanconi anaemia (FA) is caused by biallelic mutations in the *BRCA2* (*FANCD1*) gene. Two parallel studies in South African black patients investigating the genetic basis of inherited breast cancer and FA not caused by *FANCG* have identified *BRCA2* as being a potentially important gene.
Subjects and Methods: 84 young black South African women with breast cancer were screened for *BRCA1* and *BRCA2* mutations using either Sanger or NGS sequencing. In a separate study 5 patients with FA were screened for mutations using a NGS panel of known DNA breakage associated genes.
Results: In the women with breast cancer, 9 *BRCA2* and 4 *BRCA1* mutations were identified. Two *BRCA2* mutations observed more than once suggest the possibility of founder mutations. There is no family history in 5 of the women with *BRCA2* mutation. Two had triple negative tumours. An FA patient with multiple birth defects and Wilms tumour had 2 pathogenic truncating *BRCA2* mutations. *BRCA2* sequence variants (unconfirmed pathogenicity) were identified in 2/5 other black patients with clinical diagnoses of FA.
Conclusions: The phenotype of *BRCA2* mutations in South African black patients may be different to that previously described, and needs to be fully characterised. The paucity of family history in young mutation carriers with breast cancer may suggest strong protective environmental effects. Possible overlapping founder *BRCA2* mutations may contribute to both young onset breast cancer and severe FA.

PS12.025

Exome sequencing to explore temporal and spatial mutational evolutionary changes in invasive breast cancer specimens

S. Mian[1], *E. Nuglozeh*[1], *M. Fazaludeen*[1], *A. Elmouna*[1], *I. Ashankyty*[1], **M. Aleskandarany**[2], *M. Diez-Rodriguez*[2], *C. Nolan*[2], *E. Rakha*[2], *I. Ellis*[2];
[1]University of Ha'il, Ha'il, Saudi Arabia, [2]University of Nottingham, Nottingham, United Kingdom.

Genetic heterogeneity of breast cancer represents a significant challenge with respect to disease course and patient clinical management. Understanding molecular evolution of tumours both temporally and spatially would contribute further insight into molecular derangements driving disease progression. Exploratory analyses have been conducted on exome sequencing data of genomic DNA extracts from six invasive breast carcinoma samples representing matched primary tumour and the corresponding axillary lymph node metastases. Data was mined regarding concordance and discordance between primary tumour samples and their respective metastatic variants. Initial findings suggest that 37 candidate indels are common to all three axillary lymph node samplings and yet absent from the three samplings of the primary tumour. Several genes have been identified as having frameshift mutations caused by indels that may lead to potential abrogation of protein function. Of the genes with indel mutations in their coding sequences include molecular players that have been previously linked to anti-angiogenesis. These initial findings provide the framework for detailed molecular analyses of the molecular evolution of primary breast cancer and their associated metastases.

PM12.026

Panel next-generation sequencing reveals a high prevalence of deleterious ATM mutations in BRCA1/2-negative breast and ovarian cancer families

A. Heimbach[1,2], *J. Hauke*[1,2], *S. Kröber*[1,2], *J. Altmüller*[3,4,5], *C. Becker*[3,4,5], *H. Thiele*[3,4,5], *P. Nürnberg*[3,4,5], *B. Blümcke*[1,2], *R. Schmutzler*[1,2], *E. Hahnen*[1,2];
[1]*Center for Hereditary Breast and Ovarian Cancer, Center for Integrated Oncology (CIO), Medical Faculty, University Hospital Cologne, Cologne, Germany,* [2]*Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany,* [3]*Cologne Center for Genomics, University of Cologne, Cologne, Germany,* [4]*Institute of Human Genetics, University of Cologne, Cologne, Germany,* [5]*Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany.*

Approximately 24% of familial breast cancer (BC) and/or ovarian cancer (OC) cases analyzed within the framework of the German Consortium for Hereditary Breast and Ovarian Cancer (GC-HBOC) are due to pathogenic *BRCA1/2* mutations. However, the mutation frequencies of non-*BRCA1/2* genes associated with familial BC and/or BC/OC are largely unknown. Here, we present the NGS analysis (TruRisk™ gene panel) of a cohort of 574 *BRCA1/2*-negative index cases which comprises 256 unselected patients with triple negative breast cancer (TNBC) and 318 cases from high-risk BC and BC/OC families. By focusing on 21 BC/OC associated genes (*ATM, BARD1, BRIP1, CDH1, CHEK2, FANCM, MLH1, MSH2, MSH6, MRE11A, NBN, PALB2, PMS2, PTEN, RAD50, RAD51C, RAD51D, SMARCA4, STK11, TP53*, *XRCC2*), we identified 40 different pathogenic variants in 38 unrelated mutation carriers derived from 318 high risk BC and BC/OC families (12%). In contrast, only 9 mutation carriers (3.5%) were discovered among the unselected TNBC cases. Interestingly, we identified a high frequency of pathogenic *ATM* mutations *(n=10, 3.1%)* in the familial cases whereas no *ATM* mutations were found in the TNBC cohort. Additionally, we found a high frequency of mutations in *CHEK2*, *PALB2*, *RAD50* and confirm *FANCM* and *SMARCA4* as novel BC/OC predisposing genes. Due to the unexpectedly high mutation frequencies in familial cases, our study highlights the importance of these genes to be included in BC/OC routine diagnostics.

PS12.027

The Estrogen Receptor -α Gene rs1801132 variation and Breast Cancer risk in Iran

S. Abbasi[1], *S. Kalbasi*[2];
[1]*Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [2]*Faculty of Veterinary, University of Tehran, Tehran, Iran, Islamic Republic of.*

Iranian breast cancer patients are relatively younger than their Western counterparts. Evidence suggests that alterations in estrogen signaling pathways, including ESR1(estrogen receptor-α), occur during breast cancer development in Caucasians. Epidemiologic studies have revealed that age-incidence patterns of breast cancer in Asians differ from those in Caucasians. Genomic data for ESR1in either population is therefore of value in the clinical setting for Iranian breast cancer.
A case-control study was conducted to establish a database of ESR1polymorphisms in Iranian women population in order to compare Western and Asian with Iranian (Asian-Caucasians) distributions and to evaluate ESR1-polymorphism as an indicator of clinical outcome. DNA was extracted from Iranian women with breast cancer referred to Imam Khomeini Hospital Complex clinical breast cancer group (150 patients) and in healthy individuals (147 healthy control individuals). PCR single-strand conformation polymorphism technology was performed.
A site of silent single nucleotide polymorphism (SNP) rs1801132 was found, The frequency of allele 1 in codon 325 (CCC→CCG) was significantly higher in breast cancer patients (39.6%) than in control individuals (28.9%; P = 0.007). The allele CCG had also significant association with the occurrence of lymph node metastasis.
Data suggest that ESR1polymorphisms in exon 4 codon 325 is correlated with various aspects of breast cancer in Iran. ESR1 genotype, as determined during presurgical evaluation, might represent a genetic marker for predicting breast cancer lymph node metastasis.

PM12.028

Nonsense mutation in FANCM confers risk for triple-negative breast cancer

J. I. Kiiski[1], *L. M. Pelttari*[1], *S. Khan*[1], *S. N. Hart*[2], *S. Vilske*[1], *A. Kallioniemi*[3], *J. Schleutker*[3,4], *A. Leminen*[1], *R. Bützow*[1,5], *C. Blomqvist*[6], *F. J. Couch*[2], *K. Aittomäki*[7], *H. Nevanlinna*[1];
[1]*Department of Obstetrics and Gynecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [2]*Division of Experimental Pathology, Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN, United States,* [3]*BioMediTech, University of Tampere and Fimlab Laboratories, Tampere, Finland,* [4]*Department of Medical Biochemistry and Genetics, Institute of Biomedicine, University of Turku, Turku, Finland,* [5]*Department of Pathology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [6]*Department of Oncology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [7]*Department of Clinical Genetics, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.*

Inherited predisposition to breast cancer is known to be caused by loss-of-function mutations in *BRCA1, BRCA2, PALB2, CHEK2*, and other genes involved with DNA repair. However, most families severely affected by breast cancer do not harbor mutations in any of these genes.
In Finland, founder mutations have been observed in each of these genes, suggesting that the Finnish population may provide a unique resource for identification of additional breast/ovarian cancer alleles. We studied 24 breast cancer patients from 11 Finnish breast cancer families with exome sequencing and further genotyped selected DNA repair variants in 3166 familial and/or unselected breast cancer patients as well as 569 ovarian cancer patients and 2090 population controls. Of all genotyped variants, a nonsense mutation (c.5101C>T, rs147021911, p.Gln1701Ter) in Fanconi Anemia complementation gene M (*FANCM*) was significantly associated with breast cancer risk (OR = 1.86, 95% CI = 1.26-2.75, *P* = 0.0018). Further assessment based on tumor pathology identified a particularly strong effect in triple-negative breast cancer (OR = 3.56, 95% CI = 1.81-6.98, *P* = 0.0002). These findings identify *FANCM* as a novel breast cancer predisposition gene, with a moderate risk of especially triple negative breast cancer for mutation carriers.
The study has been supported by the Helsinki University Central Hospital Research Fund, the Academy of Finland, the Sigrid Juselius Foundation, Nordic Cancer Union, and the Finnish Cancer Society. FJC was supported by the Breast Cancer Research Foundation, and CA116201 NIH SPORE award in breast cancer to the Mayo Clinic.

PS12.029

Associations Between HER2/neu ,TOP2A ,Chromosome 17 Copy Numbers and TWIST , RARβ2 and ESR1 Gene Promotor Hypermethylations of Patients with Breast Cancer

O. EROGLU[1,2], *A. F. NURSAL*[3,2], *O. CILINGIR*[2], *B. DURAK ARAS*[2], *M. OZDEMIR*[2], *S. ARTAN*[2];
[1]*Bilecik Seyh Edebali University, Science and Art Faculty, Molecular Biology and Genetics Department, Bilecik, Turkey,* [2]*Eskisehir Osmangazi University, Medical Faculty of Medical Genetics, Eskisehir, Turkey,* [3]*Giresun University, Medical Faculty of Medical Genetics, Giresun, Turkey.*

Introduction: Breast cancer is an important public health problem worldwide. The HER2 /neu protooncogene is amplified and overexpressed in approximately 25-30% of invasive breast carcinomas. DNA topoisomerase 2-alpha enzyme controls and alters the topologic states of DNA during transcription. TWIST expression in breast tumors correlate with increased disease recurrence and poor disease-free survival. Steroid receptor genes family members such as the RARβ2 and ESR1 genes are methylated and silenced in a fraction of breast cancer.
Method: In this study we analysed retrospective HER2/neu, TOP2A gene and Chromosome17 copy number alterations by fluorescence in situ hybridization (FISH) in primary tumor core biopsies from 100 high-risk primary breast cancer patients (tumors ≥2 cm and/or lenfatic metastase and/or distant metastases and/or under 40 years) . The methylation levels of the TWIST, RARβ2 and ESR1 gene promoters were assessed Methylation Sensitive High Resolution Melting Analysis (MS-HRM).
Results: In our study, HER2/neu amplifications were identified in 25% and TOP2A amplifications in 24% and deletions in 6% of patients. HER2/neu and TOP2A amplifications are found to be associated with IDC tumor type and high grade also HER2/neu amplifications is associated with PR(-), TOP2A amplifications is associated with ER(+). TOP2A deletions is associated with ER(-) and PR(-). Polysomy17 was present in 23% and monosomy 12% of patients. TWIST, RARβ2 and ESR1 methylation frequencies were 24%, 90% and 69% respectively.
Conclusions:. Our study is important as being the first study that analyzes association between HER2/neu, TOP2A gene copy numbers and TWIST, RARβ2 and ESR1 gene promotor methylation status in Turkish population.

PM12.030

Exome analysis of families with hereditary breast and ovarian cancer (HBOC) to identify new candidate genes related with breast cancer development

S. Glentis[1], *A. S. Dimas*[1], *A. C. Dimopoulos*[1], *K. Rouskas*[1], *I. S. Vlachos*[2,3], *F. Fostira*[4], *I. Konstantopoulou*[4], *D. Yannoukakos*[4], *J. Ragoussis*[1];
[1]*Functional Genomics Laboratory, BSRC Alexander Fleming, Athens, Greece,* [2]*Medical School of Athens, University of Athens, Athens, Greece,* [3]*Diana-Lab, BSRC Alexander Fleming, Athens, Greece,* [4]*Molecular Diagnostics Laboratory, NCSR Demokritos, Athens, Greece.*

Introduction: Breast cancer (BC) is the most common type of cancer in women worldwide. Hereditary Breast and Ovarian Cancer (HBOC) accounts for ~10% of BC cases, a fraction which stems from the genetic effects of rare alleles. At least 20 genes have been linked to BC susceptibility and a high fraction of genetic effects remains to be explained. The aim of this project is to identify genetic variants linked to HBOC through exome sequencing in Greek patients that were found to be negative for mutations in known candidate genes.
Materials and Methods: Exome sequencing was performed on a total of 50 HBOC patients and informative relatives. Exome capture was through the Ion TargetSeq Exome Capture kit and sequencing was performed on the Ion Proton platform. An analytical pipeline was compiled adapting the GATK software package to IP data.
Results: We detected an average ~55,000 variants per exome. We filtered our data using criteria based on relatedness of individuals sequenced, BC segregation in families, minor allele frequency of variants and in silico functional evaluation. This resulted into collection of shortlisted variants amounting to ~100 per family.
Conclusion: Preliminary results have highlighted candidate variants in PRDM2, EME1, XRRC1 and GAB4. Genetic variants have been validated through Sanger sequencing. Further functional validation is necessary to confirm the pathogenicity of the candidate variants. This project is funded by SYNERGASIA 2011 (NSRF 2007-2013, code: SYN11_10_19, NBCA).

PS12.031

Estrogen withdrawal, breast cell transformation, and breast cancer risk in women with the KRAS-variant

T. P. McVeigh[1], *S. Jung*[2], *D. Salzman*[3], *M. J. Kerin*[1], *S. Nallur*[3], *M. Dookwah*[3], *A. A. Nemec*[3], *J. Sadofsky*[3], *T. Paranjape*[3], *O. Kelly*[3], *E. Chan*[3], *N. Miller*[1], *K. J. Sweeney*[1], *D. Zelterman*[3], *J. Sweasy*[3], *R. Pilarski*[4], *D. Telesca*[2], *J. B. Weidhaas*[2];
[1]*National University of Ireland Galway, Galway, Ireland,* [2]*University of California, Los Angeles, Los Angeles, CA, United States,* [3]*Yale University, New Haven, CT, United States,* [4]*Ohio State University Wexner Medical Center, James Cancer Hospital, Columbus, OH, United States.*

Background:
The polymorphism rs61764370 is a functional variant in the let7a-binding site of KRAS that is associated with increased cancer risk, particularly breast and ovarian. This risk may be modified by menopausal status and HRT use.
Aim:
To evaluate the effect of estrogen exposure and withdrawal on development of breast cancer in patients with the KRAS-variant (vKRAS).
Methods:
Isogenic mammary (MCF10A) cell lines with and without vKRAS were cultured and observed for oncogenic transformation in charcoal-stripped media following oestrogen withdrawal and restoration. Cells with and without vKRAS were examined for epithelial-mesenchymal transition(EMT) by western blot, immunoflourescence, and relative quantification of EMT-associated miRNAs. The effect of the vKRAS on disease phenotype was investigated in a cohort of patients with breast cancer, comparing variant and wild-type genotype carriers. A case-control analysis was also performed using a control group of unaffected vKRAS carriers. Data was collected with respect to pathological characteristics, reproductive risk factors and anthropomorphic measurements.
Results:
Isogenic cell lines with vKRAS showed evidence of EMT, with relative overexpression of vimentin and fibronectin. Acute estrogen withdrawal by addition of tamoxifen to charcoal-stripped media led to 7.9-fold increase in oncogenic transformation, with reduction in colony formation after restitution of oestrogen. Affected vKRAS carriers were significantly more likely to have oophorectomy pre-diagnosis than wild-type patients(p=0.033). Affected vKRAS carriers with breast cancer had lower BMI(p<0.01) than vKRAS unaffected controls. HRT-discontinuation in vKRAS carriers was significantly associated with post-menopausal triple negative breast cancer.
Conclusions: Estrogen withdrawal and a low estrogen state appear to increase breast cancer and predict aggressive tumor biology in women with variant KRAS.

PM12.032

Clonal expansion and linear genome evolution through breast cancer progression from pre-invasive stages to asynchronous metastasis

A. B. Krøigård[1,2], *M. J. Larsen*[1,2], *A. Lænkholm*[3], *A. S. Knoop*[4], *J. D. Jensen*[5], *M. Bak*[6], *J. Mollenhauer*[7], *T. A. Kruse*[1], *M. Thomassen*[1];
[1]*Dept. of Clinical Genetics, Odense University Hospital, Odense, Denmark,* [2]*Human Genetics, Institute of Clinical Research, University of Southern Denmark, Odense, Denmark,* [3]*Department of Pathology, Slagelse Hospital, Slagelse, Denmark,* [4]*Dept. of Oncology, Rigshospitalet, Copenhagen, Denmark,* [5]*Dept. of Oncology, Odense University Hospital, Odense, Denmark,* [6]*Dept. of Pathology, Odense University Hospital, Odense, Denmark,* [7]*Lundbeckfonden Center of Excellence NanoCAN, Odense, Denmark.*

Evolution of the breast cancer genome from pre-invasive stages to asynchronous metastasis is complex and mostly unexplored, but highly demanded as it may provide novel markers for and mechanistic insights in cancer progression. The increasing use of personalized therapy of breast cancer necessitates knowledge of the degree of genomic concordance between different steps of malignant progression as primary tumors often are used as surrogates of systemic disease. Based on exome sequencing we performed copy number profiling and point mutation detection on successive steps of breast cancer progression from one breast cancer patient, including two different regions of Ductal Carcinoma In Situ (DCIS), primary tumor and an asynchronous metastasis. We identify a remarkable landscape of somatic mutations, retained throughout breast cancer progression and with new mutational events emerging at each step. Our data, contrary to the proposed model of early dissemination of metastatic cells and parallel progression of primary tumors and metastases, provide evidence of linear progression of breast cancer with relatively late dissemination from the primary tumor. The genomic discordance between the different stages of tumor evolution in this patient emphasizes the importance of molecular profiling of metastatic tissue directing molecularly targeted therapy at recurrence.

Screening of HELQ in breast and ovarian cancer families

L. M. Pelttari[1], *L. Kinnunen*[1], *C. Blomqvist*[2], *K. Aittomäki*[3], *H. Nevanlinna*[1];
[1]*Department of Obstetrics and Gynecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [2]*Department of Oncology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [3]*Department of Clinical Genetics, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.*

Several risk-alleles have been identified for breast and ovarian cancer predisposition and most of them encode proteins that function in DNA repair. In the Finnish population, recurrent founder mutations have been observed in most of the susceptibility genes whereas in out-bred populations each gene may harbor rare unique mutations. A prospective candidate for breast and ovarian cancer susceptibility is the HELQ helicase that has a role in the resolution of DNA interstrand cross-links. HELQ interacts with the RAD51 paralog complex BCDX2. Two components of the complex, RAD51C and RAD51D, increase the risk of ovarian cancer, while the other two, RAD51B and XRCC2 have been associated with breast cancer risk. To investigate the role of *HELQ* in cancer predisposition and to identify putative recurrent founder mutations, we screened the *HELQ* gene for germline variation in 182 Finnish familial breast or ovarian cancer patients. To study the role of common variation in the gene, we performed haplotype analyses for 1517 breast and 308 ovarian cancer cases and 1234 population controls. No deleterious mutations were identified among the patients and the haplotype distribution did not differ between breast or ovarian cancer cases and population controls. Our results indicate that *HELQ* is not a major breast and ovarian cancer susceptibility gene in the Finnish population. However, we cannot rule out rare risk-variants in the Finnish or other populations.

PM12.034

Clinical Characteristics of Breast Cancer in Women with a PALB2 Mutation

C. Cybulski[1], *W. Kluzniak*[1], *T. Huzarski*[1], *D. Wokolorczyk*[1], *A. Kashap*[1], *A. Jakubowska*[1], *M. Szwiec*[2], *T. Debniak*[1], *B. Gorski*[1], *V. Sopik*[3], *M. Akbari*[3], *P. Sun*[3], *J. Gronwald*[1], *S. Narod*[3], *J. Lubinski*[1];
[1]*Pomeranian Medical University, Szczecin, Poland,* [2]*Regional Oncology Center, Opole, Poland,* [3]*Womens College Research Institute, Toronto, ON, Canada.*

PURPOSE: To estimate the lifetime risk of breast cancer in Polish women who carry a founder mutation in the PALB2 gene and to establish the clinical characteristics of breast cancers in patients with a PALB2 mutation.
PATIENTS AND METHODS: 12,529 breast cancer patients from Poland and 4,702 controls were genotyped for two deleterious mutations in PALB2 (c.509_510delGA and c.172_175delTTGT). Among breast cancer patients, the ten-year survival of carriers of a PALB2 mutation was calculated and compared with that of non-carriers.
RESULTS: A truncating PALB2 mutation was found in 116 breast cancer patients (0.93%) and in 10 controls (0.21%; OR = 4.39; 95% CI = 2.3 to 8.4; p < 0.0001). The ten-year survival of women with breast cancer and a PALB2 mutation was 49%, compared to 76% for women without a mutation (HR for death = 2.14; 95% CI = 1.55 to 2.95; p < 0.0001). Among the 2,065 patients who died, 38 women (1.8%) carried a PALB2 mutation.

CONCLUSION: Women with a PALB2 mutation face increased risks of breast cancer and of death from breast cancer. Given the high incidence and case-fatality associated with mutations in this gene, preventive mastectomy should be discussed with unaffected women who are found to carry a PALB2 mutation.
Acknowledgements: The study was funded by the Polish National Science Centre on the basis of the decision number DEC-2011/03/N/NZ2/01510.

Genetic predisposition to bilateral breast cancer: bioinformatics challenges in whole exome sequencing data analysis

A. Larionov[1], *J. Redman*[1], *P. Concannon*[2], *D. Thomas*[3], *D. Duggan*[4], *J. Bernstein*[5], *WECARE Investigators*, *D. Conti*[3], *M. Tischkowitz*[1];
[1]*Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom,* [2]*Genetics Institute and Department of Pathology, Immunology and Laboratory Medicine, University of Florida, Gainesville, FL, United States,* [3]*Division of Biostatistics, Department of Preventive Medicine, University of Southern California, Los Angeles, CA, United States,* [4]*Translational Genomics Research Institute (TGEN), Phoenix, AZ, United States,* [5]*Department of Epidemiology and Biostatistics, Memorial Sloan-Kettering Cancer Center, New York, NY, United States.*

Contralateral breast cancer (CBC) is strongly associated with a heritable predisposition. The Women's Environmental Cancer and Radiation Epidemiology (WECARE) Study investigates susceptibility genes for CBC in women who received radiation treatment for the primary tumour. Whole exome sequencing (WES) was performed in DNA samples extracted from the blood of 256 women with unilateral BC and 256 closely matched women with CBC who did not have *BRCA1*, *BRCA2* and *PALB2* mutations based on previous screening. Matching was prioritised by radiation exposure, age at onset, latent period between diagnoses and family history of breast cancer. Libraries were prepared using Illumina Nextera Rapid Capture Exome kits. Sequencing was performed on Illumina HighSeq2500 machines to ~50x depth. Initial findings will be presented and challenges in data analysis discussed. The focus will be on quality control during data acquisition and current bioinformatics and statistical approaches that can be employed to detect genetic alterations associated with CBC. The quality control analysis found that longer reads may reduce efficiency of sequencing when used with Nextera library preparation kits because of the overlap in reads. Regarding the main analysis pipeline we will discuss (i) concordance assessment with previously obtained GWAS data (ii) performance and limitations of available tools for detecting structural variations and (iii) tools and resources required for adopting GRCh38 assembly in WES data analysis. Finally, we will compare statistical models that can be employed to detect single-genes as well as multi-gene patterns associated with unilateral BC versus CBC in the WECARE study.

PM12.036

Clinical utility of a breast cancer gene panel to improve clinical management of familial breast/ovarian cancer families

K. Reay[1], *N. Forrester*[2], *S. Clokie*[1], *K. R. Ong*[3], *J. Bell*[1], *D. G. Evans*[4], *Y. Wallis*[1];
[1]*West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom,* [2]*Bristol Genetics Laboratory, Bristol, United Kingdom,* [3]*West Midlands Clinical Genetics Service, Birmingham, United Kingdom,* [4]*Manchester Centre for Genomic Medicine, Manchester, United Kingdom.*

Germline mutations in the BRCA1 and BRCA2 breast cancer susceptibility genes account for up to 20% of inherited breast cancer cases. This leaves a sizable fraction of familial cases where the heritability link remains unidentified meaning affected families may not receive appropriate clinical management including predictive testing for at-risk family members. In recent years a number of other breast cancer susceptibility genes have been identified. Although they may be individually less prevalent, together they promise to account for a significant proportion of familial cases. An extended breast cancer gene next generation sequencing strategy has therefore been developed to determine the role these genes play within the clinical diagnostic setting. A large cohort of families previously found not to have a pathogenic BRCA1/2 gene mutation were screened for mutations in an additional 10 genes (ATM, BRIP1, CDH1, CHEK2, PALB2, PTEN, RAD51C, RAD51C, STK11, and TP53) enriched using the Illumina TruSight Cancer Panel. Sequencing data was processed using an in-house bioinformatics pipeline optimised for sensitive indel detection. To date this new strategy has been used to screen 121 patients. Twelve patients (10%) were identified as having a class 4/5 pathogenic mutation in ATM, CHEK2, PALB2, RAD51D and TP53 according to criteria recommended by the ACGS Evaluation of Pathogenicity Best Practice Guidelines, including confirmation by RNA analysis. Given the limited penetrance of some of these genes segregation studies are offered to further support pathogenicity within individual families. This study is already indicating that this approach will improve the management of breast cancer families.

Background: The identification of novel biomarkers for early detection of breast cancer would be a great advance. Due to their role in tumorigenesis and stability in body fluids, microRNAs (miRNAs) are emerging as a promising diagnostic tool. The aim of this study was to identify miRNAs deregulated in breast tumors and evaluate the potential of circulating miRNAs in breast cancer detection.
Methods: MiRNA expression profiling of 1919 human miRNAs was conducted in paraffined tissue from 122 breast tumors and 11 normal breast tissues. Differential expression analysis was performed generating a microarray classifier. The most relevant miRNAs were analyzed in plasma from 26 healthy individuals and 83 breast cancer patients (36 pretreated and 47 postreated), and validated in 116 healthy individuals and 114 pretreated patients.
Results: We identified a large number of miRNAs deregulated in breast cancer and generated a 25-miRNA microarray classifier that discriminates breast tumors with high sensitivity and specificity. Ten miRNAs were selected for further investigation in plasma and 4 of them (miR-505-5p, miR-125b-5p, miR-21-5p and miR-96-5p) were found to be significantly overexpressed in pretreated breast cancer patients when compared with healthy individuals in two different series of plasma. MiR-505-5p and miR-96-5p were the most valuable biomarkers (AUC=0.72). Moreover, the levels of miR-3656, miR-505-5p and miR-21-5p decreased in a group of treated patients.
Conclusions: MiRNAs can discriminate breast tumors in peripheral blood. The identification of deregulated miRNAs in plasma of breast cancer patients supports the use of circulating miRNAs as a novel method for early breast cancer detection.

Not HOXB13 p.G84E, but p.R217C appears to be associated with increased breast cancer risk in the Dutch population

J. Liu[1], *W. J. C. Prager-van der Smissen*[1], *M. K. Schmidt*[2], **M. Collée**[3], *S. Cornelissen*[2], *R. Lamping*[3], *A. Nieuwlaat*[3], *J. A. Foekens*[1], *M. J. Hooning*[1], *S. Verhoef*[4], *A. W. M. Van den Ouweland*[3], *F. B. L. Hogervorst*[4], *J. W. M. Martens*[1,5], *A. Hollestelle*[1];
[1]*Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands,* [2]*Division of Molecular Pathology, Netherlands Cancer Insitute, Amsterdam, Netherlands,* [3]*Department of Clinical Genetics, Erasmus MC Cancer Institute, Rotterdam, Netherlands,* [4]*Division of Diagnostic Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands,* [5]*Cancer Genomics Netherlands, Rotterdam, Netherlands.*

HOXB13 plays an important role in breast tumorigenesis as high expression of *HOXB13* predicts poor outcome and adverse response to endocrine therapy. At the genetic level, the *HOXB13* p.G84E mutation confers a four to five-fold increased prostate cancer risk and thus *HOXB13* p.G84E might also be associated with increased breast cancer risk. Previous studies investigating this association, however, reported conflicting results. Therefore, we now have comprehensively interrogated the entire *HOXB13* coding sequence for mutations in 1250 non-*BRCA1&2* familial breast cancer cases and 800 controls. In total, seven missense mutations were identified of which five were seen only once. The p.G84E mutation, however, was identified in 4 (0.33%) of 1215 cases and 6 (0.79%) of 759 controls. Another recurrent mutation, p.R217C, was found in 6 (0.50%) of 1206 cases and 1 (0.13%) of 765 controls. Because both mutations were predicted to be damaging, we further evaluated their association with breast cancer risk by expanding our case-control study to include a total of 4520 non-*BRCA1&2* familial breast cancer cases and 3127 controls. Custom genotyping revealed that p.G84E was present in 22 (0.50%) of 4415 cases and 22 (0.71%) of 3089 controls (OR=0.70, 95% CI=0.39-1.26, *P*=0.23). The *HOXB13* p.R217C mutation, however, was identified in 16 (0.36%) of 4444 cases and 3 (0.10%) of 3077 controls (OR=3.70, 95% CI=1.08-12.72, *P*=0.033, P_{adj}=0.066). Our results show that *HOXB13* p.R217C rather than p.G84E appears to be associated with breast cancer risk. *HOXB13* p.R217C is thus a putative novel moderate-risk breast cancer susceptibility allele.

PS12.039

Identification Of Rare And Novel Alleles In Ffpe Tumor Samples Using Laser Capture Microdissection (Lcm) And Ampliseq™ Sequencing Technologies

S. Jackson[1], *P. Choppa*[2], *K. Kuar*[2], *K. Schmidt*[1], *K. Varma*[1];

[1]Thermo Fisher Scientific, South San Francisco, CA, United States, [2]Thermo Fisher Scientific, West Sacramento, CA, United States.

Tumors are becoming recognized as genetically heterogeneous masses of cells with different clonal histories. Identifying the mutations present in these heterogeneous masses can lead to important insights into the future behavior of the tumor and possible intervention mechanisms. However, the rarity of pathogenic mutations in small subsets of cells can make identification of such alleles difficult. In this study, we demonstrate a complete workflow that facilitates the identification of rare and novel alleles from FFPE tumor sections. We collected small regions with different cellular morphologies from lung tumor samples using laser capture microdissection, extracted both DNA and RNA from these regions, and characterized mutations present and transcript abundances by using Ampliseq™ targeted sequencing. We show that LCM facilitates the detection of alleles that are not detectable in macrodissected tissue scrapes. We also show that different regions of a tumor have very different patterns of alleles detectable and have a great deal of genetic diversity. Finally, we show that RNA expression patterns are also clearly different in the different regions. Interestingly, dissected regions with similar gross tissue morphologies display differences in alleles present and RNA expression patterns. These results suggest the best way to analyze mutations present in a tumor is to microdissect different subregions of the tumor, and using Ampliseq™ panels to identify the alleles present in those subregions.

Case-control genetic association study of urothelial bladder carcinoma among Pakistani population

S. H. Ali[1,2], *K. S. Bangash*[3], *A. Rauf*[4], *M. Younis*[5], *K. Anwar*[3], *M. A. Khawaja*[6], *S. Akhter*[6], *M. Azam*[2], *L. A. Kiemeney*[7], *R. Qamar*[2];
[1]Bahauddin Zakariya University, Multan, Pakistan, [2]COMSATS Institute of Information Technology, Islamabad, Pakistan, [3]Pakistan Atomic Energy Commission General Hospital, Islamabad, Pakistan, [4]Nishtar Medical College & Hospital, Multan, Pakistan, [5]King Edward Medical University, Lahore, Pakistan, [6]Department of Urology, Shifa International Hospital, Islamabad, Pakistan, [7]Department for Health Evidence and Department of Urology, Radboud University Medical Centre, Nijmegen, Netherlands.

A case-control genetic association study on Pakistani urothelial bladder carcinoma (UBC) patients (N = 200) and controls (N = 200) was conducted. VNTR polymorphism of eNOS; Alu repeat variation of ACE; null polymorphisms of GSTT1 and GSTM1 and selected common variants of GSTP1, MTHFR, PSCA, TNFα, p21, p53, CYP1B1, XPD, XRCC1, CAV1, PON1, IGFBP3, VEGFA, LEP, LEPR, PPARγ genes as well as 8q24.21 locus (rs9642880 and rs6983267) were analyzed for an overall risk assessment and with respect to smoking status, tumor grade and stage.
Variants of GSTM1, LEPR, ACE, PSCA, rs9642880 and rs6983267 were found to be associated with higher risk while IGFBP3 variant and haplotypes of CAV1 and MTHFR with reduced risk of UBC in the overall comparison.
CYP1B1, p21, ACE and rs9642880 conferred a high risk to smokers while LEPR and PSCA variants to non-smokers. In contrast, IGFBP3 variant and CAV1 haplotypes conferred protection to non-smokers.
GSTM1, LEPR and rs9642880 were found to be associated with enhanced risk of low grade and non-invasive UBC; while GSTT1, CAV1, PSCA and PPARγ with an elevated risk of high grade and invasive UBC. IGFBP3 variant protected against low and high grade tumors and non-invasive disease. Different haplotypes of MTHFR were found to confer a high risk of non-invasive tumor while providing protection against invasive.
In brief, genetic associations to UBC susceptibility, few being novel, were observed in the present study, which to the best of author's knowledge, is the first attempt to reveal genetic epidemiology of UBC exclusively among Pakistani population.

Case studies demonstrating that use of a large, augmented panel to sequence cancer genes to high depth enables clinically-relevant variant identification

M. J. Clark, R. McClory, **S. Boyle**, *E. Helman, J. Beck, G. Chandratillake, S. Garcia, D. Church, R. Chen, J. West;
Personalis, Menlo Park, CA, United States.*

Introduction: Genetic lesions in cancer can determine prognosis and have diagnostic value. Next-generation sequencing facilitates the detection of a wide array of somatic mutations, copy number alterations (CNAs), and gene fusions in a single assay. With increased sequencing depth, mutations present in only a fraction of the neoplastic tissue can be identified. Detection of these mutations after sequencing DNA and RNA involves a complex set of variant detection algorithms tailored specifically for cancer analysis.
Materials and Methods: We designed a cancer panel using an augmented target enrichment strategy optimized for even coverage across the entire span of gene content to detect small variants, CNAs, and gene fusions. The panel includes over 1,500 cancer genes and micro-RNAs. Very high depth (>500x) sequencing detects low representation alleles. We tested the panel and pipeline using over 30 different cancer samples including cancer cell lines, engineered cells containing specific cancer mutations, and primary tumors in FFPE.
Results: We demonstrate that this cancer gene panel and analysis strategy is able to detect mutations of each major type with high sensitivity and positive predictive value. We saw greater than 99% sensitivity for small variants down to 5% allele frequency. We also detected known gene fusion events including *EML4-ALK* and *BCR-ABL1* accurately in all 20 cancer samples with known fusions. Moreover, the assay was able to identify CNAs consistent with the known state, including detection of *EGFR* amplification, *EGFR*vIII, *PTEN* loss, and *p16* loss in known cases.
Conclusions: The high depth, augmented cancer gene panel assay is able to comprehensively identify cancer mutations with high accuracy.

Exome sequencing and molecular heterogeneity in a cohort of Anaplastic Large Cell Lymphoma

S. Mian[1], *E. Nuglozeh*[1], *A. Elmouna*[1], *M. Fazaluldeen*[1], *I. Ashankyty*[1], *N. Moti*[2], *T. Malcolm*[2], *C. Fairbairn*[2], *S. Turner*[2];
[1]University of Ha'il, Ha'il, Saudi Arabia, [2]University of Cambridge, Cambridge, United Kingdom.

Exome sequencing has been conducted on a panel of frozen paediatric Anaplastic Large Cell Lymphoma (ALCL) tissue samples. Exome sequencing was conducted using an Illumina MiSeq. Variants (indels/SNPs) were identified using the GATK (Genome Analysis Tool Kit) pipeline using the hg19 reference genome. A molecular characterisation has been undertaken to assess inter-patient molecular tumour homogeneity/heterogeneity and data is presented on these initial findings. One patient had tissue samples derived from a primary, and two relapse cases. SNPs and indels were detected that were concordant between all three samplings. Analysis of temporal changes between the primary tumour and second recurrence also identified SNPs and indels that were restricted only to the secondary recurrence. In-silico tools were utilised to examine potential effects upon protein function including frameshift mutations caused by indel. Several genes were identified including RBM33, SEMA5B and ZNF155 that had high impact changes to their genetic sequence with potential downstream consequences to protein structure and function. These studies provide the framework for a detailed molecular analyses of exonic dynamics and molecular evolution of ALCL tumours.

Personalized cancer mutation panel by next generation sequencing for cancer prediction

H. Chia-Cheng[1,2,3], **S. Yi-Ning**[1,2,4], *L. Tzu-Hung*[5];
[1]Phoebus Genetics Co., Ltd., Taipei, Taiwan, [2]Sofiva Genomics, Co., Ctd., Taipei, Taiwan, [3]Graduate Institute of Medical Genomics and Proteomics, National Taiwan University College of Medicine, Taipei, Taiwan, [4]Department of Obstetrics and Gynecology, School of Medicine, Taipei Medical University, Taipei, Taiwan, [5]Dianthus Maternal Fetal Medicine Clinic, Taipei, Taiwan.

Objective:
Next-generation sequencing (NGS) allows for high-throughput sequencing analysis of numerous regions of the human genome. We explored the use of targeted mutation detection by NGS for simultaneous genetic testing for multiple caner genes.
Methods: We used a personalized cancer mutation panel to target more than 2,800 mutations in the 50 key cancer genes. NGS was performed to jointly sequence captured DNA individually for 2 healthy cases.
Results: Using targeted mutations sequencing, we achieved an average sequence depth of ~1000× per base. We analyzed DNA from 2 unrelated individuals and identified a heterozygous c.1151T>A (p.V384D) mutation of the MLH1 gene in case 1, which is highly associated with pancreatic cancer; a heterozygous mutation c.2472C>T (p.V824V) of the PDGFRA gene was detected in case 2, which is highly associated with endometrium cancer.
Conclusion: The personalized cancer targeted mutation detection NGS panel allows simultaneous testing for multiple genes with high accuracy. Using this approach can fast identification of mutations in key cancer genes and can provide important individual information of tumor development and cancer prediction.

PM12.044

From national guideline recommendations to familial cancer risk assessment decision support in primary care: UK experience

W. Chorley, B. Dutton, C. Brindley, L. Robles, **N. Qureshi**;
University of Nottingham, Nottingham, United Kingdom.

Introduction: The English national guidelines on managing women with a family history of breast cancer provides criteria for specialist care referral and for patients that can be followed-up in primary care. Also there is a category, with unclear family histories, where the guidelines recommend that patients are not referred directly but discussed with specialists. We have explored the nature of family histories that fall into this category and how to integrate this information into primary care decision support software. The guidelines also recommend genetic testing, hence referral, when probability of BRCA1/BRCA2 is greater than 10%.
Materials and Methods: In our exploratory trial all women aged 30 to 60 in four General Practices, in Central England, were invited to complete a family history questionnaire. The family histories were assessed against national guidelines and Manchester Scoring System.
Results: Currently, 13.1% (126) of 963 women completing the questionnaire were recommended by guidelines to discuss with familial cancer specialist. Of these 126 participants, 9.5% (12) of pedigrees had greater than 10% probability of BRCA1/BRAC2, based on Manchester Scoring System. Further, the specialist identified that the guideline's referral criteria had not fully taken account of familial risk of related cancers and age of onset in relatives.
Conclusion: To operationalise national guidelines and implement decision support software in primary care, uncertain family histories need to be reduced. This could be achieved by combining national guidelines with consensus opinion of specialists and key attributes of evidence-based referral tools, such as Manchester Scoring Systems.

Intratumoral Genetic Heterogeneity in Clear Cell Renal Cell Carcinoma

K. Kok[1], *P. Ferronika*[1], *G. Kats-Ugurlu*[1], *J. Bergsma*[1], *J. Li*[1], *M. M. Terpstra*[1], *D. Danarto*[2], *A. Moeljono*[2], *T. Utoro*[2], *R. H. Sijmons*[1];
[1]*UMCG, Groningen, Netherlands,* [2]*Gadjah Mada University, Yogyakarta, Indonesia.*

Clear Cell Renal Cell Carcinoma (ccRCC) is well known for the heterogeneity of its clinical, histologic, and genetic profiles. We optimized the preparation of DNA samples from paraffin material to identify the genetic profile of different tumour areas of one case of ccRCC. DNA was isolated from paraffin sections of four tumour areas and normal kidney cortex. The morphological variety among different areas of the tumour has been documented. We performed pre-analytical RT-PCR to measure the quality of amplifiable DNA input. Aliquotes of 100 ng of DNA were subjected to whole exome sequencing (Agilent SureSelect All exon V2®, Illumina HISEQ 2500®) and targeted exome sequencing (NugenOvation® Target Enrichment System) as an alternative approach to obtain reliable sequence data from FFPE material. Based on published data a minimum Quantitative Functional Index (QFI) of 6-7% from RT-PCR is needed to achieve 90% confirmed variants on sequencing data. The QFI of our FFPE DNA samples showed values of 8.9-12.6%, indicating that the quality of our DNA samples was acceptable for further analysis. The quality control report of sequencing data showed a 20x coverage of 68-86%. Preliminary analyses of the sequence data identified 151 somatic mutations, including 3 indels. In these preliminary data we see a unique genetic profile shared by areas which have similar tumour histological grade. The observed mutational heterogeneity present among different areas of ccRCC may be important in cancer development.

PM12.046

Identification of pathogenic CDH1 mutations in three families in DNA extracted from FFPE tissue from deceased family members with suspected hereditary diffuse gastric cancer

T. D. Jensen, *A. H. Petersen, A. Bojesen;*
Department of Clinical Genetics, Sygehus Lillebaelt, Vejle, Denmark.

Introduction: Hereditary diffuse gastric cancer (HDGC) is a cancer susceptibility syndrome caused by pathogenic mutations in *CDH1*. HDGC is inherited in an autosomal dominant manner and mainly characterized by a high cumulative risk of developing diffuse gastric cancer (approximately 80% for both sexes) and lobular breast cancer (approximately 50% for women). As with other hereditary cancer syndromes, the task of identifying the disease-causing mutation in a family has often been difficult without affected living family members. Identifying a new family mutation in tissue-derived DNA from deceased is technically challenging for various reasons, and because of that, this diagnostic approach has not been offered on a regular basis by diagnostic departments or companies.
Materials and Methods: DNA was extracted from 9x15 µm FFPE tissue sections per sample, and DNA integrity was estimated. DNA samples were subjected to HaloPlex Target Enrichment using a custom design including *CDH1* (Agilent Technologies). After enrichment, HaloPlex libraries were diluted, pooled, denatured and 10 pM library pool was subjected to paired-end (2x150 bp), single index (8 bp) DNA sequencing on a MiSeq (Illumina).
Results: We identified a pathogenic *CDH1* mutation in three different families with one or more deceased family members with suspected HDGC. In all three cases, the mutation was identified in DNA extracted from FFPE tissue from a deceased.
Conclusions: The possibility of identifying pathogenic mutations in deceased family members is a new and important tool in the process of determining or evaluating the risk of certain cancers of family members who receive genetic counseling.

PS12.047

A multiplexed amplicon sequencing technology for FFPE and circulating cell-free DNA

L. Kurihara, *C. Couture, J. Laliberte, S. Sandhu, J. Irish, T. Harkins, V. Makarov;*
Swift Biosciences, Ann Arbor, MI, United States.

Detection of somatic mutations is challenging since percent tumor content in clinical samples is variable and is compounded by tumor heterogeneity. Additionally, circulating cfDNA and FFPE samples are limited in quantity, and FFPE samples can be damaged. To address these challenges, we developed a single tube, multiplexed amplicon sequencing method that employs hundreds of primer pairs for amplification of target loci, producing ready-to-run libraries for Illumina sequencing. The two-step method- multiplexed PCR followed by a 10 minute adapter ligation- results in amplicons that are 120-160 bp in length, enabling amplification and variant calling from cfDNA-sized DNA fragments or damaged FFPE DNA. An oncology panel was developed to target known, clinically relevant mutations in 56 genes. The panel design encompasses single exons (e.g. BRAF) and comprehensive coding exon coverage of entire genes (e.g. TP53), depending on the allele distribution across each gene. To validate this panel, a cohort of control and clinical samples with pre-validated genotypes was tested using 10ng of input DNA. Variant calling was performed using GATK and LoFreq. Robust detection of 5% mutant frequency was observed, and the limit of detection was as low as 1% mutant frequency. The percent on-target bases and coverage uniformity were both >95%, where uniformity is defined as the percent bases covered at >20% of the mean coverage. These results indicate that this multiplexed amplicon panel is an excellent tool to assess multiple oncogenes in limiting clinical samples, enabling high throughput, cost effective NGS analysis.

PM12.048

A circulating cell free DNA targeted sequencing workflow - from isolation through validation

D. Dhingra, *X. Fang, M. Carter, D. Brinza, C. Scafe, F. Hyland, K. Bramlett;*
Thermo Fisher Scientific, South San Francisco, CA, United States.

Circulating cell free DNA has been shown to have the potential as a non-invasive substrate for the detection of cancer and its progression as well as the determination of therapeutic resistance. As circulating tumor DNA is often present at low frequencies within circulating cell free DNA, targeted sequencing is an optimal tool for mutation detection. Here, we demonstrate a complete workflow from isolation through validation of circulating tumor DNA.
We have optimized an easily automatable protocol using magnetic beads to isolate circulating cell free DNA. It is also scalable for any input volume and can elute in volumes down to 15 µL resulting in no loss of low frequency alleles. We demonstrate comparable performance between this bead based isolation and column based isolation.
We then completed molecular characterization of the isolated circulating cell free DNA using the multiplexing capabilities of AmpliSeq™ and the Ion Torrent™ platform for targeted sequencing of 50 genes of interest. We demonstrate good reproducibility of amplicon representation as well as allelic frequencies. We have determined the limit of detection of hotspots circulating cell free DNA on the Ion Torrent™ platform to be below 1%. We further demonstrate proof of principle of this workflow on circulating cell free DNA and matched FFPE samples complete with TaqMan® validation.
Our results validate the accuracy and ease of our workflow. This protocol, from isolation through targeted sequencing and validation, will not only re-

sult in a simple sample preparation for circulating cell free DNA but also facilitate rapid mutation detection to advance cancer research.

Comprehensive genomic characterization of intrahepatic cholangiocarcinoma

T. Heß[1,2], *D. Bertrand*[3], *C. Chan*[4], *J. Becker*[1,2], *A. Hofmann*[1,2], *I. Gockel*[5], *I. Hornstein*[6], *M. M. Nöthen*[1,2], *A. M. Hillmer*[4], *J. Schumacher*[1];
[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]Department of Genomics, Life&Brain Center, University of Bonn, Bonn, Germany, [3]Computational and Systems Biology, Genome Institute of Singapore, Singapore, Singapore, [4]Cancer Therapeutics and Stratified Oncology, Genome Institute of Singapore, Singapore, Singapore, [5]Department of Visceral; Transplantation; Vascular and Thoracic Surgery, University Hospital of Leipzig, Leipzig, Germany, [6]Department of General; Visceral and Transplant Surgery, University Hospital of Mainz, Mainz, Germany.

Intrahepatic cholangiocarcinoma (ICC) is a cancer arising from the epithelium of the biliary tracts located within the liver. ICC represents the second most common primary liver malignancy with significant rise in incidence over the past three decades. The molecular mechanisms underlying ICC tumorigenesis are not well understood, although recently the first whole-exome sequencing (WES) studies have been performed on tumor samples derived from patients with Asian descent.
In order to identify common genomic alterations driving ICC development, we conducted the largest WES study on patients of Central European origin. We collected tumor and matching control tissue samples from 38 ICC-patients and performed WES as well as microarray genotype and gene expression analyses. The data were used to obtain genomic profiles comprising somatic mutations, copy number aberrations and gene expression patterns.
In line with previous studies, somatic mutations affecting tumor suppressor genes implicated in chromatin remodeling including ARID1A (14%), BAP1 (14%) and PBRM1 (11%) could be identified. In addition, the oncogenes IDH1 and IDH2 (14%) showed frequent mutations and may also play an important role in the development of ICC. Other frequent alterations affected genes implicated in the p53 and MAPK signaling pathways. Integrative analysis of the data sets further revealed ICC driver gene candidates. Their role in the development of ICC will be examined by functional studies and by screening larger tumor collectives in the near future.
In conclusion, the results of the current study confirm and expand the genomic landscape of ICC. This, finally, will help to find new therapeutic approaches for the treatment of this orphan cancer.

PM12.050

Molecular characterization of commonly used chondrosarcoma cell lines

J. AURY-LANDAS[1,2], *M. BARREAU*[1,2], *N. GIRARD*[1,2], *E. LHUISSIER*[1,2], *K. BOUMEDIENE*[1,2], *C. BAUGE*[1,2];
[1]UNICAEN, EA4652 MILPAT, Caen, France, [2]Normandie Univ, Caen, France.

Chondrosarcomas (CHS) are malignant tumours of bone that produce hyaline cartilage matrix. Primary CHS is the second most frequently primary malignant tumour of bone after osteosarcoma, and represents about 25% of bone sarcomas. Prognosis is strongly correlated with histological grading. Grade I CHS typically does not metastasize, in contrast with grade II and III CHS. The ten-year survival is 83% for patients with grade I, 64% for grade II and 29% for grade III. CHS is highly resistant to both chemotherapy and radiation, making surgical resection the only curative treatment.
Due to the limited amount of primary tumour specimens, inclusion of in vitro models for CHS investigation is of high importance. In addition, as comprehensive genomic analyses of CHS become available, there is a growing need for corresponding cell models to performed functional analysis of new identified variants. To date, commonly used CHS cell lines has been only partially screened by target-genes approaches.
Our study is the first which aims to extensively characterize commonly used human CHS cell lines by exome sequencing to identify somatic variants and biological pathways potentially involved in the tumorigenesis. We generate an average of 4.9 Gb of sequence per cell line with a mean depth of 67-fold and with 90% of the targeted bases which have a QPhred score > 30. On average, 56 000 variants were identified per exome, including 1700 new variants.
In conclusion, this study will be useful to highlight genetic alterations associated with malignant transformation and potential molecular therapeutic targets.

PS12.051

Loss Of The Y Chromosome In Myelodysplastic Syndromes

D. Costa, *M. Nomdedeu, X. Calvo, C. Muñoz, A. Carrió, A. Arias, C. Gómez, E. Campo, B. Nomdedeu;
Hospital Clinic, Barcelona, Spain.*

Introduction: The clinical association between loss of the Y chromosome and MDS has been debated, because both phenomena are related to aging. The objective of this study was to asses if the the mean age is related to the loss of the Y chromosome.
Material and Methods. From 1986 to July of 2014, 875 patients were diagnosed of Myelodysplastic Syndrome (MDS) in the Hospital Clinic of Barcelona and 275 (55%) were male. ANOVA was used for age comparison between groups.
Results. Twenty-six (6%) patients showed a loss of the Y chromosome, in most of them as a sole abnormality. According to the WHO classification about half of these 28 patients were affected of refractory cytopenia with multilineage dysplasia (RCMD) (n=16). The mean age in patients with loss of the Y chromosome was 77 years old (95%CI: 74 to 80), significantly higher than that observed in patients with either a normal karyotype (71 y.o.; 95%CI: 70 to 73) or with an abnormal karyotype without loss of the Y chromosome (61 y.o.; 95%CI: 65 to 70).
Conclusion. Based on our results, the loss of the Y chromosome is observed more frequently in a group of elder MDS patients.

Potential new player in prostate cancer susceptibility and survival in Finland

C. Sipeky, *E. Kaikkonen, J. Schleutker, The PRACTICAL/ ELLIPSE consortium;
Department of Medical Biochemistry and Genetics, University of Turku, Turku, Finland.*

CIP2A (Cancerous Inhibitor of PP2A) gene has been demonstrated as potential cancer susceptibility gene. Aim of this study is to explore the population diversity of CIP2A rs2278911 common variant in Finnish, to elucidate its role in prostate cancer (PCa) susceptibility, survival, potential in development of aggressive disease, association with specific, clinically different subtypes of PCa.
We genotyped 2738 men with PCa, 2427 healthy controls within the Finnish Genetic Predisposition to Prostate Cancer Study (iCOGS) using Illumina iSelect custom SNP genotyping platform.
This is the first comprehensive case-control study assessing the prevalence of the CIP2A R229Q variant, which revealed that the ancestral C allele is the major allele, the variant T is the minor allele in Finnish population. The overall minor allele frequency in entire sample set 13.8%. Notably, CIP2A rs2278911 minor allele showed slightly, but not significantly protective effect in PCa cases (13.2%) relative to controls (14.3%) (OR, 0.912; 95% CI, 0.815-1.020; p=0.106). This is underlined by the fact that the minor allele significantly confers to belong to the least serious combined PCa stage group (OR, 1.212; 95% CI, 1.010-1.454; p=0.039). Association between CIP2A rs2278911 variant and the development of castration resistant PCa, clinically detected, progressed cases, PCa cancer specific death was not revealed in Finnish samples. Survival between PCa diagnosis and progression, progression and overall or PCa-specific death were not affected by CIP2A R229Q variant.
In genetically homogenous Finnish CIP2A rs2278911 minor allele alone suggests slight protection against PCa, which need to be ascertained in pooled European samples.

PS12.053

Sensitive Mutation Detection By Sequencing Circulating Cell-Free DNA

N. Fang, *R. Akinci-Tolun, K. Heitz, A. Wolf;
QIAGEN GmbH, Hilden, Germany.*

Circulating DNA, the cell-free DNA (cfDNA) in serum or plasma, has become a powerful tool used for Non-Invasive Prenatal Testing (NIPT) as well as cancer liquid biopsy. It has been shown that the quantity, integrity, as well as the mutation contents of the cfDNA in cancer patients could differ from that in healthy controls and therefore serve as biomarkers for cancer diagnosis, prognosis, and stratification. High-throughput sequence analysis of the cfDNA with the rapidly developing next generation sequencing (NGS) technologies provides a highly sensitive method in detecting and characterizing somatic mutations in the cancer patients. However, the concentration

of the cfDNA in the serum is normally very low, which posts challenges in sequencing library construction. Here we describe an optimized workflow that combines high-efficiency NGS library construction, unbiased library amplification, and target enrichment to sensitively and reliably detect mutations in cfDNA samples.

PM12.054

Detecting hypomethylation in circulating, cell-free DNA to monitor cancer burden

T. Harkins, *C. Schumacher, R. Spurbeck, J. Laliberte, C. Couture, S. Chupreta, L. Kurihara, V. Makarov;*
Swift Biosciences, Ann Arbor, MI, United States.

Circulating, cell-free DNA (cfDNA) is a powerful, non-invasive sample source that contains tumor associated DNA. Characterizing the genome-wide methylation state of cfDNA is a powerful and economical biomarker that can be used for providing an effective means to monitor disease and treatment efficacy. The challenges in performing deep sequencing of cfDNA include: a requirement for fast turnaround times due to sample degradation issues, limited sample material, short DNA fragments <170 bp, and limit of detection issues caused by both normal and tumor DNA being present. This study describes a novel library preparation suitable for the Illumina platforms that requires only 10 million sequencing reads making it cost-effective, sensitive, and specific to assess the methylation status of cfDNA.
To characterize the methylation status of cfDNA, NGS libraries were generated utilizing a chemistry that sequentially ligates the adapters to each end of the DNA molecules. As the library is generated after bisulfite treatment, a high recovery of DNA library molecules is observed, thus enabling high complexity library preparation from 5 ng of cfDNA.
Preliminary analysis of the hypomethylation status of the cfDNA from 8 cancer subjects ranged from 0.4% to 44% when compared to a set of healthy controls. The cfDNA sample with 0.4% hypomethylation originated from the plasma of a subject with a high-grade serous adenocarconima in the fallopian tube, and it believed that this tumor type sheds very little DNA into the blood compartment. The most hypomethylated cfDNA came from the plasma of subject with metastatic adenocarcinoma of the colon which had metastasized to the liver.

PS12.055

Circulating miRNA expression profiling in chronic lymphocytic leukemia (CLL) patients - preliminary results

A. A. Filip, *A. Grenda, S. Popek, D. Koczkodaj, M. Michalak-Wojnowska, M. Budzyński, S. Zmorzyński;*
Department of Cancer Genetics, Medical University of Lublin, Poland, Lublin, Poland.

MicroRNAs regulate gene expression on post-transcriptional level. miRNA expression is altered in cancer, and its profiling helps to diagnose the disease, to stratify patients into risk groups, and to predict the response to treatment. Circulating miRNA molecules were identified in different body fluids, and in many cancer types their expression reflected expression in tumor cells.
In our study we used qT-PCR to assay peripheral blood serum of 22 CLL patients for the expression of 84 miRNAs which were associated with differentiation and maturation of B and T lymphocytes.
We have found that the general expression of examined miRNAs in CLL patients was lower when compared to the expression levels in serum of healthy volunteers. Only miR-32a-5p, miR31-5p, miR-155-5p, miR-150-5p, miR-15a-3p and miR-29a-3p were expressed on higher level. Considering prognostic factors, the most important differences in miRNA expression were observed among patients depending on B2M level, CD38 expression status, and aberrations of chromosomes 12 and 13. When the functional miRNA groups were considered, the important factors for all examined groups included age, CD38 expression, NOTCH1 status and the status of chromosomes 11 and 12. Interestingly, neither ZAP70 expression, nor TP53 gene status were differentiating factors.
Alterations in circulating miRNA expression in CLL patients affected miRNAs associated both with B and T lymphocyte differentiation, which proves the role of the latter cells in leukemogenesis. Further study utilizing larger test group of patients may warrant the identification of a panel of several circulating mRNAs which would be used at diagnosis for prognostic and predictive purposes.

PM12.056

A polymorphic GGC repeat in the NPAS2 gene and its association with melanoma

A. Franzoni[1], *E. Markova-Car*[2], *S. Devic- Pavlic*[2], *D. Jurisic*[3], *C. Puppin*[4], *C. Mio*[4], *M. De Luca*[4], *G. Petruz*[4], *S. Kraljevic Pavelic*[2], *G. Damante*[1,4];
[1]*Medical Genetics Institute, University Hospital S. Maria della Misericordia, Udine, Italy,* [2]*Department of Biotechnology, University of Rijeka, Rijeka, Croatia,* [3]*University Hospital Centre Rijeka, Rijeka, Croatia,* [4]*Department of Medical and Biological Sciences, University of Udine, Udine, Italy.*

Circadian rhythms are influenced by the expression of clock genes, which are controlled by a feedback mechanism that allows a rhythmic variation during 24 hours. Various evidences indicate that clock genes are important in neoplastic transformation. *NPAS2 (MOP4)* is a clock gene that can act as a tumor suppressor. We are searching for the presence of polymorphisms in the 5' region of *NPAS2*. By using Sanger sequencing and capillary electrophoresis, we found a polymorphic GGC repeat in the untranslated (first) exon of *NPAS2*. Allele and genotype frequencies of the GGC repeat were measured in 72 subjects affected by melanoma and 77 controls. In both groups four alleles were present, with 7, 9, 12 and 13 GGC repeats. Alleles 7 and 9 were the most frequent (either having a frequency > 40% in controls or melanoma subjects). In both groups allele and genotype frequencies were in Hardy-Weinberg equilibrium. In terms of allelic frequencies no statistical difference was found between melanoma and control subjects. In contrast, significant differences were found in genotype frequencies. In particular, the genotype 7/9 was more frequent in controls (57.1%) than in melanoma subjects (34.7%) (p: 0.0084); the genotype 9/9 was more frequent in melanoma subjects (26.3%) than in controls (9.0%) (p: 0.0087). No statistical difference was found for other genotypes. Therefore, the homozygous genotype of the 9 GGC repeat of the *NPAS2* gene could be a susceptibility factor for melanoma.

Introduction: Biallelic germline mutations in the mismatch repair (MMR) genes cause a recessive form of childhood cancer that has been referred to as Constitutional Mismatch Repair Deficiency (CMMR-D) syndrome. Family members of CMMR-D patients are at risk of being a heterozygous MMR mutation carrier and thus for having Lynch syndrome (LS). The cancer risks for these family members have not yet been analyzed. It is expected that their cancer risk will be different than cancer risks reported before for LS families that were ascertained because of cancer in the family. CMMR-D families have not been ascertained because of cancer in the family, but because the index patient has a distinct phenotype.
Methodology: Data collection of CMMR-D families started in 2014 and is still in process. In the first half of 2016 a competing risks analysis will be performed to calculate cancer risks for family members up to the 6th degree. For family members of whom the carrier status is unknown, the probability of carriership will be computed based on the distance to obligate carriers and phenotypes in the family.
Results: Thus far we have collected data on 46 PMS2, 15 MSH6, 4 MSH2 and 6 MLH1 families of CMMR-D-patients including 1764 family members. This numbers includes 340 proven and obligate heterozygote mutation carriers, 104 proven non-carriers and 1220 non tested family members. Data analysis will be done at a preliminary basis.
Conclusion: Analysis of cancer risks in CMMR-D families are relevant for appropriate screening advice for family members and MMR mutation carriers detected through population based screening.

PM12.058

Systematic meta-analyses and field synopsis of genetic association studies in colorectal adenomas

J. Little[1], *Z. Montazeri*[1], *E. Theodoratou*[2], *C. Nyiraneza*[1], *M. Timofeeva*[2], *H. Campbell*[2];
[1]*University of Ottawa, Ottawa, ON, Canada,* [2]*University of Edinburgh, Edinburgh, United Kingdom.*

Background: Colorectal cancer (CRC) constitutes a major global public health challenge. Most CRCs develop from preneoplastic asymptomatic lesions known as colorectal adenoma (CRA). We have previously summarized the associations between common genetic variants and CRC in a field synopsis of genetic association and GWAS, but the genetic basis of CRA is less well documented. We now present the first synthesis of all published genetic association data for CRAs and the results of meta-analyses to summarise risk estimates.
Methods: Using Medline and the HuGENet phenopedia™, we identified and synthesized all published genetic association data for CRAs. We conducted meta-analyses of the identified studies and data from two GWAS to summarise risk estimates. We applied the Venice criteria and Bayesian False Discovery Probability (BFDP) to assess the levels of the credibility of associations.
Results: 9750 titles and abstracts were initially screened, and 1750 publications were identified for full text screening of which 130 articles met the inclusion criteria. Data were extracted for 181 SNPs in 74 genes. The variant at 8q24.21 (rs6983267) was considered as "highly credible" and *MTHFR* (C677T), *NAT1*, *NQO1* (Pro187Ser), and *TP53* (Arg72Pro) as "less credible".
Conclusion: The identification of genetic variants with influence on CRA risk may provide new insights into the fundamental biological mechanisms involved in early CRC development and help to inform future research. Further, CRA risk-associated SNP variants may also show utility in contributing to future risk scores for accurate population risk stratification which could be of potential value in improving CRC screening modalities.

PS12.059

Overexpression of HDAC3 in colorectal cancer

*M. Nemati[1], **E. Sakhinia**[2], S. Hashemzadeh[3], S. Rezapour[2];*
[1]Department of biology, Tabriz university, Tabriz, Iran, Islamic Republic of, [2]Department of medical genetics, Tabriz university of medical sciences, Tabriz, Iran, Islamic Republic of, [3]Liver and gastrointestinal disease research center, Tabriz university of medical sciences, Tabriz, Iran, Islamic Republic of.

Introduction: Histone deacetylase 3 (HDAC3) is involved in many important biological processes including transcriptional regulation, cell cycle progression and developmental events. Aberrant expression of HDAC3 is observed in several human cancers, indicating a critical role in carcinogenesis and a potential as a tumor marker in cancer. The aim of this study was to investigate the expression level of HDAC3 in colorectal cancer and its relationship with the clinicopathological features of patients.
Materials and Methods: Total RNA was first isolated from 48 pairs of colorectal cancer tissues and adjacent non-tumor tissues. Afterwards cDNAs were synthesized and the expression level of HDAC3 was quantified by real time PCR. The Correlation between the expression level of HDAC3 and clinicopathological features was studied and the capability of HDAC3 to function as a CRC tumor marker was also explored.
Results: Over expression of HDAC3 was observed in colorectal cancer tissue samples compared with their paired adjacent nontumour tissue samples (P=0.03). The Receiver operating characteristic (ROC) curve analysis on HDAC3 showed that the area under the ROC curve was high (0.72). There was no significant correlation between HDAC3 expression and clinicopathological features of patients.
Conclusions: These findings suggest that HDAC3 can serve as a novel prognostic indicator in colorectal cancer and may be a potential target for diagnosis and gene therapy.

PM12.060

Detection of copy number alterations in pediatric acute lymphoblastic leukemia using the 450k DNA methylation array

N. Marzouka[1], *J. Carlsson Almlöf[1], J. Nordlund[1], C. L. Bäcklin[2], G. Lönnerholm[3], A. Syvänen[1];*
[1]Department of Medical Sciences, Molecular Medicine and Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [2]Department of Medical Sciences, Cancer Pharmacology and Computational Medicine, Uppsala University, Uppsala, Sweden, [3]Department of Women's and Children's Health, Pediatric Oncology, Uppsala University and for the Nordic Society of Pediatric Hematology and Oncology (NOPHO), Uppsala, Sweden.

Pediatric Acute Lymphoblastic Leukemia (ALL) represents about one quarter of pediatric cancers. Our previous study (Nordlund *et al.* Genome Biology, 2013) investigated differences in genome-wide DNA methylation patterns across the recurrent ALL subtypes. Here we focus on structural alterations and Copy Number Alterations (CNAs), which are important genetic factors in ALL. This is the first study that uses bioinformatic tools for CNA analysis in cytogenetic subtypes of pediatric ALL based on DNA methylation data.
The Illumina Infinium HumanMethylation450 Bead Array was applied for 756 diagnostic ALL samples and 50 controls. The signals from the array were first normalized using functional normalization and then segmented using the circular binary algorithm. Methylation data was analyzed using the R packages Minfi and CopyNumber450k. CNVs were detected using an in-house modified version of the CopyNumber450k package adapted to cancer samples, in particular within the high hyperdiploid subtype (>50 chromosomes).
The unbalanced cytogenetic aberrations characteristic of the recurrent ALL subtypes were observed. In many cases, our results showed higher sensitivity than traditional karyotyping, in particular in the detection of duplicated and deleted chromosomes. Data from CNAs will be compared across all patients to identify potential novel aberrations associated with clinical outcome of ALL. Paired samples from the same individual will be compared at different disease stages: diagnosis, relapse, and remission. Significant differences will be selected for further functional investigations.
The results suggest that the DNA methylation arrays can be used to detect somatic structural alterations and CNAs with high accuracy in ALL and other leukemias.

PS12.061

Cost-effectiveness of UGT1A1 genotyping before colorectal cancer treatment with irinotecan: A decision analytic model from the perspective of the German statutory health insurance

*B. Butzke[1], F. Oduncu[2], F. Severin[1], A. Pfeufer[1], V. Heinemann[2], C. Gießen[2], B. Stollenwerk[1], **W. Rogowski**[1];*
[1]Helmholtz Center Munich, Neuherberg, Germany, [2]LMU, Munich, Germany.

Irinotecan is an anti-cancer agent that is used for the treatment of metastatic colorectal cancer. Although it prolongs survival, it can cause severe toxicity, especially diarrhea and neutropenia, in patients who carry the UGT1A1*28 allele. This study evaluates the cost-effectiveness of UGT1A1 genotyping prior to irinotecan-based chemotherapy in order to prevent adverse side effects from the perspective of the German statutory health insurance.
A decision-analytic Markov model with a life time horizon was developed. No testing was compared to (1) dose reduction of irinotecan-based chemotherapy and (2) administration of a prophylactic G-CSF growth factor for patients with a UGT1A1*28 variant. Probability, utility and cost parameters used in this study were extracted from published literature. Uncertainty was assessed by deterministic and probabilistic sensitivity analyses.
Strategy (1) dominated all remaining strategies. Compared to no testing, it resulted in only marginal QALY increases but a cost reduction of €600 per patient. Strategy (2) resulted in the same health gains but increased costs by €11,000. Deterministic sensitivity analysis shows that uncertainty for this strategy originated primarily from costs for irinotecan-based chemotherapy, from the prevalence of neutropenia among heterozygous patients, and from whether dose reduction is applied to both homozygotes and heterozygotes or only to the former.
This model-based synthesis of the most recent evidence suggests that pharmacogenetic UGT1A1 testing prior to irinotecan-based chemotherapy dominates non-personalized colon cancer care in Germany. However, as structural uncertainty remains high, these results require validation in clinical practice, e.g. based on a managed-entry agreement.

PM12.062

Diffuse large B cell lymphoma developing simultaneously in recipient and donor twenty two months after allogeneic bone marrow transplantation.

S. Laird[1], *L. Chiecchio[1,2], A. Fisher[1], C. Waterman[1,2], J. Cullis[3], M. Morgan[4];*
[1]Wessex Regional Genetics Laboratory, Salisbury, United Kingdom, [2]Faculty of Medicine, University of Southampton, Southampton, United Kingdom, [3]Haematology Department, Salisbury NHS Foundation Trust, Salisbury, United Kingdom, [4]Children's oncology and haematology centre, University Hospital Southampton, Southampton, United Kingdom.

Donor cell hematological neoplasms are rare complications arising after allogeneic hematopoietic stem cell transplantation (alloHSCT). We present an eight-year-old boy diagnosed with AML, who underwent alloHSCT a year later with his 42-year-old mother as HLA-matched donor. After twenty-two months, he presented with thigh and buttock pain; bone marrow (BM) showed 20%-30% blast-like cells, suggesting relapsed AML. However, BM cytogenetic analysis showed all cells to be of female (donor) origin. Morphology and immunostains on BM, skin and spinal lesions confirmed infiltration by diffuse large B-cell lymphoma (DLBCL). FISH on the skin biopsy showed all lymphoma cells with two copies of the X chromosome centromere and no Y centromere, confirming that the DLBCL cells were donor-derived. FISH on the spinal mass detected concurrent MYC and BCL6 rearrangements, consistent with "double hit" lymphoma. A month after the boy's lymphoma diagnosis, the donor was found with a large abdominal mass diagnosed as DLB-

CL ABC type, with evidence of a BCL6 but not a MYC rearrangement. The absence of a MYC rearrangement in the donor's tumour suggests that this was secondary to the BCL6 rearrangement, possibly arising after transfer into the recipient as a consequence of clonal evolution. It is possible that both the conditioning regimen pre-transplant and the replicative stress on the donor stem cells post-transplant had a role in the acquisition of this second event. This hypothesis is consistent with the fact that the donor achieved complete remission after six cycles of R-CHOP, while double-hit lymphoma is usually resistant to such aggressive treatments.

PS12.063

EGFR genomic variations in five different types of cancer - tissue microarray survey and potential for targeted therapy

I. Dimova[1], *B. Rukova*[1], *B. Zaharieva*[2], *D. Nesheva*[1], *R. Dimitrov*[1], *C. Slavov*[1], *D. Toncheva*[1];
[1]Medical University Sofia, Sofia, Bulgaria, [2]Ohio State University, Columbus, OH, United States.

EGFR was the first receptor that has been directly connected to carcinogenesis. EGFR-targeted agents have been showed to have different response efficacy in anti-cancer therapy suggesting the role of specific indicators such as EGFR alterations in selection of appropriate targets for treatment.
We have successfully analyzed by FISH the copy number of EGFR in samples from five different tumor types, arranged in tissue microarrays: 1075 larynx, 355 ovarian, 239 colon, 144 lung and 86 uroepithelial cancers.
The copy number increases were detected to the highest proportion in lung cancer (22.2% of them), following by 10.7% of ovarian and 10.6% of larynx cancers, 4.7% of urothelial and in very low number of colon cancer (0.8%). In the last we have observed only EGFR gain whereas in uroepithelial and larynx cancer we have found mostly EGFR amplification.
Studying the correlation with tumor phenotype, we established that EGFR aberrations affect to the highest extent the group of squamous cell lung cancer (in 23.5% of cases), mixed and non-epithelial ovarian cancer (both in 13.3% of the cases), poorly differentiated and high stage uroepithelial tumors (14.3% and 12.9%, respectively). The study provided with data which could be useful in considering of anti-EGFR anti-tumor therapeutic strategy.

PS12.065

Exome sequencing and SNP arrays to confirm genetic instability increasing from premalignant to tumour cells in monoclonal gammopathies

A. Mikulasova[1,2], *B. A. Walker*[3], *C. P. Wardell*[4], *E. M. Boyle*[5], *M. Wayhelova*[1], *J. Smetana*[1], *L. Pour*[6], *P. Kuglik*[1,7], *R. Hajek*[8,9], *G. J. Morgan*[10];
[1]Department of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic, [2]Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Centre for Molecular Pathology, Royal Marsden Hospital, London, United Kingdom, [4]Laboratory for Genome Sequencing Analysis, RIKEN Centre for Integrative Medical Sciences, Tokyo, Japan, [5]Division of Molecular Pathology, Institute of Cancer Research, London, United Kingdom, [6]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, [7]Department of Medical Genetics, University Hospital Brno, Brno, Czech Republic, [8]Department of Haematooncology, University Hospital Ostrava, Ostrava, Czech Republic, [9]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic, [10]Myeloma Institute for Research and Therapy, University of Arkansas Medical School, Little Rock, AR, United States.

Whole exome sequencing (WES) and SNP arrays have opened a new landscape to study compreshensive tumour genetic architecture and its evolution during tumour associated processes at the genome-wide level. Transformation from monoclonal gammopathy of undetermined significance (MGUS) to multiple myeloma (MM) can be used as a unique model for cancer development studies as an analysis of pure tumour population in clearly clinically distinguishable states.
Overall, 33 and 69 MGUS patients were included in a WES and SNP array study, respectively. For WES, NEBNext kit and SureSelect Human All Exon V5 (Agilent) were used, samples were sequenced by HiSeq2000 (Illumina). Copy number alterations (CNAs) were tested by SurePrint G3 CGH+SNP, 4x180K (Agilent). Results were compared to 463 and 91 MM patients analysed by WES and SNP arrays, respectively.
CNAs and somatic gene mutations (SNVs) were detected in 68% (47/69) and 100% (33/33) of MGUS patients in comparison to 100% (91/91, $p<10^{-4}$) and 100% (463/463) of MM patients, respectively. However, overall number of both CNAs and SNVs per patient was significantly lower in MGUS (CNAs: median 2, range 0-15; SNVs: median 89, range 9-315) than in MM (CNAs: median 16, range 2-49, $p<10^{-18}$; SNVs median 123, range 1-897, $p<10^{-4}$). We proved that complex genetic instability is formed before tumour clinical manifestation at the gene level followed by the chromosome level. Then, the number of random genetic hits increases to form a landscape for significant oncogenic hits driving the premalignancy transition to a clinically manifested tumour disease.

Introduction: Hereditary breast and ovarian cancer (HBOC) is a heterogeneous genetic condition. Susceptibility cancer gene panels allow simultaneous analysis of multiple genes and broaden genetic diagnosis compared to sequential single testing.
Patients and Methods: Two-hundred BRCA1/2-negative patients from HBOC families were enrolled for massive sequencing of 98 cancer susceptibility genes. Inclusion criteria were BC <35y, presence of OC <50y or at least 3 BC/OC <60y in the family. DNA samples were processed using Agilent's SureSelect Target Enrichment and sequenced on an Illumina MiSeq. Bioinformatic pipeline includes read alignment, variant calling (GATK and VarScan2), and annotation (ANNOVAR and ALAMUT).
Results: In the 49 families sequenced to date we identified 12 truncating variants in *PALB2 (2)*, *ATM (2)*, *BARD1, FANCA, FANCE, FANCI, FANCL, PTEN, SLX4* and *XRCC2*, one missense variant in *TP53*, and 25 variants predicted as probably pathogenic by bioinformatic analysis: 17 (missense) affecting protein function and eight affecting splicing (six missense, one synonymous and one small deletion of a consensus splice site). So far, the gene panel was clinically beneficial for four patients with deleterious variants in *PALB2*, *PTEN*, and *TP53*. Phenotypically, these families had one in situ BC with 1 first degree with BC, both under age 35 (*TP53*), young onset BC with family history of BC and OC (*PTEN*), or an extensive family history of BC (2 *PALB2*).
Conclusions: Multiplex genetic testing of a certain subset of high penetrant genes might be clinically useful for genetic diagnosis of HBOC families.

Diagnostic yield of a next generation sequencing gene panel in familial cancer analysis

A. P. Knopperts, *A. H. van der Hout, K. K. van Dijk-Bos, Y. J. Vos, B. Sikkema-Raddatz, C. C. van Diemen, H. Westers, R. J. Sinke, R. H. Sijmons;*
University of Groningen, University Medical Center of Groningen, Department of Genetics, Groningen, Netherlands.

Background: The current trend in familial cancer diagnostics is the use of NGS gene panels. Potentially, this method could increase the yield of molecular diagnoses. We studied 174 patients suspected of hereditary breast (ovarian) or colorectal cancer, who had been tested negatively for *BRCA1/2* and Lynch syndrome/*APC/MUTYH*, respectively.
Methods: We designed and validated a targeted NGS gene panel with 73 genes associated with familial cancer syndromes. We tested this panel anonymously on all 174 patients. Outcome was interpreted in terms of explanation of the cancer family history. We also compared the test results with the number and types of variants in the panel genes found by WGS in a control group: 498 individuals from the Genome-of-the-Netherlands (GoNL) project.
Results: In 174 patients only one new firm diagnosis was established. In addition, in another 14 cases (8.0%), a pathogenic variant was detected in 6 different autosomal dominant genes traditionally associated with cancer types that did not match the cancer family history. Of these 14 mutations, 10 were actionable. We identified 414 VOUS of which 38 (9.2%) in autosomal dominant genes that were likely pathogenic. In the GoNL controls, 22 (4.4%) pathogenic and 740 VOUS were identified of which 85 (11.4%) were classified as likely pathogenic.
Conclusions: Use of an extended gene panel did not instantly increase the number of molecular diagnoses explaining the cancer family history. Furthermore, many likely pathogenic variants were identified in both our patient and control groups, suggesting that these variants are less relevant in familial cancer diagnostics.

PM12.068

Monoallelic FANCG mutation in a patient with multiple tumours: is FANCG a tumour susceptibility gene?

A. Baumer, *S. Azzarello, R. Abbas, J. Brecher, M. Zweier, E. Wey, A. Rauch;*
Institute of Medical Genetics, Schlieren, Switzerland.

We report on the DNA sequencing results we obtained for a 54 year old female patient with suspected familial tumour syndrome. She presented with several tumours (lipoma, myoma, breast cysts) and fibromyalgia. The patient's mother died at the age of 57 of breast cancer. Her maternal grandmother died of a brain tumour. In addition, several family members present with lung cancer (all smokers).
We performed NGS using the TruSight Cancer Panel (Illumina, total of 94 cancer genes). The analysis revealed a heteroallelic frameshift mutation in the FANCG gene: p.A495Qfs*23. No further mutation was detected in the genes covered by the panel, which includes all known breast cancer susceptibility genes and all known Fanconi anemia genes. Unfortunately, no DNA samples of the patient's mother and grandmother are available for segregation analyses.
FANCG is one of the three most commonly mutated genes out of 13 genes coding for proteins active in the same DNA-repair pathway, that may lead to Fanconi anemia (FA) when biallelically mutated (exception: FANCB, X recessive inheritance). FA is a chromosome instability syndrome characterized by childhood anemia, susceptibility to leukemia and cancer.
Monoallelic mutations with increased susceptibility for breast cancer have been reported for only few FA genes: FANCD1 (BRCA2), FANCN (PALB2), FANCJ (BRIP1) and very recently FANCM. We consider the possibility that the FANCG mutation detected in our patient may underlie the familial tumour syndrome in her family and suggest FANCG heterozygosity as a novel breast cancer susceptibility factor.

PS12.069

Characterization of a Fanconi anemia candidate gene

J. Kuehl, *D. Schindler;*
Department of Human Genetics, Wuerzburg, Germany.

Fanconi anemia (FA) is a rare autosomal or X-linked recessive disease which displays a heterogeneous phenotype. Besides congenital developmental defects, FA is characterized by bone marrow failure and genomic instability resulting in cancer predisposition. Due to a DNA repair defect the cellular phenotype is characterized by hypersensitivity to DNA-crosslinking agents, leading to increased chromosomal breakage, reduced cell survival and G2 phase arrest in the cell cycle. Currently 16 FA genes (*FANCA, -B, -C, -D1, -D2, -E, -F, -G, -I, -J, -L, -N, -O, -P, -Q* and *-S*), whose products are members of the FA/BRCA pathway, were reported to be causative for FA. Based on the association of corresponding mutations with the loss or retention of FANCD2/FANCI monoubiquitination, these genes are classified as *upstream* or *downstream* FA genes. In one cell line derived from an FA patient we detected a homozygous *single nucleotide exchange* in an FA candidate gene, which is a member of the FA/BRCA pathway but not an FA gene. The mutation results in an amino acid substitution at a conserved position. This cell line exhibits reduced levels of FANCD2 monoubiquitination and FANCD2 foci formation as well as MMC-induced G2 phase arrest in the cell cycle. Complementation with the wild type form of this gene rescues the MMC sensitivity and normal cell cycle progress. In addition, FANCD2 monoubiquitination and FANCD2 foci formation were raised. Currently, we are generating animal and human cell models in order to draw closer connections to the FA/BRCA pathway.

PM12.070

Gene editing of FAAP100 by the CRISPR-Cas9 system

S. Pickel, *J. Kühl, D. Schindler;*
University of Wuerzburg, Department of Human Genetics, Wuerzburg, Germany.

FAAP100 is a component of the Fanconi anemia (FA) nuclear core complex. Together with FANCL and FANCB it forms a subcomplex, which is necessary for the monoubiquitination of FANCD2 and FANCI and the stability of the core complex. Chicken DT40 cells that are faap100-deficient show a cellular phenotype similar to human FA cells, which includes reduced mitomycin C-induced cell survival and increased chromosomal breakage rates as well as compromised FANCD2 monoubiquitination.
In order to generate an FAAP100-deficient cell line we used the recently discovered RNA-guided CRISPR-Cas9 system. The CRISPR-Cas9 technology for genome engineering is based on the adaptive immune system of bacteria and archaea. This system can be applied to introduce DNA double strand breaks at a target sequence into genomic DNA similar to ZFN nucleases and TALENS. After DSBs have been elicited, the damage can be repaired through error-prone non-homologous end joining (NHEJ) or through error-free homology-directed repair (HDR) if a homologous DNA template is available. In our work, we targeted exon 5 of FAAP100 in U2OS cells. Initial experiments revealed that the CRISPR-Cas9 tool is suitable for tackling FAAP100 in U2OS cells and that stable InDel mutations were introduced through NHEJ. Currently we are trying to isolate single cell clones with a deleterious mutation and to grow an FAAP100 null cell line for further experiments including immunoblots, analysis of chromosomal breakage and cell cycle analysis.

PS12.071

Unusual characteristics in Fanconi anemia subtype FA-Q

I. Rost[1], *K. Chandler*[2], *M. Punekar*[3], *M. Meenakshi*[4], *D. Schindler*[1], *S. Meyer*[5];
[1]*University of Wuerzburg, Department of Human Genetics, Würzburg, Germany,* [2]*Central Manchester Foundation Trust, Manchester, United Kingdom,* [3]*Lancashire Teaching Hospitals, Preston, United Kingdom,* [4]*Genetic Medicine, Central Manchester Foundation Trust, Manchester, United Kingdom,* [5]*University of Manchester, Manchester, United Kingdom.*

Fanconi anemia (FA) is a rare X-linked or autosomal recessive genetic disorder, characterized by a broad genetic and clinical heterogeneity. Molecular testing is impeded by the presence of at least 16 genes, which are components of the FA/BRCA pathway (FANCA, -B, -C, -D1, -D2, -E, -F, -G, -I, -J, -L, -N, -O, -P, -Q, S). Stringent genotype-phenotype correlations are usually not applicable to these FA subtypes.
A majority of patients belong to the complementation groups FA-A, -C and -G. For several rare subgroups only a few patients have been identified so far. Long term phenotype-genotype data collection of these minor subgroups is essential for a better understanding of the molecular roles of the corresponding proteins as well as for the clinical management of those patients.
Here we report on a 49-year-old patient who belongs to the rare and unusual subgroup FA-Q. Causative are biallelic mutations in the ERCC4/XPF gene. Other mutations in this gene have been associated with Xeroderma pigmentosum, Cockayne syndrome or a progeria syndrome (XF-E). Unlike most individuals with FA our patient never developed bone marrow failure or malignancies, typical features of other FA patients at that age. Interestingly, she shows skin photosensitivity to sunlight, a trait previously not seen in FA patients of other complementation groups except for one of the two previously described FA-Q patients. Hence, sunlight sensitivity in unclassified FA patients may give a hint for their assignment to complementation group FA-Q such that mutations in ERCC4 should be tested preferentially.

PM12.072

Participation of apoptosis-related genes in breast tumorigenesis and their association with clinicopathological features of disease

A. Mendelova[1], *I. Kapustova*[2], *P. Zubor*[2], *P. Moricova*[2], *V. Holubekova*[1], *K. Kajo*[3], *I. Svecova*[2], *Z. Lasabova*[1], *J. Danko*[2];
[1]*Department of molecular biology, Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Martin, Slovakia,* [2]*Department of Gynecology and Obstetrics, Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Martin, Slovakia,* [3]*Department of Pathology, Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Martin, Slovakia.*

Fas and its ligand (FasL) are known to play a crucial role in the genetically controlled mechanism of cell death and disruption of this pathway has been associated with tumorigenesis. The goal of this study is to investigate the association between -1377G/A (rs2234767) and -670A/G (rs1800682) polymorphisms in Fas and single nucleotide polymorphisms -844C/T (rs763110) in FasL in a breast cancer samples. The study group consists of 254 subjects, including 122 patients with breast cancer and 132 healthy controls. DNA extracted from peripheral blood was analyzed by TaqMan real-time PCR and allelic discrimination assay. We have found a significant association between patients with aberrant A allele in genotype for FAS-1377 SNP and larger size of tumors compared to GG genotype carriers (p=0.0356). Moreover patients with FAS-1377A and FASL-844T genotype showed significant association to poorly differentiated breast cancer specimens of higher tumor grade (G2+G3) (p=0.0378 and p=0.0001, respectively). Patients with FAS-1377A and FAS-670G genotype showed significant association to positive expression status of progesterone receptor (p=0.0263 and p=0.0169, respectively). The significant association was observed also between the FAS-670G and FASL-844T genotypes with HER-2 positive status (p= 0.0177 and p= 0.0009, respectively). These data suggest that functional polymorphisms in the death pathway genes FAS and FASL may contribute to the occurrence of breast cancer and modify its biological profile in Slovak population.

Clinical University Hospital Lozano Blesa, Zaragoza, Spain.*

Introduction: In a previous study (EPIC-Eurgast) of association between genetic variation in candidate genes and gastric cancer (GC) risk we observed several associations that required replication in independent populations.
Methods: 96 SNPs from 57 genes that in the EPIC-Eurgast study were found associated with GC or any of its subtypes were genotyped (Fluidigm SNPtype assays) in 328 non-EPIC GC cases and 322 healthy controls from different Spanish regions, as well as 375 GC cases and 709 controls from the North of Portugal. Associations were analyzed using unconditional logistic regression.
Results: Unless otherwise stated, the results indicated are those obtained in the combined analysis of both the Spanish and the Portuguese populations, under the additive model. These results confirmed previously reported associations between GC and PSCA rs2294008 (OR=1,21; 95%CI:1,06-1,40) and MUC1 rs4072037 (OR=0,82; 95%CI:0,72-0,94). Furthermore, associations with GC were replicated in another six genes. DRD4 rs12280580 (OR=0.83;95%CI: 0,72-0,97), VEGFA rs833060 (OR=0,84;95%CI:0,72-0,97), TFF3 rs8133510 (OR=0,75;95%CI:0,61-0,93; AG vs GG) and MIRLET7I rs10877888 (OR=1.29;95%CI:1,00-1,65; recessive model), were associated with GC in general. ABO rs657152 was associated with diffuse GC (OR=1,45;95%CI:1,02-2,06; dominant model) and NQO1 rs7359387 was associated with cardia CG (OR=0,50;95%CI:0,30-0,85).
Conclusions: variation in PSCA and MUC1 also is associated with GC risk in Iberian populations. Variants in genes for cell signalling (DRD4 and VEGFA), mucosa protection (TFF3), region of MIRLET7I (micro RNA let7i), blood group (ABO) and carcinogen metabolism (NQO1), also are associated with GC or its histological/anatomical subtypes in European populations.

Vitamin D and prostate cancer: a Mendelian randomization study

O. Trummer[1], *E. M. Thurner*[2], *T. Langsenlehner*[2], *U. Langsenlehner*[3], *S. Krenn-Pilko*[2], *T. R. Pieber*[1], *W. Renner*[4], *B. Obermayer-Pietsch*[1];

[1]*Division of Endocrinology and Metabolism, Department of Internal Medicine, Medical University of Graz, Graz, Austria,* [2]*Department of Therapeutic Radiology and Oncology, Medical University of Graz, Graz, Austria,* [3]*Division of Internal Medicine, GKK Outpatient Department, Graz, Austria,* [4]*Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria.*

Introduction: Decreased 25-hydroxy (25-OH) vitamin D levels have been associated with prostate cancer, but it is unclear whether this association is causal. To examine the hypothesized inverse relationship between vitamin D status and prostate cancer we performed a Mendelian randomization study and studied the association between a common single-nucleotide polymorphism (SNP) strongly associated with 25-OH-vitamin D and prostate cancer.
Material and Methods: Genotypes of the group-specific component gene (GC, rs2282679) were determined in the prospective PROCAGENE study comprising 702 prostate cancer patients with a median follow-up of 82 months. Logistic regression was used to estimate the associations between the genetic variants and biochemical recurrence, development of metastasis and mortality of prostate.
Results: GC genotypes were not associated with biochemical recurrence (HR 0.89, 95% CI 0.70 - 1.13; p = 0.32), development of metastases (HR 1.20, 95% CI 0.88 - 1.63; p = 0.25) or overall survival (HR 1.10; 95% CI 0.84 - 1.43; p = 0.50).
Conclusion: We conclude that a causal role of vitamin D status, reflected by the GC polymorphism, in prostate cancer is unlikely.

PM12.076

The frequency and functional significance of TP53 mutations in the russian patients with de novo DLBCL

E. Voropaeva[1], *T. Pospelova*[2], *M. Voevoda*[1], *V. Maximov*[1];

[1]*Institute of Therapy and Preventive Medicine SB RAMS, Novosibirsk, Russian Federation,* [2]*State Medical University, Novosibirsk, Russian Federation.*

Introduction: *TP53* dysfunction is implicated in lymphomagenesis and disease progression. Information about the frequency and spectrum of *TP53* mutations in the russian pathients with diffuse large B-cell lymphoma (DLBCL) in the current version of the IARC *TP53* Mutation Database R17 is not represented. The goal of this work was to study the frequency, spectrum and functional significance of *TP53* mutations in russian patients with DLBCL.
Material and Methods: At the present time the pilot group of 14 patients were included in the study. Diagnosis was assessed according to the criteria of the WHO classification system. Genomic DNA was isolated from formalin-fixed, paraffin embedded tissue blocks. Direct sequence analysis of gene *TP53* was performed according to the IARC protocol, 2010 update.
Results: In two patients were identified single nucleotide substitutions that are not described in the current version of the PubMed database. All of mutations occurred in the DNA-binding domain of p53. The nonsense mutation Arg196Ter was detected in one patient. Previously it was shown that formation of this premature stop codon might activate the nonsense-mediated RNA decay pathway. The second patient had two missense mutations - Leu130Phe and Arg156Cys. The first of them leads to p53 inactivation according to the analysis of the functional importance of amino acid substitutions using service PolyPhen-2.
Conclusions: We detected *TP53* mutation in 14% cases. The mutational rate in our study is in good agreement with other studies where the frequency of the TP53 mutations in patients with DLBCL ranged mostly from 13 to 23%.

PS12.077

Genome-wide association study of childhood acute lymphoblastic leukemia risk with gender-specificity

S. K. Singh[1], *P. J. Lupo*[2], *M. E. Scheurer*[2], *A. Saxena*[1], *A. E. Kennedy*[3], *B. Ibrahimou*[1], *J. L. McCauley*[4], *M. Okcu*[2], **M. T. Dorak**[5];

[1]*Florida International University, Miami, FL, United States,* [2]*Baylor College of Medicine, Houston, TX, United States,* [3]*National Cancer Institute, Bethesda, MD, United States,* [4]*University of Miami, Miami, FL, United States,* [5]*Liverpool Hope University, Liverpool, United Kingdom.*

Similar to most cancers, males have a higher risk than females for childhood acute lymphoblastic leukemia (ALL). To gain insight into the genetic basis of this difference, we performed a case-only GWAS to identify gender-specific risk markers among 240 ALL cases recruited at Texas Children's Cancer Center using the Illumina Infinium HumanCoreExome Chip. Results were ranked both by statistical significance and effect size, and then subjected to bioinformatics analysis to evaluate relevant pathways and potential underlying mechanisms. RASSF2 rs4813720 yielded the statistically most significant result for interaction with sex (OR = 0.29; P = 2E-06). Two HLA-DQA1 missense SNPs (rs12722042 and rs12722039) and ADAM28 rs11992342 yielded the largest effect sizes (OR > 14.0; P < 0.05). The HLA-DQA1 SNPs correspond to DQA1*01:07, and their association with risk confirms a previously reported male-specific association with DQA1*01. No sex chromosome variant appeared to be involved in the interaction of risk with sex. While bioinformatic screening of our top hits did not implicate a particular mechanism for male-specific risk, RASSF2 has an estrogen receptor-alpha binding site in its promoter. Additionally, a functional SNP among our top hits (by P value) in (MAGI2 rs798292) is associated with expression of KAT7 in lymphoblastoid cells (P = 2E-08), which is a histone acetyltransferase that represses androgen receptor-mediated transcription. Our results suggest that autosomal variants are likely to underlie the sex differential in childhood ALL risk. Our approach and results provide a foundation for further studies to fully characterize the sex differential in childhood ALL risk.

PM12.078

Spectrum of mutations identified in a 25-gene hereditary cancer panel for patients with breast cancer

L. Sharma[1], *J. Kidd*[1], *J. Abernethy*[1], *H. McCoy*[1], *K. Brown*[1], **K. Copeland**[2], *J. Saam*[1], *M. Landon*[1], *R. Wenstrup*[1];

[1]*Myriad Genetic Laboratories, Inc., Salt Lake City, UT, United States,* [2]*Myriad Genetics, Inc., Zurich, Switzerland.*

Introduction: Advancements in next generation sequencing allow patients with a personal and/or family history of cancer that may not be suggestive of one cancer syndrome to be tested for mutations in multiple cancer-predisposing genes simultaneously. The focus of this analysis was to determine the spectrum of gene mutations observed in patients with a personal history

of breast cancer.
Methods: A commercial laboratory database was queried for patients with a personal diagnosis of breast cancer who underwent testing with a 25-gene hereditary cancer panel from September 2013 through November 2014. The panel includes *BRCA1, BRCA2, TP53, PTEN, MLH1, MSH2, MSH6, PMS2, EPCAM, APC, BMPR1A, CDH1, CDKN2A, MUTYH, SMAD4, STK11 CHEK2, PALB2, ATM, NBN, BARD1, BRIP1, CDK4, RAD51C* and *RAD51D*. All patient data regarding clinical history was obtained by health care provider report on the test requisition forms.
Results: A total of 17,142 patients with a personal history of breast cancer were identified. In this cohort, 9.8% (n=1,685) of patients were positive for at least 1 pathogenic mutation, 49.9% of which were in *BRCA1/2*. The 51.1% of patients with mutations in genes other than *BRCA1/2* included 151 patients with mutations in genes not associated with breast cancer. 45 patients were identified with mutations in more than one gene.
Conclusions: Testing patients using a 25-gene panel provided a 104.5% increase in mutations identified over *BRCA1/2* testing alone. Panel testing also allowed patients with mutations in genes not associated with breast cancer or with multiple mutations to make more appropriate medical management decisions.

Identification of gains and losses of genomic regions characteristic for head and neck cancers of oral cavity and oropharynx/hypopharynx.

N. Kokalj Vokac, *B. Zagradisnik, D. Krgovic, S. Stangler Herodez, A. Zagorac, A. Erjavec Skerget, B. Lanisnik, B. Cizmarevic;*
University Medical Centre Maribor, Maribor, Slovenia.

Introduction
Copy number variations of large genomic regions are an important mechanism implicated in the development of head and neck cancer however for most changes their exact role is not well understood. It was the aim of this study to find possible associations between gains/losses of genomic regions and clinically distinct subgroups of head and neck cancer.
Methods
Array CGH analysis was performed on DNA samples from 64 patients with cancer in oral cavity oropharynx or hypopharynx. Overlapping genomic regions created from gains and losses were used for statistical analysis.
Results
Following regions were overrepresented: in tumors with stage I,II a gain of 2.98 Mb on 6p21.2-p11, a gain of 7.4 Mb on 8q11.1-q11.23; in tumors with grade I histology a gain of 1.1 Mb on 8q24.13, a loss of a large part of chromosome 3p, a loss of a 1.24 Mb on 6q14.3, a loss of 32 Mb telomeric region (8p23.3); in cases with affected lymph nodes a gain of 0.75 Mb on 3q24, a gain of 0.9 Mb on 3q26.32-q26.33; in cases with unaffected lymph nodes a gain of 1.1 Mb on 8q23.3; in patients not treated with surgery a gain of 12.2 Mb on 7q21.3-q22.3 and a gain of 0.33 Mb on 20q11.22.
Conclusions
Our analysis identified several genomic regions of interest which appear to be associated with various clinically distinct subgroups of head and neck cancer. They represent a potentially important source of biomarkers useful for clinical management of head and neck cancer.

Whole exome sequencing identifies novel variants for head and neck squamous cell carcinoma

M. Lin[1,2], *W. Y. Wu*[1], *T. Liu*[3], *H. Wang*[4], *M. Wu*[5], *S. Tai*[6], *M. Yang*[7,8];
[1]*Institute of Public Health, National Yang-Ming University, Taipei, Taiwan,* [2]*Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan,* [3]*VTY Genome Research Center, National Yang-Ming University, Taipei, Taiwan,* [4]*Institute of Microbiology and Immunology, National Yang-Ming University, Taipei, Taiwan,* [5]*Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan,* [6]*Division of Laryngology-Head and Neck Surgery, Taipei Veterans General Hospital, Taipei, Taiwan,* [7]*Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan,* [8]*Department of Hematology, Taipei Veterans General Hospital, Taipei, Taiwan.*

Introduction: The head and neck squamous cell carcinoma (HNSCC) is ranking as the fifth most common cancer worldwide and it is also the second leading cause of cancer deaths in the South-East Asia region, including Taiwan. The major risk factors associated with HNSCC are smoking, alcohol consumption, and human papillomavirus subtype 16 (HPV-16) infection. However, most of the HNSCC patients in Taiwan were HPV-16 infection negative. This implicates that genetic variants underlying the HNSCC in Taiwan might be different from other populations. To obtain a comprehensive overview of genetic alternations underlying HNSCC, we applied whole-exome-sequencing on HNSCC patients.
Methods: Nine pairs of tumor and adjacent normal tissue samples with stage III-IV HNSCC were obtained from the Tissue Bank of the TPEVGH. DNA were captured using SureSelect Human All Exon kit and Illumina Paired-End Sequencing Library Prep, then were sequenced by Illumina Genome Analyzer IIx platform.
Results: In total, 1788 novel variants, including 676 missense, 146 synonymous, 61 nonsense, and 7 splicing site variants, were identified (with an average 199 variants per patient, range 51-532 variants). Genetic variants on ninety-nine genes were recurrently found in maximally two patients. Five out of nine HNSCC patients carried the TP53 novel variants. Most of the variants are located on the PI3K, MAPK, EGFR, and NOTCH pathways, while some of them are oncogenes, tumor suppressor genes, and DNA repair genes.
Conclusion: Using exome sequencing, we identified several candidate genes for HNSCC predisposition. Their contribution to HNSCC will be further investigated by using larger cohort of patients with HNSCC.

PS12.081

NOVEL CHEK2 LARGE GENOMIC REARRANGEMENTS IDENTIFIED IN GREEK BREAST CANCER PATIENTS

P. Apostolou[1], *V. Mollaki*[1], *F. Fostira*[1], *T. Walsh*[2], *E. Faliakou*[3], *G. Fountzilas*[4], *M. C. King*[2], *I. Konstantopoulou*[1], *D. Yannoukakos*[1];
[1]*NSCR Demokritos, Athens, Greece,* [2]*University of Washington, Seattle, WA, United States,* [3]*Mitera Hospital, Athens, Greece,* [4]*Aristotle University of Thessaloniki, Thessaloniki, Greece.*

Although certain germline missense and loss-of-function CHEK2 mutations have been reported, Large Genomic Rearrangements (LGRs) seem to be quite rare genomic events. To date, only two LGRs have been reported, a 5.6 kb deletion encompassing gene's exons 9 and 10, which is a founder Czech mutation, and a duplication encompassing gene's exons 8 to 14.
The present study aimed to define the contribution of CHEK2 LGRs in Greek breast cancer patients.
Initially, 2355 breast cancer patients (mean age of onset 54.6 years) were genotyped for the Czech LGR by diagnostic PCR. No individuals of Greek descent were found to carry the particular deletion.
Subsequently, three novel LGRs were detected by BROCA panel and were confirmed by MLPA. These included: a ~600bp deletion including the 5' UTR region, a ~1100bp deletion of exons 2 and 3 and a ~7.5Kb deletion including exon 6. The genomic breakpoints of the latter were determined (g.30219_37783del7565, p.D308fsX0) and subsequently analyzed by a custom-designed diagnostic PCR. The deletion was detected in 0.22% (5/2355) of breast cancer cases, indicating a possible Greek founder effect. Three carriers were diagnosed with early onset breast cancer, while all of them had at least one additional family member diagnosed with breast cancer. None of the 1163 controls carried the aforementioned deletion. Characterization and screening of the two other LGRs is in progress.
The present study highlights the existence of rare genomic events in breast cancer predisposing genes which can explain a small -but significant- proportion of high risk families.

PM12.082

Prevention of hereditary breast cancer by personalized optimization of body Se, Zn, Fe levels using diet supplements

J. Lubinski[1], *A. Morawski*[2];
[1]*Read-Gene SA, Szczecin, Poland,* [2]*Westpomeranian University of Technology, Szczecin, Poland.*

Hereditary predisposition to breast cancer (HBC) can be diagnosed in ~1.5 mio. of women in Poland including ~100 000 carriers of BRCA1mutations. Up to now, the critical preventive options for above females give strong adverse effects (preventive adnexectomy and mastectomy, tamoxifen). Therefore, the main goal of herein project is validation of results from pilot studies indicating that risk of breast cancers can be reduced significantly (even 10 times) by personally tailored optimization of Se, Zn and Fe levels using diet supplements.
The major tasks will include:
I. Elaboration of diagnostic "DNA test basic for chemoprevention of breast cancers." (10 candidate changes; sera collected before breast cancer detection in 150 cases; 300 matched controls).
II. Hereditary breast cancer risk reduction by providing Se, Zn, Fe diet supplements in amounts to achieve optimal serum levels individualizing them also depending on DNA changes. (2000 females with BRCA1 mutation, 12 000 unaffected women with other forms of HBC randomly selected for studied and control groups; expected results - patents owned by Read-Gene SA and publications on new method of HBC prevention.
III. Zn, Fe diet supplements - large scale production, studies of their stability

and delivery for clinical trial.
Acknowledgements: The study is funded by the National Centre for Research and Development on the basis of the agreement number INNOMED/I/16/NCBR/2014.

Increased risk of male cancer and identification of a potential prostate cancer cluster region in *BRCA2*

H. R. Nielsen[1,2], *J. Petersen*[3], *C. Therkildsen*[4], *A. Skytte*[5], *M. Nilbert*[6];
[1]Odense University Hospital, Odense, Denmark, [2]University of Southern Denmark, Odense, Denmark, [3]HNPCC Register, Clinical Research Center, Copenhagen University Hospital,, Hvidovre, Denmark, [4]HNPCC Register, Clinical Research Center, Copenhagen University Hospital, Hvidovre, Denmark, [5]Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark, [6]Institute of Clinical Sciences, Division of Oncology and Pathology, Lund University, Lund, Sweden.

Background The risk of cancer in men from BRCA families is relevant to define to motivate genetic testing and optimize recommendations for surveillance. In a cohort of 301 Danish families with mutations in *BRCA1* and *BRCA2* we assessed the risk of cancer in male mutation carriers and first-degree relatives in relation to a sex-matched and birth-matched control population.
Results Men in *BRCA1* families were not at increased risk of cancer, except for a trend for prostate cancer before age 65, whereas men in *BRCA2* families were at increased risk of male breast cancer and prostate cancer. Male *BRCA2* mutation carriers were at a cumulative risk of 11% for breast cancer 19% for prostate cancer. Male breast cancers developed at a mean age of 59 years and were typically ER/PR positive ductal carcinomas. Prostate cancer developed with a HR of 4.0 (p<0.001) in mutation carriers and a HR 3.3 (p=0.001) in first-degree relatives. The *BRCA2*-associated prostate cancers developed at a mean age of 68 years and were frequently high-grade with Gleason scores ≥8 in 22% of the tumors. Genotype - phenotype correlations were identified with a HR of 9.7 (p≤0.001) for men with mutations in a region of *BRCA2* defined by nucleotides 6373-6492.
Conclusion Male mutation carriers and first-degree relatives in *BRCA2* families are at an increased risk of breast cancer and prostate cancer with a potential prostate cancer cluster region within the *BRCA2* gene.

Identification of rare CDH1 non-coding variants in Hereditary Diffuse Gastric Cancer

H. Pinheiro[1,2], P. Oliveira[1,2], S. Sousa[1,2], K. Shumansky[3], S. Shah[3], J. Senz[3], G. Almeida[1,2], D. Ferreira[1,2], J. Carvalho[1,2], D. Huntsman[3], **C. Oliveira**[1,2,4];
[1]IPATIMUP, PORTO, Portugal, [2]I3S, Instituto de Inovação e Investigação em Saúde, Porto, Portugal, [3]BCCA, Vancouver, BC, Canada, [4]Departamento de Patologia e Oncologia, Universidade do Porto, Porto, Portugal.

Introduction
Hereditary diffuse gastric cancer (HDGC) is a rare, severe, highly penetrant and difficult to diagnose syndrome. Forty-five percent of HDGC-families are associated with germline CDH1/E-cadherin coding alterations.1-3 Other susceptibility genes were recently implicated in ~5% of CDH1-negative families.4 Of the 50% that remain without molecular diagnosis, 2/3 present germline monoallelic CDH1 downregulation5,6 and >90% display loss of E-cadherin expression in tumours.7 HDGC families lacking CDH1-coding mutations may harbour causative germline alterations in non-coding regions.
Material and Methods
The entire CDH1 locus was sequenced from the germline DNA of 90 HDGC probands without mutations in classically screened regions. Bioinformatics criteria were used to prioritize novel NCVs to be evaluated from a biological standpoint: 1) chromatin status from the adjoining region; 2) occurrence in putatively transcribed regions; 3) conservation level; and 4) predicted creation/deletion of repressors/enhancers consensus sequences.
Results and Discussion
Thirty rare heterozygous germline CDH1 NCVs were sorted-out as putatively disease causative for 25% of CDH1-negative probands. NCVs were clustered in silico suggesting the existence of two different pathways impacting gene expression: 1) promoter/enhancer-related variants that create/eliminate binding sites for CDH1 expression repressors/enhancers; and 2) transcription-related variants that may impair the normal CDH1 locus expression pattern. This hypothesis will be biologically addressed in order to confirm NCVs impact in CDH1 expression. Any pathogenic alteration will warrant a complete redefinition of the screening methodology currently applied to HDGC families, providing simultaneously important insights for the understanding of CDH1 expression regulation.

A cancer susceptibility hotspot in HLA class I region

A. E. Kennedy[1], *C. Lane*[1], *D. Seminara*[1], *M. T. Dorak*[2];
[1]Epidemiology and Genomics Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Rockville, MD, United States, [2]School of Health Sciences, Liverpool Hope University, Liverpool, United Kingdom.

The HLA region is well recognized as the regulator of immune response, but is less known for its non-HLA gene content. Besides having the highest gene density in the genome, the HLA region also has remarkable gene diversity. A particular subregion in the HLA class I region contains a number of candidate cancer susceptibility genes and a large number of ncRNA genes. Using disease association databases, we screened SNPs from the overlapping genes CCHCR1/TCF19/POU5F1 and flanking regions (chr6:30.9-31 .4Mb) correlated with cancer susceptibility, and annotated them to assess their causality. At the statistical significance threshold of 0.0001, there were independent associations (rs6457327, rs1634718, rs130067, rs2596503, rs3130544, rs7750641) with lung/breast/cervical/prostate cancers, non-Hodgkin lymphoma, and glioma. The lung cancer-associated SNPs were not in LD (r2<0.50) with the primary lung cancer risk marker BAG6 rs3117582. Each one of these SNPs had a RegulomeDB score <2b and/or CADD C-score >2.5, suggesting high functionality, although none of the cancer-associated SNPs in the region were deleterious to protein function. When their statistically similar (r2>0.8) SNP sets were examined, they also had high functionality scores (C-scores up to 15.8; RegulomeDB scores up to 1f). Most of these SNPs were eQTLs for ncRNAs in this subregion (linc00243 which derives from IER3; HCG22 which is expressed exclusively in lymphoid tissues, lung, breast, prostate, brain and few other tissues). These data suggest that the subregion of HLA class I region examined in this survey contains multiple independent cancer susceptibility risk for multiple cancer types, which may act via modifying the activity of ncRNA content.

PM12.086

Determination of the JAK2 V617F mutation in thrombosis patients

S. Magmuang, *S. Kantak, N. Ngaoburanawit, K. Krathong, T. Chareonsirisuthigul, B. Rerkamnuaychoke;*
Human Genetics Laboratory, Departments of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

Introduction: Janus kinase 2 (JAK2) gene mutation causes uncontrolled myeloproliferation independent of cytokines and abnormal formation of endogenous erythroid colony. This mutation was found in myeloproliferative disorders (MPDs) especially in polycythemia vera (PV) and essential thrombocythemia (ET). In addition, MPDs represent a risk factor for development of thrombosis that is a major cause of morbidity and mortality in patients.
Materials and Methods: We aimed to consider the correlation between JAK2 mutation and thrombosis. Thirty-nine patients who had clinical diagnosis as thrombocytosis and Budd-Chiari syndrome from 2010 to 2014 were collected to determine JAK2 V617F mutation. DNA from all specimens were amplified and detected the presence of JAK2 V617F mutation by AS-PCR.
Results: In this study, we demonstrated JAK2 V617F mutation in both patients who had clinical diagnosis as thrombocytosis and Budd-Chiari syndrome. We found that 11 of 37 (29.7%) thrombocytosis patients had JAK2 V617F mutation. Moreover, one of two patients who had represent as Budd-Chiari syndrome was detected JAK2 V617F mutation.
Conclusions: JAK2 V617F mutation has associated with thrombosis. However, further study in large series is needed to support. Determination of the JAK2 V617F mutation may be useful for screening latent or occult MPDs patients who have occurrence of thrombosis to adjust the appropriate treatment for good patient outcome.

Frebourg*[1,8], *the French LFS network;*
[1]Inserm U1079, University of Rouen, Institute for Research and Innovation in Biomedicine, Rouen, France, [2]Department of Genetics, Curie Institute, Paris, France, [3]Department of Genetics, Gustave Roussy Institute, Villejuif, France, [4]Department of

Pediatric Oncology, Gustave Roussy Institute, Villejuif, France, [5]Department of Medical Oncology, Gustave Roussy Institute, Villejuif, France, [6]CNRS UMR 5558, University of Lyon 1, Leon Berard Cancer Centre, Lyon, France, [7]Inserm UMR-S 669, University of Paris-Sud, Villejuif, France, [8]Department of Genetics, University Hospital, Rouen, France.

Li-Fraumeni syndrome (LFS) is a remarkable cancer predisposition characterised by extensive clinical heterogeneity. We performed, in the context of a national study, a clinical update from the mutation carriers that we identified over the last 20 years. From 1730 patients suggestive of LFS, we identified 415 mutation carriers in 214 families harbouring 133 distinct *TP53* alterations. The 322 affected carriers developed 552 tumours and 43% had developed multiple malignancies. The mean age of first tumour onset was 24.9 years, 41% being affected by age 18. In childhood, the LFS tumour spectrum was characterised by osteosarcomas, adrenocortical carcinomas (ACC), central nervous system tumours, and soft-tissue sarcomas (STS) observed in 30, 27, 26 and 23% of the patients, respectively. In adults, the presentation was characterised by the predominance of breast carcinomas observed in 79% of the females, and STS observed in 27% of the patients. The *TP53* mutation detection rate in children with ACC or choroid plexus carcinomas, and in females with breast cancer before 31, without additional features indicative of LFS, was 45%, 42% and 6%, respectively. The mean age of tumour onset was statistically different ($p<0.05$) between carriers harbouring dominant-negative missense mutations (21.3 years) and those with all types of loss of function mutations (28.5 years) or genomic rearrangements (35.8 years). Affected children, except those with ACC, harboured mostly dominant-negative missense mutations. The clinical gradient of the germline *TP53* mutations suggests that it might be appropriate to stratify the clinical management of LFS according to the class of the mutation.

PM12.088

Comparison of Real-Time PCR, fluorescent in situ hybridization and Immunohistochemistry for detection of MDM2 gene amplification in Well-Differentiated and Dedifferentiated Liposarcoma about 15 cases

S. Louati[1,2], *L. Chbani*[1,3], *N. Senhaji*[1,2], *K. Amrani Joutei*[2], *S. Bennis*[1,3];
[1]*CHU Hassan II, Fez, Morocco,* [2]*Faculty of Science and Technology, Fez, Morocco,* [3]*Faculty of Medicine and Pharmacy, Fez, Morocco.*

Introduction
Liposarcomas are a heterogeneous group of malignant adipocytic neoplasms that consist of 3 distinct clinicopathological entities: well-differentiated/dedifferentiated liposarcoma, myxoid liposarcoma, and pleomorphic liposarcoma. Dedifferentiated liposarcoma (DDLPS) results from the progression of a well-differentiated liposarcoma (WDLPS) to a nonlipogenic sarcoma of variable histologic grades and morphologic patterns that acquires metastatic potential.
Our objective is to a correlate between Real-Time PCR (RT-PCR), fluorescent in situ hybridization (FISH) and Immunohistochemistry (IHC) for detection of MDM2 gene amplification in WDLPS and DDLPS.
Methods
15 cases of liposarcoma were selected from the Pathological Anatomy service to make this correlation. Diagnosis is based on a standard histology. Immunohistochemical confirmation was carried out by the antibodies anti-MDM2 and anti-CDK4. The amplification of MDM2 was performed by FISH and RT-PCR.
Results
The average age of patients is 54 years, ranging from 27 to 75 years with a slight female predominance.
8 cases of tumors are diagnosed WDLPS and 7 other cases DDLPS. These tumors are characterized by a heterogeneous aspect of malignant cells and positivity of anti-MDM2 and anti-CDK4 antibodies. MDM2 amplification by FISH was found in 6 of 15 liposarcoma cases ((3/8) of WDLPS and (3/7) of DDLPS) and in 7 cases by RT-PCR ((3/8) of WDLPS and (4/7) of DDLPS) something which shows more than 85% concordance between the two techniques knowing the sensitivity of FISH is higher than that of the RT-PCR.
Conclusions
MDM2 amplification has been shown to have high sensitivity in characterizing WDLPS and DDLPS.
Differences in MDM2 amplification profiles among liposarcomas could help further define and predict progression to high-grade neoplasia.

Rapid aneuploidy screening of plasma DNA samples from cancer patients using a modified FAST-SeqS approach

J. Belic[1], *P. Ulz*[1], *M. Auer*[1], *K. Fischereder*[2], *E. Petru*[3], *T. Bauernhofer*[4], *J. B. Geigl*[1], *M. R. Speicher*[1], **E. Heitzer**[1];
[1]*Institut of Human Genetics, Graz, Austria,* [2]*Department of Urology, Graz, Austria,* [3]*Department of Obstetrics and Gynecology, Graz, Austria,* [4]*Division of Oncology, Graz, Austria.*

Introduction
Recent progress in the analysis of cell-free DNA fragments (cell-free circulating tumor DNA, ctDNA) now allows monitoring of tumor genomes by non-invasive means. However, previous studies with plasma DNA from patients with cancer demonstrated highly variable allele frequencies of ctDNA. The comprehensive analysis of tumor genomes is greatly facilitated when plasma DNA has increased amounts of ctDNA. Therefore, a fast and cost-effective pre-screening method to identify such plasma samples without previous knowledge about alterations in the respective tumor genome could assist in the selection of samples suitable for further extensive qualitative analysis.
Methods
To address this, we adapted the recently described FAST-SeqS method, which was originally established as a simple and effective, non-invasive screening method for fetal aneuploidy from maternal blood.
Results
We show that our modified FAST-SeqS method (mFAST-SeqS) can be used as a pre-screening tool for an estimation of the ctDNA percentage. Plasma samples with an mFAST-SeqS z-score above 5 showed highly concordant results compared to copy number profiles obtained from our previously described plasma-Seq approach. Therefore, mFAST-SeqS revealed a general overview about the aneuploidy status of the tumor genome on the resolution of chromosome arms.
Conclusion
Advantages of this approach include that no prior knowledge about the genetic composition of tumor samples is necessary in order to identify between plasma DNA samples with more than 10% of ctDNA content, and the speed and cost-effectiveness of the assay.

Pharmacogenomic study of non-small cell lung cancer

Z. Hammoudeh[1], *N. Chilingirova*[2], *L. Balabanski*[3], *S. Ivanov*[3], *R. Vazharova*[3], *D. Nesheva*[1], *B. Rukova*[1], *S. Karachanak-Yankova*[1], *O. Antonova*[1], *R. Staneva*[1], *S. Hadjidekova*[1], *I. Dimova*[1], *V. Damyanova*[1], *G. Kurteva*[2], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria,* [2]*Specialized hospital for active treatment in oncology –Sofia, Sofia, Bulgaria,* [3]*Malinov hospital, Sofia, Bulgaria.*

Background: Lung cancer is a leading cause of death. Non-small cell lung cancer (NSCLC) accounts for approximately 85% of all cases. Platinum based therapy is used as standard treatment for patients with NSCLC. The epidermal growth factor receptor (EGFR) has been shown to play an important role in the growth and survivor of many solid tumors, including NSCLC. Gefitinib and erlotinib are EGFR tyrosine kinase inhibitors (EGFR-TKI) that blocks the signal transduction pathways implicated in the proliferation and survival of cancer cells. Little is known about other pharmacogenetic variants in NSCLC.
Methods: We performed DNA analysis on 19 patients with NSCLC. Tumor sample DNA was extracted from formalin-fixed paraffin-embedded samples. The samples were NGS sequenced using Illumina cancer panel (96 genes and 256 variants) by MiSeq instrument. The pharmacogenetic significance of our variants was evaluated using the information from PharmGKB database.
Results: Pharmacogenetic variants were found in different genes: ERCC2 (63% of the samples), TP53 (74%), XPC (68%). These variants define NSCLC as sensitive to treatment with the platinum based therapy. Another variant in EGFR gene (EGFR R497K) sensitive to EGFR-TKI was found in 47% of the samples by NGS sequencing. These variants can't be detected by the current IVD labelled real time PCR assays for NSCLC target therapy.
Conclusion: Our data shows that next generation sequencing tests reveals a new useful information for the personalized therapy of NSCLC.

PS12.091

HLA Region Contains Multiple Lung Cancer Susceptibility Genes

I. Stasik[1], *A. E. Kennedy*[2], *S. K. Singh*[3], *M. T. Dorak*[1];
[1]*Liverpool Hope University, Liverpool, United Kingdom,* [2]*National Cancer Institute, Bethesda, MD, United States,* [3]*Florida International University, Miami, FL, United States.*

The major histocompatibility complex (MHC) was strongly implicated in the development of lung cancers in animal experiments. Lung cancers show the highest number of cancer associations with human MHC (HLA) region. For a systematic analysis, we extracted 73 SNPs located within chromosome 6: 29 to 33Mb and associated with lung cancer from the GWAS catalog, dbGAP, and GRASP database (P<5E-04), of which 59 exceeded the genome-wide statistical significance threshold (P < 5E-08). Only three of those were listed in the GWAS catalog (rs3117582, rs3817963, rs2395185), with BAG6 rs3117582 being the most consistently observed. Associations were with squamous

cell and adenocarcinoma, as well as lung cancers in never-smoked women. These SNPs also show associations with Hodgkin lymphoma, breast, and prostate cancers. Three SNPs occur as somatic mutations in breast and colon cancers (rs7750641, rs3749971, rs3134942). Two SNPs (rs3117582, rs1150752) map into CgG islands, one (rs9276472) is within 500bp of a microRNA sequence (MIR3135B), three in non-coding RNA genes, and two are deleterious missense variants (rs9262143, rs7775397) in KIAA1949 and C6orf10. Only one SNP was in an HLA gene (rs2187668, HLA-DQA1, non-coding) and none were in a sequence encoding peptide-binding region of HLA molecules. However, 35 of the 73 SNPs scored the highest gene regulatory function in RegulomeDB analysis. Most notably, rs3117582 and its six statistically indistinguishable (r2 = 1) and 41 statistically similar (r2 > 0.8) SNPs had high levels of functionality. These results strongly suggest that the HLA region contains multiple lung cancer susceptibility markers acting via more than one and non-immune-related mechanism.

PM12.092

Genomewide Copy number variation analysis and Targeted Next Generation Sequencing in suspected Lynch syndrome families reveals novel potential causative candidate genes

K. Kayser[1], *F. Degenhardt[1], S. Holzapfel[1], I. Spier[1], E. Holinski-Feder[2,3], W. Schmiegel[4], S. Horpaopan[1], M. Draaken[1], B. Royer-Pokora[5], M. von Knebel-Doeberitz[6,7], H. Schackert[8], C. Engel[9], M. Löffler[9], J. Wijnen[10], M. Nöthen[1,11], P. Hoffmann[11], S. Herms[11], A. Hofmann[11], S. Aretz[1], V. Steinke[1];*

[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]Department of Medicine, Ludwig-Maximilians-University, Munich, Germany, [3]Center of Medical Genetics, Munich, Germany, [4]Clinic of Internal Medicine, Knappschaftskrankenhaus, University of Bochum, Bochum, Germany, [5]Institute of Human Genetics, Heinrich Heine University of Düsseldorf, Düsseldorf, Germany, [6]Department of Applied Tumor Biology, Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany, [7]Cooperation Unit Applied Tumor Biology, German Cancer Research Center (DKFZ), Heidelberg, Germany, [8]Department of Surgical Research, Technical University Dresden, Dresden, Germany, [9]Institute for Medical Informatics Statistics and Epidemiology, University of Leipzig, Leipzig, Germany, [10]Leiden University Medical Center, Department of Clinical Genetics, Leiden, Netherlands, [11]Institute of Human Genetics Department of Genomics, Life&Brain Center, University of Bonn, Bonn, Germany.

Introduction: In up to 50% of suspected Lynch syndrome (LS) families with typical signs of mismatch repair (MMR) defect in tumor tissue, no germline mutation in the MMR genes can be detected. Loss-of-function copy number variants (CNVs) in these patients might give a hint to yet unidentified genes responsible for LS.
Methods: Genomic DNA from 81 unrelated mutation-negative patients from the German HNPCC Consortium and four patients from the Netherlands was genotyped. Putative CNVs were identified and filtered according to stringent criteria to select rare, non-polymorphic deletions and duplications. Candidate genes in validated CNVs were screened for germline point mutations by a targeted NGS approach in 44 patients.
Results: In total, 30 deletions and 18 duplications encompassing 71 protein-coding genes were found in 35 patients. Five of these genes are promising candidate genes that are highly expressed in normal colorectal tissue. Three of these genes are involved in cell adhesion, cell development and transformation, cell cycle checkpoint regulation, and cell volume or polarity control. One is involved in double strand break repair and recombination and the last one possesses DNA helicase activity. Analysis of NGS data is still ongoing.
Conclusion: By applying stringent filter criteria we identified a group of rare, non-recurrent loss-of-function CNVs which might contain novel predisposing genes for LS. The ongoing NGS analysis will reveal whether there are also point mutations in one of these genes confirming a possible causative effect for LS.
The study was supported by the German Cancer Aid (grant no 109370).

PS12.093

Unexplained hereditary hypermethylation of the *MSH2* promoter

M. Ariaans[1], *J. Moline[2], M. Schouten[1], N. Hoogerbrugge[1], I. Nagtegaal[1], A. Mensenkamp[1], M. Ligtenberg[1];*

[1]Radboudumc, Nijmegen, Netherlands, [2]Cleveland Clinic Foundation, Cleveland, OH, United States.

A 43-years old male was diagnosed with two primary colorectal cancers (CRC). The family fulfilled the Amsterdam criteria, with a father and paternal grandmother with CRC at age 57 and 50, respectively. A sister was diagnosed with a colorectal adenoma at age 42.
The CRCs of both our index and his father were MSI-high with lack of nuclear staining of MSH2. Neither a germline mutation in *MSH2* or *MSH6* nor a copy number alteration in *EPCAM* and the intergenic region between *EPCAM* and *MSH2* was detected. In the 3'UTR of *EPCAM,* about 280 nt upstream of the poly-adenylation signal, a heterozygous variant was present: c.*136C>G. Hypermethylation of the *MSH2* promoter was found in both tumors and normal colon tissue, but not in peripheral blood or oral mucosa cells of our index patient, mimicking the situation in patients with a 3'end *EPCAM* deletion.
The heterozygous *EPCAM* variant cosegregated
with hypermethylation of the *MSH2* promoter in his father and sister. A Lynch-like surveillance regimen was advised for all first-degree relatives.
Cosegregation of the *EPCAM* variant c.*136C>G with *MSH2* promoter methylation in the tumors indicate that an aberration in the *EPCAM-MSH2* locus other than a deletion of the polyadenylation signal of *EPCAM* can induce hypermethylation of the *MSH2* promoter. Whether there is a causal relation between this variant and hypermethylation of the *MSH2* promoter is currently unclear.

PM12.094

An unusual case study of Lynch syndrome solved through Next Generation sequencing

B. S. Speight[1], *T. Elsen[1], S. Abbs[1], M. Tischkowitz[1,2];*

[1]East Anglian Medical Genetics Service, Addenbrooke's Hospital, Cambridge, United Kingdom, [2]Academic Dept of Medical Genetics and National Institute for Health Research, Cambridge Biomedical Research Centre, University of Cambridge, Cambridge, United Kingdom.

Lynch syndrome caused by inherited *MSH6* mutations is characterised by an increased cancer risk, predominantly of the bowel and endometrium. This case study describes a cluster of three endometrial cancers in first-degree relatives, with the proband diagnosed at 60 years. Her mother and sister were diagnosed at 59 and 74 years, respectively. The proband's tumour showed loss of *MSH2* and *MSH6* protein immunostaining, but no mutations in either gene were identified by dHPLC and MLPA testing methods in 2008. Colonoscopy screening was initiated for the proband and close family members according to Lynch syndrome guidelines. In 2014, *MSH2* and *MSH6* gene testing was repeated using Next Generation sequencing and a heterozygous duplication of a single nucleotide in exon 5 of *MSH6* was identified which was verified by fluorescent sequence analysis. This finding confirmed the diagnosis of Lynch syndrome in the proband and the need for bowel screening in this family. The result also enabled predictive gene testing in relatives and the exclusion from risk of some individuals found not to carry the familial mutation.
This case study highlights the importance of Lynch syndrome testing in families with endometrial cancer that do not meet clinical diagnostic criteria. It also shows 1) the utility of multi-gene testing following aberrant immunostaining results and 2) how updated genetic testing techniques can detect pathogenic mutations previously missed by older methods. The role of the Clinical Genetics professional in conveying new personal risk information derived from the use of updated technology is also discussed.

PS12.095

Assessment of clinical history, immunhistochemical phenotype, and germline DNA analysis in detection of LS-related PMS2 gene mutations in at risk individuals from Ontario/Quebec, Canada.

J. M. Kerkhof[1], *M. Braga[1], J. Baril[1], J. A. Stuart[1], P. J. Ainsworth[1,2];*

[1]London Health Sciences Centre, London, ON, Canada, [2]Department of Pathology, Western University, London, ON, Canada.

Lynch Syndrome (LS) is characterized by mutations in the DNA mismatch repair genes MSH2, MLH1, MSH6, and PMS2. However, the identification of PMS2 specific mutations is complicated by the presence of PMS2 pseudogenes, along with the allelic diversity of the 3' region of PMS2, a complexity which has probably led to under-reporting PMS2 gene mutations as a cause of LS. Acting as a referral centre serving a population of >2m. people we have developed a technique to identify deleterious PMS2 gene mutations by combining MLPA analysis with SNP-specific probes, along with methodology, adapted from Clendenning et al. (Human Mutation, 2006), utilizing genomic long-range PCR enabling sequence analysis of both PMS2 and PMS2CL.
Over the past two years 85 patients were referred to this centre for PMS2 analysis because of a personal and family cancer history, and/or mis-match repair protein immunohistochemical (IHC) tumour analysis suggestive of LS. IHC findings were reviewed where available, along with tumour DNA for microsatellite instability, and leukocyte-derived germline DNA was examined for PMS2 gene mutations.
24 of the 85 referred patients demonstrated an isolated IHC loss of PMS2, 14 of the 24 (58%) proved to be PMS2 mutation positive, with 2 of the 24 demonstrating an MLH1 mutation. In the remaining 61 patients (primarily showing MLH1/PMS2 loss by IHC) no PMS2 gene mutations were identified. We propose that it is reasonable to limit PMS2 gene analysis to patients considered to be at risk of LS to those individuals who demonstrate isolated IHC loss of PMS2 protein.

Uterine cancer in Lynch syndrome: clinico-pathological and molecular features

L. Libera[1], *I. W. Carnevali*[1], *L. Cimetti*[1], *N. Sahnane*[1], *A. Chiaravalli*[1], *D. Furlan*[1], *T. Rossi*[2], *A. Viel*[3], *F. Sessa*[1], *C. Riva*[1], *M. Tibiletti*[1];
[1]*Department of Surgical and Morphological Sciences, University of Insubria and Ospedale di Circolo, Varese, Italy,* [2]*Department of Gynecology and Obstetrics, University of Insubria and Ospedale Filippo Del Ponte, Varese, Italy,* [3]*Division of Experimental Oncology I, CRO, Aviano, Italy.*

Background: Lynch Syndrome (LS) arises from a germline mutation in MMR genes and predisposes to colorectal and uterine cancers (UC). The aim of this work was to deeply characterize the UC in LS. **Methods:** 29 LS-UC and 38 sporadic cancer for comparison were studied for clinicopathological features, MMR IHC, MSI and MLH1 methylation. **Results:** The mean age at the UC diagnosis of LS patients was 46 years respect to patient with sporadic UC (55 years, p=0.007). BMI of LS patients was 24 (normal weight) respect to the patients with sporadic cancer (BMI=27,3; p=0.04). UC arose as first manifestation of the pathology in 34,5% of LS patients. Corpus of the uterus was the prevalent site of onset, while 3 LS-UC arose in the Lower Uterine Segment (LUS) and 4 in the cervical canal. Most of the tumors showed an endometrioid histotype. Abundant tumor-infiltrating lymphocytes (TIL) and peritumoral lymphocytes (PL) were observed in LS-UC in comparison to the sporadic ones. IHC loss of at least one MMR protein was observed in 27 cases (93%), including 19 cases with MSH2 and/or MSH6 loss and 8 cases with MLH1 and PMS2 loss. MSI was detected in 27 cases (93%). Interestingly, 4 LS-UC presented also MLH1 promoter methylation. **Conclusions:** This study demonstrates that the evaluation of these clinico-pathological and molecular features is an efficient strategy to identify LS and to refer those patients to the genetic counseling.

PS12.097

Developing and implementing gene-specific clinical management guidelines for Lynch syndrome

B. DeSouza[1,2], *Z. Kemp*[1], *J. Wiggins*[1], *K. Kohut*[1], *A. George*[1,2], *N. Rahman*[1,2], *H. Hanson*[1,2];
[1]*Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom,* [2]*Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom.*

Background: Lynch syndrome is genetically heterogeneous, caused by mutations in the mismatch repair (MMR) genes: MLH1, MSH2 (including EPCAM-deletion mediated MSH2 hypermethylation), MSH6 and PMS2. It is characterised by predisposition to colorectal (CRC), endometrial and other cancers. Cancer surveillance and risk-reduction strategies have been introduced on the basis of cancer risks in MLH1 and MSH2 mutation carriers. However, emerging data suggest the cancer spectrum and penetrance may differ substantially between the MMR genes.
Objectives: To review cancer penetrance and evidence for risk-reducing interventions in MMR mutation carriers, and to provide management recommendations for carriers based on individualised cancer risks.
Methods: A systematic literature review was conducted to identify relevant studies meeting inclusion and quality criteria. Using these data management recommendations were then developed and implemented following a consensus meeting.
Results: Available data supports gene-specific management protocols for the MMR genes. We recommend colonoscopy at 18-monthly intervals starting at 25yrs for MLH1 and MSH2 carriers and 30yrs for MSH6 and PMS2 carriers. This is based on the reduced and later age-dependent CRC penetrance for MSH6 and PMS2 carriers. We recommend female MLH1 and MSH2 carriers consider risk-reducing hysterectomy and bilateral-salpingo-oophorectomy (BSO) from 40yrs, but available data does not support recommendation of BSO in premenopausal MSH6 and PMS2 carriers.
Conclusion: We have implemented gene-specific protocols for MMR mutation carriers at the Royal Marsden. The protocols, accompanying FAQs and background document are freely available at www.icr.ac.uk/protocols (protocols 9-12).
This work was funded by the RM/ICR NIHR BRC

Prognostic significance of cytogenetic and molecular-genetic changes in patients with MDS

A. Strnkova[1], **B. Drevojankova**[1], *M. Stoklasova*[1], *L. Truhlikova*[1], *A. Burdova*[1], *T. Sablaturova*[1], *M. Wrobel*[2], *D. Klodova*[2], *J. Gumulec*[3], *D. Adamova*[4], *M. Brejcha*[2];
[1]*Laboratore AGEL a.s., Novy Jicin, Czech Republic,* [2]*Hospital Novy Jicin a.s., Novy Jicin, Czech Republic,* [3]*Faculty Hospital Ostrava, Ostrava, Czech Republic,* [4]*Hospital Opava, Opava, Czech Republic.*

Introduction: The myelodysplastic syndromes are a group of hematopoietic disorders characterized by clonal hematopoiesis, impaired differentiation, peripheral-blood cytopenias, and a risk of progression to acute myeloid leukemia. Conventional cytogenetic analysis (CCA) is one of many prognostic factors included in International Prognostic Scoring System (IPSS).
Patients and Methods: We investigated 804 patients with primary MDS in years 2003-2014. The CCA was performed on bone marrow samples using short time cultivation. Interphase FISH was carried out using DNA probes designed to detect 5q, 7q, 11q, 12p, 17p and 20q deletions, trisomy 8, loss Y (MetaSystems Germany, Abbott Molecular).
Results: We cultivated 94,5 % of samples successfully. Chromosomal aberrations were detected in 23 % of patients using CCA and I-FISH. CCA revealed chromosomal aberrations in 9 % of patients with negative I-FISH results. For statistical analysis of our data we followed The New Comprehensive Cytogenetic Scoring System of chromosomal aberrations in MDS defined by Schanz *et al.* (2012) and we classified patients according to chromosomal abnormalities into five prognostic subgroups: *very good* - 3,0 %, *good* - 80,9 %, *intermediate* - 5,8 %, *poor* - 3,7 % and *very poor* - 6,6 %.
Conclusion: Our comparison with New Comprehensive Cytogenetic Scoring System defined by Schanz *et al.* (2012) will be discussed in the poster. However we were able to classify 757 of our patients into this scoring system. According to our results it is important to combine both cytogenetic methods (CCA and I-FISH) to correct classification of patients into prognostic subgroups and suggest appropriate therapy.

PS12.099

The analysis of somatic mutations in melanoma patients using hybridization with diagnostic biochips

M. Emelyanova[1,2], *L. Lyubchenko*[2], *L. Demidov*[2], *A. Zasedatelev*[1,2], *T. Nasedkina*[1,2];
[1]*Engelhardt Institute of Molecular Biology Russian Academy of Sciences, Moscow, Russian Federation,* [2]*Clinical Oncology Research Institute, N. N. Blokhin Russian Cancer Research Center of Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Melanoma is one of the most aggressive cancers. Target inhibitors are being developed for the treatment of cancer patients with particular tumor genotype. A diagnostic biochip has been developed which allowed analyzing 40 somatic mutations in *BRAF*, *KIT*, *NRAS*, *MEK1/2*, *GNAQ* and *GNA11* genes potentially relevant to existing and emerging targeted therapies in melanoma. The technique of LNA-blocking PCR was used for specific amplification of mutant DNA in a large excess of wild-type DNA. The amplified fragments were labeled via incorporation of fluorescently labeled nucleotide during the second round of PCR and were hybridized with specific oligonucleotides immobilized on a biochip. The assay was tested using cell lines, fresh-frozen tissue, and formalin-fixed paraffin embedded tissue. The clinical samples from 52 patients with melanoma of skin were analyzed. Mutation in *BRAF*, *NRAS*, *KIT* genes were detected in 52%, 15% and 3% of patients, respectively. The validation was done using Sanger sequencing. This approach was able to detect approximately 1% of mutated alleles in wild-type DNA background.
We consider that the biochip-based assay is a reliable and inexpensive method for the identification of melanoma patients, who may respond to a specific target therapy.
This work was supported by grant of the Russian Science Foundation (grant # 14-35-00107) and the co-financing provided by the Federal Agency for Scientific Organizations.

PM12.100

Genetics of inherited cutaneous melanoma in Latvia: functional and next-generation sequencing approach

A. Ozola, *R. Veinalde, I. Mandrika, D. Pjanova;*
Latvian Biomedical Research and Study Centre, Rīga, Latvia.

Introduction: Approximately 10% of cutaneous melanomas occur in the familial setting. Hereditary melanoma is mainly caused by germline mutations in the *CDKN2A* gene (in approximately 39% of all families) and rarely in *CDK4*, *BAP1*, *POT1*, *MITF*, and *TERT* genes. However, in more than half of the families the inherited mutations causing melanoma are still unknown. In Latvia melanoma predisposition is mainly associated with R24H mutation in the *CDK4* gene and recently the first family with *CDKN2A/p14ARF* promoter deletion c.– 20677_–20682delGTACGC was found. Although, in the majority of families (19/23 (83%)) the inherited gene mutations causing melanoma are not found. The aim of this study was to analyse the association of *CDKN2A/p14ARF* promoter deletion with melanoma and to test its functionality, as well as, to analyse Latvian melanoma families for mutations in newly characterized melanoma susceptibility genes using next-generation sequencing.
Materials and Methods: *CDKN2A/p14ARF* promoter region with deletion was genotyped on an ABI 3100 Sequencer. Two sided Fisher's exact test was applied for statistical analysis. Luciferase expression system was used for

deletion's functionality assessment. Agilent SureDesign tool was used to create HaloPlex custom design panel for next-generation sequencing on the Ion Torrent™ system.
Results: *CDKN2A/p14ARF* deletion c.-20677_-20682delGTACGC was found in 7 of 211 melanomas patients and 2 of 326 controls (OR=6.35, 95% CI 1.34-30.22, p=0.017). Deletion's functionality and next-generation sequencing results using HaloPlex platform that includes six full size (*BAP1*, *TERT*, *POT1*, *CDKN2A*, *CDK4*, *MC1R*) and 60 SNPs from 15 other melanoma susceptibility genes will be discussed.

PS12.101
Severity score for multiple endocrine neoplasia

A. Sakurai[1,2], *S. Suzuki*[2], *T. Okamoto*[2], *T. Imai*[2], *S. Kosugi*[2], *S. Uchino*[2];
[1]*Sapporo Medical University, Sapporo, Japan,* [2]*MEN Consortium of Japan, Sapporo, Japan.*

Multiple endocrine neoplasia (MEN) is autosomal dominantly inherited tumor syndrome which is characterized by occurrence of various endocrine and non-endocrine tumors. Clinical features and severity of each manifestation varies among patients even in the same family. As involvement of many specialists of different specialty is necessary for comprehensive clinical care of patients with MEN, parameters to objectively evaluate patient's clinical severity will be useful. For this purpose, members of the "MEN consortium of Japan" prepared a "Severity score chart for MEN1 and MEN2" in trial. In this chart, evaluation of each patient is performed with three steps. In Step 1, absence or presence of each disorder and degree of burden is evaluated by five-level rating scale (0, absence of the disease; 4, the most severe). Degree of burden is judged based on Karnofsky Performance Status Scale (Karnofsky and Burchenal, 1949). Then in Step 2, absence or presence of distant metastasis of the tumor is scored and in Step 3, severity grade of the patient is judged. Presymptomatic subjects who have pathogenic mutation but no apparent diseases are categorized as Grade I and the most severe case is categorized as Grade VI. Although current trial model solely evaluates physical disorders, we are aware that patient's psychological burden should also be evaluated. We are now estimating the utility of this score chart for future standardization after necessary modification.

PM12.102
mir-221 as a pre- and post-operative plasma biomarker for laryngeal squamous cell carcinoma patients

S. Salman Yilmaz[1], *E. Guzel*[1,2], *O. F. Karatas*[1,3], *M. Yilmaz*[4], *M. B. Duz*[1], *M. Ozen*[1,2,5];
[1]*Department of Medical Genetics, Istanbul University Cerrahpasa Medical School, Istanbul, Turkey,* [2]*Biruni University, Istanbul, Turkey,* [3]*Molecular Biology and Genetics Department, Erzurum Technical University, Erzurum, Turkey,* [4]*Department of Otorhinolaryngology, Cerrahpasa Medical School, Istanbul University, Istanbul, Turkey,* [5]*Department of Pathology & Immunology Baylor College of Medicine, Houston, TX, United States.*

Larynx Cancer (LCa) comprises about 1% to 2.5% of all human neoplasms and it mostly originates from squamous cell carcinoma. Although distinct diagnostic and therapeutic approaches have been suggested for LCa, they are still controversial and more efforts are required for their effective use. MicroRNAs (miRNA) have been shown to play significant roles in the regulation of carcinogenesis and they were demonstrated to be present in a stable form in various human body fluids including plasma. Besides, miRNAs have been postulated in distinct studies as strong diagnostic or prognostic biomarkers.
In this study, we aimed to compare the miRNA profile of plasma samples obtained from 30 LCa patients (pre-operative and post-operative serum samples) and 30 healthy controls to identify a miRNA expression signature, which can be used to distinguish LCa patients from healthy individuals.
MiRNA profiling of eight plasma samples (four from pre-operative LCa samples, four from control individuals) were performed using miRNA microarray. Two of the significantly deregulated miRNAs were selected for further confirmation using quantitative reverse-transcription PCR (qRT-PCR). Statistical analysis was performed using Student's t-test.
Microarray profiling showed that miR-221 was upregulated and miR-133b was downregulated in LCa plasma samples. qRT-PCR analysis confirmed the overexpression of miR-221 in plasma samples of LCa. Further analysis qRT-PCR analysis demonstrated the reduced level of miR-221 to the normal level in the post-operative plasma samples.

PS12.103
Assessment of MLH1 promoter methylation in patients with endometrial cancer.

K. Ambler, *M. Zawitkowski, M. Ho;*
SA Pathology, Adelaide, Australia.

Lynch syndrome (LS) is an autosomal dominant inherited cancer caused by a germline mutation in one of the DNA mismatch repair (MMR) genes: *MLH1*, *MSH2*, *MSH6*, or *PMS2*. Individuals with LS will commonly present with colorectal cancer (CRC), however female carriers also have an increased risk of developing endometrial cancer (EC). It is important to distinguish LS patients from sporadic cancer patients in order for appropriate disease surveillance and family members to be counselled.
The Molecular Oncology Laboratory currently performs a number of genetic tests aimed at identifying these patients, including immunohistochemistry (IHC), microsatellite instability (MSI) and MLH1 promoter methylation.
Methylation of specific regions of the promoter for the MLH1 gene results in epigenetic silencing of the gene and the patient may present with a similar clinical picture to a patient carrying a germ-line MMR gene mutation. Identification of MLH1 methylation will indicate that LS is unlikely and that MMR gene mutation screening is not required.
Methylation testing is carried out using a methylation-sensitive multiplex-ligation dependent probe amplification (MS-MLPA) technique which targets 5 sites in the MLH1 promoter corresponding to regions A, B, C and D and intron 1.
A review has been performed comparing the MLH1 methylation results at 5 sites in EC patients, with results in CRC patients. The incidence of EC patients with MLH1 methylation is 86%, with 97% of patients showing methylation across all 5 regions, compared with 74% of CRC patients. Therefore MLH1 promoter methylation testing in combination with IHC and MSI provides a useful diagnostic tool for identifying patients with LS.

PM12.104
Sanger sequencing of low amount of genomic DNA and FFPE DNA with PCR Primers derived from the Ion AmpliSeq cancer hotspot panel

K. Varma[1], *E. Schreiber*[1], *A. Broomer*[2], *M. Adams*[2];
[1]*Thermo Fisher Scientific, South San Francisco, CA, United States,* [2]*Thermo Fisher Scientific, Carlsbad, CA, United States.*

The introduction of Ion AmpliSeq™ panels for characterization of mutations occurring in tumor tissue has revolutionized translational oncology research. The Ion Ampliseq™ cancer hotspot panel version 2 (CHP v2) includes 207 actionable mutation targets in 50 genes and the Ion Oncomine™ cancer panel over 2000 mutations. A hallmark of these Ampliseq cancer panels is the low amount of input DNA needed which is critical when specimen material is limited such as with needle biopsy or FFPE samples. Typically, 10 ng of DNA is sufficient to produce informative sequencing data. Often, cancer-causing or promoting mutations are detected at low allele frequencies like 10-20 % compared to the normal allele. Many researchers wish to verify these low frequency mutations by an orthologous method such as Sanger sequencing on a capillary electrophoresis (CE) instrument. To that end, we have developed a workflow that enables the amplification and traditional Sanger sequencing of individual Ion AmpliSeq targets directly from the AmpliSeq library starting material. The method requires 1 µl (~ 5%) of the original AmpliSeq preamplification material. A dilution of this aliquot is used as template source for individualized PCR/sequencing reactions. We show that a selection of 48 targets from the CHPv2 panel could be successfully amplified and Sanger-sequenced from an Ampliseq library originally prepared from 10 ng of FFPE DNA. Furthermore, we show the successful Sanger-re-sequencing of all individual 24 targets covering the TP53 exons from the same sample processed and pre-amplified with the OncoMine AmpliSeq panel. This method enables researchers to reflex-test potential mutations from very material-limited specimen using Sanger CE sequencing.

PM12.106
NAB2-STAT6 fusion gene: Meningeal hemangiopericytomas and meningomas comparative study.

S. Trabelsi[1], **D. H'mida Ben Brahim**[1], *N. Mama*[2], *M. Ladib*[3], *S. Popov*[4], *A. Burford*[4], *M. Chourabi*[1], *M. Haddaji Mastouri*[1], *M. Mokni*[5], *K. Tlili*[6], *H. Krifa*[7], *C. Jones*[4], *M. T. Yacoubi*[8], *A. Saad*[1];

Department of Histopathology-Cytopathology, Farhat Hached University Hospital, Sousse, Tunisia, Sousse, Tunisia,* [6]*Departement of radiology, Sahloul university Hospital, Sousse, Tunisia., Sousse, Tunisia,* [7]*Departement of Neurosurgery, Sahloul university Hospital, Sousse, Tunisia., Sousse, Tunisia,* [8]*Departement of pathology, Farhat HACHED Hospital, Sousse, Tunisia., Sousse, Tunisia.*

Background: Meningeal hemangiopericytoma (MHPC) is a vascular tumor

arising from pericytes. Most intracranial MHPCs resemble meningiomas (MNGs) in their clinical presentation and histological features and may therefore be misdiagnosed, despite their important differences in prognosis.
Methods: We report 8 cases of MHPC and 5 cases of MNG collected from 2007 to 2011 from the neuro-Surgery and histopathology departments. All 13 samples were re reviewed by two independent pathologists and investigated by immunohistochemistry (IHC) using mesenchymal, epithelial and neuro-glial markers. Additionally, we screened all tumors for a large panel of chromosomal alterations using Multiplex Ligation Probe Amplification (MLPA). Presence of the NAB2-STAT6 fusion gene inferred by immunohistochemical staining for STAT6.
Result: Compared with MNG, MHPCs showed strong VIM (100% of cases), CD99 (62%), bcl-2 (87%), and p16 (75%) staining but only focal positivity with EMA (33%) and NSE (37%). The p21 antibody was positive in 62% of MHPC and less than 1% in all MNGs. MLPA data did not distinguish HPC from MNG, with PTEN loss and ERBB2 gain found in both. By contrast, STAT6 nuclear staining was observed in 3 MHPC cases and was absent from MNG.
Conclusion: MNG and MHPC comprise a spectrum of tumors that cannot be easily differentiated based on histopathology. The presence of STAT6 nuclear positivity may however be a useful diagnostic marker.

PS12.107
Genome-wide copy number analysis of pediatric malignancies.

P. Clark[1], *S. Addya*[2], *K. McCormick*[2], *P. Koduru*[3], *L. J. Kricka*[4], *D. Rakheja*[3,5], *A. Ertel*[2], *E. Londin*[6], *J. Y. Park*[7,5], *P. Fortina*[8];
[1]*Department of Pathology and Laboratory Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA, United States,* [2]*Cancer Genomics Laboratory, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, United States,* [3]*Department of Pathology, University of Texas Southwestern Medical Center, Dallas, TX, United States,* [4]*Department of Pathology and Laboratory Medicine, University of Pennsylvania Medical Center, Philadelphia, PA, United States,* [5]*Department of Pathology and Laboratory Medicine, Children's Health, Dallas, TX, United States,* [6]*Computational Medicine Center, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, United States,* [7]*Eugene McDermott Center for Human Growth and Development, University of Texas Southwestern Medical Center, Dallas, TX, United States,* [8]*Cancer Genomics Laboratory, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, Philadelphia, PA, United States.*

Neuroblastoma and hepatoblastoma are two cancers commonly characterized by chromosomal abnormalities such as copy number gains and losses, and regions of loss of heterozygosity (LOH). Typically, these abnormalities are detected through traditional cytogenetic and microsatellite assays. The heterogenous nature of these diseases suggests that additional genomic events, such as DNA variants and chromosomal gains/losses contribute to the disease etiology. With this in mind, we explored the use of the Affymetrix OncoScan FFPE Assay to improve on the diagnostic cytogenetics of these 2 cancer types. DNA was tested from FFPE pediatric tumor samples from 6 hepatoblastoma and 8 neuroblastoma cases. 6 of 8 neuroblastoma cases had MYCN amplification assessed by FISH. Cytogenetics was normal for the 6 hepatoblastoma cases, while Oncoscan testing revealed all 6 had copy number gains in 1q32 or 2p24, previously reported to be frequent in hepatoblastoma. For neuroblastomas, the cytogenetic and FISH findings were all confirmed by Oncoscan. In addition, multiple CNV and LOH were identified by Oncoscan. Furthermore, Oncoscan analysis of all tumor samples revealed 6 single nucleotide variants in 4 genes previously shown to be associated with neoplasia. The variants were independently validated using targeted panels on both the Ion Torrent and MiSeq DNA Sequencers. These results show that the OncoScan assay can accurately identify both chromosomal abnormalities and DNA variants that may otherwise be missed by traditional methodologies.

PM12.108
Homozygosity for MSH6 mutations Misdiagnosed as Neurofibromatosis Type 1

S. M. Sharif, *A. Dobbie;*
Yorkshire Regional Genetics Service, Leeds, United Kingdom.

Homozygosity for MSH6 mutations Misdiagnosed as Neurofibromatosis Type 1
Saghira Malik Sharif, Dr Angus Dobbie
Yorkshire Regional Genetics Service, Leeds, United Kingdom
A 7 year old girl presented with multiple café au lait patches and mild developmental delay. She was the middle of three children of consanguineous Pakistani parents. She was given a diagnosis of Neurofibromatosis Type 1 (Nf1). At age 9yr, she developed seizures and a brain MRI showed a multi focal grade 3 anaplastic astrocytoma. She was seen in the genetics clinic. She had multiple café au lait patches and unusual speckled hyperpigmentation darker than usually seen in Nf1. She had very mild axillary and groin freckling. Her head circumference was on the 97th centile. Her grandmother was affected with bowel cancer. Homozygous pathogenic MSH6 mutations were found in our patient, confirming a diagnosis of mismatch repair cancer (Turcot) syndrome. No mutations were found in the Nf1 gene.
At age 11yr she developed two bowel malignancies. Her mother was also diagnosed with colon cancer.
There are only 6 reports of MSH6 homozygosity in the literature. Sadly the prognosis is poor. Problems include childhood intracranial astrocytomas or lymphomas, and colon cancer from 8yrs but usually in the teens or twenties. The parents and other family members will be MSH6 mutation carriers and require surveillance for bowel and endometrial cancers.
The presence of atypical signs, consanguinity or a family history of bowel cancer means that the diagnosis may not be Nf1 even in a child who meets the diagnostic criteria.

PS12.109
Genetic Testing Of Hereditary Breast And Ovarian Cancer Using Next Generation Sequencing And MLPA.

V. FELIPE, *L. Pérez-Cabornero, D. Valero-Hervás, A. Romera-López, D. Cantalapiedra, G. Hernández, M. Roca, D. Diego-Alvarez, C. Buades, C. Collado-Micó, Á. Arilla-Codoñer, G. Marco, O. Rodríguez, J. Triviño, S. Santillán;*
SISTEMAS GENOMICOS, PATERNA, Spain.

Molecular diagnosis of Hereditary Breast and Ovarian Cancer (HBOC) is essential for the appropriate genetic counseling and to establish preventive screening strategies. *BRCA1* and *BRCA2* screening is offered to patients from high risk families. Several studies have demonstrated the potential of NGS in the field of research and genetic diagnosis.
Therefore, we designed a NGS targeted panel for genes associated with HBOC. Target regions (coding exons, splice sites and 5'-3'UTRs) for *BRCA1* and *BRCA2* were enriched and captured using SureSelect system (Agilent) and sequenced with MiSeq (Illumina). This panel was validated for diagnostic use with two HapMap cell lines and a set of cases with a previously known mutation detected by Sanger sequencing. After validation, samples from 180 patients with clinical suspicion of HBOC were tested in our laboratory. Clinically relevant findings were confirmed by Sanger sequencing. Negative results were tested for large genomic rearrangements using MLPA. A test report was issued in 5 weeks.
We identified 69 variants in 55 patients. All sequence variants could be confirmed by Sanger. Thirty-one were classified as disease-causing (8 novel mutations; 18 in *BRCA1* and 13 in *BRCA2*) and 38 as VUS. Thirty out of 180 patients (16.6%) were genetically diagnosed. The mutation spectrum included SNVs, small deletions/duplications, and large rearrangements.
Our results suggest that the combined NGS + MLPA panel may benefit appropriately selected patients for the molecular diagnosis of HBOC, as it has been proven as a fast, reliable and cost-effective alternative to Sanger sequencing.

PM12.110
Predisposition to breast cancer in NF1 occurs before, but not after, age 50y and is unrelated to NF1 gene mutation type or site

I. M. Frayling[1], *R. van Minkelen*[2], *D. Baralle*[3], *D. M. Eccles*[3], *A. Varan*[4], *S. Aktas*[5], *H. Cox*[1], *S. Ferkal*[6], *P. Wolkenstein*[7], *V. Mautner*[8], *M. Upadhyaya*[1];
[1]*Institute of Medical Genetics, Cardiff, United Kingdom,* [2]*Klinische Genetica, Erasmus MC, Rotterdam, Netherlands,* [3]*Faculty of Medicine, Southampton University, Southampton, United Kingdom,* [4]*Hacettepe Üniversitesi Kanser Enstitüsü, Hacettepe, Turkey,* [5]*Dokuz Eylül Üniversitesi, Izmir, Turkey,* [6]*Service de Santé Publique, Hôpital Henri Mondor, Créteil, France,* [7]*Immunity Transplantation Infections, Hôpital Henri Mondor, Créteil, France,* [8]*Neurofibromatose–Ambulanz–Hamburg, Hamburg, Germany.*

Breast cancer (BC) is reported to occur in women with NF1 at increased incidence, especially those under 50y. We therefore ascertained women with NF1 and BC known to colleagues across Europe: total = 31. NF1 testing had found mutations in 26. Five had also undergone BRCA1/2 testing, revealing one BRCA2 mutation (BC age 46y; excluded).
Mean age of onset of BC was 44.7y (n = 20; range 30-65y; SD 10y). 15 cases occurred <50y, with 5y cohort standardised incidence ratios significantly raised in this group: 45-49y = 4.6(1.2-11.7), 40-44y = 5.8(1.2-17), 35-39y = 19.2(6.2-45), 30-34y = 27.0(5.4-79), but it is not possible to estimate the precise absolute risk from our data.
There was no difference in mutation type: truncating v. missense, compared to the NF1 LOVD (23, 3, 2158, 288; Fishers exact, ns).[www.lovd.nl/NF1] Mutations were distributed from exons 6 - 54, not significantly different from those on the LOVD, and there was also no relationship with either the GRD or ATP-binding domains.(Fisher's exact).

This is the first such study combining clinical and molecular data. We conclude that BC occurs in a subset of women with NF1 at a young age, and while the absolute risk is low, the relative risks appear high. The risk >50y is not increased. This predisposition does not appear to be a function of the underlying NF1 mutation type or site. This needs to be confirmed in other or larger cohorts, or possibly prospective studies, before recommendations might be made regarding surveillance. Genomic analysis may provide additional insights.

PS12.111

Next Generation Sequencing (NGS) analysis of 850 patients with Hereditary Breast and Ovarian Cancer: mutational spectrum in 94 cancer associated genes

A. Benet-Pagès[1], *A. Rump*[2], *R. Janavicius*[3], *C. Rapp*[1], *A. M. Nissen*[1], *A. Laner*[1], *M. Locher*[1], *E. Schröck*[2], *E. Holinski-Feder*[1];
[1]*MGZ - Medizinisch Genetisches Zentrum, Munich, Germany,* [2]*Institut für Klinische Genetik, Medizinische Fakultät Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany,* [3]*Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania.*

Breast and Ovarian Cancer (HBOC) is caused by germline mutations mainly in BRCA1 and BRCA2 (BC:5-7%, OC:11-15%), but mutations in low-penetrance susceptibility genes have been also demonstrated to account for significant cancer risk. Knowing the underlying molecular defects can be very valuable for diagnosis, guiding treatment and estimating recurrence risks. Here we report the results of panel-based NGS screening of 94 genes associated with hereditary cancer predisposition. 850 patients were consecutive tested for BRCA1/BRCA2 and a comprehensive diagnostic HBOC-panel including 38 genes. Patients with negative or inconclusive results were further analyzed for the remaining genes. Target enrichment with the Illumina TruSight Cancer Panel was followed by paired-end sequencing and bioinformatics data analysis. Diagnostic quality criteria ensured a minimal depth of 30X in at least 98% of the analyzed regions with 99.99% sensitivity and specificity in variant calling. For BRCA1/BRCA2 more stringent criteria were required (i.e. 100% coverage at >30X and deletion/duplication analysis). Results show that 8% of the patients have BRCA1/BRCA2 pathogenic mutations (class 4, 5), 7% were inconclusive (class 3) and 85% were negative (class 1, 2). Analysis of the HBOC-panel increased the diagnostic yield to 20%. Pathogenic variants were additionally found in ATM, BLM, BRIP1, BUB1B, CHEK2, FANCA, FANCC, FANCD2, NBN, PALB2, RAD51D, RECQL4 and TP53. 41% presented VUS and 39% were negative. Further screening of the remaining cancer predisposition genes revealed pathogenic variants in genes with no confirmed association with HBOC: BAP1, ERCC2, ERCC3 and MUTYH. Some of the genes were identified as causative only once, emphasizing the advantage of diagnostic panels for HBOC testing.

PM12.112

Multigene panel testing in hereditary breast and ovarian cancer patients

U. E. A. Faust, *C. Schroeder, T. Benkert, F. Harmuth, M. Heilig, S. Hertler, S. Gauß, M. Sturm, K. Grundmann-Hauser, K. Bosse, H. Nguyen, O. Riess, P. Bauer;*
Dept of Medical Genetics and Applied Genomics, Tuebingen, Germany.

Objective: Here, we summarize our experience over the last 2.5 years of HBOC-NGS-panel testing in a cohort of 364 patients that were referred to our institute for genetic testing.
Methods: DNA of all patients was enriched using a custom-design panel (Haloplex, Agilent) and sequenced on a MiSeq (Illumina). A median of 1.45 million reads was generated per sample resulting. Further analysis was limited to a set of 12 core genes. The median overall 20x-coverage was 98.01 %. Genes directly requested by the genetic counselor were complemented by MLPA as well as Sanger sequencing for low coverage regions (< 20x). The custom-design panel was continuously optimized and a reduction of missing bases by a factor of four was possible over time.
Results: Adding 10 more genes in diagnostic HBOC testing revealed the genetic underlying cause in additional 6% of all patients. In total, 19.4 % of our patients carried a mutation within one of the 12 core genes: 7.82 % in BRCA1, 4.85 % in BRCA2, 4.04 % in CHEK2, 1.35 % in ATM, 0.81 % in CDH1 and 0.27 % in NBN.
Conclusion: Taken together, we demonstrate that NGS is a fast and cost efficient genetic screening tool to analyze for variants in genes associated with the development of hereditary breast cancer However, with an increasing number of genes, correct variant interpretation is challenging and requires extensive genetic expertise. Furthermore, clinical guidelines for the new diagnostic BRCA genes still need to be agreed on.

PS12.113

Detection of NRAS and KRAS mutation in AML patients by Pyrosequencing

A. Kongruang, *N. Limsuwannachot, T. Chareonsirisuthigul, B. Rerkamnuaychoke;*
Human Genetics Laboratory, Departments of Pathology, Faculty of Medicine Ramathibodi Hospital,Mahidol University, Bangkok, Thailand.

Introduction: RAS genes play important roles in the regulatory processes of proliferation, differentiation, and apoptosis. RAS mutations result in occurrence of protein that induces uncontrolled cell proliferation and inhibit apoptosis. These mutations have been described in various human malignancies including acute myeloid leukemia (AML).
Materials and Methods: We demonstrated NRAS and KRAS mutation in AML patients by pyrosequencing. Twenty samples from AML patients were evaluated for mutation of these genes around the hot spots in codons 12, 13 and 61. Pyrosequencing was performed for detection of KRAS and NRAS mutation on the Pyromark Q24 system.
Results: Three of twenty patients (15%) had NRAS mutations and one of twenty patients (5%) had KRAS mutations. We found NRAS mutation in all of three codons; one case in codons 12, one case in codons 13 and one case in codons61. Both NRAS mutation in codons 12 and codons 13 were resulting in changes from glycine to asparagine (GGT>GAT) whereas NRAS mutation in codons 61 was resulting in changes from glutamine to histidine (CAA>CAT). Only one case that found KRAS mutation in codons 12 was resulting in changes from glycine to asparagine (GGT>GCT).
Conclusion: In this study, pyrosequencing is a powerful tool for detection of and KRAS mutation. The detection rate of NRAS mutation is higher than KRAS mutation in AML patients. However, a large number of AML cases is needed for further studying the molecular mechanisms in the pathogenesis and for prognostic value of the KRAS and NRAS mutations.

From oral cancer genetic and epigenetic alterations to clinical outcome prediction

I. P. Ribeiro[1,2], *F. Caramelo*[3], *F. Marques*[2,4,5], *A. Domingues*[1], *A. Estevinho*[1], *M. J. Julião*[6], *A. Ferreira*[7], *I. P. Baptista*[2,4], *J. B. Melo*[1,2], *I. M. Carreira*[1,2];
[1]*Cytogenetics and Genomics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [2]*CIMAGO - Center of Investigation on Environment, Genetics and Oncobiology - Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [3]*Laboratory of Biostatistics and Medical Informatics, IBILI - Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [4]*Department of Dentistry, Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [5]*Stomatology Unit, Coimbra Hospital and University Centre, CHUC, EPE, Coimbra, Portugal,* [6]*Department of Pathology, Coimbra Hospital and University Centre, CHUC, EPE, Coimbra, Portugal,* [7]*Maxillofacial Surgery Unit, Coimbra Hospital and University Centre, CHUC, EPE, Coimbra, Portugal.*

Introduction: Oral cancer is a clinical and molecular heterogeneous malignancy characterized by low survival and high mortality rates. The biological behavior of this neoplasm varies and tumors with the same clinic-pathological features often respond differently to the same treatment. Thus, the identification of genetic and epigenetic biomarkers is mandatory to improve diagnosis, prognosis, early detection of tumors and relapses and ultimately to delineate individualized therapy. Methods: Tumor tissues from 73 patients with oral tumors and gingival samples from 16 healthy donors were used as controls. Methylation-Specific Multiplex Ligation-dependent Probe Amplification (MS-MLPA) was conducted to screen copy number alterations and DNA methylation patterns in 54 tumor suppressor genes. Results: From the 54 tumor suppressor genes analyzed those that most frequently exhibited hypermethylation were WT1, MSH6, PAX5 and GATA5. The most frequent copy number alterations were located at chromosomes 3, 9, 11, 12, 16, 17 and 19, highlighting, for example, CTNNB1 and FHIT genes with losses and CDH1, BRCA1, PYCARD, STK11 and CHFR genes with gains. It was possible to find some statistically significant associations among these alterations and the clinic-pathological features of the patients, such as metastases and also smoking habits. Conclusion: The combination of genetic and epigenetic studies together with the pathological diagnosis seems to be mandatory not only to early detect these tumors and relapses but also to predict their clinical behavior. In this way, the increasing knowledge about the genetic and epigenetic mechanisms associated to oral cancer, opens new possibilities at the diagnostic, prognostic and treatment level.

PS12.115

Impact of multi-gene testing in ovarian carcinoma patients selected for personal and/or family history

M. T. Ricci[1], *V. Gismondi*[1], *V. Rea*[1], *P. Bruzzi*[2], *L. Varesco*[1];
[1]*IRCCS AOU San Martino-IST, Unit of Hereditary Cancer, Genoa, Italy,* [2]*IRCCS AOU San Martino-IST, Unit of Clinical Epidemiology, Genoa, Italy.*

Background: 20-25% of Ovarian Carcinomas (OC) are the result of an inhe-

rited predisposition. Besides *BRCA* and MMR genes, several additional contributing genes have been identified. Multi-gene panel testing provides an efficient method for a comprehensive assessment of genes associated with cancer risks. We report our experience of effective multi-gene testing in OC patients selected during genetic counselling (GC) for personal and/or family history.
Methods: The myRisk panel from Myriad Genetics Laboratories (25 clinically significant genes) was run in consecutive patients who met one of the following criteria: diagnosis before age 40, multiple primary tumors and/or at least one first/second degree family member affected by a distinctive cancer of known hereditary cancer syndromes at any age.
Results: Twelve out of 20 OC patients who underwent GC from September 30, 2014 to December 31, 2014, met inclusion criteria: 5 of 12 (42%) carry deleterious mutations (2 in *BRCA1*; 1 each in *BRCA2*, *MSH6*, *PMS2*). Ten variants of unknown significance (VUS) (2 in *NBN*; 1 each in *PMS2*, *BRCA2*, *ATM*, *APC*, *PTEN*, *MLH1*, *P53*, *BRIP1*) were identified in eight subjects (8/12; 67%): of these, three also carried a deleterious mutation and one was a suspected somatic mosaicism. Moreover, two deleterious monoallelic *MUTYH* carriers were detected.
Conclusion: The use of multi-gene panels including *BRCA* and MMR genes allows the "one-step" detection of actionable mutations in a large fraction of OC patients with second primaries and/or family history. The identification of VUS is stimulating from a scientific perspective but should be appropriately managed during GC.

PM12.116
High uptake of risk-reducing bilateral salpingo-oophorectomy in BRCA1 and BRCA2 gene mutation carriers at The Royal Marsden

A. George[1,2], *J. Wiggins*[1], *K. Kohut*[1], *Z. Kemp*[1], *N. Rahman*[1,2], *H. Hanson*[1,2];
[1]Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom, [2]Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom.

Background: Risk-reducing bilateral salpingo-oophorectomy (RRBSO) in BRCA1 or BRCA2 mutation carriers is highly effective in reducing ovarian cancer (OC) risk, by up to 95%. However, reported rates of RRBSO uptake vary widely. We recommend consideration of RRBSO to BRCA1 carriers aged ≥40yrs and BRCA2 carriers aged ≥45years. Here we have assessed RRBSO uptake amongst BRCA1 and BRCA2 carriers at Royal Marsden (RM) hospital.
Methods: We reviewed the electronic patient record for carriers in the RM Genetics unit BRCA carrier register. Our primary endpoint was uptake of RRBSO. Secondary endpoints were rates of occult malignancy at RRBSO and reasons for not undergoing RRBSO.
Results: 858 female mutation carriers were identified, of whom 557 met our age criteria (304 BRCA1, 253 BRCA2). 73 women had been diagnosed with OC, leaving 265 BRCA1 and 219 BRCA2 carriers. Of these, 234(88%) BRCA1 carriers and 192(87%) BRCA2 carriers underwent RRBSO. Occult OC was identified in three BRCA1 carriers; two further BRCA1 carriers had intraepithelial neoplasia. Reported reasons for not undergoing RRBSO were personal choice (36 women), metastatic breast cancer (12 women) and preservation of fertility (six women - all BRCA1 mutation carriers in early 40s). We do not undertake NHS ovarian surveillance because of unproven efficacy but of those who declined RRBSO, six have private ovarian surveillance.
Conclusions: We observed a high rate (87%) of RRBSO uptake amongst BRCA1 and BRCA2 carriers at the Royal Marsden.
This work was funded by the RM/ICR NIHR BRC.

PS12.117
Analysis of PALB2 and other predisposing genes in patients without mutations in the BRCA1 and BRCA2 - benefits for counseling in families with recurrent breast cancer

A. Panczak[1], *M. Janatová*[2], *M. Borecká*[2], *J. Stříbrná*[2], *J. Kotlas*[1], *J. Soukupová*[2], *P. Kleiblová*[2,1], *K. Veselá*[1], *J. Židovská*[1], *J. Přibylová*[3], *Z. Ušiaková*[3], *M. Zimovjanová*[3], *Z. Kleibl*[2], *P. Pohlreich*[2];
[1]Institute of Biology and Medical Genetics, General Faculty Hospital and First Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Biochemistry and Experimental Oncology, First Faculty of Medicine, Charles University, Prague, Czech Republic, [3]Oncology Clinic, General Faculty Hospital and First Faculty of Medicine, Charles University, Prague, Czech Republic.

Mutations in BRCA1 and BRCA2, main predisposing to breast (BC) and ovarian cancer (OC) genes, were found in less than half of the families suspect for hereditary form of BOC; mutation carriers in either gene constitute only about 25% of the population of high risk patients. Other genes were identified (ATM, CHEK2, NBN, PALB2 etc.), whose mutations can increase the risk of BC in BRCA1 and 2 negative patients. These were described as medium-risk genes or genes with moderate penetrance. Mutations in the ATM and NBN genes were recorded with low frequency in Czech population, and therefore they can not be recommended for routine clinical testing. In contrast, the analysis of c.1100delC mutation and large exon 9 and 10 deletions in CHEK2 gene were recommended for practice in the CzR; currently, missense variants of this gene are subject of focused research. PALB2 gene testing in patients with BOC, but with a normal sequence in BRCA1 and 2 showed that point mutations and major reconstruction of PALB2 (16 in total, 3.9%) can cause the disease in Czech patients (n = 409). Most of these mutations were observed in the subgroup of patients with the inherited form of BC - here occurrence reaches 5.5% (13/235). Thus, the significance of PALB2 gene mutation analysis in this particular subpopulation is comparable to that of the BRCA2 gene. We believe that the PALB2 should be included in the algorithm of clinical genetic testing in BC patients negative for mutations in the BRCA1 and 2.

Germline and somatic HIF2A mutations associated with Phaeochromocytoma and Paragangliomas.

G. R. Clark[1], *D. M. Walsh*[2], *H. Mujcic*[1], *A. Luchetti*[1], *G. Kirby*[3], *M. A. Simpson*[4], *R. C. Trembath*[4], *E. R. Woodward*[2], *E. R. Maher*[1];
[1]University of Cambridge, Academic Dept. of Medical Genetics, Cambridge, United Kingdom, [2]Centre for Rare Diseases and Personalised Medicine, University of Birmingham, Birmingham, United Kingdom, [3]3Centre for Rare Diseases and Personalised Medicine, University of Birmingham, Birmingham, United Kingdom, [4]King's College London, London, United Kingdom.

Phaeochromocytomas (PCCs) and paragangliomas (PGLs) are rare autonomic nervous system tumours, which typically hypersecrete catecholamines. A notable feature of PCCs/PGLs is the high incidence of inherited cases, such that germline mutations in at least 12 susceptibility genes can be detected in 30-40% of all cases. Recent gene expression profiling studies have shown that a large proportion of inherited cases show activation of the hypoxic gene response pathways. It has also been shown that loss of function mutations in VHL and SDH subunit genes lead to the stabilisation of the hypoxia-inducible factor (HIF) proteins. These HIF proteins are a family of transcription factors (HIF-1, HIF-2 & HIF-3) that bind to and activate multiple genes associated with angiogenesis, glycolysis and cell growth. The stability of the HIF proteins is dependent on two specific proline residues located in the oxygen dependent degradation domain, that are hydroxylated by the oxygen dependent prolyl hydroxylases (PHDs). Once hydroxylated, the HIF proteins can be targeted for proteasomal degradation by the VHL complex. Recently, several groups have reported gain of function mutations in HIF2A/EPAS1 in PCC/PGL cases, which result in the stabilisation of the HIF-2 protein. To date, the majority of the HIF2A mutations have been detected as somatic mutations, with little evidence of germline mutations. Here we report the finding of six novel variants, four of which were found present in the germline, and cluster around the secondary hydroxylation site. We also present functional data, which provides further evidence that these variants are pathogenic.

PS12.119
Whole genome expression, gene network and pathway determination by microarray analysis in pituitary tumors

T. Demircioglu[1], *K. Koc*[2], *D. Sunnetci Akkoyunlu*[1], *E. Yilmaz*[1], *H. Savli*[1], *N. Cine*[1];
[1]Kocaeli University, Medical Genetics, Kocaeli, Turkey, [2]Kocaeli University,Neurosurgery Department, Kocaeli, Turkey.

Introduction: Pituitary tumorigenesis suggests that genetic alterations that associated with cell cycling, cell proliferation and angiogenesis may play major role in the initiation and promotion of pituitary adenomas.The aim of this study consists in identification of novel genes and/or pathways with potential roles in pituitary tumorigenesis.
Materials and Methods:RNA samples were obtained from a hundred pituitary tumors and three pituitary tissues taken from healthy cadavres.RNA quality, based on the 28S,18S ribosomal RNA ratio, was assessed with an Agilent Bioanalyzer (Agilent Technologies,Palo Alto,CA,USA) and RIN scores arrounds 4 were included.Tumor size and invasiveness were defined on the basis of preoperative magnetic resonance imaging (MRI) and surgical findings.On these basis; 24 microadenoma,30 microadenoma and 46 invasive pituitary adenoma were analyzed.RNA samples were hybridized with microarray chips (Agilent Human 4X44K Oligo Microarrays).Gene expressions, canonical pathways and network analyisis were performed using GeneSpring GX13.0 and Ingenuity Pathway Analysis software.
Results: Microarray analysis identifed 40 downregulated and 58 upregulated genes in invasive adenoma; 40 downregulated and 51 upregulated genes in macroadenomas; 41 downregulated and 42 upregulated genes in microadenomas.The canonical pathways significantly regulated were cel-

lular movement,cellular growth and proliferation,cell cycle,cell death and survival,cancer, nervous system development and function.
Conclusion: Some gene profiles showed good agreement with our data such as IDH1 and CLU.In addition, GATA3, RACGAP1, SSX2IP and PTPRA genes were overexpressed in our invasive and macroadenomas.It's suggested that these genes might be used as a molecular marker set for invasive,proliferation and agreessiveness in pituitary tumors.These candidate genes will be validate with RT-qPCR method in our future study

Frequent coexistence of hyperdiploidy and high-risk cytogenetic changes in plasma cell myeloma in Chinese

L. L. P. SIU, *W. S. Wong, H. F. Wong, K. F. Wong;*
Department of Pathology, Queen Elizabeth Hospital, Kowloon, Hong Kong.

Introduction
We report our experience in the application of fluorescence in-situ hybridization (FISH) to characterize genetic abnormalities in plasma cell myeloma (PCM) among Chinese patients.
Materials and Methods
A total of 100 patients with PCM were studied. Their age ranged from 28 to 87 years (median and mean = 59) with a male to female ratio of 1.45:1. FISH was performed on CD138-sorted bone marrow samples.
Results
High-risk genetic changes were found in 46 patients (Table 1). Some patients had more than one unfavourable factor. 15 patients had concomitant high-risk genetics and hyperdiploidy while 31 patients had high risk genetics without hyperdiploidy. 22 patients had died of their diseases. 59% (13/22) were in the high-risk group with only two having concomitant hyperdiploidy, suggesting that hyperdiploidy might have ameliorating effect. Furthermore, 14 patients were relatively young in age (60 years or below) with five having high-risk genetics but without hyperdiploidy.
Conclusions
Our results suggested a beneficial effect of concomitant hyperdiploidy in plasma cell myeloma with high-risk genetics. This will help identify patients for targeted personalized therapy.
Table 1. Incidence of high risk genetics and hyperdiploidy.

	del(1)p	1q gain	t(4;14)	t(14;16)	del(17)p	hyperdiploidy	Combined high risk genetics and hyperdiploidy
% cases	7.8	40.6	16.0	5.1	12.1	32.3	16.1

Assessment of JAK2V617F Mutation in CD133/ CD34 Cell Compartments

I. Uslu[1], *G. Atag*[1], *B. Yilmaz*[1], *H. Hekimoglu*[1], *A. S. Yavuz*[2], *S. Sozer Tokdemir*[1];
[1]*Research Institute of Experimental Medicine (DETAE), Department of Genetics, Istanbul University, Istanbul, Turkey,* [2]*Istanbul Faculty of Medicine, Internal Medicine Division, Department of Hematology, Istanbul University, Istanbul, Turkey.*

Introduction; BCR-ABL negative Myeloproliferative Neoplasms (MPNs) are clonal stem cell disorders which are the results of genetically transformed stem cells and risks of increased *leukemic* transformation. MPN includes polycythemia vera (PV), essential thrombocythosis, primary myelofibrosis. JAK2V617F mutation occurs in MPN patients with a high range between %50-98. The aim of study is to analyse and compare mononuclear and specific stem cell compartment of PV patients having JAK2V617F mutation.
Materials and Methods; The mononuclear cells were isolated by ficoll–gradient method in three PV patients' peripheral blood samples taken by phlebotomy. Those cells were stained by a group of cell surface marker and selected in cell sorter. Initially $CD45^-$ cells were gated and then $CD133^+CD34^-$, $CD133^-CD34^+$, $CD133^+CD34^+$, $CD133^-CD34^-$ stem cell compartments sorted by cell sorter.
In order to investigate JAK2V617F mutation in mononuclear cells and $CD133^+CD34^-$, $CD133^-CD34^+$, $CD133^+CD34^+$, $CD133^-CD34^-$ stem cell compartments, allel specific Nested PCR was performed.
Results; JAK2V617F mutation analysis were compared between mononuclear cells and different stem cell compartments. According to this comparison there has been no difference for JAK2 mutation screening between mononuclear cells and different stem cell compartments.
Conclusions; We aimed to investigate the presence of the JAK2V617F mutation in both stem cells compartments and mononuclear cells of PV patients in this study.
As a result of the detailed research in terms of JAK2 mutation is revealed that there has been no differences between stem cells compartments and mononuclear cells of PV patients.
This research performed limitied number of patient the increased number of patient would enhance our knowledge.

PM12.122

Therapy response monitoring in patient with prostate cancer using plasma-Seq approach

J. Belic;
Institute of Human Genetics, Graz, Austria.

Background: Prostate cancer is the most common malignancy in males. Prostate cancer progression can be inhibited by androgen-deprivation therapy but nearly all patients progress to castration-resistance prostate cancer (CRPC). There still remains the unsolved question how patients can be best matched with targeted therapies according to characteristics of their tumor genome.
Methods: We analyzed a total of 73 plasma samples from 20 CRPC and 9 CSPC (castration-sensitive prostate cancer) patients using our previously established plasma-Seq approach including low coverage whole-genome sequencing to establish copy number profiles and targeted resequencing of prostate cancer associated genes on an Illumina MiSeq platform.
Results: Analysis of plasma DNA from prostate cancer patients revealed a variety of copy number changes characteristic for prostate cancer. In a subset of patients we were able to observe the emergence of AR gene amplification at the time of progression from CSPC to CRPC. AR gene amplifications were found in approximately 70% of CRPC patients. Furthermore, we were able to monitor the evolution of novel focal amplifications and clonal shifts due to therapy changes in one third of the patients. Moreover, plasma DNA analyses reflected the treatment response to second line treatment, i.e. cytotoxic chemotherapy.
Conclusions: Our study showed that analyzing plasma DNA offers a non-invasive method to monitor patients' therapy response and may identify the occurrence of novel changes associated with resistance against a given therapy. Plasma DNA analyses may evolve to a novel tool for monitoring of patients with cancer and for development of personalized medicine.

Testicular lipomatosis as a presentation of PTEN Hamartomatous Tumour Syndrome - A case report

J. Whitworth, *K. Ong, Y. Wallis;*
Birmingham Women's Hospital, Birmingham, United Kingdom.

PTEN hamartoma tumour syndrome (PHTS) is associated with a variety of clinical manifestations including macrocephaly, characteristic skin lesions and other benign or malignant tumours in various tissues such as the thyroid gland, breast, endometrium, bowel and fat. Testicular lipomatosis has been reported in a series of individuals with PTEN mutations but it is not known what proportion of patients presenting with this condition have PTEN mutations. Here we present a case of unilateral testicular lipomatosis in a 23 year old male, referred to clinical genetics services due to the fact that macrocephaly was noted in conjunction. He had previously had two lipomas removed from the neck area at age 5 and examination revealed a lesion consistent with a lipoma on his right foot. No other features of PHTS were noted on examination or in the family history. Germline genetic analysis revealed a heterozygous G to C base substitution within the invariant splice acceptor site for exon 8 that is considered to be pathogenic. We suggest that testicular lipomatosis in conjunction with a characteristic feature of PHTS should prompt consideration of PTEN analysis.

PM12.124

The first consensus based guideline on PTEN Hamartoma Tumor Syndrome (PHTS) in the Netherlands

C. M. Kets[1], *S. W. ten Broeke*[2], *P. Bult*[1], *B. A. H. Caanen*[3], *N. Hoogerbrugge*[1], *J. A. de Hullu*[1], *T. P. Links*[4], *A. van der Mei*[5], *J. van der Meijden*[6], *S. Pouwels*[6], *J. H. Schieving*[1], *H. F. A. Vasen*[2], *M. J. Velthuis*[7], *H. M. Zonderland*[8];
[1]*Radboud University Medical Centre, Nijmegen, Netherlands,* [2]*Leiden University Medical Centre, Leiden, Netherlands,* [3]*Maastricht University Medical Centre +, Maastricht, Netherlands,* [4]*University Medical Centre Groningen, Groningen, Netherlands,* [5]*Netherlands Comprehensive Cancer Organisation, Groningen, Netherlands,* [6]*not applicable, not applicable, Netherlands,* [7]*Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands,* [8]*Academic Medical Centre, Amsterdam, Netherlands.*

Here, we present the new Dutch consensus-based guideline on PTEN Hamartoma Tumor Syndrome (PHTS). The guideline is designed to improve early diagnosis, surveillance and care of patients with PHTS.
Development of the guideline has been a collaborative effort of a multidis-

ciplinary group of health care professionals and patient representatives. Several questions on detection, surveillance and care were defined and answered by pubmed literature searches.
The guideline describes clinical criteria for PHTS diagnosis and criteria for referral for genetic counselling and/or DNA analysis of the PTEN-gene.
The following advices for surveillance are given: follow up of development is recommended from diagnosis until 18 years, including control of the thyroid. Adult male and female patients are advised to have surveillance of the thyroid above the age of 18 and of the colon above the age of 40. For female patients, surveillance of the breasts is recommended from age 25 and endometrial screening from age 30.
It is recommended to inform the patients about the benign features of PHTS and the increased risk of cancer, for which information on the exact risks is not reliable. This is because the risks in the cohort studies are probably an overestimation due to bias. Patient information can also be given on paper, websites or social media.
Surveillance is preferred in a specialized university medical centre. To support the surveillance a roadmap has been developed.
This guideline on PHTS describes recommendations on detection, surveillance, and care of patients with PHTS and aims to improve quality of care.

PS12.125
RAD51 paralogs in breast and ovarian cancer predisposition

L. Golmard[1,2], *L. Castéra*[3,4], *S. Krieger*[3,4,5], *A. Laugé*[1], *K. Abidallah*[1], *H. Tenreiro*[1], *V. Moncoutier*[1], *D. Bidon*[1], *P. Morice*[1], *J. Tarabeux*[1,2], *M. Stern*[1,2], *D. Stoppa-Lyonnet*[1,2,6], *D. Vaur*[3,4], *C. Houdayer*[1,2,6];
[1]*Département de Biopathologie, Institut Curie, Paris, France,* [2]*Inserm U830, Paris, France,* [3]*Laboratoire de Biologie et Génétique du cancer, Centre François Baclesse, Caen, France,* [4]*Inserm U1079, Rouen, France,* [5]*Université de Caen, Basse Normandie, Caen, France,* [6]*Université Paris Descartes, Sorbonne Paris Cité, Paris, France.*

RAD51 paralogs (*RAD51B*, *RAD51C*, *RAD51D*, *XRCC2*, *XRCC3*) have recently been implicated in breast and ovarian cancer predisposition: *RAD51C* and *RAD51D* in ovarian cancer, *RAD51B* and *XRCC2* in breast cancer through monoallelic germline deleterious mutations. Previous studies were mostly conducted on family cases selected for high predisposition risk. In addition, *XRCC3* polymorphisms have been associated with breast cancer in case-control studies but no deleterious mutation has been reported.
To better estimate the contribution of *RAD51* paralogs in breast and ovarian cancer predisposition, these genes were analysed in 2,991 consecutive unrelated patients diagnosed with breast and/or ovarian cancer and previously tested negative for *BRCA1/2* mutations. Deleterious truncating mutations were detected in the five *RAD51* paralogs: *RAD51B* (n=4), *RAD51C* (n=14), *RAD51D* (n=7), *XRCC2* (n=2), and *XRCC3* (n=5). The mutation rate was 1.1% (32/2,991 patients). Likely deleterious missense variants were also detected in the five *RAD51* paralogs at a lower rate: 0.5% (15/2,991 patients).
This is the first study of the five *RAD51* paralogs conducted on a large series of consecutive unrelated patients, allowing a better evaluation of mutation rate (overall rate: [1.1-1.6%]); not surprisingly, *RAD51* paralog mutation rate is lower in this series of unselected patients than previous estimates in patients at high predisposition risk. This is also the first report of *XRCC3* truncating mutations in breast and ovarian cancer predisposition. To assess more accurately the *RAD51* paralog mutation rate, functional assays for interpretation of missense variants are ongoing. This study constitutes a sound basis for penetrance risk estimates through the genetic testing of relatives of mutation carriers.

PM12.126
Breast cancer molecular classification based on DNA methylation assessed by reduced representation bisulfite sequencing

A. S. Tanas[1], *E. V. Poddubskaya*[2], *T. V. Kekeeva*[1], *I. D. Trotsenko*[3], *E. B. Kuznetsova*[1], *D. V. Zaletayev*[1], *V. V. Strelnikov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*N.N. Blokhin Russian Research Center for Oncology, Moscow, Russian Federation,* [3]*Peoples' Friendship University of Russia, Moscow, Russian Federation.*

We have developed a modification of the RRBS method applicable to assess methylation in large collections of DNA samples within biomedical research. Briefly, our modification further reduces the size of the representation to be sequenced simultaneously increasing the inner fraction of CpG islands and shores. By use of this approach we have obtained RRBS data for 80 breast cancer (BC) samples, 6 BC cell lines and 10 samples of normal breast tissue. To date, this is the most comprehensive collection of RRBS data for a set of tumors of the same organ. Cluster analysis of this data distinguishes at least five molecular subtypes of breast tissues (cells) based on the CpG methylation. Specific subtypes are assigned to normal breast tissues, BC cell lines, triple negative and HER positive (indistinguishable based on the present dataset), and two independent groups of luminal BC regardless of their HER status. The most pronounced differences of the DNA methylation patterns are observed between normal breast tissues and BC cell lines, the latter presenting the highest CpG methylation levels within the samples, notwithstanding different immunoprofiles (LumA, LumB and triple negative).
One of the most striking findings is separation of the luminal tumors into two clusters differing by the density of CpG methylation, independently on HER status (LumA or LumB). This separation may reflect differences in the tumor biology between groups and requires further research in terms of utility for prognostication and treatment that may arise from the DNA methylation markers.
The research was supported by RFBR grant 14-04-01606 A.

Resveratrol promotes apoptosis, autophagy and suppressed cell division via upregulated autophagy-related gene, caspase 3 and Cyclin dependent kinase inhibitor in human K562 cells.

Z. Mutlu[1], *C. Caliskan*[1], *B. Goker*[1], *O. Ozalp*[1], *G. Saydam*[2], *C. Gunduz*[1], *C. Biray Avci*[1];
[1]*Ege University Medicine Faculty Department of Medical Biology, Izmir, Turkey,* [2]*Ege University Medicine Faculty Department of Hematology, Izmir, Turkey.*

Chronic myeloid leukemia (CML) is a malignant disorder of the haematopoietic stem cell arisen from the reciprocal translocation between the breakpoint cluster region (BCR) gene on chromosome 22, and the Abelson (ABL) murine leukemia virus gene on chromosome 9, t(9;22)(q34;q11), resulting in the formation of Philadelphia chromosome.
Resveratrol is a natural phytoalexin and induces apoptosis, erythroid differentiation and autophagy in leukemic cells.
In this study we aimed to evaluate the cytotoxic, apoptotic and autophagic effect of resveratrol in CML cells by questioning gene expressions which are associated with CML progression.
K562 cells were treated with resveratrol time and dose dependent manner and cytotoxicity was evaluated by using WST-1 assay. The RT-qPCR is used for gene expression analysis. Gene expression levels were evaluated by using RT2 Profiler PCR Array.
Significant increase was observed in K562 cells treated with resveratrol according to control. The gene expression levels of ATG5 (autophagy-related gene), CASP3 (caspase 3) and p27KIP1(Cyclin dependent kinase inhibitor) were increased respectively 10.41, 8.63 and 36 fold via resveratrol.
Our findings showed that Resveratrol induced apoptosis and autophagy in K562 cells. Resveratrol upregulated caspase-3 activation in apoptosis and modulation of Atgs in autophagic pathway in K562 cells. Also, resveratrol regulates autophagosome formation via upregulated-ATG5 expression. Cdk inhibitor p27KIP1 is a tumor suppressor gene and includes in cell cycle process. Thus upregulated p27KIP1 expression in K562 cells induced prevented progression from G1 to S-phase and suppressed cell division. Therefore, Resveratrol prevented the formation of tumors in K562 cells. These results provide that Resveratrol may be a therapeutic candidate for chronic myeloid leukemia treatment.

PM12.128
Identification of novel mutations in RB1 gene in retinoblastoma patients

L. Abu Safieh, *S. Al Mesfer, M. Othman, M. Karoui, H. Al Katan, D. Edward;*
King Khaled Eye Specialist hospital, riyadh, Saudi Arabia.

Purpose: Retinoblastoma initiated by biallelic loss of RB1 can be successfully treated. However, multimodal treatment failures results in enucleation. We hypothesized that mutations may contribute to treatment failure.
Methods: We studied 2 retinoblastoma cases with multimodal treatment failure. Clinical findings, pathologic features following enucleation and treatment were documented. DNA extracted from patient tumor, adjacent normal and blood was subjected to direct sequencing for mutation detection in RB1 gene. Sequences were analysed using DNAstar software. Effect of variants was predicted using Polyphen-2 and mutation taster software.**Results:** Patient 1, 17 month male presented with unilateral sporadic group D. After 6 cycles of chemo and radiotherapy, patient developed recurrent active tumor. Pathology showed vitreous seeding, viable intraocular tumor without high risk features. Patient 2, 13 month male with sporadic bilateral group D retinoblastoma, right eye (enucleated). Left eye received 9 cycles of chemo and radiotherapy but progressed to stage E, also enucleated. Pathology showed viable intraocular tumor, focal choroidal invasion and optic nerve invasion with negative surgical margin. We are reporting two novel mutations in the RB1 gene. Patient 1, had insertion of two base pairs that resulted in frameshift and protein truncation (p: E97Rfs*15). Patient 2 showed a stop mutation

early in the protein sequence (p: Q35*).
Conclusion: These novel germline truncating mutations in patients with advanced retinoblastoma resulted in poor ocular survival despite extensive treatment. Truncating mutations represent over 50% of all *RB1*mutations. It is possible this type of mutations responsible for tumor resistance. Screening additional patients with similar clinical history is required to confirm this data.

PS12.129
From guideline recommendations to familial cancer risk assessment decision support in primary care: US Experience

L. A. Orlando[1], *R. Wu*[1], *C. McCarty*[2], *D. Dimmock*[3], *G. S. Ginsburg*[1];
[1]*Duke University, Durham, NC, United States,* [2]*Essential Rural Healthcare Institute, Duluth, MN, United States,* [3]*Medical College of Wisconsin, Milwaukee, WI, United States.*

Introduction: There are several U.S. guidelines for identifying and managing risk for hereditary cancer syndromes. While fundamentally similar, they each differ in details that can lead to differences in assignment of risk levels (Orlando, AJMG, 2014). In order to better understand how these differences in guidelines affect individuals, we describe preliminary results from a nationally representative population of individuals.
Materials and Methods: Eligible participants are patients visiting enrolled primary care clinics at: Duke University, Medical College of Wisconsin, Essential Rural Healthcare Institute, David Grant Medical Center, or University of North Texas. Enrolled participants enter their personal and family health history information into MeTree, a patient facing risk assessment and clinical decision support web-service.
Results: To date 222 participants have completed MeTree. Characteristics include 62% female; 89% white, and mean age 59.6 (range 24-84). The mean no. of relatives entered is 13.3 (range 6-62). In an initial assessment of one guideline 1.8% (n=4) had > 20% lifetime risk of breast cancer and 33.3% (n=148) met criteria for a possible hereditary cancer syndrome. Assessment of risk level using three additional hereditary cancer syndrome guidelines will be performed on the enrolled population as of May 30th, 2015 and data presented showing discrepancies in those identified as at risk by each guideline.
Conclusion: Hereditary cancer risk assessment guidelines are developed based on expert opinion and experience, which has the potential to lead to variations in recommendations by different agencies. Establishing a database of family health histories linked to outcomes can inform guideline development and lead to greater consistency and accuracy in risk assessment algorithms

PM12.130
An assessment of known skin cancer risk variants in a population of renal transplant patients

C. P. Stapleton[1], *M. McCormack*[1], *D. Connaughton*[2], *G. L. Cavalleri*[1], *P. J. Conlon*[1];
[1]*Royal College of Surgeons Ireland, Dublin, Ireland,* [2]*Beaumont Hospital, Dublin, Ireland.*

The risk of a kidney transplant recipient developing skin cancer is approximately 33 times higher than the general public. Multiple robust genetic loci for skin cancer have been identified via large genome-wide association (GWA) studies. We wished to test the hypothesis that these loci are risk factors for skin cancer in post-transplant populations. We were also interested in determining if the odds ratio changed in the transplant population, compared to the general population in which they were discovered. We identified 21 robustly associated SNPs from the GWA studies and tested these SNPs in a cohort of 325 cadaveric kidney transplant recipient patients. The cohort was cross referenced with the Irish cancer registry resulting in the identification of 94 cases that developed skin cancer post-transplantation and 231 controls. Illumina 660K bead-chip data was available for all 325 individuals. Logistic regression and survival analysis was applied to test for correlation with skin cancer.
A nominally significant association was found with rs885479, a SNP found in the *MC1R* gene (p= 0.0157) in the survival analysis. The variant was found to have the same direction of affect as described in the original study and the odds ratio was higher. The presence of one or more copies of the minor allele caused a significant decrease in time to develop skin cancer post renal transplant (hazard ratio = 2.06). However, none of the variants survived Bonferroni correction for multiple testing. We are now seeking to extend this analysis to additional patient cohorts.
This work is funded by the Irish Research Council for Science, Engineering and Technology.

PS12.131
Development and validation of the Oncomine Cancer Research Panel (OCP), a scalable next-generation sequencing system for assessing recurrent somatic alterations in solid tumors

K. Rhodes[1], *S. Tomlins*[2], *A. Cani*[2], *D. Hovelson*[2], *A. McDaniel*[2], *A. Liu*[2], *G. Bien*[1], *P. Choppa*[1], *J. Schageman*[1], *G. Liu*[1], *F. Hyland*[1], *R. Gottimukkala*[1], *S. Bandla*[1], *P. Williams*[1], *B. Johnson*[1], *P. Wyngaard*[1], *S. Sadis*[1], *D. Rhodes*[1];
[1]*Thermo Fisher Scientific, Carlsbad, CA, United States,* [2]*University of Michigan, Ann Arbor, MI, United States.*

Treating cancer effectively requires an understanding of the molecular alterations driving each patient's tumor. Targeted sequencing efforts that characterize prevalent somatic alterations and require limited sample input may provide an effective diagnostic approach. Herein, we describe the design and characterization of the Oncomine Cancer Research Panel (OCP) that includes recurrent somatic alterations in solid tumors derived from the Oncomine™ cancer database. Using Ion AmpliSeq™, we designed a DNA panel that includes assays for 73 oncogenes with 1,826 recurrent hotspot mutations, 26 tumor suppressor genes enriched for deleterious mutations, as well as 75 genes subject to recurrent focal copy gain or loss. A complementary RNA panel includes 183 assays for relevant gene fusions involving 22 fusion driver genes. Recommended sample inputs were 10 ng of nucleic acid per pool. Sequencing libraries were analyzed on an Ion Torrent Personal Genome Machine. Initial testing revealed an average read depth of > 1,500X with > 95% uniformity and on target frequency. The panel was shown to reliably detect known hotspots, insertions/deletions, gene copy changes, and gene fusions in molecular standards, cell lines and formalin-fixed paraffin embedded clinical specimens. Retrospective analysis of large clinical cohorts has been completed and the results of analysis of 100 lung cancer and 100 prostate cancer cases will be summarized. In addition, a prospective cohort of 100 clinical samples from the University of Michigan Molecular Diagnostics laboratory was profiled with OCP. Overall, we achieved >95% sensitivity and specificity for detection of KRAS, EGFR and BRAF mutations and ALK gene fusions.

PS12.135
Association between GWAS-derived rs966423 genetic variant and overall mortality in patients with differentiated thyroid cancer

M. Swierniak[1], *A. Wojcicka*[1,2], *M. Czetwertynska*[3], *J. Dlugosinska*[3], *E. Stachlewska*[3], *W. Gierlikowski*[1], *B. Gornicka*[1], *L. Koperski*[1], *M. Bogdanska*[1], *W. Wiechno*[1], **K. Jazdzewski**[1,2];
[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*University of Warsaw, Warsaw, Poland,* [3]*Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland.*

Background: Five germline genetic variants (rs116909374, rs965513, rs944289, rs966423, rs2439302) have been associated in genome-wide association study (GWAS) with increased risk of thyroid cancer, but their role in mortality of patients with thyroid cancer has not been established.
Study design: Retrospective study of 1836 patients with differentiated thyroid cancer (1643 women and 193 men) with a median age at diagnosis of 49 years (interquartile range, 38-57years) and an overall median follow-up time of 8.7 years (interquartile range, 5-12.5years) after initial treatment at a single comprehensive cancer center between 1990-2013.
Results: Among 5 variants, rs966423 was associated with increased mortality, which was 6.4% (33/518) vs. 3.7% (47/1259) in TT-carriers vs. CC/CT carriers (P=0.017). Deaths per 1000 person-years were 6.81 vs. 4.01 in TT vs. CC/CT patients (HR=1.6; P=0.038) after adjustment for age at diagnosis, and sex. Importantly, the association of rs966423 with mortality remained significant when lymph-node metastasis, extrathyroidal invasion, angioinvasion and distant metastasis were included in the model (HR=1.89; P=0.014). A higher rs966423-associated patient mortality was also observed in several clinicopathological subcategories, e.g. in TT patients with angioinvasion (HR=3.48; P<0.001).
Conclusions: rs966423-TT genotype was significantly associated with increased overall mortality among patients with thyroid cancers. Contrary to *BRAF* mutation and other somatic changes putatively associated with patients mortality, the status of germline rs966423 is known before the treatment, and might be used in management of mortality risk by means of modification of therapy, nevertheless it requires further investigation in large prospective studies before it is ready for clinical application.
Support: Polish National Science Centre (DEC-2013/11/B/NZ3/00193); European Commission (FP7-REGPOT-2012-CT2012-316254-BASTION).

PM12.136
An investigation of mitochondrial DNA haplogroups in patients with thyroid cancer

R. Cocos[1,2], *S. Schipor*[3], *C. Badiu*[4,3], *F. Raicu*[1,5];

[1]Chair of Medical Genetics, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [2]Genome Life Research Centre, Bucharest, Romania, [3]National Institute of Endocrinology "C. I. Parhon", Bucharest, Romania, [4]Chair of Endocrinology "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania, [5]Francisc I. Rainer Anthropological Research Institute, Romanian Academy, Bucharest, Romania.

Introduction: Recent studies have shown that mitochondrial DNA (mtDNA) haplogroups could be associated with cancer development. The present study aimed to analyze mtDNA control region variation of 114 patients with thyroid follicular adenoma (TFA), 121 patients with papillary thyroid cancer (PTC) and 212 healthy controls in order to investigate whether mtDNA haplogroups contribute to the onset of cancer.
Materials and Methods: The two hypervariable segments HVSI and HVSII of the control region were sequenced on ABI3130xl platform for all samples. The unambiguously classified samples were assessed by means of PCR-RFLP using a hierarchical system. We performed statistical analysis including Pearson's chi-square test, Fisher's exact test and binary logistic adjusted by age and gender.
Results: The haplogroup K appeared underrepresented in TFA and PTC patients when compared to healthy controls (p = 0.010; OR = 0.115; 95% CI = 0.015 – 0.883 and p = 0.010; OR = 0.109; 95% CI = 0.014 – 0.839, respectively). The haplogroup HV was associated significantly with increased TFA risk (p = 0.032 OR = 2.697; 95% CI = 1.052 – 6.910).
Conclusions: We found that HV haplogroup may be associated with increased risk of developing TFA, and K haplogroup can have a protective effect for TFA and PTC.
The study was supported by CNCS-UEFISCDI grants PN-II-ID-PCCE 2011-2-0013 and PN-II-PT-PCCA-2011-3.2-1337.

PS12.137
A polymorphism in miR-146a tailors genetic predisposition to differentiated thyroid cancer, modulates its clinical outcome and alters proliferation of tumor cells.

A. Wojcicka[1,2], *A. Kubiak[1], M. Kotlarek[1,2], A. Czajka[1], M. Czetwertynska[3], J. Dlugosinska[3], M. Swierniak[1], N. Fedoryszak-Kuska[1], B. Gornicka[1], K. Jazdzewski[1,2];*
[1]Medical University of Warsaw, Warsaw, Poland, [2]Centre of New Technologies, University of Warsaw, Warsaw, Poland, [3]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland.

Introduction: Rs2910164 in mir-146a was among the first polymorphisms described in a microRNA gene. The G-C substitution leads to reduction of the amount of miR-146a and to regulation of different set of target genes. The polymorphism was further shown to predispose to papillary thyroid carcinoma (OR=1.62). However, no study analyzed the influence of the SNP on the clinical outcome of thyroid cancer patients.
Materials and Methods: The rs2910164 was genotyped using the Sequenom technology in blood-derived DNA from 2872 patients treated for differentiated thyroid cancer (overall median follow-up time 8.7 years). Genotyping in thyroid tissue samples was performed using the Taqman assay. The influence of miR-146a on the thyroid cancer cell lines was analyzed in K1 cells with induced overexpression or silencing of pre-miR-146a.
Results: The germinal C allele in rs2910164 was associated with higher mortality among patients with follicular variant of papillary thyroid carcinoma. Deaths per 1000 person-years were 25.64 vs. 4.72 in CC vs. GG/CG patients (HR=5.88; *P*=0.008). Moreover, a somatic G-C mutation in mir-146a was observed in 6.5% of the analyzed tumor samples. *In vitro* studies showed that miR-146a significantly increased proliferation of thyroid cancer-derived cell line and the presence of the variant C allele resulted in lower proliferation rates, possibly switching the cells towards migration.
Conclusions: Rs2910164 in miR-146a predisposes to thyroid carcinoma, causes higher mortality of thyroid cancer patients and undergoes somatic mutations in tumor. G-C transition might be responsible for increased metastatic potential and aggressiveness of cancer.
Support: Polish National Science Centre (DEC-2013/11/B/NZ3/00193); European Commission (FP7-REGPOT-2012-CT2012-316254-BASTION).

PM12.138
The TSH-beta gene confers a risk for differentiated thyroid cancer in the Saudi population

M. Al-Rasheed[1], *A. Alzahrani[2], A. Macadam[3], A. Overall[3], P. Gard[3], N. Dzimiri[2];*
[1]King Saud University, Riyadh, Saudi Arabia, [2]King Faisal Spec. Hospital and Research Centre, Riyadh, Saudi Arabia, [3]Brighton University, Brighton, United Kingdom.

Background: The thyroid stimulating hormone (TSH-beta) is a heterodimeric glycoprotein which regulates the secretion of the thyroid hormone and therefore thyroid function. In the present study, we evaluated the role of the TSH-beta polymorphisms as risk factors for development of differentiated thyroid cancer (DTC).
Methods: We first sequenced the TSH-beta gene, performed a preliminary association study involving 96 cases versus 96 controls, and then selected four variants for the association studies in a larger population size using Taqman assays.
Results: In the preliminary association study, three of the discovered SNPs, rs72695872_C>T [Odds ratio (95% Confidence Interval)=1.78(1.07-2.97); p=0.029] and rs1321108_A>G [2.15(1.28-3.62); p=0.004] in the promoter region as well as the intronic rs17477369_T>A [2.50(1.03-6.06); p=0.048] were associated with DTC in a causative fashion. These results were confirmed in a larger study involving 507 cases versus 597 controls, at similar or higher significance levels. Also, 4-mer haplotype AGGT (x2=7.36; p=0.0067) and its 3-mer flanking derivatives GGT (x2=11.71; p=0.0054) and AGG (x2=7.45; p=0.0063) conferred significant risk for acquiring thyroid cancer. Another 4-mer haplotype, GAGT (x2=11.21, p=0.0008) and its 3-mer derivative AGT (x2=11.71; p=0.0006) displayed equipotently protective properties against the disease, pointing to changes in the rs1321109_G>A, rs10776792_A>G and rs1321108_A>G as the probable determinants of these observations.
Conclusion: Our results indicate that the TSHβ constitutes a potential risk for DTC in the Saudi population.

PS12.139
Identification of novel germline mutations in the TP53 gene in Swedish families

P. Kharaziha[1], *E. Tham[2], S. Bajalica Lagercrantz[1];*
[1]Department of Oncology-Pathology, Cancer Center Karolinska (CCK), Karolinska Institutet, and Clinical Oncology, Karolinska University Hospital-Solna, Stockholm, Sweden, [2]Department of Molecular Medicine and Surgery, Karolinska Institutet, and Clinical Genetics, Karolinska University Hospital-Solna, Stockholm, Sweden.

Introduction: A constitutionally inherited mutation in the *TP53* gene increases the risk of cancer. It causes an autosomal dominant inherited cancer syndrome named Li-Fraumeni syndrome (LFS). LFS is associated with a risk of a wide range of tumors, however, mainly including breast cancer, brain tumors, adrenocortical carcinomas, as well as osteo- and soft tissue sarcomas. In some families pediatric tumors are more frequent, while in others only breast cancer in adult is seen. The underlying cause for this variation remains unknown.
Results: In an attempt to understand the cancer for this genotype-phenotype correlation and to design adequate surveillance program for these families, we formed The Swedish Clinical *TP53* Study Group. The Swedish constitutional *TP53* cohort consists up to date of 32 families: Two-third of the families were diagnosed as either LFS or LFS-like and the remaining families with exclusively hereditary breast cancer. We found five novel germline mutations i.e. previously not reported. Four of these were frameshift mutations that disrupted the major transcript of *TP53* and were thus definitely pathogenic. The fifth mutation was an in-frame deletion of one amino acid that was also judged to be pathogenic.
Conclusion: No obvious difference in the *TP53* mutation spectra was seen by 3D viewer, provided by IARC TP53 database, in patients with hereditary breast cancer compared to those with LFS. Therefore, we currently analyze the novel mutations by CRISPR technology.

PM12.140
Pilot study with TruSight Cancer genes panel in high risk patients at MMCI - Czech Republic

E. Machackova, *J. Hazova, P. Vasickova, E. Stahlova Hrabincova, M. Navratilova, M. Svoboda, L. Foretova;*
Masaryk Memorial Cancer Institute, Brno, Czech Republic.

Currently, more than 200 hereditary cancer syndromes has been described, but in most countries testing is very restricted with respect to the number of genes and the number of people tested.
As a retrospective research study the TruSight cancer panel (Illumina) - NGS panel targeting 97 cancer predisposition genes was used to analyze 50 high risk cancer patients with significant personal and family history of cancer without previously identified mutation in BRCA1, BRCA2, TP53, MLH1, MSH2, MSH6, APC or CDKN2A genes. All pathogenic mutations detected by NGS technology have been confirmed by Sanger sequencing.
Several deleterious (frameshift, nonsense) mutations were detected in ATM, ERCC2, BAP1, FANCI, PMS2, RECQL4 genes. Several very likely pathogenic missense mutations were detected in the ATM, FANCA, PALB2, BRIP1, MUTYH, PMS2, MEN1 and SDHB. These mutations affect highly conserved domains and were confirmed to affect protein function by available functional assays, or were confirmed to be pathogenic as a Parent #2 allele in a serious recessive disease as Ataxia telangiectasia or Fanconi anemia. Majority of missense variants detected in other genes remain to be classified by the

clinical relevancy in the future. Intermediate or low penetrance variants are of limited clinical utility.
The value of panel genetic testing in high risk individuals with cancer provides important information with respect to the cause and optimal treatment of the current cancer, and the risk and optimal management of future cancer.
Supported by MH CZ - DRO (MMCI, 00209805) and research project of MSMT CR CZ.1.07/2.3.00/20.0045 (SuPReMMe)

PS12.141
Evaluation of anti-tumor effect of combined use of thymoquinone with mitoxantrone in YKG1 glioma cells

M. OZNUR, *O. Hatipoglu, M. Acar, B. Yılmaz, E. Karagoz, E. Gunduz, M. Gunduz;*
Turgut Ozal University, Faculty of Medicine, Department of Medical Genetics,, ANKARA, Turkey.

Introduction: Since thymoquinone is isolated from Nigella sativa, its antioxidant, anti-inflammatory and anti-cancer effects have been investigated. Thymoquinone causes decrease in cell viability in tumor cells and causes DNA damage and leads to apoptosis in tumor. Especially it has been found that it does not damage healthy cells and this makes it more important as therapeutic substance . In this study, we have proposed to reveal the role of thymoquinone on brain tumor cells by compairing with mitoxantrone and aimed to find more effective and less toxic treatment method.
Materials and Methods: YKG1 cell line has been thawed and proliferated. Main stock of thymoquinone was prepared in DMSO solution. Various concentrations of thymoquinone (T1:40 uM, T2:80 uM and T3:160uM) were prepared from main stock by diluting in DMEM solution. The cells were exposed to thymoquinone with these doses. Additionally the cells were exposed to 4 different doses of mitoxantrone (M4:0.5ug/ml, M3:0.05ug/ml, M2:0.005ug/ml and M1:0.0005ug/ml). Finally the cells were treated with both of mitoxantrone and thymoquinone series together.
Results: Antiproliferative effect of thymoquinone was seen only at T3 doses while both M3 and M4 doses of mitoxantrone showed toxic effect to the cells when they were applied individually. On the other hand, when combined use of mitoxantrone and thymoquinone were done, a significant antitumoral effect was seen in T2M4 combination.
Conclusions: The effect of T2M4 combination on the cell suppression was almost twice in M4 mitoxantrone alone application. We thought this result shows synergistic effect of thymoquinone with mitoxantrone.

PM12.142
Analysis of polymorphisms and epidemiological factors in selected genes coding for interleukins in women with uterine leiomyomas

S. Jurgec[1,2], *U. Potočnik*[1,2];
[1]*Center for Human Molecular Genetics and Pharmacogenomics, Faculty of Medicine, University of Maribor, Slovenia, Maribor, Slovenia,* [2]*Laboratory for Biochemistry, Molecular Biology and Genomics, Faculty for Chemistry and Chemical Engineering, University of Maribor, Slovenia, Maribor, Slovenia.*

Several interleukins has been known to promote tumorogenesis in different tissues. Uterine leiomyomas (ULM) are the most prevalent pelvic tumors in women and it has been shown that genetic factors contribute to development of ULM. The aim of our study was to analyze SNPs in interleukins IL12RB1, IL12B and IL23R, which play an important role in immune response and to correlate genotypes with clinical data of patients with solitary and multiple leiomyomas. In our study 169 Slovenian ULM patients and 49 controls were included. We found significantly lower frequency of genotype AA for SNP rs11575934 (IL12RB1) in patients with solitary leiomyomas (39,0%, p=0,037) and multiple leiomyomas (45,9%, p=0,036) compared to healthy controls (62,5%). The results suggest that IL12RB1 (rs11575934) AA genotype is protective factor for developing ULM in Slovenian women for both forms of ULM. The analysis of epidemiological factors compared with allele frequency showed significantly higher number of pregnancy (p=0,048) and parity (p=0,004) in women with multiple leiomyomas with A allele for SNP rs11575934 (IL12RB1). Our results suggest that IL12RB1 gene polymorphism might be candidate genetic marker for prediction of susceptibility to leiomyoma and also suggest a link between genotype and the development of one of the forms of leiomyomas in the presence of specific epidemiological factor.

PS12.143
BAP1 germline mutations in Finnish uveal melanoma patients

S. Markkinen[1], *J. Turunen*[1,2], *S. Lindh*[1], *M. Muona*[1,3], *V. Raivio*[2], *M. Täll*[2], *R. Wilska*[2], *A. Lehesjoki*[1,4], *T. Kivelä*[5];
[1]*Folkhälsan Institute of Genetics, Helsinki, Finland,* [2]*Ophthalmology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland,* [3]*Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland,* [4]*Neuroscience Center and Research Programs Unit, Molecular Neurology, University of Helsinki, Helsinki, Finland,* [5]*hthalmology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.*

Aim: Germline mutations in BRCA1 associated protein-1 (BAP1) predispose to uveal melanoma and other cancers. Here, we estimated the frequency of BAP1 germline mutations in Finnish uveal melanoma patients.
Methods: We collected genomic DNA from 149 patients treated between 2010 and 2013. In addition, we identified 10 families each with two uveal melanoma patients. We were able to collect DNA from 13 members of uveal melanoma families. All 17 exons of the BAP1 were sequenced in total of 162 patients.
Results: We identified two pathogenic heterozygous BAP1 mutations: a donor splice site mutation in a highly conserved region in intron 2 in a sporadic patient and a frameshift insertion in exon 14 in three familial patients. The frequency for sporadic mutation is 0,67% (1/149, 95%CI <0,0001 to 0,04). Including the three familial mutation carriers to calculations, the frequency of BAP1 mutations is 2,5% (4/159, 95%CI <0,0076 to 0,0651). The insertion was found in two, possibly distantly related, families. The mutations were not present in ExAC database including 3325 Finnish controls from the SISu project.
Conclusions: BAP1 mutations predispose to uveal melanoma also in Finland. Mutations explained uveal melanoma in one sporadic patient and in two families of ten. Further studies are needed to study the genetic background of uveal melanoma in Finland using genome wide analysis strategies.
Grants: Work was supported by Mary and Georg C. Ehrnrooth Foundation and Sigrid Jusélius Foundation. JAT was funded by Suomen silmälääkäriyhdistys and SM was funded by Evald and Hilda Nissi Foundation.

PM12.144
Genetic background of unilateral/bilateral Vestibular Schwannoma (VS)

R. Birkenhäger, *S. Arndt, W. Maier, A. Aschendorff, R. Laszig;*
Department of Otorhinolaryngology, Head and Neck Surgery, University Medical Center Freiburg, Freiburg, Germany.

A vestibular schwannoma (VS) (acoustic Neurinoma) is a benign tumors originated from Schwann cells (SC) of the vestibular nerve and located in the cerebello pontine angle or the inner auditory canal. The tumor results from an overproliferation of SC; these cells wrap themselves around nerve fibres, often causing gradual hearing loss, tinnitus and dizziness. It can also affect with the facial nerve causing paralysis by compression. Early detection of the tumour is sometimes difficult, because the symptoms may be subtle and may not appear in the beginning. There are two types of VS: Bilateral and unilateral. Until now there is only one single gene known for bilateral VS, that leads to neurofibromatosis type 2 (NF2). Unilateral VS account for approximately 8 % of all cranial tumours. The exact cause of unilateral VS is unknown, most occur spontaneously. Our study group consists of 144 patients (from 139 independent families) of which 23 have a bilateral VS (NF2), 119 unilateral VS and 2 with an initial suspicion of VS. All patients were clinically clearly defined. Genetically we performed a mutation analysis on the NF2 gene at the genomic and tumor level. So far we identified different missense/nonsense and splice mutations in NF2 gene, on the genomic level and in some cases exclusively in tumor cells, which all lead to a loss of function of the gene product Merlin and the appearance of VS. In addition to somatic changes and mutations there are possible indications of a genomic predisposition to unilateral Vestibularisschwannome.

Complex chromosomal aberrations with gain of 1q32.2 and 3q25 to 3qter and deletion of 17p in relapsed Waldenström's macroglobulinemia

N. Yu[1], *S. Shin*[2], *Y. Kim*[3], *J. Kim*[3], *Y. Kim*[4], *K. Lee*[2];
[1]*Samkwang medical laboratories, Seoul, Korea, Republic of,* [2]*Department of Laboratory Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,* [3]*Department of Laboratory Medicine, Yonsei University Wonju College of Medicine, Seoul, Korea, Republic of,* [4]*Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Seoul, Korea, Republic of.*

The genetic abnormalities in Waldenström's macroglobulinemia (WM) are relevant for the differential iagnosis of related B-cell malignancies as well as for risk stratification in WM patients. We present a case of WM progressed to therapy-related acute myeloid leukemia, showing complex chromosomal abnormalities found during tumor progression, including gains of 1q and 3q, deletion of 17p, and monosomies 18 and 20.
In 2002, our patient at 53-years old was diagnosed with extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue by par-

otid gland biopsy. She was treated with local radiotherapy and achieved complete remission. In 2010, she was diagnosed with WM and treated with 6 cycles of a fludarabine, mitoxantrone, and dexamethasone regimen. But in 2011, BM biopsy revealed involvement of LPL (52.2% of ANCs), and the karyotype was normal. In 2013, Microarray and conventional karyotyping from BM involvement sample revealed 45,XX,add(3)(q27),-18,-20,+mar[10/25].arr[hg19] 1q32.2(207,319,569-207,838,127)x3,3q25.1q27.1(150,744,552-183,300,655)x2~3,17p13.3p11.2(18,900-16,450,821)x1~2,18p11.32p11.21(136,304-14,144,899)x1~2,18q21.2q23(51,396,071-77,611,182)x1~2,20q11.21q13.33(31,027,513-62,532,060)x1~2. The *MYD88* L265P and *ARID1A* mutation, identified as a recurring mutation in WM, were not detected in our case. In December 2013, she was diagnosed with t-AML and treated with decitabine, but died in 2014.

Deletion of 17p13, recurrent abnormalities in WM and associated with disease progression, was found in our case in the advanced stage suggests that the aberrations occur as a secondary event. Among these duplicated 3q region in our case, *KLHL6* (kelch-like protein 6) was identified as a target of somatic hypermutation in CLL from whole-genome sequencing experiments. Close monitoring of cytogenetic abnormalities during WM treatment would be needed for possibility of therapy-related leukemogenesis.

Y chromosome loss in blood is associated with colorectal and prostate cancer

P. Noveski[1], *S. Madjunkova*[1], *N. Matevska Geshkovska*[2], *A. Eftimov*[2], *E. Sukarova-Stefanovska*[1], *A. Dimovski*[2], *D. Plaseska-Karanfilska*[1];

Efremov", Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Center for Bimolecular Pharmaceutical Analysis, Faculty of Pharmacy, University Ss Cyril and Methodius, Skopje, Macedonia, The Former Yugoslav Republic of.*

Although age-related loss of chromosome Y (LOY) in normal hematopoietic cells is a well known phenomena, the phenotypic consequences of LOY have been elusive. Recently, LOY was found in association with smoking, shorter survival and different types of cancer. It was suggested that LOY in blood could become a predictive biomarker of male carcinogenesis.

The aim of our study was to investigate the association of LOY in blood with colorectal (CC) and prostate cancers (PC). For this purpose we have analyzed DNA samples, isolated from peripheral blood of 102 CC patients (mean age 59.8±13.2), 70 PC patients (mean age 68.8±8.0) and 93 healthy control males (mean age 65.8±16.6). The methodology included multiplex quantitative fluorescent (QF) PCR of chr.X/chr.Y (amelogenine gene), chr.1/chr.Y and chr.3/chr.X homologous sequences followed by automatic detection and analysis on ABI 3500 Genetic Analyzer. The mean Y/X ratios were significantly lower in CC (0.881±0.15; p=2.32x10-9) and PC patients (0.941±0.06; p=0.00012) in comparison to the controls (1.015±0.15). Substantial LOY (determined as Y/X ratio < 0.70) was significantly more frequent among CC patients (10/102 or 9.8%) in comparison to the controls (2/93 or 2.15%; p=0.0352) and PC patients (0/70 or 0%; p=0.0059). Multivariate regression analysis adjusting for tumor localization, stage and Y chromosome lineage was unable to link substantial LOY to certain colorectal cancer subgroups.

Our results support the recent findings of association of LOY in blood with carcinogenesis in males. They also show that LOY is more significant among colorectal cancer than prostate cancer patients.

A 17p13.3 microduplication including the PAFAH1B1 and YWHAE genes resulting from a maternal balanced 17; 3 translocation

M. Hadj Amor[1], *S. Dimassi*[1], *A. Mlika*[2], *H. Hannachi*[1], *K. Ben Hela*[3], **A. Saad**[1], *S. Mougou-Zerelli*[1];
[1]*Laboratoire de Cytogénétique, Génétique Moléculaire et Biologie de la Reproduction Humaines, CHU Farhat Hached, Sousse, Tunisia,* [2]*Service de pédiatrie, CHU Farhat Hached, Sousse, Tunisia,* [3]*Service de pédiatrie, CHU Ibn Jazzar, Kairouan, Tunisia.*

Introduction: 17p13.3 is a chromosomal region of genomic instability due to extensive repetitive sequences. In literature, microdeletions and microduplications have been described leading to different clinical phenotypes.

Materials and Methods: We describe the case of 2-year-old girl with a microduplication of the MDS critical region, involving the *PAFAH1B1* and *YWHAE* genes. The microduplication is resulting from maternal balanced translocation. The patient presented with delayed psychomotor development and dysmorphic featurs. She is born of inbreed marriage at the 2nd level, she had a brother and a sister died at one year old due to lissencephaly. His MRI is normal. To explore the genetic level, R-band karyotype and Fluorescence *in Situ* Hybridation (FISH) and Array CGH are performed.

Results: We conducted a FISH using a probe specific for the *LIS1* gene en 17p13.3 and telomeric probes en chromosomes 3, which showed a 17p13.3 duplication and subsequently duplication of LIS1 gene and 3p26 deletion for many reasons: the deletion of 2.9 Mb on chromosome 17 and the duplication of 3.6 Mb on chromosome 3 in her sister detected by CGH Array, the maternal translocation between the chromosome 3 and the chromosome 17.

Conclusions: Phenotypic comparison with the other patients found in the literature revealed common phenotypic characteristics such as mild to moderate developmental delay psychomotor and facial dysmorphism including high forehead and small mouth. Frequently, MRI of patients shows agyria, pachygyria···etc. However, our MRI patient returned normal but this does'nt mean that the duplication of the *LIS1* gene causes neuronal migration disorders.

PM13.02

A new microdeletion involving 1q32.1 region identified by high-density chromosomal microarray analyses

C. Venegas-Vega[1,2], *M. Guardado*[3], *A. Martinez*[4], *S. Kofman*[3], *J. Berumen*[5];
[1]*Unidad de Genetica, Hospital General de Mexico, DF, Mexico,* [2]*Facultad de Medicina. UNAM, Df, Mexico,* [3]*Hospital General de Mexico, DF, Mexico,* [4]*Facultad de Medicina UNAM, DF, Mexico,* [5]*Unidad de Medicina Genómica, Hospital General de Mexico, DF, Mexico.*

Background: To our best knowledge, only one case with a deletion involved 1q32.1 characterized by aCGH has been previously reported. **Methods and Results:** Here, we described a 16 year-old female patient with mild facial dysmorphic features, intellectual disability (ID) and marfanoid habitus (MH). CytoScan HD array analyses identified a 1q32.1 interstitial microdeletion of 1.87 Mb (hg19:200,852,854-202,726,877). To date, only one case with 1q32.1 microdeletion that overlaps with our patient has been reported. We identified 3 additional cases with similar deletions annotated in the databases [DECIPHER (259811-288679) and ISCA (nssv575720)]. Interestingly, Olson *et al* (2012) described two patients with similar microduplications at 1q32.1 associated with neurodevelopmental delay that overlap with the four cases mentioned above. Excluding one case (259811) all had neurodevelopmental delay (NDD) or intellectual disability (ID). Our patient presented the shorter genomic imbalance and the genotype-phenotype correlation allowed us to identify a minimal overlapping region (MOR) that includes 31 RefSeq genes. We analyzed which of these genes are expressed in the brain and the probability of haploinsufficiency (HI) of this genomic region, resulting *KDM5B* as the best candidate for the NDD/ID. *KDM5B* is a histone lysine demethylase which play a role in neuronal differentiation. Neurodevelopment genetic disorders involving alterations in this mechanism have been described. **Conclusions:** We propose that the microdeletion of 1q32.1 is a rare pathogenic CNV and that the MH is an unspecific finding of this genomic deletion. Finally, we suggested that the (HI) of *KDM5B* gene could be involved in the NDD/ID.

Array Based Comparative Genomic Hybridization Applying for Multiple Congenital Anomalies, Developmental Delay/Intellectual Disability, Autism Spectrum Disorders, and Seizure disorder in Taiwan

C. H. Lee[1], *H. Y. Lin*[1], *C. K. Chuang*[2], *P. S. Wu*[3], *C. P. Chen*[2], *S. P. Lin*[1];
[1]*MacKay Chlidren's Hospital, Taipei, Taiwan,* [2]*MacKay Memorial Hospital, Taipei, Taiwan,* [3]*Gene Biodesign Co. Ltd, Taipei, Taiwan.*

Array Based Comparative Genomic Hybridization (array-CGH) has been confirmed to increase the diagnosis of unexplained multiple congenital anomalies (MCA), developmental delay/intellectual disability (DD/ID), autism spectrum disorders (ASD), and seizure disorder (SD). The purpose of this study was to provide related information in Taiwan because of the limited statistic data before. We retrospectively collected the array-CGH results and medical records of 145 patients with MCA, DD/ID, ASD, or SD at Mackay Children's Hospital from June 2010 to December 2014. Blood samples were analyzed by Affymetrix GeneChip Genome-Wide Human SNP array 6.0 with a resolution ranging from 100 Kb to 200 Kb and NimbleGen ISCA plus Cytogenetic Array with a resolution of 30 Kb. Of the 145 patients in this study, 79 (54%) males and 66 (46%) females were enrolled and the median age was 5.16 years. The proportions of MCA, DD/ID, ASD, and SD were 68% (99/145), 43% (62/145), 6% (8/145), and 9% (13/145), respectively. Some patients had more than one clinical feature. Copy number variants were detected in 57 patients, including microdeletions in 37, microduplications in 8, and two different rearrangements in 12 patients. Among these 145 patients, 99 (68%) also had G-banded karyotyping examination. The positive results of array-CGH and G-banded karyotyping were found in 47 patients (47%) and 9 patients (12%), respectively. Our results further demonstrated the

higher diagnostic yield in the assessment of patients with unexplained MCA, DD/ID, ASD, and SD. The use of array-CGH also strongly supports as the first-tier cytogenetic test in place of G-banded karyotyping.

PM13.04
Array-CGH analysis in a large cohort of patients with intellectual disability and/or congenital malformations

C. Pinato, M. Cassina, **C. Rigon**, *D. Frizziero, V. Vicenzi, A. Calò, D. Zuccarello, L. Salviati, E. Trevisson, M. Clementi;*
Department of Women's and Children's Health, University of Padova, Padova, Italy.

Array-CGH analysis has improved the detection of pathogenic imbalances in patients with intellectual disability and congenital malformations and demonstrated that copy number variations (CNVs) are a major source of genetic diversity between normal individuals. Recurrent CNVs are usually caused by non-allelic homologous recombination (NAHR) between LCRs, while several microhomology-mediated repair mechanisms including Non Homologous End Joining (NHEJ) and Fork Stalling and Template Switching (FoSTeS) have been proposed to explain the etiology of non-recurrent CNVs.
In this study we evaluated the frequency of CNVs in a cohort of 1051 patients referred to our institution because of intellectual disability, developmental delay, autism or multiple congenital anomalies. CNVs breakpoints were analyzed to identify sequence microhomologies that may have mediated the rearrangement. We also assessed whether the mechanism of formation or the CNV pathogenicity were associated with the inheritance (*de novo* or inherited anomaly), the type (deletion or duplication) or the size of the imbalance.
Array-CGH analysis detected at least one pathogenic or likely pathogenic CNV in 15.8% of patients and the anomalies were more likely deletions and CNVs arisen *de novo*. Most of the imbalances were caused by microhomology-mediated mechanisms (74.2%) but no significant differences were observed with regard to the type of CNV or the pattern of inheritance.
Moreover, while most of the NAHR-mediated CNVs had dimensions ranging between 1Mb and 5Mb and were concentrated in few chromosomes, microhomology-mediated CNVs had variable size and their frequency was statistically positively correlated with the dimensions of chromosomes.

PS13.05
Reciprocal autosomal balanced translocation and Yq duplication in an azoospermic man

M. Simioni, *A. T. M. Guerra, G. G. Junior, N. L. Viguetti-Campos, V. L. Gil-da-Silva-Lopes;*
University of Campinas, Campinas, Brazil.

In male infertility sperm counts usually range from oligospermia to azoospermia. Azoospermia is defined as the absence of live spermatozoa in semen, and may be obstructive or nonobstructive depending on the presence of blockage of the tubules or ducts. Chromosomal rearrangements are a recognized cause of reproductive failure in males, with a significantly higher rate of cytogenetic anomalies observed in azoospermic (13.7%) than in oligospermic men (4.6%). In addition, Y chromosome microdeletion is a major genetic cause, specifically involving azoospermia factor regions (AZF). However, duplications involving AZF at Yq have been described both in infertile and fertile men. Here we report the case of an azoospermic man with a reciprocal autosomal balanced translocation and Yq duplication. Karyotype in blood lymphocytes was 46,XY, t(6;13)(p12;p13) and array genomic hybridization was performed to search for copy number alteration at breakpoints. No abnormalities were found in these regions; although, a 968kb duplication (24017591-24985599, hg19) at Yq11.223 was detected, including part of AZFc region and twelve genes, including *RBMY1*, which is expressed during spermatogenesis. As the role of increased expression of some genes inside the duplicated AZF region is controversial and Yq duplication is inherited from his normal father, can be hypothesized that the translocation led to meiotic impairment or (and) disruption of an autosomal gene involved in gametogenesis. Cases of male infertility in carriers of translocations involving chromosomes 6 or 13 have been described. This case reinforces the importance of cytogenetic together with molecular characterization. Supported by Fapesp (2011/23794-7 and 2012/10071-0) and CNPq (304455/2012-1).

PS13.07
Molecular analyses of the effects of clock gene SNPs on the Biological Clock

i. Baris, *B. Gurkan, M. Tardu, H. Kavakli;*
Koc University, istanbul, Turkey.

Circadian clocks coordinate physiology and behavior with the 24 h solar day to provide temporal homeostasis with the external environment. The mammalian circadian clock is based on a transcription-translation feedback loop in which CLOCK and BMAL1 proteins act as transcriptional activators, CRYs and PERs proteins repress CLOCK/BMAL1. SNPs in the clock genes are associated with many physiological disorders like sleep disorders, metabolic disorders, and infertility. However, the effects of SNPs on biological clock and the related disorders are not well understood.
In the present study, the effects of SNPs on core clock protein's function and thus, on the biological clock was investigated. For each gene 8-10 SNPs that placed in functional domains like HLH and PAS1-2 were chosen based on the SIFT and PolyPhen bioinformatics tools. Gene variants were created by site-directed mutagenesis. The effects of the SNPs were examined by looking the interaction between clock proteins, and CLOCK/BMAL1 dimer driven transciption. We performed preliminary studies with Bmal1 gene. Based on lusiferase analyses, p.Arg84Cys (COSM296154) or p.Leu196Gln (rs112626431) variation result in decrease in transactivation capacity of BMAL1/CLOCK dimer. Additionally, CRY2/PER2 dimer has different inhibition effect on variant BMAL1/CLOCK dimer than wild type BMAL/CLOCK dimer.
As far as we know, this study will be the first study investigating the effects of SNPs resulting in amino acid changes in clock proteins at molecular level. The findings of the study will enable us to investigate the relation between investigated candidate clock SNPs and clock related diseases such as cancer, metabolic disorders, diabetes, and obesity. This study was supported by TUBITAK 114Z879 grant.

PM13.08
Characterization of the complex breakpoint junction of a CFTR gene deletion with discordant MLPA and qPCR findings

S. A. Taylor[1,2], *S. Haase*[2], *N. Antonishyn*[1,2], *M. Somerville*[1,2], *M. Thomas*[3], *L. Colvin James*[3], *G. Bendiak*[4], *C. Bjornson*[4], *S. Hume*[1,2];
[1]Medical Genetics, University of Alberta, Edmonton, AB, Canada, [2]Molecular Diagnostic Laboratory, University of Alberta Hospital, Edmonton, AB, Canada, [3]Clinical Genetics, Alberta Children's Hospital, Calgary, AB, Canada, [4]Paediatrics and Respirology, Alberta Children's Hospital, Calgary, AB, Canada.

The reported incidence of rearrangements of the CFTR gene varies from 2-20% in affected probands with multiple underlying mutation mechanisms proposed. More recent investigations reveal that sequences at the breakpoints of CFTR rearrangements can reflect more complex patterns of breakage and rejoining. As part of our provincial newborn screening program, a male infant was found to be heterozygous for the deltaF508 variant (CFTR c.1521_1523delCTT). Subsequently he had an abnormal sweat chloride test and full gene analysis for sequence variants and gene rearrangements of the CFTR gene was initiated. By MLPA he was found to carry a deletion of exons 17-20. Analysis by quantitative real-time PCR could only confirm the presence of a deletion of exons 18-20. Sequencing of the deletion breakpoint revealed a complex rearrangement that confirmed the loss of exons 18-20, but also found inserted at the breakpoint junction an inverted portion of intron 18 (119 bp) joined to a GA dinucleotide and then an inverted portion of exon 17 (66bp) (CFTR c.2908+353_c.3368-1088delins(c.2988+1022_c.2988+1141inv:GA:c.2717_c.2782inv)). The abnormal MLPA result for exon 17 is hypothesized to be due to the duplicated portion of exon 17 acting as a "sink", binding the MLPA probe whilst not permitting amplification. Microhomologies (2-8bp) and short repetitive elements at or near the breakpoints, the size of the rearranged sequences, and their proximity to one another suggest that a replicative-based mechanism such as fork stalling and template switching may underlie this rearrangement. To our knowledge this represents the most complex CFTR rearrangement reported in the literature.

PS13.09
Three cases of complex X chromosome rearrangements that appear to have been mediated by chromoanasynthesis

S. E. Anderson[1], S. F. Jose[1], F. Elmslie[2], S. J. Davies[3], D. A. Barrell[1], **S. M. Morgan**[1];
[1]Laboratory Genetics Service for Wales, Cardiff, United Kingdom, [2]South West Thames Regional Genetics Service, London, United Kingdom, [3]All Wales Medical Genetics Service, Cardiff, United Kingdom.

In recent years there have been a number of reports of chromothripsis-like events in patients with developmental delay and congenital abnormalities. Chromothripsis is believed to involve an initial trigger which causes chromosome shattering and repair by non-homologous end joining (NHEJ). However, the vast majority of reported cases of constitutional chromothripsis have copy number profiles that more closely resemble a replication-based event distinct to chromothripsis called chromoanasynthesis (Liu et al., 2011). The key difference between the two processes is that whilst chromothripsis is characterised by loss and retention of heterozygosity, chromoanasynthesis

can also result in gains, including duplications and triplications. We report three patients, two male and one female, each with a developmental disorder, who were referred for array CGH analysis. They were all shown to have multiple duplications on the X chromosome. This has resulted in the partial duplication of the MECP2 gene in one patient and the partial duplication of the CDKL5 gene in another. The presence of multiple copy number gains clustered on a single chromosome is consistent with chromoanasynthesis. No similar complex rearrangements involving an autosome chromosome have been detected in our laboratory. To the best of our knowledge, these are the first patients reported with multiple copy number gains on the X chromosome.

PM13.10
Chromosomes in a genome-wise order change the landscape of genetics

T. Liehr, *S. Bhatt, K. Piaszinski, N. Kosyakova, F. Xiaobo, E. Alhourani, J. P. Chaudhuri, A. Weise;*
University Hospital Jena, Institute of Human Genetics, Jena, Germany.

Although a non-random distribution of chromosomes was suggested already in the early days of human cytogenetics it is commonly accepted by the majority of cytogeneticists that chromosomes in a metaphase spread are arranged in a completely random way. Since the observation of the bilaterally symmetric distribution of DNA and chromosome specific fluorescence in situ hybridization (FISH) signals in leukocytes in 1990, we demonstrated in a series of publications the genome-wise organization of chromosomes in human and murine cells. In other words, the maternal chromosomes are tethered to one centriole while the paternal chromosomes are connected to the other. Between 1956 and 1991 similar observations were made in human, insect and plant cells, still these observations were widely ignored. As a rule, rather than an exception, we found this genome-wise haploid order of chromosomes in a variety of samples from different human and other mammalian tissues; in numerically aberrant human karyotypes and samples with small supernumerary marker chromosomes (sSMC). Detailed analysis of the 3 cases with SMC and uniparental disomy showed that there is a defined nuclear architecture in metaphase allowing bilateral organization of the two haploid sets of chromosomes organized in haploid groupings corresponding to parental origin. Thus, we may have to refine the terms "Comparative Genomic Hybridization" or "Loss of Heterozygosity" by specifying the involvement of the maternal and/or paternal genomes. Supported by Carl Zeiss MicroImaging GmbH, Germany.

PS13.11
PMS2 inactivation by a complex FoSTeS-mediated rearrangement involving the inverted 100-kb duplicon on 7p22.1 and a HERV retroelement

J. Vogt[1], *A. Wernstedt[1], T. Ripperger[2], B. Pabst[2], J. Zschocke[1], C. Kratz[3], K. Wimmer[1];*
[1]Division of Human Genetics, Medical University Innsbruck, Innsbruck, Austria, [2]Institute of Human Genetics, Hannover Medical School, Hannover, Germany, [3]Department of Pediatric Hematology/Oncology, Hannover Medical School, Hannover, Germany.

Biallelic PMS2 mutations are responsible for more than half of all cases of constitutive mismatch repair deficiency (CMMRD), a recessively inherited childhood cancer predisposition syndrome. The 3' region (exons 9-15) of the PMS2 gene is located in a 100-kb sequence that is duplicated ~0.7-Mb centromeric in inverse orientation on 7p22.1. Sequence exchange, primarily homologous recombination (HR) with crossover between the 100-kb duplicons, is thought to be responsible for the known genomic inversion polymorphism of the 0.7-Mb sequence intervening the duplicons. PMS2 transcript and MLPA analysis in a new CMMRD patient rendered results that were best explained by a genomic rearrangement separating the N-terminal from the C-terminal region of the gene. GenomeWalker analysis and 3'RACE PCR uncovered the breakpoints of a complex rearrangement that is characterized by a ~918-kb inversion that exceeds the known inversion polymorphism by ~220-kb. This inversion was further associated with a duplication of ~100-kb of the inverted region. Fork stalling and template switching/microhomology-mediated break-induced replication (FoSTeS/MMBIR) is the most parsimonious mechanism by which the rearrangement truncating the PMS2 gene could be explained. These findings support the hypothesis that inverted segmental duplications can not only mediate the formation of simple inversions by HR but also more complex structural rearrangements. It further suggests that complex rearrangements with copy number alterations could be hidden among the genomic inversion on 7p22.1.

PM13.12
Whole exome sequencing detects p.Q155X mutation in CRYBB2 gene; evidence of heterogeneity genetic in a family with autosomal dominant pulverulent cataract

O. Messina-Baas[1], *M. Gonzalez-Garay[2], J. Toral-Lopez[3], H. Urueta-Cuellar[1], M. Rivera-Vega[1], S. Cuevas-Covarrubias[4];*
[1]Hospital General de Mexico, Mexico DF, Mexico, [2]UTHSC at Houston, Institute of Molecular Medicine, Houston, TX, United States, [3]Ecatepec Medical Center, Toluca, Mexico, [4]Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.

Congenital cataract is an entity clinical and genetically heterogeneous with high penetrance and represents 10% of a treatable cause of childhood blindness. Thirty percent of the cataracts are heredity with the nonsyndromic autosomal dominant form. About 30 loci have been associated to congenital cataract. CRYBB2 gene belongs to β crystallin family together with 6 genes (4 CRYBA and 2 CRYBB) on several chromosomes and is related to congenital cataract. In the present study, we analyzed a Mexican family affected by autosomal dominant pulverulent cataract in four generations through whole exome and identified the cC475T (pQ155X) mutation on CRYBB2. Nonsense cC475T (pQ155X) mutation has been reported previously from five different countries and predicts a stop codon on Q155 losing 51 aminoacids and four Greek key domain in the C-terminal region of the CRYBB2 protein. Gene conversion seems to be the cause of this type of cataract cataracts. This is the first Mexican family with pulverulent cataract associated to a pQ155X mutation. This data shows evidence of heterogeneity genetic in autosomal dominant pulverulent cataract but a consistent presence of this morphology when CRIBB2 is affected. Exome sequencing comes more as a powerful tool for the detection of genetic origins of cataracts due to genetic and clinical heterogeneity in this type of disease

PS13.13
Sequencing of CFTR gene at the patients with classical and atypical forms of cystic fibrosis

J. A. Nasykhova[1], *T. E. Ivashchenko[1], T. E. Gembitskaya[2], A. V. Orlov[3], T. A. Stepanenko[2], A. G. Chermenskiy[2], V. S. Baranov[1];*
[1]Ott Institute of Obstetrics & Gynecology, St-Petersburg, Russian Federation, [2]Pavlov First Saint-Petersburg State Medical University, St-Petersburg, Russian Federation, [3]St Olga Municipal Children's Hospital, St-Petersburg, Russian Federation.

Cystic fibrosis (CF) is a common autosomal recessive disease caused by mutations in the CFTR gene encoding for the cystic fibrosis transmembrane conductance regulator protein. The CFTR gene is characterized by an extremely large number of mutations (more than 1900). To date, after the routine genetic testing including the analysis of the most frequent mutations of CFTR gene about 30% of mutations remain unidentified. We studied CFTR gene in cohort of 50 CF patients with one or both unknown mutations. We performed sequencing to characterize the mutations in coding regions, promoter and splice sites in CFTR gene. To exclude large gene deletions/insertions the method of MLPA was used. 71% of patients including in this study have classical form of CF and 29% - atypical mild form of disease. We identified 5 rare mutations with quite high frequency in Russian population (3849+10kbC/T, E92K, 489+1G>T, Ser1231ProfsX4, L1335P) that aren't included in panel of mutations for routine CF testing in Russia. Three novel nonsynonymous mutations (E92A, K1468R, Ile1328Lys), one deletion (3816_3817delTG) were identified. One patient had a large deletion from 3 to 10 intron (CFTR40kbdel). In our study mutations of CFTR gene were found in 85,6% of CF chromosomes. Among patients with classical form mutations were identified in 94% of CF chromosomes whereas among patients with atypical form - only in 61%. These results prompt studies of noncoding regions of CFTR, including intronic regions, potentially involved in the regulation of gene expression at the patients with atypical form of CF.

PM13.14
DNA repair factors are upregulated following Dental Cone Beam CT irradiation

M. Louka[1], *L. Berkas[2], E. Boutou[1], G. Terzoudi[3], C. Vorgias[1], A. Donta[2];*
[1]Faculty of Biology, Athens University, Athens, Greece, [2]Dental School, Athens University, Athens, Greece, [3]NCSR "Demokritos", Athens, Greece.

The Dental Cone Beam CT (DCBCT) has been specifically developed for dental use and offers a volume 3-dimensional imaging similar to medical CT but with significantly lower radiation exposure of the patient. Still, ionizing irradiation is a source of DNA damage.
The aim of this study is to determine DCBCT irradiation consequences at molecular level by studying the expression of factors involved in DNA Damage Response (DDR) pathways.
HEK293 cells, used as experimental material, were placed into a house-

made phantom device, manufactured to mimic as possible the respective doses an adult tissue would receive. Cells were irradiated using a NewTom DVT 9000, DCBCT. DDR response was monitored by detecting γH2AX, p53, Rad51, p21^{waf1} and BRCA1 proteins in two time points following irradiation, by immunofluorescence and western blot. The respective mRNA levels were also studied.
Characteristic foci of phosphorylated γH2AX, a marker of ds DNA damage, were clearly detected in HEK293 cell nuclei, in just half an hour after irradiation. In accordance, altered protein levels of key molecules involved in DNA repair such as BRCA1 and Rad51, were also observed. More specifically, BRCA1 protein was significantly induced in at least half an hour after irradiation, while Rad51 protein levels were higher than normal 48hours following irradiation. No significant modification was observed in p53 and p21^{waf1} protein levels.
In conclusion, DCBCT irradiation of HEK293 cells results in at least temporary modification of molecules involved in DNA damage detection and repair. Based on these results, a more concrete evaluation of DCBCT irradiation risk assessment at the molecular level is required.

The Human Developmental Biology Resource (HDBR) is a unique resource funded by the MRC and Wellcome Trust. It provides human embryonic and fetal tissue for gene expression studies related to congenital disease, including birth defects and inherited metabolic disorders. Use of the material should particularly illuminate developmental gene expression underlying aspects of functioning that characterise humans as opposed to lower animals (e.g. higher brain function, language). This research is essential if we are to introduce new methods for prevention of congenital defects and develop an improved understanding of "what makes us human".
The HDBR has Tissue Bank ethics approval for the collection, storage and distribution of material between 4 and 22 weeks of gestation. A significant proportion of the HDBR material is karyotyped and chromosomally normal material is provided for research but karyotypically abnormal material can also be provided on request. The HDBR's material can be used to generate cell lines, stem cells, protein, RNA and DNA. The HDBR can also provide cDNA from embryonic tissue for gene expression analysis. In addition, paraffin wax and frozen sections of embryos and early fetuses are available for in situ hybridisation and immunohistochemistry. Individuals wishing to use human and fetal tissue do not need to apply for local ethical permission as the HDBR ethics covers distribution of tissue to end users. Human embryonic and fetal tissue is provided free to registered users of the HDBR.
Further information can be found on our web site www.HDBR.org.
Joint MRC/Wellcome Trust grant # 099175/Z/12/Z.

14q32.3 deletions: molecular findings and genotype-phenotype correlations in two cases

I. A. Demidova[1,2,3], *S. G. Vorsanova*[1,2], *K. S. Vasin*[1,2,3], *A. D. Kolotii*[1,2], *M. A. Zelenova*[1,2,3], *Y. B. Yurov*[1,2,3], *I. Y. Iourov*[1,2,4];
[1]*Mental Health Research Center, RAMS, Moscow, Russian Federation,* [2]*Research and Clinical Institute for Pediatrics at the Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.*

14q32.3 deletions are rare chromosome abnormalities. Nonetheless, studying genomic rearrangements by array CGH has shown 2 cases out of 350 to demonstrate 14q32.2q32.33 and 14q31.31q32.33 deletions. Deleted regions spanned 6,26 Mb at 14q32.2q32.33 and 4,83 bp at 14q32.31q32.33, involving 386 and 268 genes, respectively. The former case also demonstrated mosaic 14q32.13q32.2 duplication (4,53 Mb) spanning 38 genes and non-mosaic 14q32.2 duplication (1,87 Mb) spanning 24 genes. We speculate that duplications flanking the deletion are likely to contribute to the formation. The first case presented with microcephaly, structural congenital myopathy, spinal defects, congenital heart defect, short stature and failure to thrive. The second patient presented with severe developmental and speech delays, autism, hyperactivity, microcephaly, mild congenital heart defect and bilateral nephroptosis. To assess molecular basis of phenotypes, we performed bioinformatic analysis. We found that DYNC1H1, HSP90AA1, TECPR2, TRAF3, CDC42BPB, CKB, KLC1, C14orf2 and PACS2 are candidate genes for neuropsychiatric abnormalities. CRIP2 and ADSSL1 are candidate genes for congenital heart defect. ZFYVE21, PPP1R13B, JAG2 and NUDT14 are associated with myopathy, spinal and kidney defects as well as contribute to immunological problems reported in these cases. The present study demonstrates that application of high-resolution array CGH analysis coupled with bioinformatics is able to shed light not only on gene misbalance, but also on formation mechanisms as well as molecular/cellular and phenotypic outcome of genomic variations through gene-centric genotype-phenotype correlations. Supported by a grant from the Russian Science Foundation (project №14-15-00411).

PS13.17
Functional characterization of congenital GPI-anchor deficiencies reveals substantial differences in the expression profiles of GPI-anchored substrates

A. Knaus[1,2], *U. Kölsch*[3], *D. Horn*[1], *S. Mundlos*[1,4,2], *P. M. Krawitz*[1,4,2];
[1]*Institute of Medical and Human Genetics, Charité University Medicine Berlin, Berlin, Germany,* [2]*Max Planck Institute for Molecular Genetics, Berlin, Germany,* [3]*Institute of Medical Immunology, Charité University Medicine Berlin, Berlin, Germany,* [4]*Berlin-Brandenburg Center for Regenerative Therapies (BCRT), Charité University Medicine Berlin, Berlin, Germany.*

Glycosylphosphatidylinositol (GPI)-anchor deficiencies represent a phenotypically highly variable and diverse new class of congenital disorders of glycosylation. Over the recent years pathogenic mutations have been identified in 12 genes of the GPI-anchor synthesis and maturation pathway. There are certain features that are shared by most patients with a GPI-anchor deficiency such as intellectual disability or epilepsies. However, other features such as a characteristic facial gestalt, certain organ malformations or abnormalities in routine laboratory parameters, allow the delineation of distinct syndromes (Mabry syndrome, CHIME syndrome, MCAHS1-3).
With more than 300 known GPI-anchored proteins (GPI-AP), we hypothesized that the differences in the phenotypic landscape of GPI-anchor deficiencies might also be due to mutation specific changes in GPI-AP expression. We established a comprehensive flow cytometric protocol comprising 10 different GPI-anchored markers for different types of cell culture. We screened a cohort of 20 patients with pathogenic mutations in 5 different genes of the GPI-anchor synthesis and maturation pathway.
We found characteristic flow cytometric expression patterns for GPI-anchored markers for each analyzed gene. So far it has been assumed that any impairment of GPI-anchor synthesis would affect all GPI-APs uniformly. Thus our results are an unexpected finding and suggest that there might be a correlation between certain phenotypic features and the absence of certain GPI-APs.

PM13.18
Tissue distribution pattern of SMS1 protein implies active post-transcriptional regulation

I. B. Filippenkov, *O. Y. Sudarkina, S. A. Limborska, L. V. Dergunova;*
Institute of Molecular Genetics RAS Dept. of Molecular Bases of Human Genetics, Moscow, Russian Federation.

Sphingomyelin synthase 1 (SMS1) catalyses the synthesis of sphingomyelin and diacylglycerol from phosphatidylcholine and ceramide in eukaryotic cells. Sphingomyelin forms membrane rafts, which are important in membrane sorting and transport of proteins and in receptor signalling. The consumption and production of important regulators of cell processes such as ceramide and diacylglycerol, respectively, link SMS1 function to the processes of membrane transport, cell proliferation and apoptosis. We have previously determined the structure of the SGMS1 gene encoding this enzyme and a number of its alternative transcripts. Here, we present a study of the expression of the full-length SMS1 protein and the sum of the alternative transcripts encoding this protein in human tissues. Abundance of SMS1 protein was detected using immunodetection. SMS1 abundance was normalized to the total protein amount. Abundance of SGMS1 gene coding transcripts was detected using real-time PCR. The amounts of the transcripts of SGMS1 gene were estimated relative to the average mRNA level of housekeeping genes (LDHA, GAPDH and RPL3). The highest SMS1 protein expression level was detected in the kidney; low levels were observed in the placenta and the lymph node. Transcripts encoding the full-length SMS1 were most abundant in the placenta, minimal level were observed in liver. Thus, the SMS1 protein and mRNA levels in tissues differed significantly and were not correlated. Computer sequence analysis of the SGMS1 gene mRNA has revealed many binding sites of miRNA associated with Argonaute proteins in coding region and 3'UTR. We imply the active post-transcriptional regulation of SGMS1 gene expression.

PS13.19

Dosage effect of common trisomies in humans

M. Volk, *A. Maver, L. Lovrečić, B. Peterlin;*
Institute of Medical Genetics, UMC Ljubljana, Ljubljana, Slovenia.

Chromosomal trisomies represent a significant share of morbidity and mortality in the paediatric population. We performed a comprehensive survey of transcriptional landscape in three potentially viable human trisomies (T21, T18, T13) to investigate whether global gene expression profile of these trisomies reflects a common homeostatic genome response or represents a specific gene-dosage effect of the underlying trisomy.

Transcriptomic analyses, comparing global gene expression profile between trisomic and normal cell line, using Agilent's Whole Human Genome Expression arrays, were performed in three groups: first and second comprised of the cultivated amniocytes with T21 and T18 (10 and 9 samples), while the third consisted of the cultivated cells of T13 chorionic villi (11 samples). For each group, a comparable number of tissue-matched normal cell line samples were used for comparison against reference expression profile.

Comparative analysis of differentially expressed genes in T21, T18 and T13 precipitated a subset of genes, differentially expressed in all three trisomies: WBP4 and PRPF8, involved in the mRNA splicing and PPID involved in protein folding. In addition, a co-expression network analyses demonstrated modular deregulation of gene clusters involved in cell division, RNA processing and transcriptional factors shared between T18 and T21, but not with T13.

Our data confirm that common trisomies induce transcriptome deregulation already in prenatal period. Moreover, we suggest that transcriptional alternations related to common trisomies reflect a genomic response associated with deregulation of genes involved in the cell cycle control, mRNA processing and important cellular signaling pathways. Further studies are needed to address the question of common homeostatic genomic response in common human trisomies.

PM13.20

Molecular characterization of a novel c.1092T>A splicing mutation in the IDS gene

T. Kovacova[1], *L. Grodecka*[1,2], *S. Seneca*[3], *O. Ticha*[4], *K. Hrncirova*[1,2], *P. Lockerova*[2], *E. Buratti*[5], *W. Lissens*[3], *T. Freiberger*[1,2];
[1]*Central European Institute of Technology, Masaryk University, Brno, Czech Republic,* [2]*Molecular Genetics Laboratory, Centre for Cardiovascular Surgery and Transplantation, Brno, Czech Republic,* [3]*Center for Medical Genetics, and Research Group Reproduction and Genetics, UZ Brussel, Vrije Universiteit Brussel, Brussel, Belgium,* [4]*Institute of Clinical immunology and Allergology, St. Anne´s University Hospital, Masaryk University, Brno, Czech Republic,* [5]*International Centre for Genetic Engineering and Biotechnology, Trieste, Italy.*

Pre-mRNA splicing is a fundamental step of gene expression by which introns are removed and exons are joined in pre-mRNAs to form the mature mRNA.

In this study, we have focused on the pathological c.1092T>A mutation in the *IDS* gene. Besides creating a *de novo* splice site, the mutation leads to the utilisation of multiple upstream cryptic splice sites and to the production of multiple aberrant transcripts in patient´s blood cells. This implies that a mutation likely changes a splicing regulatory element as well.

In order to elucidate the molecular mechanisms responsible for the altered splicing pattern we have used computational and minigene analyses. *In silico* predictions suggested that the mutation could lead to both disruption and creation of an exon splicing silencer, as well as of an exon splicing enhancer (ESE). Minigene analyses of the c.1092T>A mutation and of artificial deletion mutants indicated, that the c.1092T>A mutation indeed leads to the creation of a new splicing regulatory element. This outcome was further specified by results of an ESEdependent splicing assay that showed the creation of exon splicing silencer. Such silencer element might inhibit the use of the authentic splice site resulting in the observed complex splicing pattern. Our study highlights the importance of splicing regulatory elements analyses when examining splicing mutations. These sequences are relatively poorly defined and their alteration can lead to unexprected splicing patterns, with a significant impact on resulting phenotype.

PS13.21

Methods of reprogramming to iPSC associated with chromosomal integrity and delineation of a chromosome 5q candidate region for growth advantage

M. Sobol, *D. Raykova, L. Cavelier, A. Khalfallah, J. Schuster, N. Dahl;*
Uppsala University, Uppsala, Sweden.

Induced pluripotent stem cells (iPSCs) have brought great promises for disease modeling and cell-based therapies. One concern related to the use of reprogrammed somatic cells is the loss of genomic integrity and chromosome stability, a hallmark for cancer and many other human disorders. We investigated the 16 human iPSC lines reprogrammed by non-integrative Sendai virus (SeV) and another 16 iPSC lines generated by integrative lentivirus for genetic changes. At early passages we detected cytogenetic rearrangements in 44% (7/16) of iPSC lines generated by lentiviral integration whereas the corresponding figure was 6% (1/16) using SeV based delivery. The rearrangements were numerical and/or structural with chromosomes 5 and 12 as the most frequently involved chromosomes. We present herein the karyotypic aberrations in the iPSC lines including a duplication on chromosome 5q13-q33 that restricts a candidate region for growth advantage. Our results suggest that the use of integrative lentivirus confers a higher risk for cytogenetic abnormalities at early passages when compared to SeV based reprogramming. In combination, our findings expand the knowledge on acquired cytogenetic aberrations in iPSC after reprogramming and during culture.

PM13.22

A deletion at 4p15.2 and disruption of PITX2 gene due to pericentric inversion in a patient with Axenfeld-Rieger syndrome and developmental delay

Ž. Čiuladaitė, *E. Preikšaitienė, A. Utkus, V. Kučinskas;*
Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

Balanced rearrangements in patients with abnormal phenotype are often associated with cryptic microdeletion/microduplication or disruption of gene at the breakpoint. We report on a 2-year-old patient, a female, referred for genetic testing due to developmental delay and clinical features specific to Axenfeld–Rieger syndrome. It is long known that *PITX2* gene mutations, deletions or translocations involving *PITX2* or its surrounding genotypic landscape cause Axenfeld–Rieger syndrome.

Conventional karyotype of the patient revealed the presence of *de novo* pericentric inversion – inv(4)(p14q21~25). Array-CGH (1M) was performed and 2.4 Mb interstitial deletion at 4p15.2 was detected. FISH analysis using BAC FISH probes, RP11-118N21 (4p15.2) and RP11-313B13 (which encompasses the *PITX2* gene), confirmed the 4p15.2 deletion at the first breakpoint and indicated that the second chromosomal breakpoint at 4q25 was within or very close to the *PITX2* locus. The breakpoint at 4q25 directly interrupts *PITX2* gene structure or its regulatory elements and presumptively causes alteration of *PITX2* expression leading to clinical features of Axenfeld–Rieger syndrome. Haploinsufficiency of *DHX15* and/or *PPARGC1A* due to deletion at 4p15.2 may have contributed to manifestation of additional clinical features, as developmental delay, in the patient. To our knowledge, this is the first report of Axenfeld–Rieger syndrome, caused by pericentric inversion.

The work was funded by the Lithuanian-Swiss cooperation programme to reduce economic and social disparities within the enlarged European Union under project agreement No. CH-3-ŠMM-01/04, UNIGENE project and the World Federation of Scientists (Geneva, Switzerland) under the Lithuanian National Scholarship Programme.

PS13.23

Unsuspected diagnosis of Jacobsen syndrome in a patient with craniosinostosis surgically treated

P. Linares-Chavez[1], *J. Valdes-Miranda*[1], *M. Rivera-Vega*[1], *A. Perez-Cabrera*[1], *L. Gonzalez-Huerta*[1], *S. Cuevas-Covarrubias*[2];
[1]*Hospital General de Mexico, Mexico DF, Mexico,* [2]*Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.*

Partial deletions of the distal region of the long arm of chromosome 11 cause Jacobsen syndrome (JS). The breakpoints of deletion region occur around 11q23.3 and generally range from 7 to 20Mb. Occurrence of JS is 1 in 100,000 newborns with a female predominance. The cardinal clinical findings are growth retardation, intellectually disability, dysmorphism and thrombocytopenia/pancytopenia. Sometimes, systemic anomalies are found to be present. In general, the spectrum of the clinical manifestations depends on the size of the deleted region; however, a variable phenotype could be observed. Diagnosis is suspected on the basis of phenotype, but his must be confirmed by cytogenetic analysis or aCGH. The aim of the present study is to describe a patient with Jacobsen syndrome which underwent surgery to correct the craniosinostosis and had a heavy bleeding due to unsuspected diagnosis. Patient was a 18-months male, product of healthy, young and non-consanguineous parents. At birth, he presented dolichocephaly. At 5 months of age he underwent sagittal suturectomy presenting profuse bleeding. Physical

examination at 18 months of age revealed trigonocephaly, exotropia, reverse epicanto, high and narrow palate, micrognathia, right cryptorchidism and mild psychomotor retardation. Blood analysis reported normal platelet count with increased platelet volume. He again underwent surgery to correct craniosinostosis presenting hypovolemic shock. When the patient is referred to the Genetic Service it is detected a karyotype 46,XY,del(11)(q23) and an aCGH with a loss of 14.2 MB which corresponds to a Jacobsen syndrome. It is important to make an early diagnosis of patients with Jacobsen syndrome, in order to avoid complications during surgical procedures.

PM13.24
Karyotype is not dead (yet)!

L. Pasquier[1], *S. Odent*[1,2], *M. Fradin*[1], *H. Journel*[3], *E. Cherot*[1], *J. Lucas*[4], *M. Belaud-Rotureau*[4], *S. Jaillard*[4];
[1]*Rennes University Hospital - CLAD Ouest, Rennes, France,* [2]*CNRS UMR 6290 (IGDR), Université de Rennes 1, Rennes, France,* [3]*Service de Génétique, CH Vannes - CLAD Ouest, Vannes, France,* [4]*Cytogenetics Unit - Rennes University Hospital, Rennes, France.*

As array-comparative genomic hybridization (a-CGH) and high-throughput sequencing (exome) technologies have swiftly spread throughout the medical field, karyotype has gradually lost its leading role among genetic tests. For example, in case of a child with intellectual disability (ID), without any specific sign leading to a precise clinical diagnosis, several international guidelines recommend to start with a-CGH screening then go on with exome analysis. Generalized use of whole genome sequencing increases etiologic diagnoses rate up to 30% in case of ID. These technologies are definitely major steps in the etiological process of ID.
However, physicians have to deal with the lack of qualitative information of the genome. Especially, exome and a-CGH analysis fail to reveal chromosomal rearrangements because breakpoints are either located in introns or not associated with a gain or lost of genetic material. If theses quantitative technologies cannot easily identify chromosomal translocations or inversions which sometimes split a gene in two, karyotype does.
Here, we show 3 cases whose karyotype swiftly provided us the right diagnosis for a monogenic disease while gene molecular analysis had remained unsuccessful. When clinical diagnosis of a monogenic disease is suggested, the molecular analysis of the targeted gene may sometimes fail to identify the causal mutation. Then it could be very useful to carry out a karyotype in order to reveal a chromosomal rearrangement involving the targeted gene. If this gene is split in two confirmed by FISH, then the physician is not only able to confirm the causing disease but also to give the appropriate genetic counselling.

PS13.25
Investigating clinical impact and mechanism of formation of karyotypically balanced chromosomal rearrangements: the power of combining breakpoint mapping by mate-pair sequencing and copy number analysis by aCGH

A. C. S. Fonseca[1,2], *A. Bonaldi*[1], *M. Bak*[2], *K. T. Abe*[3], *N. Tommerup*[2], *A. M. Vianna-Morgante*[1];
[1]*Department of Genetics and Evolutionary Biology, University of São Paulo, São Paulo, Brazil,* [2]*Wilhelm Johannsen Centre for Functional Genome Research, Department of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark,* [3]*Sarah Network of Rehabilitation Hospitals, Brasilia, Brasília, Brazil.*

About 7% of karyotypically balanced chromosomal rearrangements (BCRs) are associated with developmental disorders (DD) due to gene or regulatory element disruption, cryptic imbalances on rearranged chromosomes and position effect. In this study we illustrate the power of mate-pair sequencing (MPS) and aCGH to investigate the clinical impact and to disclose the mechanisms of formation of BCRs in patients with DD. In our cohort of 43 BCRs (28 translocations, 10 inversions, five complex rearrangements), 180K aCGH revealed 32 likely pathogenic imbalances (2.2kb-6.6Mb) on rearranged chromosomes in 12 BCRs. Breakpoint mapping by MPS were performed in 27/43 BCRs. MPS expanded the number of breakpoints detected by karyotyping or aCGH from 114 to 162 (resolution <2kb). The 48 additional breakpoints were found in nine BCRs. The number of breakpoints/BCR ranged from 2-22; the five most complex BCRs (10-22 breaks) displayed hallmarks of *chromothripsis*. Gene disruption was observed in 25/27 BCRs: 10 BCRs disrupted known diseases genes or their regulatory region, and five others disrupted candidate genes. Overall pathogenic imbalances on rearranged chromosomes and/or disrupted known disease genes/regulatory regions were identified in 19/44 BCRs, proving the effectiveness of aCGH/MPS for genotype-phenotype correlations. Among 30 Sanger-sequenced breakpoint-junctions from 13 BCRs, five contained >45 nucleotide deletions; 19 breakpoint-junctions had <23 nucleotide insertions or deletions; six had no alterations. Micro-homology of 2-7 nucleotides were detected in 11/30 breakpoints-junctions; one breakpoint-junction had a 30 nucleotide homology. These findings implicate non-homologous (NHEJ) or microhomology-mediated (MMEJ) end joining mechanisms in the formation of these BCRs. Financial support: FAPESP.

PM13.26
Deep sequencing detects very low-grade somatic mosaicism in the unaffected mother of siblings with nemaline myopathy

N. Matsumoto, *E. Koshimizu, S. Miyatake;*
Yokohama City University, Yokohama, Japan.

When an expected mutation in a particular disease-causing gene is not identified in a suspected carrier, it is usually assumed to be due to germline mosaicism. We first report very low-grade somatic mosaicism in ACTA1 detected only by deep resequencing using next-generation sequencer in an unaffected mother of two siblings affected with nemaline myopathy of neonatal form. We identified a novel heterozygous mutation in ACTA1, c.448A>G (p.Thr150Ala), in the affected siblings. 3D structural modeling suggested this mutation may affect polymerization and/or actin's interactions with other proteins. Autosomal dominant inheritance with either parent being either a germline or somatic mosaic was mostly expected. Sanger sequencing identified no mutation. Further deep resequencing of this mutation by next-generation sequencer identified very low-grade somatic mosaicism in the mother: 0.4%, 1.1%, and 8.3% in saliva, blood leukocytes, and nails, respectively. Our study demonstrates the possibility of very low-grade somatic mosaicism existing in suspected carriers, instead of germline mosaicism.
Drs. Yukiko K. Hayashi, Kazushi Miya, Masaaki Shiina, Kazuhiro Ogata, Ichizo Nishino are highly appreciated for their contribution to this work.

Non-identical twins: miR-96-5p and miR-96-3p expression during mouse development

M. Robusto[1,2], *V. Massa*[3], *C. Chiereghin*[1,2], *E. Di Fede*[3], *R. Asselta*[1,2], *S. Duga*[1,2], **G. Solda'**[1,2];
[1]*Humanitas University, Rozzano (Milan), Italy,* [2]*Humanitas Clinical and Research Center, Rozzano (Milan), Italy,* [3]*Department of Health Sciences, Università degli Studi di Milano, Milan, Italy.*

Introduction. We previously reported a deafness-causing mutation within the MIR96 microRNA gene, miR-96(+57T>C), which alters the correct maturation of the miR-96 precursor and also affects the seed region of miR-96-3p (also called miR-96*). Although the function of miR-96-5p in the inner ear has been highly investigated, the biological role of its partner strand still remains unclear.
Methods and Results. We analyzed the expression pattern of both miR-96-3p and -5p in the developing mouse embryo (from 10.5 days post coitum to the end of gestation), using specific LNA probes for in-situ detection. Although both mature miRNAs were co-expressed in several tissues (neural tube, somites, and developing ear) a different spatio-temporal distribution between the -3p and -5p was found. To understand which factors may influence miRNA strand selection, we are currently combining miRNA in-situ hybridization and immunohistochemical staining for proteins involved either in miRNA biogenesis or in RNA interference (e.g. Ago1-4, TRBP). Finally, candidate miR-96-3p targets were predicted and are being functionally validated by ex-vivo assays.
Conclusions. For the first time, we report the highly specific and regulated pattern of expression of miR-96-3p during mouse development, suggesting both distinct and common roles compared to its partner miRNA.
We thank the University of Milan Departmental funds for Young Researchers (linea B), the Italian Telethon Foundation grant GGP11177, and the Fondazione Cariplo, grant no 2013-0825 for financial support.

UNCOMMON NUMERICAL CHROMOSOMAL ABNORMALITY: MOSAICISM 47, XY(+8)/ 47, XY (+21) Case report

C. M. Jurca[1], *K. Kozma*[1], *M. Bembea*[1], *O. Iuhas*[2], *C. Cladovan*[1], *A. Jurca*[1];
[1]*University from Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania,* [2]*Municipal Clinical Hospital „dr. Gavril Curteanu", Oradea, Romania.*

Introduction. Trisomy 8 is a rare numerical chromosomal abnormality characterized by the presence of additional chromosome 8. The complete form is fatal resulting in early death. Life expectancy in trisomy 8 mosaicism, in the absence of serious malformations is that of the general population. The incidence of trisomy 8 mosaicism is 1:25000-1:50000, more common in boys (5:1) although the explanation for this does not exist. Objectives. The authors present a case of numerical chromosomal abnormality. Method. Case report. Results. We present the case of a 5-month-old infant who presented at birth a plurimalformative syndrome characterized by craniofacial

dysmorphism, dermatoglyphic anomalies, bone abnormalities. Cytogenetic analysis revealed mosaicism 47, XY (8) / 47, XY (21). Conclusions. Very rare anomaly. Mosaicism trisomy 21 with trisomy 8 is rarely reported in the literature, only one case is reported.

PS13.29
Characterization of type-1 NF1 deletions

M. Hillmer[1], *V. Mautner*[2], *D. N. Cooper*[3], *H. Kehrer-Sawatzki*[1];
[1]*Institute of Human Genetics, University of Ulm, Ulm, Germany,* [2]*Department of Neurology, University Hospital Hamburg-Eppendorf, Hamburg, Germany,* [3]*Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom.*

Neurofibromatosis type 1 (NF1) is caused by mutations in the NF1 gene. In 5% of all NF1 patients large deletions encompassing the entire NF1 gene and its flanking regions are detected. The majority of these deletions span 1.4-Mb (type-1 NF1 deletions) and are characterized by breakpoints located within low-copy-repeats termed NF1-REPa and NF1-REPc. Previous studies have suggested that most type-1 NF1 deletion breakpoints cluster within hotspots of nonallelic homologous recombination (NAHR) termed PRS1 and PRS2, but a methodical analysis of breakpoint position in a large number of type-1 NF1 deletions has not so far been performed. The aim of our present study is to determine the precise breakpoint positions in 67 patients with type-1 NF1 deletions initially identified by MLPA in order to identify their breakpoints (sites of strand exchange) at the highest possible resolution. To do so, we performed SNP genotyping of paralog-specific PCR-products as well sequence analysis of breakpoint-spanning PCR-products. Our analysis indicates that 52 of the 67 type-1 NF1 deletions investigated harboured breakpoints within the 2-kb PRS2 hotspot. Only 12 deletions (18%) had breakpoints located within PRS1 whereas 3 deletions exhibited breakpoints that were located outwith PRS1 and PRS2. Our findings indicate that PRS2 is a very strong NAHR hotspot since it harbours 78% of all type-1 deletion breakpoints. The sequence analysis of the regions of strand exchange in all type-1 NF1 deletions promises to provide further information about recombination initiation sites and the processing of the recombination intermediates of type-1 NF1 deletions.

Nonsyndromic cleft lip and palate (nsCLP) is one of the most common birth defects and has a multifactorial etiology. In a recent meta-analysis we identified a risk locus on chromosome 13q31, with the top-associated variant mapping to a non-coding region (~210 kb upstream of *SPRY2*). Here, we indented to follow-up this GWAS finding by (i) identifying the putative causal SNP, (ii) functionally annotating the top-associated region and (iii) understanding the biological relevance that explains the genetic association *in vivo*. Based on imputation results, we identified rs1854110 to be the functional candidate SNP ($P_{imputing}$=1.96×10^{-11}, relative risk=1.38 (95% confidence interval: 1.19-1.60). This marker was found to be located in a putative regulatory enhancer element relevant for craniofacial development. We cloned this element, together with a conserved region shown to be an enhancer region in neural crest cells, into a Tol2-vector system. First results revealed that zebrafish embryos injected with the enhancer element show GFP expression in cephalic regions. In order to determine the exact nature of GFP-positive cells, further experiments using immunostaining with antibodies against neural crest cell-specific markers will be conducted.
Our study provides first hints towards a specific regulatory element at an nsCLP-associated risk locus detected by GWAS. Further studies are currently ongoing to confirm and follow-up the initial findings, including a quantitative luciferase assay for the risk allele. Our studies will provide deeper insights into the biological mechanism underlying nsCLP association on chromosome 13q31.

Duplication of SHANK3 gene in a case of schizophrenia associated with autism

A. Belengeanu[1], *C. Giurgi-Oncu*[1], *S. Farcas*[1], *D. Misceo*[2];
[1]*University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [2]*Department of Medical Genetics, Oslo University Hospital, University of Oslo, Oslo, Norway.*

The autistic spectrum is comprised of the Asperger syndrome, Heller syndrome, Rett syndrome, atypical autism, disorganized schizophrenia, as well as, although somewhere marginally placed, schizoid personality disorder and obsessive compulsive disorder.
We present a case of a 21 years old female with a psychopathological picture that consisted of: psychomotor agitation, a suicide attempt by defenestration, which was secondary to delusional ideation, auditory and visual hallucinations, anxiety, lack of insight, mixed insomnia. Our case, diagnosed with schizophrenia, also presents manifestations that are characteristic for autistic spectrum disorders. Based on her academic performances, our patient might have a superior than average intellect.
The result of the arrayCGH analysis showed genomic imbalances including several genes. From the list of deleted/duplicated genes, one that was previously reported in patients with psychotic disorders is the SHANK3 gene. ArrayCGH analysis for our case identified an 82.3 Kb duplication of chromosome 22q from 51.055.575-51.137.968 bp; this region encompassed the SHANK3. The patient's mother did not carry the duplication. The genetic analysis for father was not possible because he is deceased. Several papers have reported SHANK3 gene variants in autistic spectrum consisting of both copy number variants and point mutations.
The presence of three copies of the SHANK3 gene was reported in association with autistic spectrum disorders in other papers. These findings led to the idea that both haploinsufficiency, as well as an over-expression of the SHANK3 gene are associated with manifestations of autistic spectrum disorders and other neurobehavioral abnormalities.

PS13.33
Unbalanced translocation (X;13) as a cause of two diverse phenotypes in siblings due to duplication versus haploinsuficiency of SHOX gene and skewed inactivation pattern.

K. Adamová[1], *V. Curtisová*[1], *M. Godava*[1], *D. Černá*[2], *Z. Dobčáková*[3], *D. Grochová*[3], *P. Čapková*[1], *H. Filipová*[1];
[1]*Department of Medical Genetics, University Hospital and Palacky University, Olomouc, Czech Republic,* [2]*Department of Medical Genetics, University Hospital, Ostrava, Czech Republic,* [3]*Cytogenetic Laboratory Brno, Brno, Czech Republic.*

We report a male patient with an unspecific facial stigmatization, developmental delay, microcephaly and a tall stature. His G - banded karyotype was normal. FISH of subtelomeric regions revealed deletion in subtelomeric part of chromosome 13q and a duplication in Xpter. These findings were due to a balanced translocation (X;13) present in proband's mother.
Array CGH revealed that the Xp duplication spans 3.5 Mb and contains 27genes from OMIM database including SHOX gene. The deletion on 13q spans 5 Mb and contains 19 genes from OMIM database.
We performed FISH examination of proband´s apparently healthy sister and revealed the deletion of SHOX gene region (Xp22.3) and a duplication of 13qter. Haploinsuficiency of SHOX gene resulted in previously undiagnosed Léri-Weill syndrome (short stature, mesomelia of upper limbs and Madelung's deformity of the wrists). Because of the skewed inactivation pattern with silencing of the derived X chromosome there was no impact of the partial trisomy 13q.

PM13.34
Chromosomal rearrangements in the 11p15 imprinted region: sixteen new 11p15.5 duplications with associated phenotypes and putative functional consequences

S. Heide[1], *S. Chantot-Bastaraud*[1], *B. Keren*[2], *F. Brioude*[3], *S. Azzi*[3], *S. Rossignol*[3], *J. Siffroi*[1], *Y. Lebouc*[3], *I. Netchine*[3];
[1]*Cytogenetics, Armand Trousseau Hospital, APHP, Paris, France,* [2]*Cytogenetics, Pitié Salpêtrière Hospital, APHP, Paris, France,* [3]*Pediatric Endocrinology, Armand Trousseau Hospital, APHP, Paris, France.*

The 11p15.5 imprinted region contains two clusters of genes which play an important role in prenatal and postnatal growth and which are controlled by two imprinting centers, ICR1 (Imprinting Control Region 1) and ICR2 (Imprinting Control Region 2).
Opposite genetic and epigenetic anomalies of this region result in two distinct syndromes with growth disturbance: Beckwith-Wiedemann syndrome (BWS, MIM #130650), characterized by overgrowth and Silver-Russell syndrome (SRS, MIM #180860), characterized by growth retardation.
Cytogenetic anomalies are rare in both syndromes and represent less than 3% of SRS or BWS. Large duplications encompassing the two imprinting centers have already been described as associated with SRS or BWS, depending on the parental origin of the duplication. However, smaller Copy Number Variants (CNV), encompassing totally or partially one or another of the imprinting centers have only been recently reported. These CNV are

sometimes difficult to interpret and require the help of clinical features and methylation profile.
We report here 16 new SRS or BWS patients with 11p15 microduplication encompassing either both domains ICR1 and ICR2, either one of them or only part of one of them, and discuss the possible functional consequences of the rearrangements after a review of the literature.

PS13.35
Mosaic patterns can be missed by SNP array because of absence of heterozygosity in the normal cells

B. Leegte, *P. Rump, B. Sikkema - Raddatz, M. Benjamins, T. Dijkhuizen, R. Sinke;*
Department of Genetics, Groningen, Netherlands.

Introduction: SNP array allows the integration of genotype and copy number information, which permits the simultaneous detection of (low-level mosaic) copy number variations, consanguinity and UPD in cases of isodisomy. We report on a case where a mosaic pattern was missed by SNP array due to the absence of heterozygosity in the normal cells.
Case presentation: Array analysis of non-consanguineous parents was performed because the array result of their child showed a terminal deletion of at least 4.3 Mb in 6q27 (chr6: 166,863,544-qter). An Illumina Omni Express 850K was used for the trio analysis and the mother showed the same deletion. While the mother is healthy, the child presented with moderate developmental delay, autism and delay of motor skills. Distal 6q deletions have been described in literature and the patients' main characteristics are intellectual disability, hypotonia, seizures, brain anomalies and specific dysmorphic features. At least part of the clinical features of the child can be explained by this deletion. Because the mother has no phenotypic features we considered a mosaic pattern for the deletion. Therefore we performed FISH resulting in detection of the deletion in 49 of the 100 analyzed metaphases indicating that the mother is indeed a mosaic carrier for the deletion.
Conclusion: The reason we missed the mosaic pattern and only detected the deletion must have been caused by the absence of heterozygosity of the critical region. Therefore, we recommend FISH analysis in case a healthy carrier has a deletion to detect a possible mosaic pattern.

PM13.36
Non-sequential and multi-step splicing of the dystrophin transcript

I. Gazzoli, *I. Pulyakhina, N. Verwey, Y. Ariyurek, J. F. J. Laros, P. A. C. 't Hoen, A. Aartsma-Rus;*
Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands.

The long (2.2Mb) human dystrophin transcript (DMD) takes 16 hours to be transcribed and is co-transcriptional spliced. The presence of long introns (24 over 10kb long, 5 over 100kb long) poses challenges to the splicing machinery. Additionally, the heterogeneity in intron size suggests that intron removal not always takes place consecutively. Here, we explored the order of intron removal and potential multi-step splicing for the DMD transcripts in human skeletal muscle cell lines. A customized library of probes covering all exons and introns, has been generated capturing pre-mRNA and targeting DMD, followed by Hiseq sequencing. We developed a new pipeline (SplicePie) to analyze capture-pre-mRNA-sequencing data. Analysis showed that DMD introns can be removed non-sequentially generating exon blocks - joined blocks of exons flanked by unspliced introns. Exon blocks were detected by analysis of the coverage of paired-end reads and validated experimentally using PCR and Sanger sequencing. No correlation between intron length and speed of intron removal was observed. Computational analysis and experimental validation revealed that intron removal takes place in several steps for the majority of dystrophin introns. We found two mechanisms of multi-step intron removal in DMD- recursive and nested splicing. Non-sequential and multi-step splicing events were found throughout the DMD gene across three cell lines. We believe that our findings of non-sequential and multi-step splicing provide insight in the splicing mechanism and will be useful to optimize therapeutic strategies that interfere with the splicing process.

PS13.37
Non-mosaic structural chromosome rearrangements predisposing to larger mosaic ones: evidences for the existence of locus-specific constitutional chromosome instability

I. Y. Iourov[1,2,3], *S. G. Vorsanova*[1,2,4], *M. A. Zelenova*[1,2,4], *A. D. Kolotii*[1,2], *I. A. Demidova*[1,2,4], *V. S. Kravets*[1,2], *M. L. Gordeeva*[2], *Y. B. Yurov*[1,2];
[1]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [2]*Russian National Research Medical University named after N.I. Pirogov, Separated Structural Unit "Clinical Research Institute of Pediatrics", Ministry of Health of Russia, Moscow, Russian Federation,* [3]*Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation,* [4]*Moscow City University of Psychology and Education, Moscow, Russian Federation.*

The origins of somatic genome variations manifesting as structural chromosomal rearrangements remain largely unknown. However, it is generally accepted that susceptibility to structural chromosome aberrations can be produced by alterations to DNA sequences flanking the breakpoints or to rearranged chromosomal regions (i.e. CNV). Addressing genome variations in children with intellectual disability, autism, epilepsy and/or congenital malformations (n=200) by high-resolution CNV analysis (molecular karyotyping; resolution: 1 kbp or higher), we have surprisingly found that somatic structural chromosome abnormalities can co-occur with non-mosaic ones within the same loci. More precisely, we detected 8 cases (4%) (4 duplications and 4 deletions) demonstrating small non-mosaic structural chromosome rearrangements encompassed by larger mosaic ones. The duplications were mosaic dup3p26.3p26.1 (5.8 Mb) vs. regular dup3p26.1 (2.9 Mb); mosaic dup14q32.13q32.2 (4.5 Mb) vs. regular dup14q32.2 (1.8 Mb); mosaic dup17p13.1p11.2 (6.9 Mb) vs. regular dup17p12 (1.4 Mb); mosaic dup18p11.32p11.31 (5.3 Mb) vs. regular dup18p11.32p11.31 (4.8 Mb). The deletions were mosaic del5q35.1q35.3 (9.2 Mb) vs. regular del5q35.2q35.3 (2.3 Mb); mosaic del14q11.2 (2.2 Mb) vs. regular del14q11.2 (0.5 Mb); mosaic del15q13.1q14 (8.2 Mb) vs. regular del15q13.2q13.3 (2 Mb); mosaic delXp22.32p22.2 (4.7 Mb) vs. regular delXp22.31 (0.7 Mb). These findings allowed us to hypothesize small regular structural variations (CNV) to be able to produce locus-specific constitutional chromosome instability resulting in larger somatic rearrangements. Our speculations are also supported by previous communications reporting specific local genomic changes to underlie common microdeletions/microduplications at several of the aforementioned loci. Supported by Russian Scientific Fund (Grant #14-15-00411).

PM13.38
Utilising CRISPR/Cas9 genome editing to validate novel genes associated with telomere length in humans

N. F. Shamkhi, *P. Jones, M. A. Kaiser, N. J. Samani, V. Codd, T. R. Webb;*
University of Leicester, Leicester, United Kingdom.

Introduction: Telomere length (TL) shortens with each round of cell division due to the inability of DNA polymerase to fully replicate the 3' end of the DNA. TL is therefore regarded as a marker of cellular age and has been proposed as a marker of biological ageing. Shorter mean leukocyte TL has been shown to be associated with several age-related diseases. GWA studies have identified seven loci that associate with telomere length in humans. Of these loci, five contain genes with known roles in telomere biology (TERC, TERT, NAF1, OBFC1, RTEL1) but the remaining two do not, therefore potentially identifying novel genes involved in telomere length determination in humans. In order to investigate this we have employed a CRISPR/Cas9 genome editing approach to explore the function of genes within one of these loci (ACYP2/TSPYL6) with respect to telomere length maintenance.
Materials and methods: We have used the CRISPR/Cas9 system to knockout ACYP2 and TSPYL6 as well as telomerase reverse transcriptase (TERT) as a positive control in human induced pluripotent stem cells. Lines have undergone multiple passages and TL is currently being measured by Q-FISH and qPCR.
Results: We have successfully created knock-out lines for ACYP2, TSPYL6 and TERT individually as well as ACYP2/TERT and TSPYL6/TERT double knock outs. We will present preliminary data on telomere length maintenance in these lines.
Conclusions: We have utilised the CRISPR/Cas9 genome editing system as a means of investigating the role of novel genes in the control of telomere length in humans.

The t(8;22)(q24.13;q11.2) has been identified as one of several recurrent constitutional translocations mediated by palindromic AT-rich repeats (PATRRs). Although the breakage on 22q11 utilizes the same PATRR as that of the more prevalent constitutional t(11;22)(q23;q11.2), the breakpoint regi-

on on 8q24 has not been elucidated in detail since the analysis of palindromic sequence is technically challenging. In this study, the entire 8q24 breakpoint region has been resolved by next generation sequencing. Eight polymorphic alleles were identified and compared with the junction sequences of previous and two recently identified t(8;22) cases . All of the breakpoints were found to be within the PATRRs on chromosomes 8 and 22 (PATRR8 and PATRR22), but the locations were different among cases at the level of nucleotide resolution. The translocations were always found to arise on symmetric PATRR8 alleles with breakpoints at the center of symmetry. The translocation junction is often accompanied by symmetric deletions at the center of both PATRRs. Rejoining occurs with minimal homology between the translocation partners. Remarkably, comparison of der(8) to der(22) sequences shows identical breakpoint junctions between them, which likely represent products of two independent events on the basis of a classical model. Our data suggest the hypothesis that interactions between the two PATRRs prior to the translocation event might trigger illegitimate recombination resulting in the recurrent palindrome-mediated translocation.
These studies were supported by a grant-in-aid for Scientific Research from the Ministry of Education, Culture, Sports, Science, and Technology of Japan.

PM13.40
Down syndrome caused by mirror duplication of chromosome 21 : conventional cytogenetic, FISH and array CGH

T. Dery[1], *A. Receveur*[1], *N. Chatron*[2], *G. Morin*[3], *M. Benkhalifa*[1], *D. Sanlaville*[2], *G. Jedraszak*[1,3], *F. Jobic*[1], *H. Copin*[1];
[1]*Service de Médecine et Biologie de la Reproduction, Cytogénétique et CECOS de Picardie CHU d'Amiens & Université de Picardie Jules Verne, Amiens, France,* [2]*Laboratoire de Cytogénétique Constitutionnelle, Hospices Civils de Lyon, Lyon, France,* [3]*Centre d'Activité de Génétique Clinique et Oncogénétique, CHU d'Amiens, Amiens, France.*

Down syndrome (DS) is a well-known syndrome; the frequency is about 1 in 2000 live births. The most common form (95%) is due to an extra copy of chromosome 21 in all cells, in 2% of the cases the trisomy is a mosaism, and 2% present with robertsonian translocation. In the last 1%, it is due to a structural abnormality in the 21q22 region.
However a rare variant is the duplication of the chromosome 21 with mirror duplication (reverse tandem). It is characterized by partial duplication and partial deletion of chromosome 21.
Here, we report the case of a child with typical DS features. At birth, we performed standard karyotype which showed that she carried mirror duplication of the chromosome 21.
An array comparative genomic hybridization was performed to define exactly the triplication and to highlight a possible monosomy. It showed a duplication of 29,9 Mb of the region 21q11.2q22.3 and a deletion of 2,8Mb of the region 21q22.3. The couple has been through 3 miscarriages.
After the birth of their third child, the analyses were completed in order to highlight a paracentric inversion or other chromosomal rearrangement in chromosome 21 in the parents' karyotype.
After such a karyotype for the children and the antecedent of miscarriages for the couple, it is necessary to go further in the analysis, and to look for chromosomal rearrangement in the karyotypes of the parents. This can explain that association of duplication deletion, and adjust the genetic counselling.
Furthermore the description of those trisomies 21 with duplication deletion helps to refine a genotype-phenotype correlation.

PS13.41
X-linked ichthyosis in a patient with a novel nonsense mutation in the STS gene.

M. Murillo[1], *J. Toral-Lopez*[2], *L. Gonzalez-Huerta*[1], *M. Rivera-Vega*[1], *S. Cuevas-Covarrubias*[3];
[1]*Hospital General de Mexico, Mexico DF, Mexico,* [2]*Centro Médico Ecatepec, ISSEMYM, Ecatepec, Mexico,* [3]*Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.*

X-linked recessive ichthyosis (XLI) is a genodermatosis due to steroid sulfatase deficiency. XLI is characterized by dark, adhesive, polygonal and regular scales and presents a frequency of 1 in 2000-6000 males. Ninety percent of XLI patients have deletions of the entire STS gene and flanking sequences; currently, 14 point mutations and seven partial deletions have been reported worldwide. The aim of the present study is to describe the STS gene in a patient with X-linked ichthyosis and a mild phenotype. XLI diagnosis was confirmed through steroid sulfatase assay in leukocytes. Genomic DNA was extracted through conventional methods. Exons 1-10 of the STS gene were analyzed by polymerase chain reaction and DNA sequencing analysis. XLI proband had undetectable levels of STS activity. The DNA sequence analysis showed a novel nonsense mutation on 3 exon of the STS gene producing a stop codon. This data enriches the mutational spectrum of the STS gene in XLI patients and remarks the variability in the phenotypic spectrum independently of the molecular defect.

Background. Effective platelet inhibition has become a cornerstone in the management of patients with acute coronary syndromes (ACS). The current standard of care includes dual antiplatelet therapy with aspirin, and one of the three currently available ADP P2Y12 inhibitors: clopidogrel, prasugrel and ticagrelor. We used a novel point-of care lab-on-chip tool in order to genotype patients experiencing ACS to identify the carriers of the ABCB1 3435, CYP2C19*2 and CYPC2C19*17 alleles and so assessing a pharmacological approach incorporating these genetic variants.
Methods and Results. Between October 2013 and January 2015, 800 patients were enrolled into a two-armed, single blind, randomized controlled trial assessing the clinical usefulness of adding pharmacogenomic data on top of clinical variables when choosing dual antiplatelet treatment. In the pharmacogenomic arm, genotyping was done at the patients' point-of-care by means of a newly developed portable real-time PCR system (Q3) by scoring the CYP2C19*2, CYP2C19*17 and ABCB1 3435 alleles in a turnaround time of 70 min from DNA extraction to final genotype calls. When compared to other gold-standard conventional laboratory genotyping techniques, the newly developed system showed 100% concordance.
Conclusions. The Q3 system proved to be as reliable as the current available techniques. Genotyping in the ACS setting should not be delegated to centralised clinical laboratories for matter of time however the genotyping at the patients' bedside represents the opportunity to realise large, randomized trials in order to assess the clinical improvement of adding genotype data (gathered bed-side) to the classical clinical variables for the outcomes of patients with ACS.

As next generation sequencing evolves, the ability to create reproducible, high quality libraries becomes increasingly important. The Ion AmpliSeq™ method has proven useful to reliably generate quality libraries from as little as 10 ng of nucleic acid. We developed the Ion Chef system to offer an automated solution for templating and sequencing chip preparation. Here we demonstrate the marriage of Ion AmpliSeq™ reagents with the Ion Chef system to create a fully automated library preparation solution. This system includes a new set of consumables and software to enable DNA to loaded chip in less than 24 hours with only two touch points. Eight Ion AmpliSeq libraries can be prepared in less than 7 hours with less than 15 minutes of hands on time. Using an 8000 amplicon targeted cancer panel we observe >95% uniformity for all 8 samples, which compares favorably to manually prepared libraries. Additionally, using Equalizer™ normalization we observe highly reproducible barcode balance with less than 10% CV between libraries. We have seen similar high performance with a variety of panels ranging from 50 to 25,000 amplicons from high quality genomic DNA as well as FFPE DNA. With the pushbutton automation of Ion AmpliSeq™ library preparation, we boast the first NGS system with a fully automated workflow from sample to answer.

M. Seri[3], G. La Manna[2], V. Mantovani[1,3];
[1]Center for Applied Biomedical Research (CRBA), S.Orsola-Malpighi University Hospital, Bologna, Italy, [2]Department of Experimental, Diagnostic and Specialty Medicine (DIMES), Nephrology Dialysis and Transplantation Unit, S.Orsola-Malpighi University Hospital, Bologna, Italy, [3]Medical Genetics Unit, S. Orsola-Malpighi University Hospital, Bologna, Italy, [4]Department of Biological, Geological and Environmental Sciences, Laboratory of Molecular Anthropology, Bologna, Italy, [5]Centre for Genome Biology (CGB), University of Bologna, Bologna, Italy, [6]Department of Pediatrics, Pediatric Nephrology and Dialysis Unit, S.Orsola-Malpighi University Hospital, Bologna, Italy.

Introduction: Autosomal recessive polycystic kidney disease is characterized by cysts development in the collecting ducts often associated with hepatic involvement and it is caused by mutations in *PKHD1* gene. Due to the large size of this gene the conventional mutation screening is time-consuming and expensive, so that a molecular diagnosis is often missed.
Materials and Methods: A NGS method for screening of *PKHD1* gene based on Ion Torrent platform was developed and validated in this study. 26 subjects were submitted to our NGS protocol, 14 with known mutations in *PKHD1* gene and 12 without a molecular characterization.
Results: Our NGS method allowed to detect all the mutations previously identified by conventional sequencing. Additional mutations were also identified, providing more information about the carrier status or completing the molecular characterization in probands. All additional or newly detected variants were confirmed by Sanger sequencing. Our NGS approach allowed to identify the mutations also in all the not yet tested subjects. During our analysis 17 previously undescribed variants were detected, contributing to extend the spectrum of known mutations in *PKHD1* gene.
Conclusions: This method resulted accurate, robust and more sensitive than the conventional sequencing, with a considerable reduction of work times and costs. Although it will be necessary to test more patients, our study is a proof of concept showing the feasibility of our NGS protocol for diagnostic purpose, improving and accelerating molecular diagnosis and genetic counseling for families.

PM14.004

Revisiting previously classified Copy Number Variants - Is it worthy for management of clinical strategy?

J. B. Melo, *P. Cruz, S. I. Ferreira, L. M. Pires, N. Lavoura, A. Mascarenhas, A. Jardim, I. M. Carreira;*
Cytogenetics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Microarray-based comparative genomic hybridization (array-CGH) allows the possibility to screen the whole genome at once and with high resolution, allowing the detection of Copy Number Variants (CNVs). Taking into account the existence of known syndromes, relevant genes for the phenotype and CNVs in healthy population, we have proposed the classification of CNVs into different classes: Class I are deletions/duplications in regions associated with a syndrome; Class II are deletions/duplications not reported in normal subjects and involving known coding genes; Class III are /duplications reported in low frequency in normal subjects or not involving genes; Class IV are deletions/duplications reported in healthy subjects -common variants.
We have revisited 250 cases with intellectual disability and/or Autism spectrum disorders, analyzed by oligonucleotide array-CGH (Agilent 4x180K platform) from 2011 and 2012 in order to evaluate if the observed CNVs would be reclassified according to the update of databases.
In~70% of the reviewed cases there were no changes in the CNVs' classification. In the other ~30% of cases: 1 classification changed from Class II to I, 10 from II to IIIA, 5 from II to IV, 17 from IIIA to IV, 3 from IIIB to IIIA, 45 from IIIB to IV. About 95% of the classification changes made reduced the probability of the imbalance being responsible for the phenotype.
Although progress and knowledge have improved the content of databases, the findings of this revision have not changed the clinical strategy neither the management of patients. We can conclude that our CNV classification system is robust.

PS14.005

High-resolution array CGH analysis of patient samples in the Deciphering Developmental Disorders study.

E. Prigmore, *D. Rajan, N. Krishnappa, D. Barrett, L. Mason, S. Gribble, K. Ambridge, T. Bayzetinova, A. Tivey, S. Clayton, T. Fitzgerald, P. Jones, R. Miller, C. Wright, M. Hurles;*
The Wellcome Trust Sanger Institute, cambridge, United Kingdom.

One of the aims of the DDD project was to perform array CGH analysis on a large cohort of child patient samples using a 2x 1 million feature Agilent microarray. A high-throughput pipeline was established to carry out this analysis.
Patient DNA was derived from blood or extracted in house from saliva. Saliva samples were collected using Oragene kits and DNA was extracted using a QiaSymphony robot. For array CGH analysis samples were fluorescently labeled using an Agilent commercial kit and a BRAVO robot. Samples are combined with a reference DNA (pooled DNA from 500 male blood donors) and hybridized for 3 nights in batches of 24. The arrays were then washed in batches of 8 using a Little Dipper wash station. Arrays were scanned using an Agilent G2565CA scanner, and the data extracted using Feature Extraction 10.5. Arrays were handled in a humidity, temperature and ozone controlled environment. 95 patient samples were processed within 10 days. An in house LIMS tracked samples through the pipeline.
We have analysed over 1000 normal control samples, generating a control data set to aid interpretation of patient data. We have now processed ~7,700 DDD patient samples. Patient DNA samples typically produce a median DLRs value of 0.17. Copy number changes are detected using an in house analysis pipeline and the inheritance status evaluated by comparison with exome CNV data. Variants identified were assessed in attempt to identify the cause of the child's developmental disorder.
Health Innovation Challenge Fund (HICF-1009-003), a funding partnership between the Wellcome Trust (WT090851) and the UK Department of Health.

An efficient NGS tool for cascade genetic screening of Familial Hypercholesterolaemia

P. Couvert[1,2,3], A. Coiffard[1], A. Rotthier[4], S. Larrreur[1], L. Heyrman[4], J. Lacorte[1,2,3], J. Del-Favero[4], **A. Carrié**[1,2,3];
[1]Hôpital Pitié-Salpêtrière, Service de Biochimie Endocrinienne et Oncologique, APHP, Paris, France, [2]Institute of Cardiometabolism and Nutrition, Paris, France, [3]Université Pierre et Marie Curie 06, Unité Mixte de Recherche_S 1166, Paris, France, [4]Multiplicom N.V, Niel, Belgium.

Introduction Familial hypercholesterolemia (FH) is a common autosomal-dominant disorder caused by mutations in known genes (LDLR, APOB or PCSK9). In addition, APOE may be considered as the 4th locus of autosomal-dominant hypercholesterolemia (ADH) and the main modifier-gene of FH and cardiovascular risk. Cascade screening of FH using genetic testing for ADH has been suggested by international guidelines but a proportion of patients may have a polygenic cause which could compromise the efficiency of cascade testing. Recently Talmud et al. described a polygenic score that helps identifying the polygenic contribution in FH. We have developed a NGS tool combining the detection of monogenic as well as polygenic forms of FH.
Materials and Methods Complete coding regions of LDLR, PCSK9 and APOE, and a specific region (c.10200 to c.11100) of APOB are amplified, generating 65 amplicons in 4 multiplex PCR reactions (ADHMASTR kit developed in collaboration with Multiplicom). Ten control fragments are added for the detection of Copy Number Variations (CNV). A fifth plex was added corresponding to fragments containing the 12 SNPs used for the polygenic score.
Results Multiplexed PCR products of 96 patients are sequenced in each MiSeq run (V3 chemistry). Bioinformatic analysis allowed us to detect point mutations in the 4 genes analyzed as well as CNV. In FH patients without identified mutation, the polygenic score was calculated to classify them as of polygenic origin.
Conclusions We have developed an efficient and cost-effective NGS tool allowing the detection of monogenic and polygenic forms of FH. This kit is well adapted to high-throughput cascade screening of ADH.

Diagnostic value of methylation analysis by pyrosequencing in Beckwith-Wiedemann and Silver-Russell syndromes

A. Koparır, *M. Seven, E. Fenercioglu, H. Ulucan;*
Istanbul University Cerrahpasa Medical School, Istanbul, Turkey.

Beckwith-Wiedemann syndrome (BWS) and Silver-Russell syndrome (SRS) are characterized by opposite clinical findings. Main features of BWS are pre-postnatal macrosomia, macrogglossia, ear crease and/or pits, visceromegaly, abdominal wall defects, hemihyperplasia and increased risk for embryonic tumors. In contrast to these findings, SRS is characterized by pre-post natal growth retardation.
BWS and SRS are associated with epigenetic alterations of chromosome 11p15.5. Cytogenetical methods can identify alterations of chromosome 11p15.5 in fewer than 1% BWS patients. The rate to detect epigenetic alterations of chromosome 11p15.5 in BWS patients by molecular methods is 75-80%. 50% of SRS patients can be diagnosed genetically by demonstrating epigenetic alterations of chromosome 11 and 7. Methylation-spesific Multiplex Ligation-Dependent Probe Amplification (MS-MLPA) is being used efficiently in a few laboratories to detect epigenetic alterations. In recent studies, methylation specific pyrosequencing (MS-pyrosequencing) was performed to confirm clinical diagnosis of BWS and SRS patients and

it was suggested to be more powerful than MS-MLPA. The purpose of our study is to demonstrate the diagnostic value of MS-pyrosequencing in our BWS and SRS patients.

PM14.008

Validation of the Beta-Thal Modifier StripAssay: A novel test predicting disease severity of beta-thalassemia

H. Puehringer[1], *S. Pissard*[2], *P. Joly*[3], *B. Rauscher*[1], *C. Oberkanins*[1], *C. Badens*[4];
[1]*ViennaLab Diagnostics GmbH, Vienna, Austria,* [2]*Département de Génétique, GHU Henri Mondor, Créteil, France,* [3]*Laboratoire de Biochimie et Biologie Moléculaire, Hôpital Edouard Herriot, Lyon, France,* [4]*Laboratoire de Génétique Moléculaire, Hôpital d'Enfants de la Timone, Marseille, France.*

Background: The clinical phenotype of patients with beta-hemoglobinopathies is extremely heterogenous, ranging from nearly asymptomatic forms of thalassemia intermedia to severe transfusion dependent thalassemia major. The wide phenotypical variability is associated with the type of beta-globin mutation, the coinheritance of alpha-thalassemia and the ability for persistent production of fetal haemoglobin (HbF) in adult life. Three major quantitative trait loci, accounting for 20-50% of HbF variation, have been identified by now. Single nucleotide polymorphisms in the gamma-globin gene promoter (*HBG2*), in the *BCL11A* gene and *HBS1L-MYB* intergenic region contribute to the calculation of the Thalassemia Severity Score (TSS), a free web-based tool (http://tss.unica.it/home/#.VNNSCS7CT2c) for the prediction of clinical severity.
Methods: We developed a teststrip-based reverse-hybridisation assay for the simultaneous detection of polymorphisms in quantitative HbF loci: *Xmn*I (g.-158 C>T, rs7482144) in *HBG2*, rs1427407 and rs10189857 in *BCL11A*, and rs28384513 and rs9399137 in the *HBS1L-MYB* region. A total of 75 pretyped samples were retested in three different French thalassemia centers for assay validation.
Results: StripAssay results were 100% concordant with genotypes previously obtained by reference methods in the three participating laboratories. The Beta-Thal Modifier StripAssay quickly and correctly identifies disease modifying alleles and thus supports the use of TSS for the prediction of patients likely to display less severe phenotypes.
Conclusions: Testing for genetic modifiers allows a more specific and effective treatment and may also support clinical decisions regarding the onset of transfusion therapy in beta-thalassemia patients. Furthermore, the knowledge about prognostic markers could find an implication in the future, in genetic counselling and prenatal diagnosis.

Bisulfite conversion of DNA: performance comparison of different kits and methylation quantitation of epigenetic biomarkers used in Non-invasive Prenatal Testing

C. A. Leontiou[1], *M. D. Hadjidaniel*[1], *P. Mina*[1], *P. Antoniou*[2], *M. Neophytou*[1], *A. Keravnou*[1], *K. Tsangaras*[1], *S. Stylianou*[1], *M. Ioannides*[1], *P. C. Patsalis*[1,3];
[1]*The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus,* [2]*NIPD Genetics Ltd, Nicosia, Cyprus, Nicosia, Cyprus,* [3]*The Ministry of Health, NIcosia, Cyprus.*

Epigenetic alterations, including DNA methylation, play an important role in the regulation of gene expression. Several methods exist for evaluating DNA methylation but bisulfite sequencing is the gold standard. The challenge of the method is that the desired outcome (conversion of unmethylated cytosines) positively correlates with the undesired side effects (DNA degradation and inappropriate conversion), thus several commercial kits try to adjust a balance between the two. Here, we compared the performance of four bisulfite conversion kits [Premium Bisulfite kit (Diagenode), EpiTect Bisulfite kit (Qiagen), MethylEdge™ Bisulfite Conversion System (Promega) and BisulFlash DNA Modification kit (Epigentek)] regarding conversion efficiency, DNA degradation and conversion specificity.

Performance was tested by combining fully methylated and unmethylated λ-DNA controls in a series of spikes and we assessed them by Sanger sequencing (0%, 25%, 50% and 100% methylated) and Next-Generation Sequencing (0%, 3%, 5%, 7%, 10%, 25%, 50% and 100% methylated).

We also studied the methylation status of two of our previously published differentially methylated regions (DMRs) at base resolution by using spikes of CVS in whole blood. The kits showed different but comparable results regarding DNA degradation, conversion efficiency and conversion specificity. However, the best performance was observed with the MethylEdge™ Bisulfite Conversion System (Promega) followed by the Premium Bisulfite kit (Diagenode). The DMRs were confirmed to be hypermethylated in the CVS and hypomethylated in whole blood. Finally, we showed that bisulfite amplicon sequencing is a suitable approach for methylation analysis of targeted regions.

Molecular inversion probe based BRCA1/2 re-sequencing in a clinical setting

M. Nelen*[1], *A. Mensenkamp*[1], *M. Kwint*[1], *M. Tychon*[1], *H. Ouchene*[1], *E. Boyle*[2], *B. Martin*[2], *B. O'Roak*[2], *K. Neveling*[1], *J. Shendure*[2], *A. Hoischen**[1], *M. Ligtenberg**[1];
[1]*Radboud UMC, Nijmegen, Netherlands,* [2]*University of Washington, Seatle, OR, United States.*

Mutations in BRCA1 and BRCA2 confer high risks of hereditary breast and ovarian cancer. Over the years capillary Sanger sequencing and MLPA were used to detect causal variants in breast cancer families. Next generation sequencing technologies allowed implementing new strategies thereby reducing costs without losing sensitivity. Today sequencing costs of targeted NGS-based sequencing strategies are largely determined by enrichment procedures. Molecular inversion probes (MIPs) have shown to be a cost-effective enrichment used in multiplex, particularly if used in large cohorts. Here we present a workflow of re-sequencing BRCA1 and BRCA2 using single molecule molecular inversion probes (smMIP) in combination with NexSeq500 sequencing. The strategy involves the analysis of all coding exons and their flanking intronic sequences. We designed 402 overlapping smMIPs on both strands avoiding known SNPs in probe binding sites. Every base was targeted by at least two independent smMIPs. This yielded 100% coverage of all targeted bases. Next all BRCA1 and BRCA2 positive cases in our laboratory from 01/2010 till 07/2014 were sequenced for both genes, these were 103 BRCA1 and 71 BRCA2 disease causing mutations. All disease causing mutations and all known polymorphisms in both genes were detected, including one SNP that was missed using capillary sequencing due to allelic dropout. No false positives were reported.
In conclusion, targeted BRCA1 and BRCA2 re-sequencing using smMIPs shows high sensitivity and specificity and can replace sequencing workflows in a clinical setting. smMIPs allow low enrichment costs per sample and highly scalable workflows.

Next-generation sequencing of the BRCA1 and BRCA2 genes for the genetic diagnostics of hereditary breast and/or ovarian cancer

D. Trujillano, *M. Weiss, J. Schneider, J. Köster, E. Papachristos, V. Saviouk, T. Zakharkina, N. Nahavandi, L. Kovacevic, A. Rolfs;*
Centogene AG, Rostock, Germany.

Genetic testing for hereditary breast and/or ovarian cancer (HBOC) mostly relies on laborious molecular tools that use Sanger sequencing to scan for mutations in the BRCA1 and BRCA2 genes. We have explored a more efficient strategy based on next-generation sequencing (NGS) of the BRCA1 and BRCA2 genes in 210 (HBOC) patients. We first validated this approach in a cohort of 115 samples with previously known BRCA1 and BRCA2 mutations and polymorphisms. Genomic DNA was amplified using the Ion AmpliSeq™ BRCA1 and BRCA2 panel. The DNA Libraries were pooled, barcoded and sequenced using an Ion Torrent PGM sequencer. The combination of robust bioinformatics tools allowed us to detect all previously known pathogenic mutations and polymorphisms in the 115 samples, without detecting spurious pathogenic calls. The assay achieved a sensitivity of 100% (95% CI: 99.71% to 100%), with a specificity of detecting non-variant sites from the reference sequence of 99.99% (95% CI: 99.99% to 100%), a positive predictive value of 91.17% (95% CI: 89.72% to 92.62%), and a negative predictive value of 100% (95% CI: 100% to 100%). We then used the same assay in a discovery cohort of 95 uncharacterized HBOC patients for BRCA1 and BRCA2. In addition, we describe the allelic frequencies across 210 HBOC patients of 74 unique definitely and likely pathogenic, and uncertain BRCA1 and BRCA2 variants, some of them not previously annotated in the public databases. Targeted NGS is ready to substitute classical molecular methods to perform genetic testing on the BRCA1 and BRCA2 genes, and provides a greater opportunity for more comprehensive testing for at-risk patients.

PM14.012

A comparative study of *BRCA1*/2 mutation screening methods in use in European clinical diagnostics laboratories.

G. Ellison[1], *A. J. Wallace*[2], *A. Kohlmann*[3], *S. J. Patton*[4];
[1]*AstraZeneca, Macclesfield, United Kingdom,* [2]*Manchester Centre for Genomic Medicine,*

Manchester NHS Trust, Manchester, United Kingdom, [3]AstraZeneca, Cambridge, United Kingdom, [4]European Molecular Quality Network, Manchester, United Kingdom.

BRCA1/2 mutation screening is offered by a large number of clinical laboratories in Europe. Practice is changing rapidly due to increased demand for testing, the advent of treatment focussed genetic testing and the rapid uptake of next-generation sequencing technologies.
Following a survey of current *BRCA1/2* mutation screening methods circulated to ~1500 members of the European Molecular Genetics Quality Network, 20 laboratories were selected to participate covering a representative range of standard (Sanger sequencing and mutation scanning) and NGS methodologies including different platforms and library preparation methods. The selected laboratories reported a significant clinical caseload per annum.
Eight cell line DNA samples with a range of *BRCA1/2* mutation types and 2 samples with no mutations were distributed to participating laboratories. Laboratories were given two months to complete their analyses and asked to report significant findings (would be include in a clinical report) and all differences from a reference sequence.
There was no significant trend identified with respect to the genotyping accuracy of the different methodologies. Seventeen (85%) study laboratories identified all clinically significant *BRCA1/2* variants- no false-positive mutation calls were made. Four genotyping errors (false-negatives) were made by three laboratories: A comparison of the variant calls across samples showed 84% concordance of the different coding variants detected across all samples. For these variants, there was a mean score of 99% concordance of variant calling between the laboratories.
All methods used by experienced clinical laboratories performed well on a challenging range of *BRCA1/2* mutations. The errors identified are likely due to problems with downstream analyses processes rather than the wet-lab methodology.

PS14.013

Sensitive detection of whole exon deletion/duplications using the TruSight Cancer panel

A. Fowler[1], *E. Ruark*[2], *S. Mahamdallie*[2,3], *V. Cloke*[3], *S. Seal*[2,3], *G. Lunter*[1], *N. Rahman*[2,4], *Mainstreaming Cancer Genetics Programme;*
[1]Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, [2]Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom, [3]TGLclinical, Institute of Cancer Research, London, United Kingdom, [4]Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom.

Targeted next generation sequencing (NGS) panels are increasingly being used in clinical genomics to increase volume, throughput and affordability of gene testing. Identifying whole exon deletions/duplications in NGS panels that only target coding regions has proved challenging, particularly for single exon variants. Many labs currently use a separate method for their detection, adding to the test cost and turnaround.
We are using the Illumina TruSight Cancer Panel (TSCP) to test for mutations in cancer predisposition genes in a clinical testing laboratory, TGLclinical. We process 48 samples at a time, and sequence using a HiSeq2500 (2x48), generating median coverage of 500X across the panel.
After evaluation of multiple tools we selected and optimised ExomeDepth for use with exon targeted NGS panels. We evaluated its performance using 96 samples with independently validated data, including 36 samples with large variants, primarily in BRCA1 or BRCA2. The optimised ExomeDepth achieved 100% sensitivity for BRCA1 and BRCA2 large variant detection, identifying all 21 mutations including 9 single exon deletion/duplications, while retaining a low false discovery rate of 0.09. We performed extensive simulations to confirm a high sensitivity for detection of single exon variants under a range of experimental parameters, and to establish robust criteria for a negative result. Finally, we implemented ExomeDepth in a clinical pipeline in 2,064 samples with validation by MLPA identifying 16 single exon deletion/duplications whilst maintaining a low false positive rate.
This work was undertaken by the MCG programme (www.mcgprogramme.com) funded by the Wellcome Trust Grant 098518/Z/12/Z.

PM14.014

Multi-gene panel testing in hereditary cancer: a diagnostic service review and recent developments

H. Lindsay[1], *R. Robinson*[1], *N. Camm*[1], *C. Watson*[2], *L. Crinnion*[2], *A. Kraus*[3], *J. Adlard*[3], *R. Charlton*[1];
[1]Leeds Genetics Laboratory, St James's University Hospital, Leeds, United Kingdom, [2]Translational Genomics, St James's University Hospital, Leeds, United Kingdom, [3]Yorkshire Regional Genetics Service, Chapel Allerton Hospital, Leeds, United Kingdom.

The rapid expansion of NGS within diagnostic laboratories has led to the introduction of multi-gene services offering comprehensive mutation screening for complex disease. Services based on simultaneous investigation of large gene panels result in faster, more cost-effective tests. In 2014 we introduced an 82 gene hereditary cancer panel, based on local clinical demand. The gene list is fully customisable; therefore the panel is ideally suited for patients with complex personal and/or family histories of cancer.
Samples are tested using Agilent SureSelect chemistry and Illumina sequencing. To date, we have tested over 250 patients, achieving 100% coverage at 50x and a diagnostic yield (likely pathogenic and pathogenic variants) of 12%. As clinicians typically opt for a relatively small phenotype-focused subset of genes, the discovery of variants of uncertain clinical significance is minimised (13% reports). In the event of a negative result, additional genes may be analysed if appropriate without the need to perform further laboratory work.
A recent major development in our service is the adaptation of the NGS pipeline for the detection of large duplications and deletions using comparative depth of coverage analysis. Validation studies confirmed 325 individual gene results, including 38 dosage abnormalities. This method enables comprehensive dosage analysis on a larger scale and at a lower cost compared to using a stand-alone method e.g. MLPA.
As laboratory and analysis pipelines become increasingly automated, we aim to meet a turnaround time of 40 working days for all cancer referrals and anticipate a significantly reduced test cost, ultimately leading to improved patient care pathways.

PS14.015

Evaluation of NRF2 Gene Expression in CD133+ Stem Cells Derived from Umbilical Cord Blood of New Born Minor Beta Thalassemia Treated with Thalidomide and Sodium Butyrate

E. Mahmoudi[1], *S. Abroun*[2], *M. Noruzinia*[1], *A. Dehghanifard*[1], *S. Samadpoor*[1];
[1]Sarem Cell Research Centre-SCRC, Tehran, Iran, Islamic Republic of, [2]Tarbiat Modares University, Tehran, Iran, Islamic Republic of.

Efficient induction of fetal hemoglobin (HbF) considers as an important and proper therapeutic approach in patients with beta thalassemia and sickle cell anemia.
Thalidomide and sodium butyrate are both considered as active HbF inducer medication with p38 MAPK activation potential for gamma globin gene induction. NRF2 as key molecule of p38MAPK signaling pathway upregulates following stress oxidation status and cause over-expression of gamma globin gene.Studying the importance of this molecule in the induction of HbF by thalidomide and sodium butyrate can cause more precise underestanding about molecular mechanisms interfering in HbF induction.
Therefore, in this study the effect of thalidomide and sodium butyrate on erythroid progenitors derived form CD133+ cells with minor beta thalassemia mutation was evaluated in invitro. Flowcytometry analysis shows about 96% purity of extracted CD133+ cells. Afterwards, this cells were cultured in erythroid differentiation medium.
In day 6 drug treatment was done and erythroid progenitors were analysed after 12 day of differentiation. Real-time PCR analysis showed significant increased expression of the NRF2 transcript in cell culture groups containing thalidomide and sodium butyrate as compared to control. Moreover, Real-time PCR analysis did not show significant increasing the expression of the NFE2 transcript in cell culture groups containing thalidomide and sodium butyrate as compared to control ($P<0.05$). With regard to the specific role of both drugs given in the induction of fetal hemoglobin expression, it seems that regulation of NRF2 can play an important role in the expression of gammaglobin gene.

PM14.016

Benefits from applying an extended CFTR screening protocol to a heterogeneous population

M. Poulou, *M. Tzetis, I. Fylaktou, E. Kanavakis, S. Kitsiou-Tzeli;*
Department of Medical Genetics, University of Athens, Athens, Greece.

Introduction: Cystic fibrosis (CF) (MIM#219700) is the second most common autosomal recessive disorder in Greece after thalassemias. The carrier frequency is estimated approximately at 3-4% of general population with an incidence of about 1 in 2500-3500 live births. The frequency and distribution of mutations show clear ethnic and geographical distribution and Greece, due to its geographic position, presents high mutational heterogeneity.
Materials and methods: The extended screening protocol included screening of the whole coding sequence, intron-exon boundaries, as well as screening for abnormal copy numbers (deletions and duplications) using MLPA® (SALSA MLPA P091 CFTR probemix). Screening was performed by High Resolution Melting Analysis (HRM) using LightScanner® (Idaho Technologies, Utah, USA) and all positive findings were confirmed by bi-directional Sanger

sequencing.
Results: This approach was applied to 94 patients selected due to having one or both undetermined causative mutations and we were able to identify both causative mutations in 59 of them. The protocol was also applied to 2300 individuals from risk groups (partners of CF carriers/patients, couples presenting with echogenic bowel at the second trimester of pregnancy, males with CBAVD) and 50 carriers were identified, that with other screening protocols would have been missed.
Conclusions: The extended protocol described herein proves to be necessary when screening an extremely heterogeneous population such as the Greek population. The necessity for identifying both causative mutations in a patient is especially important nowadays that innovative therapeutic agents available aim at specific genotypes.

PS14.017

Rapid detection method for the 4 most common CHEK2 mutations based on melting profile analysis

P. Borun[1], *K. Salanowski[1], D. Godlewski[2], J. Walkowiak[3], A. Plawski[1];*
[1]Institute of Human Genetics, Poznan, Poland, [2]Cancer Prevention and Epidemiology Center, Poznan, Poland, [3]Department of Pediatric Gastroenterology and Metabolic Diseases, University of Medical Sciences, Poznan, Poland.

CHEK2 is a suppressor gene, encoding a protein kinase, involved in the regulation and control of the cell cycle. Changes in the structure of CHEK2 affecting the functionality of the expression product are associated with an increased cancer risk in various organs. The elevated risk, in a significant percentage of cases, is determined by the presence of 4 most common mutations in the gene CHEK2, including three point mutations c.470T> C, IVS2 + 1G> A, c.1100delC, and one large rearrangement del5395. The substantial role of these variants in increasing the risk of various cancers leads to the need of development of methods for their detection.
Here we present a rapid and effective method for the detection of 4 most common CHEK2 gene mutations based on high-resolution melting (HRM) analysis, and its modification (C-HRM) enabling simultaneous detection of CNVs. The analysis is performed in two multiplex PCR reactions followed by melting analysis, without any additional reagents or handling beside that used in a standard HRM.
Validation of the method was conducted on a group of 103 patients with diagnosed breast cancer, a group of 176 members from families with cancer cases in organs associated with the CHEK2 gene mutations, and a control group consisting of 100 unrelated, healthy individuals from polish population.
The developed methodology enables to improve the genetic diagnostics of patients. Moreover, it reduces the cost of such analysis, and facilitates their implementation. Therefore, it will be possible to cover a larger group of patients, and at the same time, increase the efficiency of identification of people at risk.

PM14.018

Sensitive multiplex diagnostics of fusion genes in childhood leukemia using biochip

T. V. Nasedkina[1,2], *A. Y. Ikonnikova[1], D. O. Fesenko[1], Y. I. Ammour[1,2], Y. N. Zhukova[2], A. V. Chudinov[1], A. S. Zasedatelev[1];*
[1]Engelhardt Institute of Molecular Biology, Moscow, Russian Federation, [2]Federal Scientific Clinical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation.

Chromosomal rearrangements and fusion genes play key role in leukemogenesis and contribute to different leukemic subtypes. It is practical and helpful to detect the fusion genes in diagnostics of leukemia using inexpensive high-throughput methods. Standard reverse transcription polymerase chain reaction (RT-PCR) approach to detect the fusion transcripts is effective, but time-, labor- and patient material consuming. To simplify and accelarate parallel analysis of multiple targets, we established a method whish combined multiplex RT-PCR and microarray (biochip). The system allows detecting 22 most clinically important chromosomal rearrangements in acute leukemia generating more than 70 fusion gene variants (ETV6-RUNX1; BCR-ABL1 p190 and p210; MLL-AFF1; PML-RARA; RUNX1-RUNX1T1; TCF3-PBX1; MLL-MLLT3; CBFB-MYH11; MLL-MLLT10; MLL-MLLT1; SIL-TAL1; MLL-MLLT4; NPM1-ALK; TCF3-HLF; MLL-ELL; MLL-EPS15; PICALM-MLLT10; MLL-MLLT11; DEK-NUP214; RBM15-MKL1; FUS-ERG). Reverse transcription was performed using a set of specific primers and was followed by PCR with primers containing gene-specific sequences and universal adapters. The target was labeled during PCR by incorporation of fluorescent triphosphate analogs. The fluorescently labelled PCR products were hybridized with a biochip containing immobilized probes. To increase sensitivity of the approach new near-infrared labels (Cy7) were tested. The method allows detecting 1 leukemic blast in 10000 normal cells. Using the approach 100 clinical samples were screened for the presence of translocations. The detected fusion genes were validated with RT-PCR. Our data suggested that the RT-PCR-biochip approach could screen 22 fusion genes with high accuracy and sensitivity. The work is supported by Federal Target Program of Ministry of Education and Science of Russia (grant №14.604.21.0117, RFMEFI60414X0012).

PM14.020

Efficient diagnostic routing using clinical exome sequencing results in a high diagnostic yield of 28 %, limiting the need for whole genome sequencing.

M. M. Weiss, *D. van Beek, I. Bakker, P. Zwijnenburg, H. Meijers-Heijboer, E. Sistermans, Q. Waisfisz;*
VU University Medical Center, Amsterdam, Netherlands.

Clinical exome sequencing (CES) can provide a molecular diagnosis in families with an unexplained phenotype. When using this technique in a diagnostic setting it is important to follow a well documented diagnostic routing. Here we present an effective routing and the results of the first 129 families. Furthermore, we compare the diagnostic yield of our exome pipeline with the yield of Whole Genome Sequencing (WGS).
In a multidisciplinary team, candidate families are discussed and selected. The diagnostic routing prior to WES is defined: exclusion of other genes in differential diagnosis and deletions/duplications (array), revealing the regions of homozygosity (SNP array), and determination of the primary filtering strategy according to the expected inheritance model. Prioritization of variants is performed with Cartagenia Bench Lab NGS using validated variant filtering trees (de novo, recessive, X-linked, multiple affected AD/AR).
The diagnostic WES procedure was evaluated for the first 129 families. A conclusive diagnosis was made in 36/129 patients (28%), including intellectual disability (ID, n=90, yield 24%) and phenotypes without ID (n=39, yield 39%). Nine incidental findings were detected, two clinical diagnoses and seven carrierships.
Furthermore, we performed an in silico analysis of how well our strategy would have performed compared to WGS, by determining the number of mutations that we would have missed based on a large WGS study (Gilissen, Nature 2014). Our strategy would have identified 17/21 mutations, at much lower costs.
In conclusion, we have implemented an efficient strategy for CES. The diagnostic yield is high (28%), and this yield is close to that of WGS.

Establishing a clinical genetic testing laboratory to rapidly implement research advancements into clinical practice

A. Strydom[1,2], *V. Cloke[2], S. Seal[1,2], F. Smith[2], L. Steedman[2], S. Mahamdallie[1,2], R. Linger[2], A. Elliott[1,2], E. Ruark[1,2], N. Rahman[1,2,3];*
[1]Division of Genetics & Epidemilogy, Institute of Cancer Research, London, United Kingdom, [2]TGLclinical, Institute of Cancer Research, London, United Kingdom, [3]Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom.

TGLclinical laboratory was established in Oct 2012 as a clinical testing laboratory operating to ISO 151589:2012 medical laboratory standards. TGLclinical is embedded within a long established research laboratory and clinical unit and was formed with the specific objective of translating sequencing technologies and analytical pipelines developed through research into immediate benefit for clinical services. We outline the timeline and processes involved in achieving this, including the pathway to achieving accreditation to ISO 15189 standards.
TGLclinical is now delivering testing for cancer predisposition genes to the Royal Marsden Hospital using next-generation sequencing with the Illumina TruSight Cancer Panel. This has increased throughput at greatly reduced costs and turn-around times. TGLclinical interpretation services are fully integrated with local clinical and research expertise and provide a standard of clinical interpretation that can be used effectively by both oncology clinicians during the routine care of patients with cancer and by genetic clinicians in standard genetic services.
The establishment of TGLclinical has enabled significant changes and improvements over the past 3 years to the genetic services available at the Royal Marsden Hospital. For *BRCA1* and *BRCA2* gene tests as an example, the charge per test has reduced by ~75%, the number of patients being tested has increased 3.5 fold and the average turn-around time for results has reduced from 8 weeks to less than 4 weeks. The establishment of TGLclinical was made possible through start-up funding from The Royal Marsden Cancer Charity.

PS14.023

Improving CNV detection from next generation exome sequence data (multiple algorithms and dynamic segment ranking)

D. H. de Vries, *T. W. Fitzgerald, P. Jones, C. F. Wright, M. E. Hurles;*
Wellcome Trust Sanger Institute, Hinxton Cambridge, United Kingdom.

The Deciphering Developmental Disorders (DDD) is a project at the Wellcome Trust Sanger Institute focussing on identifying rare genetic variants in a cohort of approximately 12,000 patients with undiagnosed developmental disorders. Next Generation Exome sequencing and array comparative genomic hybridization (aCGH) are used to scan patient genomes for a wide range of genomic variation, including copy number variation (CNV).
Here we introduce a pipeline to perform CNV detection on large numbers of Next Generation Exome Sequencing datasets. Within this pipeline the following detection algorithms have been implemented: ADM3, CANOES, CoNIFER, CoNVex, ExomeDepth, GADA and XHMM. A new method has been developed for the combining and ranking of CNV detections, called: split segment ranking. This is a dynamic ranking system that converts confidence scores from existing algorithms into a new comparable ranked score.
We show that by combining the CNV detections of multiple algorithms we can improve call specificity, while retaining a solid number of detections. Using 500 samples from the DDD project we assessed the CNV calling rates across all algorithms in terms of sensitivity and specificity. By using the proportion of common CNV detections made as an estimate for specificity we show that by using multiple algorithms we achieved a common CNV detection rate of approximately 90% which is in line with previous studies into rare CNV. However, by implementing the split segment ranking method we can potentially achieve a similar specificity while retaining more CNV detections overall.

PM14.024

External assessment of competency to authorise diagnostic genetic reports

Z. Deans[1], *F. Khawaja*[1], *S. Abbs*[2], *R. Mountford*[3];
[1]*UK NEQAS for Molecular Genetics, Edinburgh, United Kingdom,* [2]*East Anglian Medical Genetics Centre, Cambridge, United Kingdom,* [3]*Merseyside & Cheshire Regional Genetics Service, Liverpool, United Kingdom.*

The ISO 15189 standard requires laboratories to train and continually competency assess all levels of staff for a range of activities to ensure a high standard of testing is delivered. This includes demonstrating individual proficiency of staff authorising genetic test results. Laboratories often find it difficult to assess and provide evidence of the expertise of the process of report authorisation. Due to participant demand the UK National External Quality Assessment Service (UK NEQAS) for Molecular Genetics delivered a pilot external quality assessment (EQA) during 2014 to assess if EQA could help evidence this competency.
Twenty eight genetic laboratories participated in this pilot run and were supplied with three clinical case scenarios for patients referred for cystic fibrosis molecular testing. Details of the test performed, the genotyping results obtained and the draft report were supplied and participants were required to review the reports according to the referral information and results provided, and state whether or not each report should be authorised. If the report was deemed not fit to be authorised then reasons were required. Two reports were considered to be suitable for issuing and the majority of laboratories stated that these reports would be authorised. One report had two major errors plus two minor clerical errors and all laboratories would have not issued this report. However many comments were received regarding the format and content of the EQA reports which highlighted the changing requirements of the content of reports and the differences between laboratory reporting styles.

PM14.026

Newborn screening for cystic fibrosis (CF) using likelihood ratios derived from bloodspot Immunoreactive trypsinogen (IRT) and Pancreatitis Associated Protein (PAP)measurements

S. A. Alghamdi[1], *M. Fitch*[2];
[1]*Taif University, Taif, Saudi Arabia,* [2]*Biochemical Genetics Department, Institute of Medical Genetics, Glasgow, United Kingdom.*

Background
In Scotland around 350-400 DNA tests per year are required to detect around 30 cases and 35 carriers of CF. Recently, a second marker, PAP has been reported to be elevated in newborns with cystic fibrosis and a combination of IRT and PAP may provide improved specificity.
Objective
To develop an algorithm based on universal IRT measurements and subsequent PAP measurements in infants with elevated IRT levels which will maintain high detection rates but reduce the number of cases referred for DNA analysis and the incidental detection of carriers
Methods
PAP was measured prospectively by ELISA (Dynabio,France) in dried blood spots in 29 CF cases, 32 CF carriers, 314 unaffected infants with elevated IRT and 2,886 infants with IRT values <99.5th centile. IRT and PAP results were log transformed to give overlapping Gaussian distributions for the control and CF cases, from which likelihood ratios were derived for each individual IRT and PAP result.
Results
The product of the likelihood ratios can therefore be calculated thus combining the information from two markers. Setting a threshold LR of 30 as the action point for DNA testing would result in a 40% reduction in DNA testing and a 50% reduction in the number of CF carriers identified. One CF case would be missed.
Discussion
Selecting cases for DNA analysis based on subsequent measurement of PAP in infants with elevated IRT offers a cost effective method for reducing the number of DNA tests and incidental detection of carriers without the need to measure PAP in all infants.

PS14.027

Droplet digital PCR using a single primer tailed universal hybridisation probe system to confirm array CGH imbalances

A. R. Thompson[1], *Y. Patel*[1], *K. Laing*[2], *J. Short*[1], *R. Taylor*[1];
[1]*SW Thames Regional Genetics Laboratory, London, United Kingdom,* [2]*Infection and Immunity Research Institute, St George's University of London, London, United Kingdom.*

Small imbalances identified by array comparative genomic hybridisation (aCGH) require follow-up investigations to verify the finding and determine inheritance. FISH is the gold standard method used; however, this technique cannot be applied to identify small deletions and duplications. Droplet digital PCR (ddPCR) is a third generation PCR technology that allows sensitive and precise absolute quantification of copy number variations, without the need for standard curves. These qualities make this technology desirable over traditional dosage detection techniques such as quantitative PCR (qPCR).
Droplet dPCR, using Bio-Rad QX100 technology, was used to investigate the suitability of a single primer tailed universal hybridisation probe system, developed in-house, to investigate aCGH imbalances. This system can be applied to any genomic region in question, and therefore negates the need to use expensive custom Taqman probes for each region of interest, making the system versatile and affordable in a diagnostic laboratory.
All ddPCR results were consistent with the aCGH findings, and this technique was successfully applied in follow up family investigations. Furthermore, we have shown that ddPCR is sensitive to identify mosaic imbalances. To further increase affordability and to broaden the potential applications of this technique, multiplexing was also investigated, and this has been shown in principle to work using our detection method. Case studies are presented, along with cost evaluation. Future applications of ddPCR in a diagnostic laboratory are also discussed.

PM14.028

The EMQN scheme for early onset hearing loss (*DFNB1*): Facts and figures for the first six schemes.

L. H. Hoefsloot[1], *M. Bitner-Glindzicz*[2], *H. J. Bolz*[3,4], *A. Roux*[5,6];
[1]*Dept Clinical Genetics, Erasmus Medical Center, Rotterdam, Netherlands,* [2]*UCL Institute of Child Health, London, United Kingdom,* [3]*Center for Human Genetics, Bioscientia, Ingelheim, Germany,* [4]*Institute of Human Genetics, University Hospital of Cologne, Cologne, Germany,* [5]*Laboratoire de génétique moléculaire, CHU Montpellier, Montpellier, France,* [6]*Université de Montpellier, Montpellier, France.*

Early onset hearing loss is a very heterogeneous condition. However, mutations at the *DFNB1* locus can explain up to 20% of cases. The *DFNB1* locus contains two genes, *GJB2* and *GJB6*. Testing for mutations at the *DFNB1* locus has been implemented in many diagnostic laboratories because it is the first line genetic test requested by clinicians dealing with children with (prelingual) hearing loss. An external quality control scheme instigated by the European Molecular Quality Network (EMQN) started with a pilot scheme in 2008, and continued as a yearly full scheme in the following years. Here, we report on the results of the first 6 schemes.
In the annual quality control schemes, three validated DNA samples with mock clinical case descriptions were distributed to participating labs. We retrospectively analyzed the final results of each year. The number of labs participating in the last five years was on average 70. The diagnostic er-

ror rate (incorrect genotype possibly leading to a misdiagnosis) declined over the years, being the highest in 2011 (7.3%) and lowest in 2014 (1.3 %). The average genotyping score (maximum 2.00) increased from 1.76 to 1.96. However, the interpretation score varied, probably related to the perceived difficulty of the clinical questions. Overall, we have seen a general improvement in both the completeness of testing and in the reporting. This external quality control scheme is therefore a successful tool to improve the performance of participating labs and has demonstrated an improvement on reporting practice and decreasing diagnostic error rates.

PS14.029

Dissecting the diagnostic yield in clinical genomic testing

D. M. Church, *G. Chandratillake, S. Chervitz, G. Bartha, J. Harris, S. Luo, A. Patwardhan, J. Tirch, J. Yen, S. Garcia, J. West, R. Chen;*
Personalis, Inc., Menlo Park, CA, United States.

Genomic testing has been a part of diagnosing genetic disorders since the detection of aneuploidies using cytogenetic techniques. Technological advances in high throughput, low cost DNA sequencing coupled with the availability of a high quality reference assembly have allowed us to interrogate the genome with greater precision than ever before. Together with increased understanding of the genetic underpinnings of disease, these advances mean our success rate in diagnosing genetic disease is higher than it has ever been, however the diagnostic yield of WGS/WES is only 25-50%. Improving this yield requires reexamination of the entire process, including assay development, bioinformatics analysis approaches as well as processes for robustly associating variants with disease. Assay development is critical as no single sequencing method can identify the spectrum of variant types nor can they access all regions of the genome equally. This becomes even more critical when testing for diseases that deviate from Mendelian expectations, such as cancer or diseases arising from somatic mosaicism. We are also beginning to learn that the reference assembly itself can have an impact on variant identification and interpretation. Our early, simplistic assembly models are insufficient for robust genome analysis and we must develop new models and analysis paradigms. Lastly, processes for understanding how detected variants may contribute to a particular disorder must be examined. Every person carries approximately 100 seemingly damaging variants, most of which do not contribute to rare disease. Identifying the variants contributing to specific phenotypes requires the integration of diverse biological knowledge.

PM14.030

TaqMan® Rare Mutation Assays for QuantStudio® 3D Digital PCR System

K. Varma, B. Ho, N. Majumdar, L. Lac, T. Straub, P. Cifuentes, I. Russell, D. Keys, F. Chan, R. Saathiya, **M. Laig**;
Thermo Fisher Scientific, South San Francisco, CA, United States.

Detection and quantification of mutant alleles in tumor tissue allow for research disease monitoring and the research of drug efficacy. Detection of emerging secondary mutations in the same tumor tissue causing resistance to potential treatment will help guide decisions on future treatment plans. A less invasive research method than using tumor tissue is testing for the presence of mutations in circulating free DNA (cfDNA).
We created a research tool for mutation detection at a sensitivity level of 1% and below. This allows researchers to find correlation between mutation types and tumor types and determination of potential secondary mutations.
The tool combines TaqMan® SNP Genotyping Assays with digital PCR. A set of assays was optimized for use in digital PCR with the QuantStudio® 3D Digital PCR System. In digital PCR, partitioning the sample into many individual reaction wells facilitates detection and quantification of rare mutant alleles. TaqMan® SNP Genotyping Assays ensure reliable discrimination of mutant and wild-type allele.
Our initial set of 38 assays covers mutations commonly found in tumor tissues: BRAF V600E, mutations in EGFR exons 19, 20 and 21, KRAS codons 12 and 13, PIK3CA exons 9 and 20, and the JAK2 V617F mutations.
All assays were wet-lab tested at a 10% mutation rate and a 1% mutation rate using mutant plasmid spiked into wild-type genomic DNA. Additionally, selected assays were tested at the 0.1% mutation rate using mutant cell lines spiked into wild-type genomic DNA.
Wet-lab results confirm that all assays showed superior performance discriminating mutant and wild-type alleles. Mutant alleles were successfully detected as low as 0.1%.

PS14.031

Determining the Limit of Detection of Rare Targets Using Digital PCR

N. Majumdar, *T. Wessel, M. Laig, B. Ho, L. Lac, T. Straub, Y. Wu, D. Keys, F. Chan, I. Russell, P. Cifuentes;*
Thermo Fisher Scientific, SAN BRUNO, CA, United States.

Detection and quantification of mutant alleles in tumor tissue allow for disease monitoring, the evaluation of drug efficacy and guide decisions on future treatment plans. Testing for the presence of mutations in circulating free DNA (cfDNA) is one of the less invasive research methods available at this time. Digital PCR presents a research tool for mutation detection in cfDNA at a sensitivity level of 1% and below.
Challenges associated with digital PCR experiments for rare allele detection include understanding the limit of detection of the assay and platform. This work compares false positive assessment strategies using the signal levels of the no-amplification cluster. Once the false call rate is established, the paper outlines a method to determine the limit of detection of the assay and platform, at a given level of confidence. The tradeoffs between sample load and sensitivity, given the number of partitions, the interrogated volume and the false call rate are also discussed.
The mathematics outlined to calculate the theoretical limit of detection is applied on a set of assays from Thermo Fisher Scientific covering the KRAS codons 12 and 13 mutations commonly found in tumor tissues. Experimental results showing a detection of at least 0.1% mutation rate are presented as examples. Test samples were created using both mutant plasmid and mutant genomic DNA mixed with wild-type genomic DNA at a predefined percentage.
For Research Use Only.

PM14.032

Dystrophinopathies: An NGS approach for the molecular analysis of DMD gene

L. Gonzalez-Quereda[1], *A. Lasa*[1], *M. Baena*[2], *M. Rodriguez*[2], *M. Baiget*[1], *P. Gallano*[1];
[1]*Genetics Dept. Hospital de la Santa Creu i Sant Pau, U-705 CIBERER, Barcelona, Spain,* [2]*Genetics Dept. Hospital de la Santa Creu i Sant Pau, Barcelona, Spain.*

OBJECTIVES: DMD gene, located on Xp21, comprises 79 exons along 2400Kb, whose mutations originates Duchenne/Becker muscular dystrophies (DMD/BMD). 70% of DMD/BMD patients show deletions/duplications of one or more exons. The remaining 30% present a nonsense, missense, frameshift or splicing mutations, distributed along the entire gene. Detection of point mutations is an expensive task in terms of technical and economic issues.
The introduction of next-generation sequencing technology (NGS) in our laboratory has allowed exponentially increase sequencing throughput.
MATERIALS AND METHODS. We studied DNA samples from 60 patients with clinical suspicion of DMD/BMD who had previously ruled out the presence of an exon deletion or duplication in the DMD gene.
The generation of amplicon libraries was performed using the kit DMD MASTR of Multiplicom and they were sequenced using the MiSeq platform from Illumina. Sequencing data were analysed using Variant Studio and DNA Nexus softwares. The pathogenic changes were confirmed by Sanger sequencing and were compared with the LOVD database and Alamut and Polyphen-2 softwares.
RESULTS: We have identified 31 mutations, which have been confirmed as the cause of the pathology.
CONCLUSIONS: The analysis of point mutations in DMD gene by NGS is a breakthrough in molecular analysis time and cost, compared to Sanger technique. Thus, targeted NGS can contribute to alleviate the diagnosis delay and to overtake the genetic counseling.
In those patients in whom no mutation was identified in gDNA, the DMD/BMD clinical diagnosis should be confirmed by immunohistochemistry in muscular biopsies and afterwards the mRNA sequencing.

PS14.033

Northern Lights Assay: A versatile method for comprehensive detection of DNA damage

B. Gudmundsson[1,2,3], *H. G. Thormar*[1,3], *S. Thongthip*[4], *A. Sigurdsson*[1], *W. Dankers*[1], *M. Steinarsdottir*[2], *A. M. Halldorsdottir*[2], *A. Smogorzewska*[4], **J. J. Jonsson**[1,2];
[1]*Univ. of Iceland, Reykjavik, Iceland,* [2]*Landspitali - National University Hospital of Iceland, Reykjavik, Iceland,* [3]*Lifeind ehf., Reykjavik, Iceland,* [4]*Rockefeller University, New York, NY, United States.*

Introduction: Detction of DNA damage has many applications including testing quality of DNA samples in biobanks, monitoring complex molecular procedures, genotoxicity testing, diagnosing genome instability, and in cancer theragnostics. We tested the suitability of the Northern Lights Assay (NLA) for these applications.
Materials And Methods: NLA is based on Two-Dimensional Strandness-De-

pendent Electrophoresis (2D-SDE), a technique of nucleic acid separation based on size, standness, and conformation changes induced by damage. Each specimen is analyzed in sample pairs of non-digested DNA to detect single- and double-stranded breaks and MboI-digested DNA to detect other lesions. NLA has been adapted to a microgel platform to improve sensitivity and speed of analysis. We tested NLA on various samples including DNA in solution, intermediate products of complex procedures, various cell cultures treated with genotoxic agents, and body fluid samples from patients.
Results: NLA could detect single-stranded breaks, double-stranded breaks, interstrand and intrastrand DNA crosslinks, single-stranded DNA, bulky lesions and mismatches in all types of samples. The sensitivity of the method was comparable to other methods for DNA damage detection. The main advantage of NLA compared to the comet assay was detection of both intrastrand and interstrand crosslinks and other abnormal DNA in a direct manner.
Conclusions: NLA is a versatile method for comprehensive and simultaneous analysis of various types of DNA damage both in purified DNA and in biological samples from cells and body fluids. NLA is useful in biomedical research and diagnostics including Omics technologies.
Grants: Icelandic Centre for Research. University of Iceland Research Fund, Landspitali University Hospital Research Fund and investments in Lífeind ehf.

PM14.034

Comparison of two different methods for brain DNA extraction

A. Sönmez[1,2], *A. H. Schapira*[1], *C. Proukakis*[1];
[1]UCL Institute of Neurology, London, United Kingdom, [2]University of Heidelberg, Heidelberg, Germany.

Recent appreciation of the extent of mosaicism in human tissues, including the brain, implies that analysis of peripheral blood lymphocyte DNA may be insufficient. For correct assessment of CNVs, particularly mosaicism, an even genome extraction is crucial. To determine if the extraction method influences brain DNA quality and quantity, two widely used kits, DNeasy and Puregene by Qiagen, were compared.
DNA was extracted from the cerebella of three Parkinson's patients and three controls with both methods, using different starting amounts on the DNeasy for four of these. DNA was compared using Nanodrop, Qubit and electrophoresis.
DNA purity was comparable. Electrophoresis revealed a smaller main band and more smeary appearance with DNeasy. Increasing the amount of brain tissue (5, 25 and 50 mg) used with DNeasy led to a lower yield per mg brain, and a more smeary appearance. Puregene yielded up to three times more DNA per mg brain compared to the best DNeasy extractions, with yields close to the expected value based on cerebellar cell density.
Therefore DNeasy yields less DNA of worse quality per mg tissue than Puregene, and increasing starting tissue leads to lower amount and worse quality with DNeasy. Excess protein may prevent all DNA from passing through the filter, and we are concerned this might lead to different relative amounts of parts of the genome, resulting in inaccurate copy number calls. We recommend Puregene for brain DNA extractions, although we have not compared phenol chloroform, which should also be considered.
Funding: Michael J. Fox foundation

PS14.035

Assessment of automated DNA extraction for peripheral blood, bone marrow and amniotic fluid specimens

N. Ngaoburanawit, *J. Thanakitgosate, T. Chareonsirisuthigul, B. Rerkamnuaychoke;*
Human Genetics Laboratory, Department of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

Introduction: Reliable of DNA extraction is a key step in molecular assay. DNA extraction using phenol-chloroform or spin-column remains the labor-intensive and time-consuming. Therefore, the automated DNA extraction is urgently needed for the routine diagnostic laboratory. The aim of this study was to evaluate the automated DNA extraction for peripheral blood, bone marrow and amniotic fluid specimens.
Materials and Methods: DNA from peripheral blood (PB), bone marrow (BM) and amniotic fluid (AF) specimens were extracted using the spin-column; QIAamp DNA blood mini kit and the automated DNA extraction; EZ1 Advanced XL. DNA concentration was quantitated by NanoDrop Spectrophotometers. For comparison of analytical performance, DNA from PB and BM were detected for mutation analysis of hematologic malignancy markers. In addition, DNA from AF was evaluated for molecular prenatal diagnosis using QF-PCR and Bacs-on-Beads technology.
Results: DNA concentration of PB and BM from QIAamp DNA blood mini and EZ1 advanced XL were 11.1 to 299.9 ng/µl and 19.1 to 108.2 ng/µl, respectively. Moreover, DNA concentration of AF from QIAamp DNA blood mini and EZ1 advanced XL were 7.5 to 19.2 ng/µl and 2.9 to 5.2 ng/µl, respectively. Analytical performance of both DNA extraction methods were concordance in all types of samples and all assay.
Conclusions: DNA concentration and quality from QIAamp DNA blood mini kit and EZ1 Advanced XL is not significantly difference. The incorporation of the automated DNA extraction into the routine DNA analysis process may reduce the need for labor-intensive, time-consuming using the spin-column DNA extractions.

PM14.036

Efficiency of Computer-Aided Facial Dysmorphology Analysis in the Medical Genetics Clinic

I. Akalin, *S. Yilmaz;*
Istanbul Medeniyet University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey.

Computer-aided facial dysmorphology analysis program has recently been introduced to clinicians. It has been shown (Basel et al., ASHG 2014) that the accuracy of computer-aided dysmorphology analysis is comparable to that of human experts in dysmorphology. Here, we evaluated the performance of such technology by comparing computer-aided analysis of a set of 2D facial images of patients with molecularly confirmed diagnoses.
Of a total sample of 280 frontal facial images of patients who were referred to our department processed with Face2Gene. The following criteria for selection were applied for this present study: images of patients with a molecularly confirmed diagnosis; cases with syndromes currently supported by the technology cases, with well documented dysmorphic features and proper consent.
The resulting sample for this study is a test group of 12 patients affected by 8 syndromes (Table).
A match was considered positive where the diagnosed syndrome was listed among the top ten syndromes under the "Gestalt Matches" list in Face2Gene.
In 10/12(83%) patients there was a positive match between the confirmed diagnoses and matching syndromes detected by Face2Gene. The average rank of match was 3.8 (1 being the most similar and 10 being the least).
We believe that routine use of computer-aided dysmorphology analysis in the clinic will assist to clinicians, particularly to medical geneticists, in reaching a more accurate differential diagnosis and shorten the time and the cost for achieving molecular confirmation of rare disease patients.

Common Diseases enrolled in the study.

Prader-Willi Syndrome; PWS
Wolf-Hirschhorn Syndrome; WHS
Rubinstein-Taybi Syndrome
Chromosome 22q11.2 Deletion Syndrome
Down Syndrome
Achondroplasia; ACH
Williams-Beuren Syndrome; WBS
Trichorhinophalangeal Syndrome

PS14.037

Use of an augmented exome for disorders with high genetic heterogeneity

G. Chandratillake[1], S. Garcia[1], J. Tirch[1], E. Chen[2], P. Suwannarat[3], C. Kobelka[2], S. Strom[4], A. Martinez[5], M. B. Gorin[6], **J. West**[1], *R. Chen[1];*
[1]Personalis, Inc., Menlo Park, CA, United States, [2]The Permanente Medical Group, Inc., San Francisco, CA, United States, [3]Mid-Atlantic Permanente Medical Group, Rockville, MD, United States, [4]University of California, Los Angeles, Los Angeles, CA, United States, [5]Cedars-Sinai Heart Institute, Los Angeles, CA, United States, [6]Jules Stein Eye Institute, University of California, Los Angeles, Los Angeles, CA, United States.

As exome sequencing enters clinical care, a dilemma in testing for disorders with high genetic heterogeneity arises: to order a gene panel test, or exome sequencing? Core to this dilemma is that the sensitivity of each approach is compromised, albeit differently. While the analytical sensitivity for genes on a panel tends to be high, the *diagnostic* sensitivity of such tests can be compromised through failure to include some genes associated with the condition. In contrast, while conventional exome sequencing assays more genes, it suffers from issues of analytical sensitivity, e.g. poor coverage of known disease genes, which in turn compromise diagnostic sensitivity.
To address this dilemma, an augmented exome sequencing assay, the ACE Clinical Exome Test, was developed. Coverage of >8000 biomedically relevant genes is enhanced, with >6000 considered "finished" (>99% of bases covered at 20x). To further improve sensitivity, the test includes coverage of interpretable non-exonic regions and genome-wide detection of structural variants.
In cases involving disorders with high genetic heterogeneity, current gene

panel tests were examined to determine if they included the disease-associated genes identified through augmented exome sequencing. This revealed that the genetic diagnoses of several individuals would have been missed through gene-panel testing. Examples including cases of Charcot-Marie-Tooth disease and Leber congenital amaurosis are presented.
For disorders with high genetic heterogeneity, an augmented exome test that addresses the issues of analytical sensitivity associated with conventional exome sequencing, can provide diagnoses that may be missed through gene panel testing, and simplify the panel vs. exome test-selection dilemma.

PM14.038

Coverage Analysis of Lists of Genes involved in Heterogeneous Genetic Diseases following Benchtop Exome Sequencing using the Ion Proton

M. Krahn[1,2], *C. Lacoste*[1,2], *J. P. Desvignes*[1], *D. Salgado*[1], *C. Pécheux*[2], *L. Villard*[1,2], *M. Bartoli*[1,2], *C. Béroud*[1,2], *N. Lévy*[1,2], *C. Badens*[1,2];
[1]Aix Marseille Université, INSERM UMR_S 910, GMGF, Marseille, France, [2]APHM, Département de Génétique Médicale, Hôpital Timone Enfants, Marseille, France.

Exome sequencing has been proven efficient for clinical applications in heterogeneous genetic diseases, including exome sequencing associated with data filtering for selected genes. However, previous reports have been based mainly on the use of large-scale Next-Generation-Sequencing platforms, difficult to implement in medium-scale genetic diagnosis laboratories. In this context, the Ion Proton™ (Life Technologies, CA, USA) allows for facilitated implementation of exome sequencing in medium-scale laboratories, through an easy set-up in 6 hour runs on a benchtop apparatus producing high quality exome data.
As a requirement for diagnostic mutation screening using Ion Proton™ exome sequencing, we precisely evaluated sequence coverage data for six groups of genetically heterogeneous diseases, of interest for genetic diagnostic laboratories: myopathies (82 genes), hereditary motor and sensory neuropathies (55 genes), early onset epileptic encephalopathies (30 genes), isolated and combined dystonia (12 genes), non syndromic deafness and hereditary hearing loss (60 genes), and intellectual disability (107 genes for X-linked transmission; 39 genes for autosomal recessive transmission, 37 genes for autosomal dominant transmission). In addition, we evaluated sequence coverage for a list of 57 genes for which the ACMG recommends to report incidental findings.
The simple workflow of Ion AmpliSeq™ exome enrichment combined with Ion Proton™ simplex-sample sequencing allows for >90% mean sequence coverage at ≥20X for approximately two-third of the genes of interest analyzed for the disease-groups myopathies, hereditary motor and sensory neuropathies, early onset epileptic encephalopathies, non syndromic deafness and hereditary hearing loss, and intellectual disability (X-linked, autosomal recessive, and autosomal dominant forms), and the list of genes for which the ACMG recommends to report incidental findings.

PS14.039

The translation of exome sequencing into diagnostic genomics

I. R. Berry[1], *C. M. Watson*[2], *L. Crinnion*[2], *N. Camm*[1], *I. Carr*[2], *R. Charlton*[1], *A. Dobbie*[3];
[1]Leeds Genetics Laboratory, Leeds, United Kingdom, [2]University of Leeds, Leeds, United Kingdom, [3]Yorkshire Regional Genetics Service, Leeds, United Kingdom.

Introduction: Until recently, the sequencing of whole exomes for the diagnosis of genetic disease remained largely in the realm of the research community. We investigated the efficacy and application of such techniques in clinical practice.
Materials and Methods: Whole or focussed exome sequencing was performed on a cohort of 93 mixed referrals using the Sureselect (Agilent) capture reagent and Illumina HiSeq sequencing platform. Two different in-house analysis pipelines were applied (dependent upon genetic heterogeneity of diagnosis), designed to maximise sensitivity and diagnostic efficiency, respectively. Filtering of variants was performed based on phenotypic gene lists, coding sequence location and predicted effect, and minor allele frequency.
Results: An overall diagnostic yield (definitely- or likely-pathogenic variants) of 42% was achieved across a range of referrals, including large sub-groups of ciliopathy and aortopathy patients, and a further 12% of cases had potentially-pathogenic variants warranting further follow-up. Horizontal and vertical coverage were superior on focussed versus full exomes, however, full exome analysis was used to identify a presumptive new gene (for primary ciliary dyskinesia), and facilitated re-analysis of data in heterogeneous conditions with rapidly-expanding lists of genetic causes. Exonic copy-number analysis using NGS data was validated, and two causative large deletions were detected. No significant incidental findings were identified.
Conclusions: Exome sequencing is a flexible and highly efficient method for mutation detection in a range of diagnostic scenarios, and promises to revolutionise laboratory diagnosis in the genomic era.

PM14.040

The clinical utility of exome analysis in the routine clinic.

J. M. Taylor[1], *T. Lester*[1], *K. Thomson*[1], *J. Williams*[1], *J. Taylor*[2], *S. Y. Patel*[3], *A. H. Nemeth*[4], *U. Kini*[4], *A. Seller*[1], *E. Blair*[4], *H. Watkins*[5];
[1]Oxford Medical Genetics Laboratory,, Oxford, United Kingdom, [2]Oxford Biomedical Research Centre, Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, [3]NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom, [4]Department of Clinical Genetics, Churchill Hospital, Oxford University NHS Hospitals Trust, Oxford, United Kingdom, [5]Department of Cardiovascular Medicine, University of Oxford, Oxford, United Kingdom.

Introduction: The Oxford Medical Genetics Laboratory and the Oxford Biomedical Research Centre are working in collaboration to translate whole exome sequencing (WES) into routine practice. This project has three main objectives: first, to reaffirm the clinical utility of exome sequencing and develop pathways for data analysis, and clinical reporting; Second, to establish an ethically approved framework for patient referral, analysis and results reporting; and third, to transition WES into a diagnostic service.
Materials and Methods: To date >190 exomes (28 Trios, 14 affected sibs, and 78 probands) have been reviewed and approved for WES by a Genomic Medicine MDT. The initial data analysis focused on known causative genes, followed by whole exome analysis with appropriate consent.
Results: Molecular confirmation of a highly likely or likely pathogenic variant was reported in ~29% of cases. ~4% of cases had a variant of unknown significance reported in a clinically relevant gene. A number of these cases highlight a short fall in previous analysis methods. We present four cases illustrating the clinical efficacy of WES across four different disorders: primary immune deficiency, neonatal cardiomyopathy, ectodermal dysplasia, and a neonatal dysmorphic disorder. These cases demonstrate how virtual gene panels allow the rapid integration of recently discovered disease-causing genes, which can have a profound impact of patient management. In addition, three of these cases demonstrate how WES influenced or outperformed established diagnostic services.
Conclusion: Our data support a focused exome in the first instance; however, WES can provide greater clinical sensitivity and influence existing clinical practice.

Exome Triage: Strategies for computational rescue when analysis in the clinical search space fails

B. N. Pusey, *C. Du, T. C. Markello, W. A. Gahl, D. R. Adams;*
NIH Undiagnosed Diseases Program, Common Fund, Office of the Director, NIH, and National Human Genome Research Institute, NIH, Bethesda, Maryland, USA, Bethesda, MD, United States.

In 2008, the National Institutes of Health (NIH) began the NIH Undiagnosed Diseases Program (UDP), whose purpose is to find diagnoses and conduct research for study participants who remain undiagnosed despite an extensive medical workup. Approximately 150 patients are admitted to the UDP per year, at which point they undergo a robust clinical evaluation and, when warranted, an in-depth genomic analysis. Since clinical exome sequencing has become incorporated into the standard armamentarium for evaluating complex patients, the UDP has increasingly needed to focus on detecting disease-causing DNA variations in regions that are missed using standard exome techniques. To this end we have created an analytic pipeline that combines standard methodology with enhancements designed to detect and/or recover variants in where standard pipelines may generate false negative results. The enhancements include such strategies as parent-aware diploid alignment, aggressive use of high-density SNP array data, and standardized-phenotype-based variant prioritization. Over time, our aim is to refine our protocols for automated and manual analysis to create a suite of "second pass" strategies for cases where standard clinical exome and genome studies have not yielded actionable results.
This research is supported by the Intramural Research Program of NHGRI and the Common Fund of the National Institutes of Health.

PM14.042

Is exome sequencing of single patients with intellectual disability an effective diagnostic strategy?

C. A. L. Ruivenkamp, *M. J. V. Hoffer, A. C. J. Gijsbers, S. Bollen, W. Arindrarto, M. Laurense-Bik, I. Fokkema, S. Smit, M. van der Wielen, E. Aten, E. Bijlsma, M. Breuning, Y. Hilhorst-Hofstee, N. den Hollander, S. Kant, A. van Haeringen, M. Kriek, J. Laros, B. Bakker, C. van Asperen, G. Santen;*
Leiden University Medical Center, Leiden, Netherlands.

Trio-sequencing can be used in all disorders, and has proven its value in

finding causes of intellectual disability (ID). We investigated whether sequencing only the affected patient without parents is sufficient to find the causative mutation, leading to a considerable reduce in costs. In this study, we enrolled 36 patients with unexplained ID, and sequenced the exome. The exome sequences were analysed with a stringent post-sequencing annotation pipeline including an ID gene panel of ~500 genes for filtering of the data. All remaining variants with a potential clinical consequence were validated by Sanger sequencing and tested in the parents for inheritance.
After variant filtering we noticed an average of 13 variants per patient (range 2 to 27) requiring further clinical interpretation. The majority of these variants were inherited from one of the parents. Hitherto, we identified 5 de novo mutations and 1 homozygous mutation in 33 patients (18%). For the remaining 27 patients both parents have been sequenced and further analysis is being performed.
Without exome sequencing the parents, a relatively high amount of potentially pathogenic variants remain. All these variants require clinical interpretation which is very time-consuming, while most of these variants were likely benign because they are inherited from one of the parents. With trio-analysis inherited variants can be filtered out suggesting that this strategy, at this moment, is more efficient in identifying the causative variant. In the future when databases are filled with more and more exome data and consequently with more rare benign variants, exome sequencing single patients will become a more realistic diagnostic approach.

PS14.043

Reshaping genetic diagnostics of rare diseases with transition to genome-wide sequencing approaches - experience of Slovenian centre for Mendelian genomics

A. Maver, *K. Writzl, H. Jaklič, G. Rudolf, M. Volk, A. Blatnik, B. Dolničar, L. Lovrečić, A. Hodžić, B. Peterlin;*
Clinical Institute of Medical Genetics, Ljubljana, Slovenia.

Establishment of diagnosis in patients with suspected genetic disorder presents a challenging task, mainly due to extensive diversity and rarity of genetic conditions. Aiming to improve the accessibility to genetic testing, enhance the diagnostic yield and rationalize genetic testing in Slovenia, we implemented clinical exome sequencing as routine mode of genetic testing for a wide variety of genetic disorders. Our experience offers unique insight into clinical effectiveness of such strategy in daily clinical practice.
We performed a comprehensive analysis of patients referred since 2013, including data on referral diagnosis, disease classification, ontological phenotype characterization and other clinical parameters. For each patient, we evaluated the outcome in light of initial diagnosis, distinguishing cases where the result either recapitulated initial diagnosis, established diagnosis in undiagnosed cases, or resulted in diagnosis reclassification. We additionally monitored added value of extended exome analyses, including detection of CNVs, mitochondrial variants and exome-based linkage analysis.
Overall, sequencing in 347 diverse patients revealed convincingly causative genetic variants in 139 (40.1%), with substantial variability across different disease categories. Causative variants were found in referred gene panels in 30.1%, while establishment of new diagnosis was reached in 6.9% and reclassification in 1.7% of cases. In 9 cases, causative variant was identified utilizing extended methods of exome data analysis.
In conclusion, we demonstrate the multifaceted efficacy of clinical exome sequencing in diagnostics of genetically and phenotypically diverse diseases. Furthermore, we show its implications in widening national accessibility of genetic testing to thousands diseases, consequentially reducing the need for cross-border genetic testing.

Whole exome sequencing (WES) has now entered the medical practice with powerful application in the diagnosis of rare mendelian disorders. Although the usefulness and cost-effectiveness of this diagnostic test is widely demonstrated, there is a critical need for reducing the results turnaround time to make WES a clinical reality. Since 2011, automation of laboratory procedures and advances in sequencing chemistry made possible a ~50-hours diagnostic whole genome sequencing from the blood sample to molecular diagnosis of suspected genetic disorders. Taking advantages of these advances, the main objective of the study was to improve the sequencing results turnaround times. WES was proposed to 18 patients with severe undiagnosed disorders with developmental anomalies, facing a medical situation requiring urgent diagnosis. Each family gave consent and new specimens were gathered. The extracted DNA was sequenced on NextSeq500 (Illumina) instrument. Data analysis was performed following standard procedures. Variants interpretation was performed using in-house software. Each rare variant affecting protein sequence with clinical relevance was tested for familial segregation. Overall, 4.4 gigabase of sequence were produced per individual, resulting in a mean coverage of 93 folds, with 93% of the RefSeq exons covered by at least 10 reads. Diagnostic rate was of 39% (7/18), with a maximum turnaround time of 8 weeks from specimen arrival to results. Direct impact of a rapid diagnostic for positive families included two prenatal testing proposals, two clinical trials inclusions. Finally, this pilot study demonstrates the feasibility of reducing the turnaround times for diagnostic WES in our primary genetic center.

PS14.045

What does exome sequencing miss? An exploration of the false-negative space in current exome sequencing

C. Du, *B. N. Pusey, T. C. Markello, W. A. Gahl, D. R. Adams;*
NIH Undiagnosed Diseases Program, National Institutes of Health, Bethesda, MD, United States.

Exome sequencing has advanced to clinical practice and has proven to be useful in the molecular diagnosis of rare genetic diseases. At the NIH Undiagnosed Diseases Program we routinely apply exome sequencing in the pursuit of disease causing variants in patients that have not been able to receive a diagnosis despite extensive medical workup. An increasing number of our new patients present with prior, negative clinical exome testing. In these cases, given the hypothesis of a genetic condition, the disease-causing variant may be hidden beyond the search space defined by current exome sequencing practice. Such false negatives may be caused by a number of factors including specific decisions made during data analysis and limitations in the basic technology. We present data from a literature review, plus examples from our own datasets where possible, to describe and quantitate the false-negative space associated with current practice. Examples include allele skewing, false *de novo* calls caused by incorrectly called parental genotypes, mis-alignment, mapable but low coverage regions, non-mapable targeted regions, misalignment and indel errors. Understanding the false-negative space associated with clinical exome sequencing provides a rational basis for future work on methods for improving detection in systematically under-assayed genomic regions.
This research is supported by the Intramural Research Program of the National Human Genome Research Institute and the Common Fund of the National Institutes of Health.

Genetic diagnosis of familial hypercholesterolaemia in the UK and Ireland using the Randox FH Biochip array

R. J. L. Martin[1], *P. J. Hart*[1], *M. J. Latten*[2], *H. A. Murray*[2], *M. A. Crockard*[2], *J. V. Lamont*[2], *S. P. Fitzgerald*[2], *C. A. Graham*[1];
[1]*Northern Ireland Regional Genetics Centre, Belfast, United Kingdom,* [2]*Randox Laboratories Limited, Crumlin, United Kingdom.*

Introduction: Familial Hypercholesterolemia (FH) is a genetic disorder characterized by high levels of low density lipoprotein in the cardiovascular system and early onset of cardiovascular disease. FH is most commonly caused by mutations ApoB, LDLR, and PCSK9 genes. FH can be treated quite effectively with lipid-lowering drugs and lifestyle changes. Genetic testing and cascade screening have been recommended by the National Institute for Health and Clinical Excellence (2008). We have developed an assay, based on a combination of multiplex PCR and biochip array hybridization, which enables the rapid simultaneous detection of 40 mutational targets within ApoB, LDLR and PCSK9. The assay detects 71% of all point mutations in FH patients within the United Kingdom (based on 465 families from a variety of ethnic backgrounds with identified FH mutations).
Materials and Methods: A total of 500 patients which met the Simon Broome criteria for possible FH were referred from across the UK for genetic scree-

ning. Testing was carried out using the FH Array biochips and the Randox Evidence Investigator analyzer. Results were processed automatically, with analysis completed within 3 hours from template DNA.
Results: Mutations were detected in 6.4% (32/500) patients tested. These consisted of 29 heterozygous LDLR mutations, 2 familial defective ApoB mutations and a patient who was compound heterozygous for ApoB R3527Q and LDLR R350X.
Conclusion: The FH array successfully identifies the most prevalent mutations in the UK and Ireland. It will aid confirmation of suspected FH cases and in cascade screening, hence reducing FH associated morbidity and mortality.

PS14.047

Development of a novel targeted panel sequencing assay to identify patients with Familial Hypercholesterolemia

A. M. Medeiros[1,2], C. Silva[1], L. Vieira[1], **M. Bourbon**[1,2]*;*
[1]Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisboa, Portugal, [2]BioISI – Biosystems & Integrative Sciences Institute, Lisboa, Portugal.

Introduction: Familial hypercholesterolemia (FH) is a common autosomal dominant disorder of lipid metabolism. Genetic diagnosis of FH currently includes the study of LDLR, APOB (2 fragments of exons 26 and 29) and PCSK9, by PCR plus Sanger sequencing. We present the development of a novel targeted panel sequencing (TPS) approach for the genetic diagnosis of FH.
Material & Methods: A TPS panel (LDLR, APOB, PCSK9, LDLRAP1, APOE) was developed using an Ilumina MiSeq platform. Design experiment uses Long Range PCR to amplify 14 different fragments: LDLR (45.66kb), APOB (43.85kb), PCSK9 (26.51kb), LDLRAP1 (26.51kb), APOE (4.84kb). Library preparation was conducted using Nextera®XT DNA Sample Preparation Kit (Illumina). Libraries were pooled and sequenced using paired-end 2x250bp reads in a single sequencing run.
Results: To test this novel approach 16 samples have been sequenced. A total of ~1.28M reads were obtained with 40.000-155.000 reads/sample. The total percentage of bases with >=Q30 was 85.5%. Variants identified by TPS will be presented and compared with those obtained by Sanger sequencing.
Discussion: Due to the recently reports of novel APOB functional mutations outside the currently studied regions and APOE deletions causing FH, it is imperative to change the FH genetic diagnosis. This TPS assay includes flanking intronic regions, may be easily expanded to include additional genes and offers a faster delivery of results compared to the traditional sequencing approach. The 424 FH mutation negative (by current genetic diagnosis) index patients, in our FH cohort, will be analysed using this novel TPS approach for patient identification improvement.

PM14.048

Accurate quantification and qualification of FFPE samples increases success rate of NGS library prep and sequencing

B. Arezi, *B. Rogers, K. Chen, B. Hsue, H. Hogrefe;*
Agilent Technologies, La Jolla, CA, United States.

FFPE tissue archiving is the most widely used method for clinical sample preservation, and provides a valuable source of diverse genetic information for cancer biomarker discovery. DNA recovered from FFPE tissues exhibits varying degrees of fragmentation, cross-linking, deamination, depurination and other lesions due to formalin fixation, paraffinization, and storage conditions; and as a result, NGS library preparation is often challenging. To increase success with FFPE-derived DNA, we developed a qPCR-based method to determine quantity of amplifiable DNA and extent of degradation. SureSelect XT libraries were prepared from multiple FFPE samples of varying integrity, and enriched using the ClearSeq Comprehensive Cancer Panel which targets 151 genes frequently mutated in solid and hematological cancers. As we will show, qPCR integrity scores are highly correlated with pre-capture PCR yield and sequencing metrics (library complexity and coverage), and can be used as a guide to determine appropriate sequencing depth for optimal coverage.

PS14.049

SuperScript® IV Reverse Transcriptase: A New Reverse Transcriptase for RNA Analysis

B. Lam[1], *K. Zhang[1], J. Guo[1], L. Li[1], K. W. Garcia[1], A. Jokubauskaite[2], M. Kaniusaite[2], T. Radzvilavicius[2], A. Lagunavicius[2];*
[1]Thermo Fisher Scientific, Carlsbad, CA, United States, [2]Thermo Fisher Scientific, Vilnius, Lithuania.

Survey and interview studies conducted over a three year period revealed that researchers are not satisfied with their current reverse transcriptase and are performing reactions with increasingly difficult samples, such as poorly purified RNA that contains inhibitors and unpurified RNA (direct RT). To meet this performance gap, the Thermo Fisher Life Sciences Solution group combined technologies from the former Thermo Fisher Scientific and Life Technologies to produce a new reverse transcriptase. SuperScript® IV is the first reverse transcriptase enzyme launched from joint efforts and experimental evidence shows that it is the most robust reverse transcriptase compared to other enzymes. SuperScript® IV characterization was performed in the context of "real world" situations where users do not have perfect RNA samples. Using a variety of stringent assays, we demonstrate that SuperScript® IV possesses superior performance in a variety of inhibitors, such as alcohols, salts, detergents, phenol, heparin, hematin, bile salts, and formalin typically found in sample preparation reagents, cell lines, blood, feces, and FFPE samples. This enzyme can even detect RNA targets in unpurified RNA samples (directly lysed cells) and whole blood without sacrificing sensitivity and yield. The introduction of SuperScript® IV enables researchers to obtain more consistent results independent of sample quality and simplify and speed up workflows by eliminating RNA purification.

PM14.050

Data sharing and interpretation amongst Dutch genome diagnostic laboratories

K. J. van der Velde[1], *M. de Haan[1], B. Miedema[1], B. Charbon[1], D. van Enckevort[1], P. Neerincx[1], A. J. Brookes[2], R. H. Sijmons[1], T. J. de Koning[1], R. C. Niessen[1], J. D. H. Jongbloed[1], members of the VKGL data sharing group and MOLGENIS team, M. E. van Gijn[3], R. J. Sinke[1], M. A. Swertz[1];*
[1]UMC Groningen, Groningen, Netherlands, [2]University of Leicester, Leicester, United Kingdom, [3]UMC Utrecht, Utrecht, Netherlands.

The interpretation of the vast amount of DNA variants NGS produces is a huge challenge. Sharing of detected variants between laboratories would be of great assistance to differentiate pathogenic and benign DNA variants. Moreover, dozens of annotation tools and databases, including tissue/cell/allele specific gene expression, QTL and GWAS associations, drug targets, pathogenicity prediction toolss, model organism studies, metabolic/signalling pathways, clinical actionability, are emerging to aid variant classificatio,. What are the best practice protocols and tools?
To address these challenges, the Dutch Society for Clinical Genetic Laboratory Diagnostics (VKGL) has started the NGS data sharing working group. Clinical diagnostics labs can easily upload individual VCF files to the national data sharing server that are then aggregated for anonymous public queries. In addition, we have built the MOLGENIS.org system so that bioinformaticians can now plug-in new annotation scripts, optimal data storage solutions (e.g. VCF, local databases, search indexes) and visualizations for rapid community evaluation.
Clinical labs can now easily interrogate patient mutations observed in other labs. We expect this effort to develop into a valuable NGS data exploration app as well as a sharing platform for best practice data and pipelines, integration with international sharing platforms such as GA4GH and Cafe Variome (for which pilots are underway), well-curated reference knowledgebases, and optimal user interfaces, results of which can disseminate into research institutes, clinical software companies and individual labs.

PS14.051

Streamlining NGS workflows by the application of the DNA Integrity Number (DIN) from the Genomic DNA ScreenTape Assay

E. Schmidt[1], *I. Pechtl[1], M. Gassmann[1], B. McHoull[2];*
[1]Agilent Technologies, Waldbronn, Germany, [2]Agilent Technologies, Edinburgh, United Kingdom.

The results of numerous molecular screening and assay methods often rely on the overall quality of the genomic DNA (gDNA) input material. However extraction of genetic material can be challenging and often results in low amounts or variable quality of gDNA samples, which are further subjected to time and cost intensive downstream applications. For example, array comparative genome hybridization (aCGH) and Next Generation Sequencing (NGS) can require intact, high quality gDNA to ensure high quality, unambiguous results. It is therefore widely recommended to perform an initial quality control (QC) of the input material. Especially as only the final step of these workflows reveals if meaningful results have been achieved. In order to provide an automated measure for gDNA integrity assessment, a software algorithm has been developed. This functionality of the 2200 TapeStation system provides a numerical determination of gDNA integrity and is referred to as the DNA Integrity Number (DIN). The data presented here demonstra-

tes how the standardization of sample integrity assessment using the DIN allows the establishment of workflow specific thresholds for the upfront QC of gDNA on the Agilent Genomic DNA ScreenTape assay. In this study the objective determination of the sample integrity resulted in significant saving of sequencing and sample preparation overhead in NGS workflows.

Melbourne Genomics Health Alliance: evaluating a whole of system approach to implementation of genomics into clinical practice

C. Gaff[1], *W. J. Wilson*[2], *I. Macciocca*[1], *N. Thorne*[1], *M. Martyn*[1], *G. Brett*[1], *E. Wilkins*[1], *S. Metcalfe*[3,4], *E. Forbes*[1], *E. Creed*[1], *T. Bakkar*[1];
[1]*Melbourne Genomics Health Alliance, Parkville, Australia,* [2]*CSIRO, North Ryde, Australia,* [3]*University of Melbourne, Parkville, Australia,* [4]*Murdoch Childrens Research Institute, Parkville, Australia.*

To optimise the use of genomics as part of routine practice, whole of system change is needed. Melbourne Genomics Health Alliance is clinically driven, addressing change in health, diagnostic, workforce and information management across seven healthcare, research and academic organisations. In the demonstration phase, barriers are identified and resolved. Adults and children (n = 250) with one of five germline or somatic conditions are being offered whole exome sequencing with targeted analysis. Importantly, this is in parallel with standard investigations. Evaluation is being performed on the process and outcomes of counselling, diagnostic testing, multidisciplinary review, reporting, data linkage, patient entry of lifestyle data and ease of access to (raw) data by researchers. Data collected includes feedback from clinicians and participants. Initial results (n=144) demonstrate a 30% diagnosis rate overall; performance relative to standard care is variable across conditions. A key feature of the project has been demonstrating that common standards for exome sequencing, curation and interpretation can be agreed and applied across different diagnostic laboratories. The common, highly-automated bioinformatics pipeline and linked database for curation of filtered variants have been well received by those performing curation. Multidisciplinary meetings to interpret results have proven a highly effective means for engagement and education. Participant expectations differed between adult participants and parents of a child participant. Data linkage has expanded the information available for research and clinical care and laid the foundation for data sharing to organisations outside the Alliance. Detailed results of the outcome and process evaluation will be presented.

PS14.053

Clinical genome analysis: delivering the right diagnosis

S. Raza, *A. Hall, H. Burton, M. Kroese, L. Luheshi;*
PHG Foundation, Cambridge, United Kingdom.

Whole genome sequencing and analysis (WGA) presents an unprecedented opportunity to transform clinical genetic services for patients with rare diseases. Yet converting whole genome data into clinically useful results is not an uncomplicated procedure. This unique project set out to influence policy, by informing policy-makers of the challenges of embedding genome sequencing in health services for patient benefit. Through consultation with a group of experts including clinical geneticists, clinical scientists and molecular scientists, we examined different aspects of the genome analysis process in the context of rare disease diagnosis to (i) explain the barriers that need addressing in order to use genome sequence data for clinical purposes, and (ii) present the changes in policy required to enable the safe and effective application of genome sequencing in healthcare. Our examination has highlighted the following challenges when applying genome analysis within a clinical diagnostic pathway: the integration of bioinformaticians within the healthcare workforce; the development and application of standards and best practice guidelines to WGA; improving the evidence base on which data analysis and interpretation depends; and optimising the mechanisms for phenotyping patients and capturing this information to support efficient WGA. These challenges to achieving accurate and effective WGA are not insurmountable, but overcoming them will take resources, commitment from stakeholders, and a methodical yet proportionate approach. Realising the benefits of WGA will require: establishing best practices in bioinformatics; determining analytic standards; improving data and knowledge exchange; establishing adequate computational infrastructure to perform genome analysis and interpretation and transfer of data.

PM14.054

Sporadic hereditary motor and sensory neuropathies: advances in the diagnosis using Next Generation Sequencing technology

C. Fallerini[1], *G. Carignani*[1,2], *G. Capoccitti*[3,4], *A. Federico*[3,5], *A. Rufa*[3,5], *A. Pinto*[1], *C. Lo Rizzo*[1,2], *F. Mari*[1,2], **M. Mencarelli**[1,2], *F. Giannini*[3,4], *A. Renieri*[1,2];
[1]*Medical genetics, University of Siena, Siena, Italy,* [2]*Genetica Medica, Azienda Ospedaliera Universitaria Senese, Siena, Italy,* [3]*Dept. Medical, Surgical and Neurological Sciences, Siena, Italy,* [4]*UOC Neurologia e Neurofisiologia Clinica, Azienda Ospedaliera, Universitaria Senese, Siena, Italy,* [5]*UOC Neurologia e Malattie Neurometaboliche, Siena, Italy.*

Hereditary motor and sensory neuropathies (HMSN) are genetically heterogeneous disorders affecting peripheral motor and sensory functions. Many different mutations in several HMSN causing genes involved in the demyelinating, the axonal and the intermediate form have been identified, for which all inheritance patterns have been described. The mutation screening currently available is based on Sanger sequencing and is time-consuming and relatively expensive due to the high number of genes involved and to the absence of mutational hot spots. To overcome these limitations, we have designed a custom AmpliseqTM panel for simultaneous sequencing of the coding DNA sequence (CDS) of 28 HMSN-related genes. We have applied this panel to three representative patients with variable HMSN phenotype and uncertain diagnostic classification because of an uninformative family history and electrophysiological findings suggestive but not fully conclusive for axonal, demyelinating or intermediate form. Using our NGS platform we rapidly identified three already described pathogenic heterozygous mutations in MNF2, MPZ and DMN2 as disease-causative mutations in the three cases, respectively. Here we show that, while utilization of traditional molecular techniques would be time-consuming and expensive, our pre-custom platform allows a fast, specific and low-cost diagnosis in sporadic HMSN cases. This prompt diagnosis is extremely useful for providing a well-timed treatment, establishing a recurrence risk and preventing further investigations poorly tolerated by patients and expensive for the health system. Importantly, our study illustrates the utility and successful application of NGS to mutation screening of a Mendelian disorder with extreme locus heterogeneity.

PS14.055

Towards a uniform nomenclature to improve the patient reports and databases: results from two pilot EGFR External Quality Assessment schemes

V. Tack, L. Tembuyser, **E. Dequeker**;
KU Leuven, Leuven, Belgium.

Introduction. Uniform reporting of mutations in an electronic database is essential. Laboratory databases as well as electronic medical records will be contacted in the future, to create large reference databases for health benefit research. The Human Genome Variation Society (HGVS) nomenclature guidelines are the golden standard for an unambiguous and uniform reporting system for mutations.
Materials and Methods. Diagnostic reports of two ESP external quality assessment schemes for *EGFR* mutation analysis were analyzed in detail regarding the nomenclature.
Results. The *EGFR* mutation was correctly identified and reported in 81 reports in 2012 and 137 reports in 2014. The number of reports with nomenclature according to the most recent guidelines of HGVS were, respectively for 2012 and 2014, 32.1% and 28.5%. The most used error, was the use of traditional nomenclature (e.g. G719S), respectively 38.3% in 2012 and 54.7% in 2014. Reporting on both DNA and protein level was done by 67.9% in 2012 and only 59.1% in 2014. The number of labs reporting a three-letter code for each amino acid has decreased from 39.5% in 2012 to 31.4% in 2014, of which respectively 8.6% and 13.9% also report the one-letter code in parallel.
Conclusion. The results show the need for improvement of mutation reporting according to HGVS guidelines. From 2014, points are deducted for non- or incorrect HGVS nomenclature in order to increase the attention of laboratories for a correct and unambiguous reporting of mutations. Further research will be performed with nomenclature results from different EQA providers.

PM14.056

Full length HLA genotyping using Pacific Biosciences SMRT sequencing

N. Cahill[1], *A. Ameur*[1], *C. Knutsson*[2], *U. Orebrand*[3], *U. Gyllensten*[1], *M. Bengtsson*[4];
[1]*SciLife Lab, Uppsala University, Uppsala, Sweden,* [2]*Rudbeck Laboratory, Uppsala University, Uppsala, Sweden,* [3]*Rudbeck Laboratory, Uppsala, Sweden,* [4]*Rudbeck Laboratry, Uppsala University, Uppsala, Sweden.*

HLA genotyping through sequence-based typing (SBT) is subjected to phase ambiguity and genotyping uncertainties, leading to delays in patient/donor typing. Herein, we summarise our experiences in setting up a high-throughput genotyping approach using Pacific Biosciences (PacBio) SMRT-sequencing as a means to provide full length HLA sequences for adequate phasing and identification of novel alleles within a clinical setting.

Locus-specific amplification of HLA Class I and II loci produced full-length amplicons encompassing the enhancer/promoter region to the 3'UTR. Following PacBio SMRT-sequencing, single-molecule sequences were analysed via the long amplicon analysis pipeline and genotyped using third-party genotyping software (n=12). Initial results revealed full concordance with the anticipated SBT results. Both alleles from both heterozygous and homozygous individuals were completely resolved and formerly ambiguous alleles were readily determined. A number of novel intronic sequence variants were also discovered.
Given the quality of the data generated, it was clear the sequencing of full-length HLA genes using PacBio approach could accommodate a high degree of multiplexing. Consequently, we are conducting a pilot study (n=50) in association with the Fred Hutchinson Centre to develop a streamlined pipeline from sample collection to genotype acquisition. Within this pilot we are evaluating optimal primer sets, level of multiplexing, automation of laboratory and data analyses steps and the use of third-party genotyping software. Preliminary results reveal that PacBio sequencing will allow for high-resolution and high-throughput sequencing of full-length HLA loci with a fast turn-around time. However, further optimisation of the pipeline is needed.

PS14.057
Genotyping of alpha thalassaemia mutations by high-resolution DNA melting analysis

C. Chassanidis, *E. Boutou, A. Balassopoulou;*
Thalassaemia Center, Laiko General Hospital, Athens, Greece.

Alpha-thalassaemia is an inherited globin gene disorder commonly found among the Greek population, composed of both non-deletional and deletional alpha-globin gene mutations. In Greece, 7% of the general population is carrier of α-thalassaemia (deletion 3.7 kb-α3.7) while 1% carries α^0 deletions or rare point mutations an (non-deletional, α^T).
The high prevalence (8%) and heterogeneity in molecular level, makes necessary the development of a reliable, cost effective and rapid scanning method for alpha globin gene analysis, easily adapted to a routine laboratory.
Here we describe the development of an alpha thalassaemia specific High Resolution Melting Analysis (HRMA) approach. Specific sets of primers were designed to cover eight regions of the HBA genes containing the most frequent hitherto reported mutations of the Greek population [$\alpha2^{Agrinio}$, $\alpha2^{Hph}$, $\alpha2^{Icaria}$, $\alpha2^{CS}$, $\alpha2^{PA1}$, $\alpha2^{PA2}$, α2 cd115(+CC)]. PCR conditions were designed identical for all amplicons, permitting thus multiplexing. Furthermore, Real-Time GAP-PCR was performed in order to identify deletions (-α3.7, --med, -20.5, -α4.2).
Initially, 75 previously genotyped samples (heterozygotes or homozygotes) were analysed. Different mutations produced distinct derivative plots when subtracted from the reference curve of a wild type control, resulting in 100% accurate mutation identification. In addition, HRMA analysis of 125 undefined samples totally matched subsequent diagnosis by either Sanger sequencing or ARMS analysis.
HRM curve analysis is rapidly becoming the prominent mutation scanning methodology representing a rapid, simple, cost-effective and highly feasible strategy for identifying effectively underlying mutations. We successfully performed HRMA for alpha-thalassaemia in order to identify frequent α-thalassaemia mutations in terms of carrier screening and prenatal diagnosis.

PM14.058
Correct result, but was the correct sample tested? Introducing the UK NEQAS for Molecular Genetics Tissue Identification EQA Scheme.

J. A. Fairley[1], *C. Anderson*[2], *Z. Deans*[1];
[1]*UK NEQAS for Molecular Genetics, Edinburgh, United Kingdom,* [2]*UHW, Cardiff, United Kingdom.*

Objectives
To provide an EQA for the molecular testing of FFPE specimens to determine identity.
Incidents occur in laboratories which result in doubt over the origin of tissue samples. Therefore it is necessary for laboratories to test samples for confirmation of the origin of the tissue, detect sample switches or identify sample mislabelling. This often aids in the delivery of a patient result and minimises the need for re-sampling.
Laboratories test formalin fixed paraffin embedded (FFPE) tissue samples using molecular fingerprinting assays. To provide laboratories with assurance of the quality of this testing and accuracy of data analysis, a pilot external quality assessment (EQA) was offered to laboratories during 2015.
Laboratories were supplied with three EQA scenarios with accompanying rolled sections of FFPE tissue (1 x 10μM curled section per sample) and were required to extract DNA and test according to their usual procedures. The results were to be interpreted with respect to the scenario provided and to determine the likelihood that the multiple tissue samples supplied were from the same patient. To ensure the tissue samples were appropriate for testing by molecular fingerprinting assays all EQA samples were validated by two independent laboratories using different assays. The results were as expected and gave high quality reportable molecular test results. Fourteen laboratories participated in the pilot EQA and the reported genotyping results, interpretation of the data and the methodologies used in the EQA run will be presented.

PS14.059
The clinical utility of QF-PCR microsatellite analysis in sample identification and patient management

C. J. Anderson[1], *S. Gable*[2], *R. Butler*[1];
[1]*Laboratory Genetics Service for Wales, Institute of Medical Genetics, UHW, Cardiff, United Kingdom,* [2]*Department of Cell Pathology, UHW, Cardiff, United Kingdom.*

An in-house QF-PCR microsatellite assay, used routinely for the prenatal diagnosis of chromosomal aneuploidy, has been re-optimised and applied in the identification and quantification of contributing genotypes within FFPE tissues. Microsatellite analysis has been used successfully to answer clinical questions arising from suspected clinical incidents; preventing patient misdiagnoses and mismanagement.
Here we present 2 cases where the results of microsatellite analysis played a crucial role in patient management. Case ONE details how microsatellite analysis of FFPE tissue and reference peripheral blood samples was not only used to prove that a patient panel of prostate core biopsies, as suspected, had been wrongly labelled, but also that of the batch of 4 patients' samples processed along-side the mislabelled sample, 2 further samples had been mislabelled. Comparison of patient prostate and reference genotypes facilitated the correct identification and assignment of all patients' prostate core biopsy samples. Case TWO details how microsatellite analysis of FFPE material was used to confirm the clinical suspicion that histologically malignant and normal tissues samples from 2 individuals had become embedded in a single resection block. Microsatellite analysis of macro-dissected FFPE material from different areas of a resection slide showing a 'mix' of tissues and comparison to a reference patient sample genotype confirmed the presence of 2 genotypes, consistent with sample mixing, preventing inappropriate clinical management.
Tumour identification services are now being offered by the Laboratory Genetics Service for Wales, Cardiff.

PM14.060
Targeted next generation sequencing a powerful tool to improve the care of blind infants.

J. Rozet[1], *S. Hanein*[2], *C. Bole*[3], *P. Nitschke*[4], *N. Delphin*[5], *O. Xerri*[1], *A. Munnich*[5], *J. Kaplan*[1], *I. Perrault*[1];
[1]*INSERMU1163 Institut IMAGINE Lab Genetics in Ophthalmology, PARIS, France,* [2]*INSERMU1163 Institut IMAGINE NGS Molecular Diagnosis, PARIS, France,* [3]*INSERMU1163 Institut IMAGINE Genomics Platform, PARIS, France,* [4]*INSERMU1163 Institut IMAGINE Bioinformatic Platform, PARIS, France,* [5]*INSERMU1163 Institut IMAGINE Genetics, PARIS, France.*

Introduction: Leber congenital amaurosis is the earliest and most severe retinal dystrophy, and a leading cause of blindness in children. The visual outcome of affected infants is variable, ranging from light perception, to low but measurable visual acuity in the first two decades of life. Blind infants with LCA are at risk of developing skeletal, neurologic and renal dysfunctions. Both the visual and extraocular outcomes strongly correlate with the disease-gene. The study presented here aimed at assessing targeted NGS (T-NGS) as a tool to improve patient care by allowing efficient and early molecular diagnosis in infants with severe visual deficiency.
Methods: 260 index LCA cases were sequenced using a T-NGS array comprising 45 genes causing isolated or syndromic LCA and 10 genes of differential diagnoses. Mutations were confirmed by Sanger sequencing and familial segregation analysis.
Results: We identified causative mutations, including 6 copy number variations, in 158/260 index cases, 130/158 of whom had mutations in genes for isolated LCA/EOSRD and 15/158 in genes for syndromic forms. In addition, we identified convincing mutations in genes for differential diagnoses in 13/260 individuals.
Conclusions: T-NGS molecular diagnosis proved powerful to improve the care of infant with severe visual dysfunction by allowing i) early identification of children with differential diagnosis which outcome is highly favorable compared to LCA (13/260; 5%) and, ii) early discrimination of children at no risk of being affected with syndromic LCA (130/158; 82%) from those,

far fewer, at risk of developing extraocular symptoms (15/158; 9%) who require extraocular explorations.

PS14.061
Identification of rarehemoglobinopathy by matrix-assisted laser desorption ionization time of flight mass spectrometry (MALDI-TOF/TOF)
P. Jittorntam;
Ramathibodhi hospital, Bangkok, Thailand.

Thalassemia and hemoglobinopathy is the public health problem in Southeast Asian population. Rare hemoglobinopathy is occasionally found from routine screening using High-Liquid Performance Chromatography (HPLC) or suspected in people with low mean corpuscular volume (MCV) and low mean corpuscular hemoglobin (MCH) of red blood cells with no obvious identified peak from HPLC. Here we develop MALDI-TOF/TOF method to detect silent hemoglobinopathy, which cannot be detected by HPLC. In addition, we also use this technology to detect the mass of rare unidentified hemoglobin (Hb). DNA sequencing of alpha and beta globin chains was done in parallel to establish molecular diagnosis.In 2013-2014, our Genetics Service received several referrals for families carrying unidentified Hb. We can identify Hb Cheverly[beta 45(CD4) Phe>Ser] and Hb La Desirade[beta 129(H7) Ala>Val] in families with unknown causes of low peripheral oxygen saturation and normal HPLC. HbDhonburi[beta 126(H4) Val>Gly]was discovered in a family with slight increased Hb A_2 suggestive of beta thalassemia carrier. Hb New York [beta 113(G15) Val>Glu], Hb Louisville [beta 42(CD1) Phe>Leu]and Hb J-Buda [alpha1 61(E10) Lys>Asn]were identified in families with unknown peak of hemoglobin performed by HPLC. However, MALDI-TOF/TOF failed to identify the mass of some Hb such as Hb E[beta 26(B8) Glu>Lys]and Hb Zurich-Langstrasse[beta 50(D1) Thr>Ser]. In conclusion, MALDI-TOF/TOF is the potential high-throughput analytic method to identify abnormal globin chain with mass difference approximately 20 Da mass.

PM14.062
Method for fast screening of Y chromosome microdeletions by multiplex real-time touchdown PCR coupled with melting curve analysis
F. Raicu[1,2], *R. Cocos*[1,2];
[1]*Chair of Medical Genetics, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania,* [2]*Genome Life Research Centre, Bucharest, Romania.*

Male infertility accounts for 40-50% of couple infertility and represents a complex reproductive health problem with a substantial genetic basis and various environmental risk factors. Microdeletions in the AZF regions of the Y chromosome represent the most frequent molecular genetic cause of severe infertility accounting for 15% of cases of non-obstructive azoospermia or severe hypospermatogenesis.
The aim of this work was to further develop a fast and accurate screening method based on multiplex real-time touchdown PCR followed by melting curve analysis to scan AZF loci looking for microdeletions.
The European 2014 best practice guideline for molecular diagnosis of Y-chromosomal microdeletions were used as a basis for designing five real-time multiplex PCR systems, in which the selected combinations of 24 STS amplicons can strikingly be identified by their melting points with EvaGreen™ as the high-performing DNA intercalating dye.
In order to validate our testing method we analysed 120 azoospermic and oligozoospermic males previously tested by independent singleplex PCRs. A group of 130 healthy men as positive controls and 10 women as negative controls were also included in this study. We precisely detected the absence/presence of STS in our patient group of infertile men based on our method. No deletions were detected in the group of healthy men and no amplification for any of the STS tested were observed in the negative control group.
Our method allows a fast, simple and low-cost screening for Y chromosome microdeletions in patients with genetic infertility. The study was supported by POS-CCE-0 2.3.1 grant 1485/SMIS-CSNR 4296.

DeCovA: A user-friendly tool for displaying gene coverage from Massive Parallel Sequencing data. Application to a panel of 41 genes causing epileptic disorders
T. Simonet[1,2], **A. Labalme**[3], *S. Dimassi*[3,4,5], *A. Campan-Fournier*[3], *R. Lamy*[3], *C. Bardel*[6,5,7], *M. Elsensohn*[6,5,8], *F. Roucher Boulez*[5,8,9], *L. Schaeffer*[2,1,5], *P. Roy*[5,8,6], *D. Sanlaville*[3,5,4], *G. LESCA*[3,4,5];
[1]*Department of Cell Biotechnology, Lyon, France,* [2]*Ecole Normale Superieure de Lyon, Lyon, France,* [3]*Department of Genetics, Lyon, France,* [4]*CNRL, CNRS UMR 5292, INSERM U1028, Lyon, France,* [5]*Claude Bernard Lyon I University, Lyon, France,* [6]*Service de Biostatistique, Hospices Civils de Lyon, Lyon, France,* [7]*CNRS, UMR 5558, Laboratoire de Biométrie et Biologie Evolutive, Equipe Biostatistique-Santé, Villeurbanne, France,* [8]*CNRS, UMR 5558, Laboratoire de Biométrie et Biologie Evolutive, Equipe Biostatistique-Santé, Lyon, France,* [9]*Service d'hormonologie, d'endocrinologie moleculaire et des maladies rares, Lyon University Hospital, Lyon, France.*

Although coverage is critical for assessing the quality and accuracy of results from massive parallel sequencing (MPS), it is often a difficult parameter to display in practice. We developed DeCovA (Depth and Coverage Analysis), a simple and easy homemade tool that combines the sequencing depth of each base and the coverage of target genes.
To illustrate DeCovA's usefulness, MPS sequencing was performed on DNA samples from 24 patients using an Ion Torrent PGM sequencer (Life Technologies). Forty-one genes that cause monogenic forms of epileptic disorders were studied in parallel.
DeCovA first determines the genomic target regions from either a bed file or a list of genes, then launches the coverageBed tool from the bedtools suite to compute the depth of sequencing on each base of these regions, for each alignment bam files to be analysed. DeCovA uses these outputs to produce graphs that show, above each gene or transcript, the stretches of DNA not covered at different thresholds set by the user. DeCovaA can also draw the sum of the samples covered at different thresholds, which is useful to identify the stretches that escape repeatedly the enrichment/sequencing methods. Bar plots can be displayed for a group of samples, allowing group or method comparisons.
DeCovA allows a fast and reliable coverage analysis. Gaps per gene are highlighted and a warning can be set in order to return correct results according to the rating level of the test (Type A, B, C of Eurogentest Guidelines).

PM14.064
Integration of Next-Generation Sequencing as a Methylation-Based Routine Diagnostic Test in Colon Cancer Tissue Screening
S. Kühner[1], *T. Hinrichsen*[1], *O. Wachter*[1], *B. Dockhorn-Dworniczak*[2], *H. Klein*[1], *I. Rost*[1];
[1]*Zentrum für Humangenetik und Laboratoriumsdiagnostik (MVZ) Dr. Klein, Dr. Rost und Kollegen, Martinsried, Germany,* [2]*Zentrum für Pathologie Kempten-Allgäu, Kempten, Germany.*

Hereditary nonpolyposis colorectal cancer (HNPCC) is an autosomal inherited tumor predisposition syndrome generally caused by germline mutations in one of the mismatch repair genes (MLH1, MSH2, MSH6, PMS2) that are responsible for repairing mismatches generated during DNA synthesis. Impaired function of these MMR proteins leads to a high risk for colorectal cancer and for other HNPCC-related tumors. One of the main aim in HNPCC diagnostics is the discrimination of sporadic carcinomas from the less frequent HNPCC-associated tumors. DNA promotor methylation is typically associated with transcriptional silencing of the affected gene. Inactivation of MLH1 due to promoter hypermethylation strongly suggests a sporadic origin of the tumor. Hypermethylation of the MLH1 promoter occurs in 40% of the tumors with known negative MMR mutation status and is very rare in HNPCC patients [1]. Moreover, only methylation of CpG sites in one small region of the MLH1 promoter, the C-region, invariably correlates with silencing of MLH1 [2]. We established an assay for methylation screening of the C-region of the MLH1 promoter in colorectal cancer tissue by combining bisulfite conversion with Next Generation Sequencing (NGS). To validate this approach, we analysed the C-region of the MLH1 promoter of colorectal cancer tissue using NGS and MS-MLPA . We obtained consistent and reproducible results. NGS is a highly sensitive tool allowing an exact quantification of methylation of all CpG sites in the relevant promotor region and can easily be integrated as a methylation-based routine diagnostic test in colon cancer tissue screening.

A systematic approach to mitochondrial DNA diagnostics through sequencing
R. Berutti[1], *T. Wieland*[1], *B. Lorenz-Depiereux*[1], *U. Ahting*[1,2], *M. Radivojkov-Blagojevic*[1], *P. Lichtner*[1], *T. Meitinger*[1,2], *H. Prokisch*[1,2], *T. M. Strom*[1,2];
[1]*Institute of Human Genetics - Helmholtz Zentrum München, Neuherberg, Germany,* [2]*Institute of Human Genetics - Technische Universität München, Munich, Germany.*

Mitochondrial DNA is widely investigated for diagnostics: we recently developed a pipeline to help switching mtDNA sequencing at our Institute from Sanger to next-generation techniques.
Our pipeline addresses three different mtDNA sources, genomic (with an approximate coverage of 10,000X), exome (50-200X) and long-range PCR

(~10,000X). Reads are aligned with BWA to the revised Cambridge Reference Sequence, now included in hg38 genome release. Using a linear reference for a plasmid may cause border effects, which are removed by building a secondary sequence overlapping the junction, aligning on it and merging the results at a latter stage. Nuclear DNA contamination is stripped by adding the genomic reference in the alignment step. Variant calling is performed using GATK and Pindel, while we used for the annotation step Mitomap (for known polymorphisms and known associations of mutations with diseases and somatic effects on tissues), Phylotree (for gene definitions plus tRNA definitions from the University of Leipzig), GenBank (for haplogroup definition and frequencies).
The pipeline needs approximately 15 minutes to analyze a sample, performing SNV and indel calling, heteroplasmy detection, functional annotation, haplogroup estimation, and disease annotation. Variants are stored into a database and are accessible through a Web front-end.
We created a tool focusing on diagnostics, which allows to analyze mtDNA sequences from different NGS sources, to identify disease causing variants and to provide data-quality feedback to the wet lab. The variant database will also support future phylogenetic and population based studies.

Roadblocks to reaching a final diagnosis with next-generation sequencing

J. P. Casey[1], *E. Crushell*[2], *S. Lynch*[1];
[1]*Temple Street Children's University Hospital, Dublin 1, Ireland,* [2]*National Centre for Inherited Metabolic Disorders, Temple Stree Children's University Hospital, Dublin 1, Ireland.*

When does a research finding become a diagnosis? Having sufficient evidence to convert a potentially-relevant Next-Generation sequencing (NGS) finding to a concrete molecular diagnosis can be a lengthy process. This is particularly true for potentially novel disorders affecting just one family. Through our NGS-based research, we encountered a number of issues that complicated diagnosis including (i) important DNA samples unavailable for segregation analysis, (ii) only partial clinical overlap with a newly-described syndrome and (iii) novel candidate genes which require extensive functional studies. In the face of these challenges, we have had to use alternative genetic methods to determine pathogenicity.
In two studies, one X-linked recessive and one autosomal dominant, paternal DNA was not available to confirm whether the identified candidate mutations were de novo (likely pathogenic) or paternally-inherited (likely benign). Sanger sequencing and SNP haplotype analysis of unaffected siblings was necessary to determine pathogenicity. For X-linked recessive disorders, showing that the mutation is not present in any of the sisters of the patient/carrier mother can help support pathogenicity. For autosomal dominant disorders, showing that the haplotype on which the mutation is present in the patient is shared by an unaffected sibling who does not carry the mutation adds weight to the likelihood that it's de novo. For some consanguineous families we have identified causal compound heterozygous variants highlighting that we cannot always assume homozygosity despite consanguinity.
NGS has eased the identification of candidate variants. However, downstream analyses are vital to generate sufficient evidence to support causality and ensure families receive the correct molecular diagnosis.

Detection of mosaicism by augmented exome sequencing

G. Chandratillake[1], *S. Garcia*[1], *J. Priest*[2], *D. M. Church*[1], *J. Tirch*[1], *J. Yen*[1], *J. Anderson*[1], *M. Morra*[1], *M. S. Williams*[3], *J. West*[1], *E. Ashley*[2], *R. Chen*[1];
[1]*Personalis, Inc., Menlo Park, CA, United States,* [2]*Stanford School of Medicine, Stanford University, Stanford, CA, United States,* [3]*Genomic Medicine Institute, Geisinger Health System, Danville, PA, United States.*

The importance of mosaicism in Mendelian disorders is being increasingly recognized. Since many proteins form multi-unit homo-oligomers (reportedly over half), a small percentage of abnormal copies can affect a much larger fraction of these assemblies. Thus variants in less than 10% of cells can lead to serious clinical consequences. For some conditions, mosaicism explains the previously low yield of clinical genetic testing. Other conditions are obligate mosaic disorders. Furthermore, low-level parental mosaicism is increasingly recognized underlying apparently *de novo* cases of disease. Mosaicism is often undetectable through Sanger sequencing and so has been underappreciated in clinical genetic testing.
Detection of mosaicism in whole genome and exome sequencing is hampered by multiple factors. Variant calling and filtration strategies often miss or exclude variants at mosaic allele percentages. False positives can be rampant, especially over paralogous sequence regions. Read depths (typically ~30X) achieved in whole genome sequencing, add to the challenge. Exome sequencing can be much deeper, but standard exome coverage is variable, incomplete within genes, and excludes medically interpretable content outside the coding regions.
In order to detect clinically relevant mosaicism, sequencing coverage must be consistently deep over all medically interpretable content, and variant-calling algorithms appropriately adjusted. We present cases of both somatic and germline mosaicism demonstrating that the use of augmented exome sequencing with modification for mosaic detection allows for the sensitive detection of mosaicism. We demonstrate that this approach has proven more sensitive to mosaic detection than both clinical testing and some whole genome-based approaches.

Introduction: Compromised nucleotide excision repair (NER) activity causes a variety of autosomal recessive diseases including the skin-cancer predisposition disorder, xeroderma pigmentosum (XP) and the severe premature ageing condition, Cockayne syndrome (CS). Considering the clinical overlap of NER-related disorders and the several genes involved, we have developed a new diagnostic approach based on the enrichment of 16 NER-related genes by multiplex amplification coupled with next-generation sequencing (NGS).
Materials and Methods: The strategy was first evaluated on a validation cohort of 11 known patients and then applied to a prospective cohort of 30 patients. Multiplex amplification and sequencing were performed using AmpliSeq protocol on Ion Torrent PGM (Life Technologies).
Results: We detected clearly pathogenic biallelic mutations in 14 out of 30 cases (47%). Five new mutations were described in both ERCC6/CSB and ERCC8/CSA Cockayne genes. We also identified two XP patients linked to the very rarely involved ERCC3/XPB gene (only 9 patients from 6 families already published). Finally, the study of a small cohort of 4 unrelated XP patients from the Basque country (Northern Spain) retrieved a common splicing mutation in POLH (XP-variant), demonstrating a new founder effect in this population.
Conclusions: Despite the small number of NER-defective patients, NGS strategy has shown to be particularly relevant, especially for patients with atypical or incomplete clinical phenotypes. NGS is an efficient alternative to sequential Sanger approach and is the essential molecular complement of cellular tests measuring DNA repair activity.
This study was supported by a grant from Agence de Biomedecine.

PM14.070
Development of a Target Region Capture Paralleled Next Generation Sequencing Platform on Monogenic Disorders of the Newborn

G. Rui[1], *P. Jiang*[1], *B. Wu*[2], *Z. Huang*[1], *C. Liu*[1], *W. Zheng*[1], *Z. Lan*[1], *Q. Wang*[1], *W. Zhou*[2], *X. Yi*[1];
[1]*BGI, Shenzhen, China,* [2]*Children's Hospital of Fudan University, Shanghai, China.*

It was estimated that one quarter of the patients in the new-borns and paediatric population are actually related to genetic disorders. In new-borns whose phenotypic evidence might not be clinically manifest in early days, a definitive diagnosis may be difficult to be provided for timely treatment or prevention. Comparing with traditional methods, NGS based second-tier testing has the potential to assist in the diagnosis and management of newborn diseases by accelerating the process and reducing false positives.
A customized genetic panel was designed including 88 genes and a couple of special regions related to 51 new-born disorders. To facilitate the clinical application, we have optimized the pipeline in terms of accelerated turnaround time to ~70 hours and easy-assessed sample as dried blood spots.

The pipeline is automated to generate variation calls for SNP, Indel and large size deletions. And an in-house validated variation database was introduced to assist the interpretation of mutations.
In the assay, we first assess the performance of the pipeline using reference materials. The coverage of the interested regions is above 95% at 30X. Then 53 previously identified specimens with 65 different mutations were applied to validate the detection ability. All mutations were correctly identified except one large transposal insertion. And among 33 patients with clinically suspected symptoms, 22 patients were identified with known or suspected mutations. We thereby demonstrated that the platform is reliable to detect causal mutations and might help facilitate clinical evaluation and early intervention in newborn screening or in NICU.

PS14.071
Implementation of an NGS-based workflow for BRCA1 and BRCA2 mutation screening

L. Artuso[1], *V. Medici*[1], *I. Bernardis*[1], *E. Tenedini*[1], *V. Artusi*[1], *M. L. Simone*[1], *C. Priore Oliva*[1], *P. Tarugi*[1], *R. Manfredini*[2], *L. Cortesi*[3], *E. Tagliafico*[1];
[1]*Centre for Genome Research, Department of Life Sciences, University of Modena and Reggio Emilia, Modena, Italy,* [2]*Centre for Regenerative Medicine "Stefano Ferrari", Department of Life Sciences, University of Modena and Reggio Emilia, Modena, Italy,* [3]*Department of Oncology, Hematology and Respiratory Diseases, University of Modena and Reggio Emilia, Modena, Italy, Modena, Italy.*

Positivity for BRCA1 and BRCA2 mutations was associated with increased probability to develop familiar breast cancer. To detect BRCA1/2 germline mutations we developed a next-generation sequencing (NGS) routine diagnostic workflow, based on the Ion Torrent PGM™ System platform. The Ion AmpliSeq™ BRCA1 and BRCA2 Community Panel was handled with a semi-automatized procedure for multiplex PCR-based library preparation and sequencing. Data analysis required the implementation of a custom designed bioinformatic pipeline for sequences alignment and for the identification, annotation and filtration of genetic variants. Sanger sequencing was performed to validate candidate mutations, and to re-sequence amplicons having low NGS coverage (<50 reads per amplicon). Negative samples were analyzed using the BRCA HP Kit (Multiplicom) for an effective homopolymeric stretches detection. This workflow together with the potentiality of our bioinformatic pipeline was blindly tested and validated onto a small cohort of patients previously Sanger sequenced, fine-tuning the parameter settings and resulting in a sensitivity of 100% in variant detection. Subsequently, 244 patients were analyzed thus confirming the need of a double check for the homopolymeric stretches with both NGS sequencing and BRCA HP Kit.
The NGS-based workflow here proposed was able to decrease the overall cost of the conventional genetic test and make the diagnostic process faster than compared to Sanger sequencing alone.

PM14.072
Targeted Locus Amplification for hypothesis neutral and complete Next Generation Sequencing and haplotyping of genes of interest.

M. J. van Min;
Cergentis, Utrecht, Netherlands.

Current methodologies in genetic diagnostics and research are limited in their ability to uncover all genetic variation in genes of interest. Clinical genetic tests often only focus on exons and therefore miss variants in the non-coding regulatory sequences of genes. In addition, structural variants, i.e. deletions/duplications (CNVs), translocations, insertions and inversions, are difficult to uncover. Their robust detection is hampered by the hypothesis-driven nature of current targeted sequencing methodologies: the collection of probes (in hybridization-based capture methods) or primers (in polymerase or ligase-based re-sequencing approaches) determines the sequences that will be analyzed. None of these methods provide haplotyping information, ultimately needed to get complete sequence information. Here we present targeted locus amplification (TLA), a strategy to selectively amplify and sequence entire genes. TLA is based on crosslinking, fragmenting and religation steps such as performed in chromatin capture technologies. We show that, unlike other targeted re-sequencing methods, TLA works without detailed prior locus information as one or a few TLA primer pairs are sufficient to amplify and sequence tens to hundreds of kilobases of surrounding sequences. This, we demonstrate, enables robust detection of single nucleotide variants, structural variants and gene fusions in clinically relevant genes. Data will be presented showing the ability of the TLA Technology to: 1) Sequence & haplotype a.o. the complete BRCA1 & BRCA2 genes for the detection of germline and somatic variation in (xenograft) tumor samples. 2) Haplotype the Human Leukocyte Antigen (HLA) region. 3) Detect all gene-fusions in genes of interest and characterize fusions at breakpoint resolution in leukemia and other cancer types.

PS14.073
Strategy for validating the ever-changing face of next generations sequencing

K. Brugger, **H. Martin**, *S. Abbs;*
Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom.

Next Generation Sequencing (NGS) has seen a revolution in the last few years with the price of sequencing constantly decreasing whilst sequencing platform throughput and the range of experimental assays that can be performed, has increased. This is the result of a constant stream of NGS improvements in the form of new sequencers, new chemistry, improved protocols and new or improved software. This constant flux puts a large burden on laboratories performing clinical grade NGS, working to accreditation standards, and having to constantly re-validate these aspects before changes are implemented.
We describe the process we have introduced to clinically validate our NGS assays that range from stratified HIV sequencing to clinical exome sequencing, and encompasses all aspects from DNA sample to final report. Furthermore we discuss our long term strategy for verifying new NGS equipment and chemistry, and changes to protocol and software, to ensure they remain fit for purpose. Finally we outline and show the output of software we have created for quickly re-validating these changes at minimal cost and requiring minimal additional laboratory work.

PM14.074
A standardized validation workflow for clinical Next Generation Sequencing (NGS) analysis

L. Laner, *A. M. Nissen, A. Benet-Pages, C. Rapp, E. Holinski-Feder;*
Medizinisch Genetisches Zentrum München, München, Germany.

The emerging use of NGS approaches in clinical laboratories has rushed the development of guidelines to ensure adherence of the same rigorous standards as in other clinical tests for direct patient care. However, a gap remains between the general published requirements and the detailed information regarding how these should be satisfied in routine practice. Hence, we developed a standardized validation process which can be applied to NGS workflows designed to detect sequence variation within a targeted set of genes. We defined key parameters and quality criteria to assess performance and limitations within NGS-processes (platform, pipeline, test). Platform precision was evaluated by testing reproducibility and repeatability of three independent samples during the laboratory process (DNA quality, fragmentation, library/pool quantification, sequencing quality, error rate). A correlation of >95% was defined as satisfying. Pipeline accuracy was assessed through analytic sensitivity and specificity of variant calling. Two HapMap specimens were sequenced and variants detected by our bioinformatics pipeline were compared to variation data of these specimens accessible via the 1000Genomes Project. Discordant calls were confirmed by Sanger. Moreover, variants called at low allele fractions, base quality (Q<30) and coverage (<30X) were also validated to assess the limits of detection. Test validation includes mapping statistics (raw, mapped, duplicate reads) and calculation of coverage distribution (>30X) to determine the analyzable region of each clinical target. Further, evaluation of repetitive sequences, pseudogenes, homologous regions and GC content to state which parts of the clinical target may not be sequenced reliably. This validation process was designed to meet the currently published guidelines.

PS14.075
Multi-Pronged Approach for Somatic Variant Detection using HaloPlex^{HS} with Molecular Barcodes

K. Zobeck, C. Le Cocq, **L. Forsmark**, *J. Chi, J. Ghosh, M. Isaksson, H. Johansson;*
Agilent Technologies, Santa Clara, CA, United States.

Agilent's HaloPlex^{HS} is a next generation PCR target enrichment method that enables enrichment of thousands of targets in a single tube. The protocol utilizes specificity gained from restriction enzyme digestion, hybridization and DNA ligation to capture the target region. Standard amplicon-based target enrichment methods are limited in sensitivity because mapping start points of paired end reads cannot be used to identify unique molecules and improve confidence in variant calling. Therefore, we have added molecular barcodes to the primer cassettes allowing detection of unique molecules.
The HaloPlex^{HS} workflow has been optimized to take <6 hours to complete and requires only 50 ng input. Using molecular barcodes, we demonstrate increased confidence and detection of variants down to <1% allelic fraction.

Furthermore, an improved probe design in Agilent's SureDesign results in increased coverage for custom designs. We demonstrate for 31 designs, >85% specificity and >90% of target regions covered at 10% of average depth when sequenced at >100X.
Finally, Agilent's SureCall 3.0 utilizes the molecular barcodes in a novel algorithm for removing duplicate PCR fragments. It assigns reads to amplicons by probe sequence matching, then uses the barcodes to merge duplicate reads while providing correction for sequencing and PCR errors and improving variant calling. SureCall can accurately call variants at 2.5% allelic fraction. We demonstrate the speed and accuracy of this method, especially for reads with non-unique mapping. With this multi-pronged approach, from probe design, to library prep, to analysis, we demonstrate that HaloPlex^{HS} provides more accurate variant calls with higher sensitivity and better coverage of custom designs.

The comprehensive analysis of a cohort of Polish patients with the suspicion of neurofibromatosis type 1 using Next Generation Sequencing

A. Wasowska[1,2], *M. Krawczyk*[1], *T. Janiszewska*[3], *M. Jurkowska*[1], *R. Szymanczak*[1], *M. Zagulski*[1];
[1]*Genomed SA, Warsaw, Poland,* [2]*Polish-Japanese Academy of Information Technology, Warsaw, Poland,* [3]*Genetic Counselling Unit, University Hospital No 1, Bydgoszcz, Poland.*

Neurofibromatosis type 1 (NF1) is a common autosomal dominant disorder affecting approximately 1 in 2000 to 3500 people. It appears to be a single gene-determined disorder characterized by complex cognitive symptoms, including cutaneous neurofibromas, cafe-au-lait spots, Lisch nodules and optic gliomas. The *NF1* gene has one of the highest rates of mutations in the human genome, with almost equal split between spontaneous and inherited mutations. Identifying the disease-causing change is complex due to the large size of gene, the presence of pseudogenes and the lack of mutation hotspots.
The present study describes screening for the *NF1* mutations in 90 patients from 76 unrelated families with phenotype fulfilling diagnostic criteria or with suspicion of neurofibromatosis type 1. The analysis included amplification of 58 coding regions and flanking splice sites (according to NM_001042492.2), library preparation and next-generation sequencing (NGS). Sanger sequencing was used for mutation confirmation or when the average coverage per region was lower than 50x. To the date of submission, 49 unique mutations were identified within 76 families, including 7 missense substitutions, 16 stopgain mutations, 19 small deletions or insertions and 7 splice site changes. Twenty one out of these mutations are registered in the Human Gene Mutation Database, four variations concern the location where a different mutation has been previously discovered and the rest are newly detected mutations with a probable pathogenicity.
This is the first comprehensive analysis of the *NF1* mutational spectrum in Polish patients with the neurofibromatosis type 1 suspicion.
Supported by UDA-POIG.01.04.00-14-246/11 and UDA-POKL-04.01.01-00-014/10-00 (INTERKADRA) projects.

PS14.077

New methodology for NGS analysis of Dushenne Muscular Dystrophy.

O. P. Ryzhkova, *A. Polyakov;*
Research Center for Medical Genetics, Moscow, Russian Federation.

Next-generation sequencing (NGS) is a new group of methods, which widely used in DNA-diagnostics lately. Whole genome sequencing, exome sequencing and different panels of causes genes are applied in clinical medicine. Advantages include: relative cost-effectiveness, analysis all potential genes at once and rapidity of diagnostic. But these methods still have problems like low/no coverage some regions and no information about it, too much information and difficulty of it processing, absence certificate for medicine.
This work purpose was development of methods Dushenne Muscular Dystrophy (DMD) diagnostic by NGS, which can use in medical practice.
The basis of our methods was AmpliSeq technology but we added one stage more. We designed own primers for all exons and adjacent intron regions of DMD, EMD, FHL and LMNA A/C genes which had used at the first stage. After PCR we have multiplex of 105 amplicons. Then we had made fragmentary analysis after second PCR with fluorescently labeled universal primer. Therefore, it becomes possible to assess quality and quantity of each amplicon. This added stage saved us the trouble of low/no or different coverage between some regions. Then we had been convinced that all fragments were in the same concentration we made PCR with sequencing primers.
Ten DMD patients have been analyzed by the claimed method on Junior (Rosh) equipment. All exons were analyzed, coverage different was 7x. Three of patients had mutation in DMD gene. Because we sequenced limited part of genome, it had no difficulty to processing NGS results.

PM14.078

NGS sounds really good! But, what kind of NGS-based test might I offer to my patient?

M. Garcia-Hoyos, L. Rausell, M. Molero, M. Lazaro, C. Ruiz, M. Bermejo, J. Valero, M. Perez-Alonso, **J. Garcia-Planells**;
Instituto de Medicina Genomica (IMEGEN), Paterna (Valencia), Spain.

Introduction: NGS is being established as a new alternative for the diagnosis of genetic diseases in the clinical practice. The great advantages of this promising technology have been duly demonstrated in research. But some considerations need to be taken into account before being implemented as a clinical routine. NGS is a great technology, or better said, a set of technologies and different applications, but more important than the technology itself is the use that is made of it.
Material and Methods: We have developed different NGS based strategies for the analysis of genetic conditions. An accurate and highly sensitive approach based on a PCR specific design, which we have called NextGeneDx®. This approach was extensively validated to be used for diagnostic applications. An exome analysis focused only to the genes associated to clinical phenotypes according to OMIM (Clinical Exome). And a targeted or Ad Hoc Exome focused to the genes associated to a specific condition or phenotype.
Sspecific bioinformatics pipelines and interpretation algorithms were implemented for all these strategies.
Conclusions: NextGeneDx® is a diagnostic and accurate NGS alternative to Sanger for genetically heterogeneous diseases or phenotypes associated to a limited number of genes. Ad Hoc Exome provides a high sensitivity and specificity and allows the exhaustive analysis of a high number of genes associated to a specific condition. Clinical exome provides the analysis of all the genes associated to a OMIM phenotype making easier the clinical interpretation of the results. This approach is very useful for unspecific conditions or phenotypes.

PS14.079

NextGeneDX®: An accurate and cost-effective NGS Application for genetic diagnosis

M. Garcia-Hoyos, *L. Rausell, M. Molero, M. Lazaro, C. Ruiz, M. Bermejo, A. Gomez, J. Valero, J. Garcia-Planells;*
Instituto de Medicina Genomica (IMEGEN), Paterna, Spain.

NGS is a very promising technology that allows to analyse millions of sequences by using a single assay, reducing costs and time significantly compared to Sanger sequencing. However, the use of NGS in routine clinical practice is still under discussion because, inter alia, variations in the specificity and sensibility associated, mainly, to the capture systems. NextGeneDX® is a NGS-based procedure validated for diagnostic applications in the clinical practice. This PCR-based targeted capture system has been developed, validated and implemented for a wide range of genetic diagnosis in the last two years.
Last years, 233 genes were analysed in 1670 patients with phenotypes associated to 73 different genetic diseases.
Capture of the regions of interest (ROIs) has been performed by specific PCR. Specificity and analytical accuracy of the PCR design have been checked by Sanger analysis. Libraries were prepared according to NexteraXT protocol and sequenced on a MiSeq. The analysis and interpretation of the results have been performed according to our own algorithms.
All pathological or probably pathological changes were confirmed by Sanger sequencing.
Our NGS-based procedure for diagnosis allowed the identification of the disease-causing change in 403 patients (24%). To date, false positives have not been detected using NextGeneDX® strategy.
NextGeneDx® approach has the same sensitivity and specificity than Sanger sequencing, with a 100% of representativity of the ROIs and a minimum depth of 100X. It is a diagnostic alternative to Sanger sequencing for analyzing large genes or several genes, associated to multigenic or genetically heterogeneous diseases, simultaneously reducing, significantly, times and costs without compromising the diagnostic accuracy and quality.

PM14.080

Next-generation errors in medical practice: A topic for clinical and laboratory geneticists to address in collaboration.

G. W. E. Santen[1], *C. A. L. Ruivenkamp*[1], *M. J. V. Hoffer*[1], *M. Kriek*[1], *R. C. M. Hennekam*[2], *J. Cobben*[2];
[1]*dpt of clinical genetics LUMC University Hospital, Leiden, Netherlands,* [2]*dpt of Pediatrics AMC University Hospital, Amsterdam, Netherlands.*

The introduction of next generation sequencing (NGS) techniques,although generally meeting its high expectations, causes new problems in clinical genetics. When testing a single gene, the prior probability of causality is high for suspicious variants, which led to the erroneous perception that any abnormal DNA test result is 100% specific. The prior probability of causality is dramatically lower when large gene panels or whole exome sequencing (WES) is performed. This demands a sceptic attitude and a higher burden of proof for causality. Rigorous assessment of the genotype-phenotype relation (deep phenotyping) is essential, and should be jointly assessed with the pathogenicity of the variant on molecular basis alone.
We have collected a series of cases illustrating these issues and have extracted several apparently common causes for mistakes:
A.
Genotype interpretation mistakes: (1) unfamiliarity with a gene; (2) over-interpretation of variant significance; (3) bio-informatic mistakes (4) misjudging what is detectable with NGS.
B.
Fenotype interpretation mistakes: (1) superficial phenotyping; (2) suboptimal utilization of phenotypic data;
Based on these errors from practice, we recommend that (I) Laboratory and clinical geneticists share responsibility for final test results; (II) DNA laboratories remain specialized on (groups of) genes; (III) Large gene panel analyses and WES should only be requested in collaboration with clinical geneticists.
We recognize that these recommendations need refinement. However, the misconception that NGS is the panacea of genetic diagnostics should be challenged, to prevent possibly serious errors. Close collaboration between clinical and laboratory specialists to optimize patient care and safety is needed.

PS14.081

Exome-wide SNP genotyping as a tool for validation of a large diagnostic next-generation sequencing panel

J. M. Polke[1], *M. Athanasopoulou[1], J. Hayward[1], A. Pittman[2], H. Houlden[1], M. G. Sweeney[1]; [1]National Hospital for Neurology and Neurosurgery, London, United Kingdom, [2]UCL Institute of Neurology, London, United Kingdom.*

Validating the sensitivity of next-generation sequencing (NGS) for diagnostic testing is essential. This involves confirming the detection of a number of positive control variants (60 to confirm >95% sensitivity, 300 for >99% sensitivity at the 95% confidence interval (CI)). Samples with known variants from previous Sanger sequencing tests can be resequenced, though this can prove costly, necessitating the NGS of many samples. We present the validation of a Neurogenetics-specific Illumina Nextera Rapid Capture Custom NGS panel of 153 genes using the Illumina Human Infinium Exome-wide BeadChip array v1.2, which includes over 240,000 exonic variants. Ten control samples were SNP-genotyped (one in triplicate, giving identical calls between the replicates). A total of 134 unique single-nucleotide variations were detected in the targeted genes, with a grand total of 311 heterozygous and 152 homozygous. All were correctly identified by NGS. There were discordant genotype calls for 2 variants, Sanger sequencing verified that the NGS was correct for both. Six samples with indels from 1-40 bp in length were also tested, all were detected. This is a total of 140 unique variants, from which a sensitivity of >97.9% at the 95% CI can be derived. Our validation also included the repeat sequencing of two samples on different runs and downsampling to establish the lowest read-depth required to call a variant. The 10 SNP-genotyped samples will provide a valuable resource for periodic verification of the performance of our panel, and validation of future NGS tests.

PM14.082

Optimization of Library Amplification For Next Generation Sequencing

K. Heitz;
QIAGEN GmbH, Hilden, Germany.

Uniform coverage of all genomic regions during Next Generation Sequencing (NGS) is critical for efficiently utilizing sequencing capacity and preventing loss of important sequence information due to drop-out or under-representation of certain regions. The coverage uniformity is especially important in applications such as microbiome-sequencing, where different microbial strains could have significantly different GC contents. GC content -related sequencing bias could potentially lead to under-representation or even complete loss of the genomic regions or microbial strains with very low or very high percentage of GC bases. The PCR step of the NGS library construction procedure has been shown to be the major source of GC bias in the NGS workflow. To solve this common problem in the NGS field, we established a test system where a mixture of high-GC and low-GC bacteria genomes is used to optimize library amplification conditions and used this system to develop a novel NGS library amplification mix that amplifies the genomes with widely different GC contents with minimal bias and high fidelity.

PS14.083

Is exome sequencing a reproducible technique under routine conditions ?

A. Trimouille[1], *S. De Diego[2], C. Hubert[2], M. Vuillaume[1,3], F. Salin[4], E. Guichoux[4], B. Arveiler[1,3], D. Lacombe[1,3], C. Rooryck[1,3], P. Fergelot[1,3,2]; [1]Service de Génétique Médicale CHU de Bordeaux, Hôpital Pellegrin, Bordeaux, France, [2]Plateforme Génome-Transcriptome, CGFB, Université de Bordeaux, Bordeaux, France, [3]Laboratoire Maladies Rares: Génétique et Métabolisme (MRGM), EA 4576, Talence, France, [4]UMR 1202 Biogeco - INRA-Université de Bordeaux, Cestas, France.*

Exome sequencing is commonly used for research or diagnosis purposes, sometimes without notion of robustness or reproducibility of the chosen techniques. However these criteria must be considered to validate NGS data. Here we present the results of an exhaustive comparison of the quality data in a series of exomes performed at the Genome Transcriptome platform of the Functional Genomics Center of Bordeaux.
Comparisons of the quality data have been performed in three steps, from raw data (FASTQ), aligned reads (BAM), and detected variants (VCF), as described in Guo and al.1. We compared 2 different libraries (SureSelect and Nextera) sequenced on a MiSeq system. In a first set, 2 exomes were performed from the same DNA sample and in a second set 4 exomes were performed from 2 different DNA extractions.
These biological replicates allowed us to evaluate the loss of information throughout the bioinformatic pipeline, because of low quality raw data, and its impact on the number of relevant variants detected. Thus, by comparing the concordance of variants detected in the 4 exomes set, we were able to show which technique of library preparation gives the most reproducible results, and which types of patient's mutations are most likely undetected by each kit.
This work allowed us to accurately assess the quality of exome datasets obtained by NGS sequencing in routine conditions, with two different library kits. This validation procedure could help in the future to make more relevant choices among the available NGS techniques.

Non-invasive prenatal diagnosis (NIPD) of Cystic fibrosis (CF): an optimized protocol using multiplex fluorescent PCR to detect the p.Phe508del mutation

F. Trau Mau Them[1], V. Debant[1], C. Guissart[1,2], A. Girardet[1,2], C. Raynal[1,2], C. Rouzier[3], E. Haquet[4], P. Khau Van Kien[5], E. Bieth[6], M. P. Brechard[7], M. Koenig[1,2], M. Claustres[1,2], **M. C. Vincent**[1,2];
[1]CHU Montpellier_Laboratoire de Genetique Moleculaire_IURC, Montpellier cedex 5, France, [2]Equipe Accueil_Université Montpellier, Montpellier, France, [3]CHU Nice, Service de génétique Médicale, Nice, France, [4]CHU Montpellier_Service de Génétique Médicale, Montpellier, France, [5]CHU Nîmes, Laboratoire de Cytologie clinique et Cytogénétique, Nîmes, France, [6]CHU Toulouse, Service de Génétique Médicale, Toulouse, France, [7]Hôpital Saint Joseph, Service de Diagnostic Prenatal, Marseille, France.

Analysis of cell-free fetal DNA (cffDNA) in maternal plasma is very promising for early diagnosis of monogenic diseases. However, NIPD of single-gene disorders has been limited by the availability of suitable technical platforms and the need to set up patient or disease specific custom-made approaches. To make clinical applications more readily accessible, we propose a simple test based on multiplex fluorescent PCR and size fragment analysis to determine the paternally inherited fetal allele. Cystic fibrosis (CF) has been taken as a model to evaluate this approach, in couples with high risk of transmitting the disease. This test combines the detection of p.Phe508del (the most frequent mutation in CF patients worldwide), nine intragenic and extragenic STR markers of the *CFTR* locus and a specific SRY sequence. All primers were designed regarding the size of cffDNA (i.e. to amplify short fragments).
This multiplex PCR protocol was successfully applied to 5 couples where fathers carried the p.Phe508del and mothers were carrying a different mutation. Our simple test provided clear results on the maternal plasma from the pregnant women. We confirmed the presence of cffDNA in the studied samples by the identification of a tri-allelic DNA profile using a miniSTR kit. All results were correlated with chorionic villus sampling or amniocentesis analyses.
This NIPD test, focused on both direct and indirect diagnosis of CF, offers many advantages over current methods: simple, rapid and cost-effective. It opens up possibilities to test a large number of couples with high risk of CF

for offspring.
This work was supported by the ' Agence de Biomedecine ' (AOR2012-U9039).

PS14.085

Karyotype level non-invasive prenatal testing by sequencing of circulating cell-free DNA from maternal plasma

A. R. Mazloom[1], *T. Liu*[1], *R. Lefkowitz*[1], *G. Hogg*[1], *J. A. Tynan*[1], *T. Burcham*[2], *D. van den Boom*[2], *M. Ehrich*[2];
[1]*Sequenom Laboratories, San Diego, CA, United States,* [2]*Sequenom, Inc., San Diego, CA, United States.*

Non-invasive prenatal testing (NIPT) has become an accepted method for the detection of trisomy 21, 18 and 13 in patients at high risk to carry a fetus with one of these chromosomal abnormalities. NIPT can also be used to detect other aneuploidies and sub-chromosomal copy number variations. With the inevitable progress of sequencing technologies, it is likely that sequencing-based NIPT will offer greater diagnostic capabilities in the same way that karyotyping-level resolution was eventually superseded by microarray analysis of invasively acquired fetal cells or tissue. We present studies that support the concept of NIPT delivering genome-wide unbalanced copy number results, analogous to what can be detected by cytogenetic G-band karyotyping.
We analyzed a set of maternal plasma samples for which karyotype confirmation of fetal anomalies were available. Next, we constructed a comprehensive *in-silico* system of maternal plasma DNA sequencing results modeled to contain sub-chromosomal events at genomic coordinates reported in the ISCA database. Finally, we constructed an analytical model system with both karyotype and microarray confirmed samples with genome wide sub-chromosomal deletion and duplication events.
In karyotype confirmed samples, we detected 17 of 18 samples with a sub-chromosomal deletion or duplication. *In-silico* modeling of 587 genome wide ISCA sub-chromosomal deletion and duplication events ≥7 Mb showed that sensitivity could reach 94% with high specificity.
Using whole genome sequencing results, we were able to model *in-silico* genome wide events and estimate sensitivity metrics for their detection. Measurement of analytical performance in mixture models with confirmed deletions/duplications is currently ongoing.

PM14.086

A new NGS-based assay for detecting PALB2 variants in familial breast & pancreatic cancer

M. A. Goldgraben[1], *J. Redman*[1], *A. Larionov*[1], *F. Rodger*[1], *K. Brugger*[2], *A. Richards*[3,4], *H. Martin*[2], *S. Abbs*[2], *M. Tischkowitz*[1,2];
[1]*Department of Medical Genetics, Addenbrookes' Treatment Centre, University of Cambridge, Cambridge, United Kingdom,* [2]*East Anglian Medical Genetics Centre, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,* [3]*Department of Pathology, University of Cambridge, Cambridge, United Kingdom,* [4]*Genetics Laboratories, Addenbrookes' Treatment Centre, Addenbrooke's Hospital, Cambridge, United Kingdom.*

Genetic testing for breast and ovarian cancer susceptibility genes, BRCA1 and BRCA2, is well established for the early identification and management of hereditary cancers. Another gene involved in the DNA damage repair (DDR) pathway is PALB2 (partner and localizer of BRCA2) or FANCN. It recruits BRCA2 to BRCA1-bound damaged DNA sites, to mediate homologous recombination. Heterozygous PALB2 mutant carriers have significant cellular DNA repair defects, whilst homozygous mutant patients develop Fanconi anemia. We recently showed that heterozygous carriers of deleterious PALB2 germline mutations have at least 5 times greater predisposition to developing breast cancer compared to the general population, with increasing risk in younger age groups. Carriers are also predisposed to pancreatic cancer, independent of BRCA1 or BRCA2 mutations.
We have developed a low-cost clinical assay for PALB2 variant detection which complements the existing BRCA1 and BRCA2 assays offered in our NHS clinical laboratory. It combines long-range PCR amplification with next generation sequencing (NGS). This provides high sequencing depth for confident variant calling and flexibility at multiplexing, thus minimizing individual sample costs. Previously known PALB2 wild-type and mutant DNA samples, detected by other NGS methods, are used to validate the assay. Another clinical utility could be for newly identified mutant PALB2 carrier breast cancer patients to be considered as candidates for PARP inhibitor therapeutics, targeting defective DDR. However, the assay will initially be included for breast and pancreas cancer screening at our NHS genetics laboratory and cost efficiency analysis is ongoing, comparing against other targeted resequencing panels.

PS14.087

Ten Years of EMQN Phenylketonuria EQA scheme

M. Witsch-Baumgartner[1], *C. Aulehla-Scholz*[2], *J. Zschocke*[1];
[1]*Division Human Genetics, Medical University Innsbruck, Innsbruck, Austria,* [2]*Institut für Klinische Genetik, Klinikum Stuttgart Olgahospital, Stuttgart, Germany.*

Objective
Analysis of the last ten EMQN-EQA (European Molecular Quality Network-European Quality Assessment) schemes regarding molecular diagnosis of Phenylketonuria (PKU)
Basics
PKU (OMIM # 261600) is an autosomal recessive metabolic disorder due to mutations in the PAH gene. Deficiency of phenylalanine hydroxylase in PKU causes excess of phenylalanine which affects brain development and function. Over 600 pathogenic PAH variants are known. Depending on mutations the phenotype severity varies from mild hyperphenylalaninemia (MHP) to mild and severe PKU. Early molecular diagnosis of PKU and correct interpretation is important for treatment planning including possible tetrahydrobiopterin cofactor responsiveness.
Method
Each year this EQA scheme consisted of three simulated cases. Over the 10 years 23 different variants and 26 different genotypes were distributed for analysis. Nearly 550 mock reports were quantitatively and qualitatively analyzed for a range of criteria including genotyping, interpretation and clerical accuracy.
Result
Participants came from 23 different countries including Australia and the US; participant number increased from 11 in 2004 to 27 in 2014. The total genotyping error rate has decreased from a maximum of 20% to 1.4% although in every year at least one lab missed at least one mutation. Many laboratories have serious shortcomings in genotype-phenotype predictions. 2007 and 2012 several laboratories offered prenatal testing for genotypes not associated with clinical symptoms (MHP).
Discussion
Quality of PAH genotyping has improved over the years but mutation interpretation remains a major challenge for a number of laboratories. Availability of improved mutation databases would probably help to further improve diagnostic quality.

PM14.088

Real-time quantitative PCR for copy number analysis: has our service improved?

S. F. Jose, *S. M. Morgan, R. Butler;*
Institute of Medical Genetics, Cardiff, United Kingdom.

Real-time quantitative PCR (qPCR) to determine copy number was introduced as a diagnostic service by the All Wales Medical Genetics Service (AWMGS) in June 2014. At this time increasing demand on the laboratory budget, in particular for the send-out budget, meant that there was an urgent need to develop a cost effective strategy for validation of dosage results, particularly following array CGH testing. An in-house qPCR method was developed and validated that allowed cost effective, flexible assay design for unique and recurrent genomic regions. We are aware that only a few laboratories within the UK have adopted this testing strategy. There are no current professional guidelines or external quality assessment schemes for qPCR.
Review of the first 6 months post implementation of this service for validation of array CGH imbalances showed evidence of the cost benefit of this service compared with previously available follow up techniques. In addition, the clinical utility of this testing has also been demonstrated through detection of a homozygous imbalance in a proband who had inherited the deletion from each of his hemizygous parents. More recently, qPCR testing has also been applied for confirmation of potential dosage imbalances detected by next generation sequencing (NGS) assays within this laboratory. Further advantages following implementation include targeted prenatal testing and targeted familial studies, eliminating the possibility of detecting incidental findings.
We present a review of the first 11 months of the qPCR service to evaluate whether we have improved our laboratory services.

PS14.089

QSTR*R-PL: Development and Validation of a QF-PCR based IVD for Rapid Aneuploidy Screening in the Event of Pregnancy Loss

G. Fitzgibbon, *G. Batman;*
Elucigene Diagnostics, Manchester, United Kingdom.

Introduction: Elucigene Diagnostics has developed QST*R-PL, a simple

to use assay for the rapid and accurate diagnosis of the six most common autosomal trisomies associated with miscarriage. QST*R-PL employs the commonly used QF-PCR (Quantitative Fluorescence-PCR) technique, which offers numerous advantages over the techniques currently used in the diagnosis of miscarriage.
Methods: A QST*R-PL performance evaluation assay was provided by Elucigene Diagnostics and evaluated using protocols developed by Elucigene Diagnostics. Testing involved 150 anonymised DNA samples extracted from fetally derived tissues/product of conception, whose aneuploidy status was previously determined using alternative testing methods including Karyotyping, FISH and Microarray. QST*R-PL test accuracy was assessed through concordance with the previous diagnosis.
Results: The QST*R-PL data demonstrated high quality results across all testing sites. Comparison of the QST*R-PL diagnostic results with that of the previous diagnostic data showed 100% concordance with no failed results.
Conclusion: The QST*R-PL assay used in the clinical setting can provide users with a rapid aneuploidy screening service for miscarriage cases and can easily integrate into any existing QF-PCR based prenatal service. QST*R-PL also enables the identification of maternal cell contamination and specific cases of triploidy which are less easily detectible using current diagnostic methods. Such a service can provide closure to patients or couples who have undergone a traumatic miscarriage event and can aid the management by modification of risk calculations for future pregnancies and can change the way recurrent pregnancy loss is managed clinically in the future.

PM14.090
Whole transcriptome next-generation sequencing to detect gene fusions in haematological malignancies

J. Chapman, *A. Stretton, R. White, S. Austin, R. Butler;*
All Wales Medical Genetics Service, Cardiff, United Kingdom.

Introduction: Current methods of detection of genetic markers for haematological malignancies include the identification of gene-fusions using fluorescence *in situ* hybridisation (FISH), karyotyping, real-time PCR (RT-PCR) and screening genes for mutations through targeted sequencing. However, Next-Generation Sequencing (NGS) has a number of potential advantages over traditional methods. We aimed to establish a workflow for detecting gene-fusion transcripts using NGS, in order to develop a service to detect a range of diagnostic and prognostic genetic markers of haematological malignancies. We have validated this method through the detection of recurrent, well-characterised *BCR-ABL1* gene fusions in patients with chronic myeloid leukaemia (CML) fusions as a proof of principle study.
Method: Whole transcriptome libraries were prepared from RNA extracted from the blood and bone marrow of patients with chronic myeloid leukaemia (CML) and acute lymphoblastic leukaemia (ALL) and known *BCR/ABL1* fusions using the Illumina TruSeq RNA Access library prep kit. These libraries were sequenced on the Illumina HiSeq 2500 and a bioinformatics pipeline was developed to detect the gene fusions.
Results: This method detected the *BCR/ABL1* fusions in the patient samples and can distinguish between different breakpoints in the genes. A comparison of different algorithms for the detection of gene fusions and a cost-benefit analysis of this technique will also be presented.
Conclusion: We have shown that whole transcriptome NGS is a promising method for detecting gene-fusions which can be developed further to detect genetic markers in a range of complex haematological malignancies.

PS14.091
Development of a Next Generation Sequencing (NGS) gene panel assay for Segmental Overgrowth Syndromes.

C. L. M. Langley, *E. Howard, S. Williams, A. Wallace;*
Manchester Centre for Genomic Medicine, Manchester, United Kingdom.

Segmental overgrowth syndromes (SOS) are a heterogeneous group of rare diseases characterised by substantial localised or asymmetrical excessive tissue growth manifesting at birth or later in life. SOS encompass disorders such as Megalencephaly-Capillary Malformation (MCM/MCAP) syndrome, Megalencephaly-Polymicrogyria-Polydactyly-Hydrocephalus (MPPH) syndrome, Congenital Lipomatous Overgrowth Vascular Malformations, Epidermal Nevi and Skeletal abnormalities (CLOVES syndrome), Proteus syndrome and Cowden syndrome. Due to overlapping phenotypes clinical diagnosis can be challenging.
Many SOS have been attributed to mutations in genes of the phosphoinositide 3-kinase PI3K-Akt signalling pathway, with both germline and somatic mutations associated. We have developed a Next Generation Sequencing (NGS) assay for key genes in this pathway with whole gene screening of PIK3CA and PTEN, and targeted screening of hotspot exons in PIK3R2, AKT1, AKT3, mTOR and CCND2. This assay uses long range-PCR as the target enrichment strategy and Illumina's MiSeq system to perform next generation sequencing, followed by analysis using a custom bioinformatics pipeline.
Assay validation was undertaken across five independent MiSeq runs comprising 20 analyses of 12 patient samples previously screened by pyrosequencing or Sanger sequencing. NGS data was directly compared to previous data with fully concordant results. Assay repeatability and sensitivity were determined, and the bioinformatics pipeline was validated to detect mutations down to a 5% admixture.
As a result of this validation, the NGS Segmental Overgrowth Syndrome assay is now offered at the Manchester Centre for Genomic Medicine. Potentially disease causing mutations have been identified in 50% of patients tested so far and confirmed using Sanger sequencing or ARMS-PCR.

PM14.092
European Molecular Genetics Quality Network (EMQN): First experience with External Quality Assessment for the molecular diagnosis of SHOX-deficiency in Europe

G. Wildhardt[1], *K. E. Heath*[2], *E. De Baere*[3], *S. Patton*[4];
[1]*bio.logis Center for Human Genetics, Frankfurt am Main, Germany,* [2]*Institute of Medical & Molecular Genetics (INGEMM), Hospital Universitario La Paz, Madrid, Spain,* [3]*Center for Medical Genetics, Ghent University, Ghent, Belgium,* [4]*EMQN, Manchester Centre for Genomic Medicine, Manchester, United Kingdom.*

The European Molecular Genetics Quality Network (EMQN) is a not-for-profit organization promoting quality in genetic testing worldwide by provision of standard External Quality Assessment (EQA) schemes and agreed best practice. Since 2011, SHOX-deficiency has been one of these EQA schemes and involves sending three DNA samples, with matched mock clinical referrals, for analysis by the participating laboratories. A panel of three assessors using previously agreed marking criteria anonymously marks the resulting clinical reports. Each participating laboratory is scored for genotyping, interpretation and clerical accuracy (max score is 2.00 per category), and tailored comments are fed back. A report summarizing the results of the scheme is also provided.
In 2014, a total of 43 laboratories from 15 countries participated in the SHOX scheme. One case involving a patient with disproportionate short stature and Madelung deformity (SHOX p.Ala170Pro mutation), had a worryingly high genotyping error rate of 26%. This mutation has previously been reported to cause an aberrant signal for the exon 4 MLPA probe of the most commonly used MLPA kit. Many laboratories did not follow best practice and failed to use an alternative method to verify this abnormal finding leading to an incorrect result. Consequently, the mean genotyping error rate for the scheme was high (8.77%). A full summary of all the results of the SHOX schemes run between 2011-2014 will be presented. The errors identified indicate a clear need for EQA to improve the standards of technical and reporting performance in clinical diagnostic laboratories offering a SHOX testing service.

PS14.093
Efficient, targeted personalized medicine by BRAF, KRAS and NRAS genotyping on a benchtop sequencer

K. De Leeneer[1], *E. De Latter*[1,2], *N. Van Roy*[1], *J. Van Dorpe*[3], *D. Creytens*[3], *L. Vandemaele*[3], *I. Rottiers*[3], *B. Verhasselt*[2], *B. Denys*[2], *K. Vandepoele*[2], *A. De Jaegher*[1], *G. Vandercruyssen*[1], *E. De Baere*[1], *K. Claes*[1];
[1]*Center for Medical Genetics Ghent, Ghent University, Ghent, Belgium,* [2]*Departments of Clinical Chemistry, Microbiology, and Immunology, Ghent University Hospital, Ghent, Belgium,* [3]*Department of Pathology, Ghent University and Ghent University Hospital, Ghent, Belgium.*

Reliable tumor tissue molecular analysis with high sensitivity and specificity is crucial to guide correct personalized medicine in cancer. Somatic mutation detection in several codons of the BRAF, KRAS and NRAS genes has a great impact on colorectal cancer treatment decision. The release of benchtop Next Generation Sequencing (NGS) instruments has paved the way to implement the NGS chemistry in a clinical setting without making sacrifices in terms of cost and turnaround time.
We developed and validated a PCR based NGS approach for mutation detection in Formalin Fixed Paraffin Embedded (FFPE) samples. Nine BRAF, KRAS and NRAS target codons are amplified in seven reactions followed by NexteraXT library preparation and sequencing on a Miseq. Except for the challenge of performing NGS with FFPE samples in terms of DNA quality and homogeneity, a thorough validation of the detection limit appeared to be essential. The detection limit is influenced by different factors including the quality of the specimen, the sequence to be analyzed, primer design and PCR bias. We investigated these factors resulting in a reliable detection of the variants down to 3% with a minimal coverage of 1000x of each target. Hence,

our approach can identify the selected mutations with a sensitivity unseen with traditional Sanger sequencing and directly quantifies the amount of the mutant allele. In brief, we developed a simple, robust, flexible and sensitive sequencing assay for somatic mutation detection in colorectal cancer using NGS, which can serve as a model for tumor tissue molecular analysis for other acquired diseases.

PM14.094
Ten years of SCA external quality assessment (EQA) schemes organised by EMQN

S. Sousa[1,2], *I. Alonso*[1,2,3], *S. Patton*[4], *D. E. Barton*[4], *S. Wieczorek*[5], *J. E. Martindale*[6], *S. Seneca*[7], *J. Sequeiros*[1,2,3];
[1]*CGPP, IBMC - Instituto de Biologia Molecular e Celular, Univ. Porto, Porto, Portugal,* [2]*I3S - Instituto de Investigação e Inovação em Saúde, Univ. Porto, Porto, Portugal,* [3]*ICBAS, Univ. Porto, Porto, Portugal,* [4]*EMQN, Manchester, United Kingdom,* [5]*Department of Human Genetics, Ruhr Univ, Bochum, Germany,* [6]*Sheffield Diagnostic Genetics Service, Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom,* [7]*Center for Medical Genetics, UZ Brussel, Vrije Universiteit Brussel, Brussel, Belgium.*

Spinocerebellar ataxias (SCAs) are autosomal dominant neurodegenerative diseases, caused by triplet-repeat expansions in the most common forms. An EQA scheme, provided by EMQN, has been running since 2004. We assessed reports for 3 mock-cases, every year, for genotype and interpretation (score: 0-2). Laboratories were expected to discriminate, and accurately size, both allele repeats for SCA1, SCA2, MJD/SCA3, SCA6 and SCA7; assessment included also (1) pre-test requirements; (2) appropriate methodologies, updated knowledge and acceptable repeat range; and (3) interpretation, reporting and recommendations.
Laboratories (28-73; mean: 51) from 34 countries (mean: 22), from all continents, increased over time. We found an improvement in genotyping and interpretation, and a decrease of gross errors (range: 0-5%). Mean scores were compared according to the participation of each lab (once, 2-6, 7-10 times). Differences (factorial ANOVA) were not significant, but labs that participated only once had lower scores (1.75) and the greatest heterogeneity. Labs participating frequently had higher scores (1.89) and the most consistent results.
Many labs do not treat EQA as their routine diagnostics. Other common problems included: missing homoallelism; not specifying both allele sizes; not reporting size of normal and/or expanded alleles; out of acceptable margins of error; not offering the minimum "menu" for SCA testing.
EMQN best practice guidelines were published in 2010, to help improving the quality of SCA testing. This EQA scheme shows a global progress in laboratory SCA testing performance. Labs participating more often showed an overall better performance. These results emphasize the importance of regular participation in EQA schemes.

PS14.095
Mapping the "Dark Matter" of Genome using Nanochannels - Long repeats, Complex Structural Variations and Their Biological Relevance

A. Hastie[1], *A. Pang*[1], *E. Lam*[1], *T. Chan*[1], *W. Andrews*[1], *T. Anantharaman*[1], *X. Zhou*[1], *J. Reifenberg*[1], *M. Saghbini*[1], *H. Sadoski*[1], *M. Austin*[1], *P. Sheth*[1], *Z. Dzakula*[1], *E. Holmlin*[1], *X. Xun*[2], *T. Graves*[3], *J. Sikela*[4], *P. Kwok*[5], **H. Cao**[1];
[1]*Bionano Genomics, San Diego, CA, United States,* [2]*BGI, Shenzhen, China,* [3]*washington University, St Louis, MO, United States,* [4]*University of Colorado School of Medicine, Denver, CO, United States,* [5]*UCSF, San Francisco, CA, United States.*

Despite NGS advancements, portions of the human genome remain unresolved. During assembly, gaps and unknown structural information, the "dark matter" of the genome, is challenging to detect with current technologies. Rapid comprehensive genome mapping in NanoChannel Arrays represents a complementary platform to DNA sequencing. *De novo* assembly of single molecules yields unprecedented long contiguous maps, advantageous in highly repetitive regions and complex structures in their native form.
We present results showing hundreds of large structural variants and haplotype differences in genomes; 11% of 24,360 large SVs found in the 22 euploid human genome are unique to a specific genome while 23% of those SVs were common to 20/22 samples. In 1 human, we detected >700 of insertions/deletions and inversions >1 kb. Without considering SVs that overlap with N-base gaps in hg19, 90% of these SVs are supported by orthogonal experimental methods or historical evidence. A high portion of complex genomes is composed of previously unknown repeating units (>2 kb) spanning several tens of kilobases to megabases, the exact locations and copy numbers often remain elusive with NGS. Without knowing the genomic context or amount of these repeats, it is difficult to attach biological relevance to them. Using BioNano's Irys® platform, repeat regions can be more accurately characterized and put into context. We found repeats and complex SV regions spanning 100-200+ kb that are clinically associated with diseases or disorders. For the first time, population scale cross-sample genome comparison to identify comprehensive genomic structural variation is feasible on a single platform.

PM14.096
Evaluation of SureSelectQXT Target Enrichment library preparation for Illumina parallel sequencing

Y. G. Patel, *S. Lillis, L. Brodd, S. Yau;*
Guy's Hospital, London, United Kingdom.

Parallel sequencing library preparation protocols using minimal sample input and manipulation, while maintaining high sensitivity are an essential requirement for a clinical laboratory. Agilent Technologies SureSelectQXT kit improves on their standard SureSelectXT library preparation times with as little as 50ng of input DNA. Using a transposase-based library preparation with improved hybridization that decreases both hands-on-time and hybridization time from 16 hours to 90 minutes.
We have evaluated the kit using 4 different focused target-enrichment gene panels (Congenital Myopothies; Congenital Muscular Dystrophies, In-born Metabolic Diseases and Breast Cancer) and 41 samples comprising of 44 previously identified variants (28 SNVs and 16 CNVs). Most of these variants were previously sequenced using the SureSelectXT protocol with Covaris randon-shearing and although the SureSelectQXT shearing is not entirely random, all the expected variants were detected. Additionally CNV coverage data from the QXT protocol seems to show more consistent and less variable CNV data compared to the Covaris SureSelectXT protocol.
Sequencing results show both a comparable percentage of on-target sequencing reads and a high concordance of variants detected by the SureSelectQXT protocol and known previously identified variants in the these samples. Overall the SureSelectQXT library preparation kit showed confident coverage of the genomic regions of interest tested here, allowing us to perform both point mutation analysis and CNV analysis from the same data. Furthermore this protocol has a reduced number of steps providing a streamlined approach that is amenable to automation on an Agilent Bravo workstation, allowing us dramatically increase our throughput from 96 to 288 samples a week.

PS14.097
A novel method for DNA and RNA target enrichment

C. L. Richard, *Y. Bei, K. Patel, B. D. Galvin;*
Directed Genomics, Ipswich, MA, United States.

Recent developments in next-generation sequencing (NGS) technologies have made a great impact on medical research. However, in order for NGS to be fully incorporated into routine diagnostic genetic testing, target enrichment methods are required that are fast, simple, and cost effective. To meet these requirements, we have developed a novel target capture technique that offers significant advantages over traditional in-solution hybridization and multiplex PCR protocols.
Our method utilizes rapid enrichment of target DNA or cDNA through the hybridization of short probes to fragmented DNA. The probes both enable the capture of the target DNA to beads and define the boundaries of the regions of interests. Off-target sequence is removed by enzymatic digestion, followed by ligation of platform-specific adaptors to the trimmed targets and PCR amplification.
To demonstrate the high specificity, sensitivity and uniformity of this method, we have applied it to the capture of genes commonly mutated in cancer.

PM14.098
GenoDENT, a targeted next-generation sequencing assay for the diagnosis and discovery of mutations in orodental disorders

Henri Poincaré, Strasbourg, France, [8]Université de Nice-Sophia Antipolis, Service d'Odontologie, Faculté de Chirurgie Dentaire, Nice, France, [9]Faculté d'Odontologie, Université de la Méditerranée, Marseille, France, [10]Département d'Odontologie Pédiatrique, Faculté d'Odontologie, Lyon, France, [11]Faculté de Chirurgie Dentaire, Service d'Odontologie Pédiatrique, Université de Nantes, Nantes, France, [12]Département d'Odontologie Pédiatrique, Faculté de Chirurgie Dentaire, Université Paris Descartes, Montrogue, France, [13]Institute of Human Genetics, Heidelberg University, Heidelberg, Germany, [14]Service de Génétique Clinique, Centre Hospitalier Universitaire Rennes, Rennes, France, [15]Odontologie Pédiatrique, Faculté de Chirurgie Dentaire, Université Paul Sabatier, Toulouse, France, [16]Centre de Référence pour les Affections Rares en Génétique Ophtalmologique, Service de Génétique Médicale, Hôpitaux Universitaires de Strasbourg, Strasbourg, France.

Oro-dental genetic disorders can manifest in both syndromic and non-syndromic forms. Of the >5000 syndromes listed in the London Dysmorphology Database, >900 have been documented to have dental manifestations. Therefore, the dental consultation can be an important port of entry for the management of a number of genetic disorders. We have developed a targeted next-generation sequencing (NGS) assay, GenoDENT, for the diagnosis and discovery of mutations in 560 known and candidate genes in orodental diseases. We demonstrate the utility of this assay for the molecular diagnosis of a variety of syndromic and non-syndromic dental disorders, eg. amelogenesis imperfecta, selective tooth agenesis, ectodermal dysplasias etc. In a cohort of 104 patients referred to the Reference Centre for Orodental Manifestations, Strasbourg, France, we delivered a definitive molecular diagnosis in 38 cases (~37%). Interestingly, in several cases a molecular diagnosis for the dental disorder led to a refinement of the patient's phenotype and supplementary clinical tests in cases suggestive of syndromes, thus having a direct impact on overall patient care. GenoDENT provides superior coverage for the targeted region as compared to whole exome sequencing (Mean Coverage: GenoDENT - 371X vs. Exome V5 - 96X; GenoDENT - 98% nucleotides covered at >20X vs. Exome V5 - 87% nucleotides covered at >20X) at lower cost. Therefore, we have developed the first NGS assay to target genes implicated in orodental disorders and development. This EU-funded project (ERDF) A27 „Oro-dental manifestations of rare diseases", is supported by the RMT-TMO Offensive Sciences initiative, INTERREG IV Upper Rhine program www.genosmile.eu.

PS14.099

High efficiency targeted sequencing for accurate identification of low frequency somatic variation in cancer

D. Burgess, *D. Green, K. Jefferson, H. Halvensleben, M. Brockman, R. Bannen, M. D'Ascenzo, K. Heilman, L. Feng, J. Voichick, T. Richmond;*
Roche NimbleGen, Inc, Madison, WI, United States.

Somatic genome variation is a key feature underlying the pronounced cellular and clinical heterogeneity observed across a wide range of cancers. The ability to detect and accurately quantify this variation in tumors, particularly as it evolves over time, will be useful for predicting and monitoring the effectiveness of therapy, the emergence of pharmacoresistance and metastasis, and projecting a patient's prognosis. An effective solution for this challenging application must be sensitive, accurate, reproducible, fast, low-cost and automatable, with robust data analysis and reporting outputs. We developed a targeted NGS method called HEAT-Seq (High Efficiency Amplification of Targets for Sequencing) based on highly optimized, multiplexed, molecular inversion probes. HEAT-Seq probes incorporate unique molecule identifiers (UIDs) to facilitate the tagging of PCR duplicates and accurate assessment of molecular complexity free of amplification bias. We evaluated the performance of this technology using a series of normal and cancer reference samples. A panel of ~700 HEAT-Seq probes targeting mutational hot spots within a set of 55 cancer genes, coupled with Illumina MiSeq sequencing, demonstrated that >98% of the target region was covered to at least 50x coverage depth, with a duplicate read rate less than 20%, and with >96% of the probes exhibiting ≥20% of the mean panel coverage. Initial evaluation of sensitivity for this panel demonstrated that known single nucleotide variants in the samples could be reliably detected when present at frequencies down to below 1%. We conclude that optimized HEAT-Seq panels are a promising solution for important applications in cancer genomics.

PM14.100

The new Illumina TruSeq Exome Enrichment kit optimized for less oxidative damage, higher enrichment efficiency and higher uniformity of coverage.

A. K. Czyz, *L. Freeberg, S. Kuersten, D. Schlesinger, A. Tan, V. Ruotti, D. Hill, R. Vaidyanathan;*
Illumina, Inc., Madison, WI, United States.

Starting from only 100ng of gDNA the newly developed Illumina TruSeq Exome Enrichment kit delivers comprehensive and highly uniform coverage of exon sequences. The product workflow consists of three general steps: acoustic DNA shearing, library preparation and rapid capture exon enrichment step. All steps have been optimized to provide high percentage of reads on target, high coverage uniformity and minimized oxidative DNA damage.
It was demonstrated that mutations can be introduced during acoustic shearing. To counter the observed oxidative damage we added EDTA to our shearing buffer. Furthermore, we optimized the library preparation procedure to obtain median insert size of ~150bp, which provides optimal enrichment metrics. Also, we reduced the number of PCR cycles to limit the amount of duplicates introduced during amplification, but still obtain sufficient yield to enable flexibility in choosing the amount sample input into enrichment.
The TruSeq Exome Enrichment kit is designed for use with Illumina's Coding, Expanded and Custom Exome pools selected using Illumina's DesignStudio. During enrichment optimization we validated a new wash buffer that further protects the DNA from artificially induced mutations. The combination of EDTA in the shearing buffer and the new wash buffer allows us to decrease probability of incorrect variant calls.
We have enabled pre-enrichment pooling of up to 12 libraries for higher throughput without compromising standard enrichment metrics of >80% reads on-target. Both the high enrichment efficiency and high coverage uniformity makes our new TruSeq Exome Enrichment kit an ideal tool for analyzing the exome or other areas of interest.

PS14.101

Sample processing for the UK Biobank Genotyping Project

S. Murphy[1], **T. Montoye**[2]*;*
[1]UK Biobank, Manchester, United Kingdom, [2]Trinean, Gentbrugge, Belgium.

UK Biobank is a health research charity which has collected biological samples and a wide range of data on over 500,000 participants aged 40-69 years old. Data and samples are available for use by bona-fide researchers to investigate aetiology of disease. A genotyping project was initiated in 2013 to perform SNP genotyping on all UK Biobank participants within 18 months. The aim of the project - now 75% complete - is to generate high quality genotype data which is available for researchers to use, via UK Biobank.
DNA extraction and quantification is performed at UK Biobank; genotyping (on the custom UK Biobank Axiom® Array) is undertaken by Affymetrix; and the Wellcome Trust Centre for Human Genetics is performing QC, phasing and imputation on the derived data.
UK Biobank used the Trinean DropSense96 instrument for DNA quantification whilst Affymetrix used the PicoGreen method. This poster describes the sample processing workflow employed on the project and presents a comparison between the two quantification methods used. Genotyping metrics for a subset of the samples are also included.

PM14.102

Deciphering the atypical and discovering the unexpected in exome-sequencing using VarElect for phenotype-based variant prioritization

D. Oz-Levi[1], **G. Stelzer**[1]*, S. Zimmerman[1], N. Rappaport[1], T. Olender[1], Y. Anikster[2,3], B. Ben Zeev[4,3], M. Safran[1], D. Lancet[1];*
[1]The Weizmann Institute of Science, Rehovot, Israel, [2]Metabolic Disease Unit, Edmond and Lily Safra Children's Hospital, Sheba Medical center, Ramat Gan, Israel, [3]The Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [4]Pediatric Neurology Unit, Edmond and Lilly Safra Children's Hospital, Sheba Medical Center, Ramat Gan, Israel.

Exome-sequencing is an effective tool to identify genes underlying Mendelian disorders. However, its routine clinical application is only beginning to emerge. A typical analysis generates a variant short-list often containing hundreds of candidates. To overcome the hurdle of connecting one variant to the patient's phenotype, we constructed VarElect, a new Variant Election software tool that attains phenotype-dependent variant prioritization, leveraging the comprehensive information within GeneCards and MalaCards. Users submit phenotype/disease related keywords and a gene list. VarElect then produces a prioritized list of contextually annotated genes, scored according to their likelihood to be disease related, thus enabling to perform the last decision step in NGS analysis in a fast and objective manner. In this realm, we diagnosed trichohepatoenteric syndrome in a girl harboring a novel mutation in *TTC37* (Oz-Levi et al. 2014).
In a second case, trio exome-sequencing of a girl with severe epileptic encephalopathy and her healthy parents revealed a novel missense mutation in *PCDH19* on chrX, causing epilepsy and mental retardation, limited to females (EFMR).
This disorder is showing a rare X-linked inheritance wherein an affected girl inherits a deleterious mutation through her unaffected father, a scenario that would not have been discovered by standard trio analysis that disregards such mutations on chrX. The *PCDH19* mutation was also found in the asymptomatic grandmother suggesting somatic mosaicism of neuronal cells

as a result of skewed X-inactivation leading to phenotypic variability. Our findings emphasis the impact of combining NGS with proper bioinformatics tools on discovery and diagnostics of the atypical and unexpected.

PS14.103

Development of a universal variant classification system and reporting scheme for routine NGS panel diagnostics for diagnostic purposes

A. Laner, *A. Benet-Pagès, U. Schön, E. Holinski-Feder;*
Medizinisch Genetisches Zentrum, Munich, Germany.

NGS is now widely used in routine molecular-genetic diagnostics and many laboratories have access to high-quality NGS data resulting in reliable variant detection. Guidelines [1] are currently formulated to standardize and harmonize many aspects of NGS testing with an emphasis on technical issues. Nevertheless, considerable inter- and intra-laboratory discrepancies concerning the classification and reporting of „variants of uncertain clinical significance" (VUS) can be observed.
There are several variant classification systems published. Some are restricted to specific genes or phenotypes (e.g. IARC [2]; HNPCC genes only), some are restricted to specific modes of inheritance (e.g. Ambry [3]; autosomal dominant and X-linked only), and most of them require extensive additional information (IARC, Ambry and Emory [4]; e.g. segregation data, functional assays, RNA data, immunohistochemical data, etc.) often unavailable at the time the report is created. We aimed to formulate a universal classification algorithm, allowing a robust and simple variant classification suitable for routine diagnostic laboratories.
Furthermore we created an algorithm for classification of variants which possibly affect RNA splicing, based on published data [5], [6], since these type of variants_although quite common_are not covered by the abovementioned systems.
Population frequency data from several exome sequencing studies and additional data (e.g. segregation analysis in families, clinical data, co-occurrence of pathogenic mutations, etc.) suggest that certain variants previously classified by the abovementioned classification schemes as pathogenic (e.g. truncating variants, variants affecting conserved splice sites, start-lost variants) should actually be classified as VUS [7]. To address this problem, we suggest a more stringent approach, classifying variants observed de novo as class 4 or 5.

PM14.104

The ABC of improving patient care and management in pediatric neurology by implementing next generation sequencing in routine diagnostic care

L. E. L. M. Vissers[1], *J. H. Schieving*[2], *K. J. M. van Nimwegen*[3], *L. Krabbenborg*[4], *T. Kleefstra*[1], *E. Kamsteeg*[1], *G. van der Wilt*[3], *H. G. Brunner*[1], *J. P. C. Grutters*[3], *M. A. A. P. Willemsen*[2], *S. van der Burg*[5], *J. A. Veltman*[1];
[1]*Dept. of Human Genetics Radboudumc, Nijmegen, Netherlands,* [2]*Dept. of Neurology, Radboudumc, Nijmegen, Netherlands,* [3]*Dept. for Health Evidence, Radboudumc, Nijmegen, Netherlands,* [4]*Dept. of IQ Healthcare, Radboudumc, Nijmegen, Netherlands,* [5]*Dept. of IQ Health care, Radboudumc, Nijmegen, Netherlands.*

Implementation of novel genetic tests into routine diagnostic practice is generally driven by technological advances as they promise to be faster and/or lead to increased diagnostic yield. Yet, other aspects including costs-to-diagnosis and the patients' information and communication needs are often not assessed prior to implementation. Here, we have addressed these aspects for the implementation of whole exome sequencing (WES) in pediatric neurology. We collected two cohorts (50 retrospectively and 100 prospectively selected patients) presenting with complex neurological problems of suspected genetic origin. Typically, finding a diagnosis in these patients is not easy, nor fast or cheap, and often involves burdensome procedures. In a unique parallel study design, all patients underwent both the conventional diagnostic procedure as well as WES. This unique set-up allowed for direct comparison of diagnostic outcomes, turn-around-times and costs involved. Analyses of the retrospective cohort indicated that WES identified significantly more conclusive diagnoses (10 *vs.* 3, p=0.04), using less genetic tests (1 *vs.* 7.72, p<0.01), in a shorter time (12 *vs* 40 months), and cost reduction for genetic testing (€4,372 *vs.* €5,321). In-depth interviews with parents pointed towards the need for more information and communication of the test and its results, and for more support in their daily struggles and concerns associated with living with a child with a rare genetic condition. Preliminary analysis of our prospective cohort confirms WES being superior to sequential genetic testing with regards to diagnostic yield. Our results provide essential information for an evidence-based implementation guideline of WES in pediatric neurology.

PS14.105

TruePrime™, a novel technology for whole genome amplification from single cells and limited material

A. Schneider[1], *A. Picher*[2], *O. Wafzig*[1], *L. Blanco*[3];
[1]*SYGNIS Bioscience, Heidelberg, Germany,* [2]*SYGNIS Biotech SLU, Madrid, Spain,* [3]*CBM, Madrid, Spain.*

TruePrime™ is a novel technology dedicated to the amplification of whole genomes and DNA from various sources. TruePrime™ is based on the combination of the highly processive Phi29 DNA polymerase with the recently discovered primase/polymerase TthPrimPol. In this setup, TthPrimPol synthesizes the DNA primers needed for Phi29 DNA pol, which allows for the exponential amplification of target DNA. TthPrimPol is a thermostable member of a recently discovered family of enzymes named PrimPol. TthPrimPol is a monomeric enzyme (34 kDa) that displays a potent primase activity, preferring dNTPs as substrates unlike conventional primases. This DNA primase activity can be activated by magnesium or manganese ions, having a wide sequence specificity for template recognition.
Key advantages of the TruePrime™ technology include complete absence of primer artefacts, insensitivity to external DNA contaminations, reduced amplification bias compared to methods using random synthetic primers, and an exquisite reproducibility when amplifying from single cells or minute DNA amounts. Moreover, TruePrime™ shows superior sensitivity, is easy to use and works perfectly well with commonly used NGS platforms such as Illumina or IonTorrent.
We believe that TruePrime™ will advance human genetic analyses from single cells or otherwise limited input material.

PM14.106

Standardising the approach to recruitment and phenotyping in rare diseases - experiences from the Genomics England Rare diseases programme

A. D. Devereau;
Genomics England, London, United Kingdom.

We report on our experiences of developing eligibility criteria and phenotypic data models for recruitment of participants into the 100,000 genomes project in England.
The Genomics England Rare Diseases Programme will recruit and whole genome sequence (WGS) 50,000 English National Health Service (NHS England) patients with the aim of transforming diagnostic services and improving the understanding of rare human diseases.
While this approach is expected to improve the accuracy and speed of genetic diagnosis for patients, the reliable identification and interpretation of disease-associated genetic variants is challenging. The success of the project depends on the selection of participants with a high probability of having a disease with an underlying monogenic cause and the collection of detailed phenotypic data.
Therefore, the implementation of the Programme has required the development of clear guidelines regarding patient recruitment and the collection of phenotypic information. Given the complexity of rare diseases (>120 are currently included within the Programme) it has been necessary to provide guidance in a disease-specific manner. This has been achieved through the creation of disease-specific eligibility statements and phenotypic capture models, and a process for their curation. In particular, we will describe the value of the process as a means of defining best practice in the assessment and diagnosis of rare diseases and clarifying relationships between independent diseases, as evidenced by the frequent re-use of models.
We are confident that the creation of these resources will be one of the legacies of the Genomics England programme.

PS14.107

Implementation of a diagnostic clinical whole exome sequencing service with virtual panel analysis: experience at Guy's Genetic Centre, London

S. M. Lillis[1], *Y. Patel*[1], *E. Thomas*[2], *M. Irving*[2], *F. Flinter*[2], *L. Izatt*[2], *D. Josifova*[2], *L. Robert*[2], *C. Deshpande*[3], *M. Holder*[2], *A. Shaw*[2], *F. Connell*[2], *M. Simpson*[4], *K. Ryan*[1], *J. Ahn*[1], *S. Mohammed*[2], *S. Yau*[1];
[1]*Viapath, Guy's Hospital, London, United Kingdom,* [2]*Clinical Genetics, Guy's Hospital, London, United Kingdom,* [3]*Clinical Genetics, Hospital de Cruces, London, United Kingdom,* [4]*Genomic Medicine Group, KCL, London, United Kingdom.*

Whole exome sequencing (WES) is becoming a frontline molecular diagnostic test in many Genetic Centres particularly for patients with heterogeneous disorders. To assess the feasibility of delivering an end-to-end Clinical WES service we have performed a pilot study of 96 patients over 6 months and describe our experience of the first 50 patients. Analysis using virtual panels restricts investigations to only clinically relevant genes, limiting the

chance of incidental findings whilst enabling panel flexibility for newly discovered genes.
Initially, 7 virtual panels were designed jointly by scientists and clinical geneticists with expertise in these disorders (dysmorphology, endocrine, neurology, ophthalmology, renal, skeletal & connective tissue disorders). Patients were phenotyped by clinical geneticists prior to testing using the Agilent SureSelect Human All Exon v5 kit on a HiSeq 2500. Variants detected within each virtual panel were filtered and those classified as potentially pathogenic were further assessed at a Multidisciplinary Team Meeting prior to verification by Sanger sequencing.
Clear pathogenic variants were identified in 26/50 (51%) of patients confirming their clinical diagnosis. The pathogenic variants identified spanned across a total of 27 different genes, include SNV, insertion/deletion and in 2 cases homozygous/hemizygous partial gene deletions. 12/27 (44%) of genes currently have no testing available on UK GTN including the PODXL gene, which was identified as a candidate gene for focal and segmental glomerulosclerosis (FSGS) in 2014.
These results show that a diagnostic WES service can achieve a high diagnostic yield in a clinically relevant time frame. We now plan to test another 150 patients.

PM14.108
Rapid screening for monogenic diseases in severely ill newborns and infants using whole genome sequencing

W. S. Kerstjens-Frederikse[1], *C. C. van Diemen[1], T. J. de Koning[1,2], B. Sikkema-Raddatz[1], J. D. H. Jongbloed1[1], K. M. Abbott[1], J. C. Herkert[1], P. B. T. Neerincx[1], M. T. [1]University of Groningen, University Medical Center, Department of Genetics, Groningen, Netherlands, [2]University of Groningen, University Medical Center, Beatrix Children's Hospital, Groningen, Netherlands.

Monogenic diseases are frequent causes of neonatal and infant morbidity and mortality. Routine molecular testing is time consuming and available for only few of these diseases. For severely ill newborns and infants quick molecular diagnosis is important for clinical decision-making and can prevent unnecessary and sometimes invasive diagnostics.
Here we describe a procedure and present the first results to analyze 2800 genes in severely ill newborns and infants by rapid whole-genome sequencing (WGS). The procedure is carried out by a multidisciplinary team of pediatricians, clinical geneticists, technicians, laboratory specialists, researchers and bioinformaticians. Thus far we have included 11 patients and analyzed them with a turnaround time of approximately one week. We have provided a diagnosis of a monogenic disease for one patient who presented with microcephaly, seizures and developmental delay and appeared to have compound heterozygous mutations in the *EPG5* gene which is associated with Vici syndrome.We retrospectively tested 4 of the patients without diagnosis using rapid clinical exome sequencing in trio design, focusing on the same set of 2800 genes, resulting in no additional diagnoses. We additionally tested 5 patients who died within the first year of life using clinical exome sequencing in trio design to further test this procedure. We found compound heterozygous mutations in *BRAT1* in one child with an unexplained severe seizure and rigidity disorder.

PS14.109
Whole genome sequencing of human saliva samples within the Deciphering Developmental Disorders (DDD) study

D. Rajan, *E. Prigmore, C. Wright, M. Hurles, „on behalf of the DDD project";*
Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.

The DDD exome pipeline routinely generates high quality DNA sequence data from saliva samples. Here we investigate the suitability of saliva DNA for whole genome sequencing (WGS). Our aim was to evaluate the potential for off-target mapping caused by the presence of bacterial DNA in the sample.
We whole genome sequenced 30 DDD trios (proband, mother, father) to an average depth of 30X on the Illumina X10 HiSeq platform. Parental DNA was extracted from saliva collected in Oragene tubes (DNA Genotek), while proband DNA was extracted from either blood or saliva.
Bacterial qPCR was performed as described by DNA Genotek (PD-PR-065). The assay utilises "universal" bacterial primers targeting a well-conserved region of the 16S ribosomal RNA gene. The median percentage of bacteria was 5.5% in adult saliva, 27.7% in child saliva and 0.02% in blood. We compared the percentage bacteria per sample to the percentage of reads mapping on-target by WGS. We discovered a high level of correlation between these two parameters. The minimum depth per sample was 10X (35% mapping), and the median depth 27X (90% mapping). Therefore even in samples with a high percentage of bacteria, a sufficient proportion of reads are mapped such that variant detection should be possible.
We find bacterial qPCR to be a robust and scalable method for screening samples for the presence of bacterial DNA. While it may not encompass the full spectrum of non-human DNA (e.g. viral, fungal), it provides a cost-effective method for detecting and filtering out poor candidates for WGS.

PM14.110
Towards gene correction of IVS1-110 β-thalassaemia

P. Patsali[1,2], *C. Mussolino[3], C. Stephanou[1,2], M. N. Antoniou[2], T. Cathomen[3], C. W. Lederer[1], M. Kleanthous[1];*
[1]Molecular Genetics of Thalassemia Department, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [2]Department of Medical and Molecular Genetics, King's College London, London, United Kingdom, [3]Institute for Cell and Gene Therapy, University Medical Center Freiburg, Freiburg, Germany.

Thalassemia is amongst the commonest single-gene disorders worldwide and caused by deficient production of α- or β-globin. The disease has limited curative treatment options, but as a monogenic disorder of the hematopoietic system is ostensibly an ideal target for gene therapy. Specific β-thalassemia mutations have already been addressed by the burgeoning field of genome editing, targeting mutations of minor prevalence in the West and combining homology-mediated gene repair with the expansion of corrected iPS cell clones
Our research is focused on the development of efficient gene-correction tools (TALENs and CRISPR-Cas9) specific for the common and severe HBBIVS1-110 (G>A) mutation, which in most Mediterranean and many Western countries has a frequency of above 20% (with 80% on the island of Cyprus) amongst β-thalassemia carriers. This mutation introduces an abnormal splice acceptor site in intron 1 of the β-globin gene, therefore retaining an intronic in-frame premature stop codon in the mature, aberrantly spliced mRNA.
In this study, we illustrate the high cleavage activity of novel IVS1-110-specific genome-editing tools (TALENs and CRISPR-Cas9) in HEK293T cells and in HBBIVS1-110-transgenic murine erythroleukaemia cells. Towards the assessment of therapeutic efficiency of our designer nucleases at the mRNA level, we have validated a multiplex RT-qPCR method for the absolute quantification of the correctly and aberrantly spliced HBB mRNAs. Finally, immunoblots indicate the partial correction of β-globin protein expression in treated HBBIVS1-110-transgenic MEL cells compared to mock controls. These preliminary data indicate HBBIVS1-110 as a suitable target for gene therapy genome editing and that our approach may serve as a model for the correction of many other intronic disease-causing mutations.

PS15.01
A patient with 4q13-q22 chromosomal deletion and Incontentia Pigmenti skin lesion. Diagnostic problems and therapeutic options

G. J. Braathen[1], *L. M. Tveit[2], V. Haugan[1], A. K. Eek[1], Ø. L. Holla[1], Ø. L. Busk[1], K. Tveten[1];*
[1]Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway, [2]Department of Pediatrics, Telemark Hospital, Skien, Norway.

Background: Deletions of the 4q13-q22 chromosomal region have infrequently been reported. The patients may be short, microcephalic and severely retarded with multiple minor anomalies. Two of the three patients reported died before 11 months of age.
Incontinentia pigmenti (IP) is a genodermatosis that segregates as an X-linked dominant disorder and is usually lethal prenatally in males. In affected females it causes highly variable abnormalities of the skin, hair, nails, teeth, eyes, and central nervous system.
Exome sequencing is a technique for sequencing all the protein-coding genes in a genome.
Material and Methods: A new born girl with some dysmorphic features developed a skin rash, cephalic hematoma and seizures. She was treated with antiepileptic drugs.
MRI and EEG were done as well as chromosomal analysis, Array comparative genomic hybridization (ACGH) and exome sequencing.
Results: Chromosomal analysis revealed the 4q13.1-22 deletion while ACGH defined the breakpoints. The skin lesion was compatible with IP.
Exome sequencing was done to look for variants in the remaining allele of the deleted genes at 4q looking for variants of importance for her phenotype and thus hopefully give possible therapeutic options. The exome results are pending.
Conclusion; 4q13-q22 deletion and Incontinentia pigmenti (IP) have never been described in the same patient and it is the first large 4q13-q22 deletion case with identified breakpoints.

To our knowledge this is the first case with a defined chromosomal deletion where exome sequencing was done to investigate the remaining allele of the deleted genes looking for possible therapeutic options.

PM15.02
Swedegene: genome-wide association study of drug-induced agranulocytosis

M. Wadelius[1], *N. Eriksson[1], Q. Y. Yue[2], P. K. Magnusson[3], E. Eliasson[3], H. Melhus[1], P. Hallberg[1];*
[1]Uppsala University, Uppsala, Sweden, [2]Medical Products Agency, Uppsala, Sweden, [3]Karolinska Institutet, Stockholm, Sweden.

Introduction: Agranulocytosis is a rare, serious condition with a case-fatality rate of 7-10%. It can be caused by a multitude of drugs, and genetic factors are believed to play a role in the pathogenesis. Swedegene (www.swedegene.se) is collecting patients with drug-induced agranulocytosis on a nation-wide basis. We aim to discover genetic and clinical factors that predispose to drug-induced agranulocytosis to enable personalised treatment in the future.
Materials and Methods: A genome-wide association study was performed on 94 adjudicated Swedish agranulocytosis cases and 4891 unrelated controls from TwinGene. Cases were genotyped with Illumina HumanOmni2.5-8 and controls with Illumina HumanOmniExpress-12v1 at Uppsala University SciLife SEQ&SNP Technology Platform. Analyses were performed using PLINK and HLA imputations using SNP2HLA. After quality control, the merged genotype set contained ~600k SNPs. The significance level was set at p<8.39x10-08.
Results: The main causative drugs were sulfasalazine, antithyroid agents and antibiotics. Statistical analyses identified significant associations in the HLA region on chromosome 6. After HLA genotype imputation, the strongest signal was HLA-C*02:02 (OR [95% CI] = 3.37 [2.25, 4.92], p=8.75x10-10). The HLA locus remained significant when utilising 233 controls matched for disease and/or treatment.
Conclusions: We found an association between drug-induced agranulocytosis and the HLA locus. We are proceeding with additional cases and controls obtained through collaboration with Spain, France and Germany to strengthen the finding. Collaborators with replication cohorts are invited.

PS15.03
CYP2D6 enzymatic deficiency and weight gain in patient treated with atypical antipsychotics

N. Andreescu, *S. Farcas, L. Nussbaum, V. Dumitrascu, R. Gradinaru, M. Puiu;*
University of Medicine &Pharmacy Victor Babes, Timisoara, Romania.

Introduction. Several atypical antipsychotic drugs are associated with metabolic side effects including weight gain, body mass index (BMI)/blood Insulin level increase. The half-life of atypical antipsychotics varies depending on the activity of the CYP2D6 enzyme, but there is lack of data regarding the impact of CYP2D6 isoenzyme polymorphisms on the long-term effects, in paediatric patients using atypical antipsychotics.
Aim. In this study we aimed to underline the role of individual genetic variation, in correlation with the CYP2D6 genotype, for weight gain in patients treated with atypical antipsychotics.
Material and methods. The study lot included 80 patients, aged between 9 and 20 years, median age being 15.75. The sex percentage in the sample was 55% girls / 45% boys. All the patients were receiving one of the choosen atypical antipsychotic-Risperidone, Aripiprazole or Olanzapine. We evaluated the BMI and the blood insulin variations for these patients in different time points during the treatment with atypical antipsychotics. CYP2D6*3, *4, *5, *41 allele identification was performed.
Results. Based on the CYP2D6 genotype, three activity groups were identified and compared. The CYP2D6 genotype in children and adolescents with schizophrenia and bipolar disorder, proved to be a good predictor for the risk of gaining weight, metabolic ratio and the increase of insulin blood level.
Conclusion. The significant correlations between the CYP2D6 polymorphisms and the weight gain/BMI and/or blood Insulin increase, as major side effects induced by antipsychotics proved the fact that the pharmacogenetic screening is needed in the future clinical practice, allowing for individualized treatment.

PM15.04
Using genetic and gene expression methods to identify biological predictors of response to cognitive behavioural therapy for anxiety disorders

J. R. I. Coleman[1], *G. Breen[1,2], T. C. Eley[1];*
[1]King's College London, Institute of Psychiatry, Psychology and Neuroscience, MRC Social, Genetic and Developmental Psychiatry (SGDP) Centre, London, United Kingdom, [2]National Institute for Health Research Biomedical Research Centre, South London and Maudsley National Health Service Trust, London, United Kingdom.

Anxiety disorders are the most prevalent group of psychiatric disorders, and represent a major global burden both to the individual and to the state. Cognitive behavioural therapy (CBT) is commonly used to treat anxiety, and is effective in children and adults. However, a substantial proportion of those receiving CBT fail to remit following treatment. The expense and distress of ineffective treatment is good justification for seeking predictors of response.
Genome-wide methodologies present a hypothesis-neutral strategy for exploring the potential of genetic variants as predictors. We have performed GWAS in a global study of predictors of response to CBT in children with anxiety disorders (the Genes for Treatment study, N=980). Although no variants reach conventional levels of genome-wide significance for response immediately post-treatment, or at a six-month follow-up, seven loci are suggestive of significance.
The results of the GWAS suggest that individual genetic variants are unlikely to predict useful amounts of variance in response. However, polygenic approaches may be valuable. We have used an independent cohort of adults receiving CBT for anxiety disorders (N=200), to perform polygenic risk scoring to predict response.
Genetic variants do not exist in isolation. Using our adult cohort, we have undertaken a combined analysis of genome-wide genetic and gene expression data. In addition to identifying cis-eQTLs for differentially-expressed transcripts, we have created modules of genes using literature-driven and data-driven modalities, and derived principal components from these to test whether genetic variants can be identified that drive the expression of relevant pathways.

PS15.05
Non-invasive genomic profiling of bladder cancer using urinary cfDNA

F. S. Togneri[1], *R. T. Bryan[2], D. G. Ward[2], J. M. Foster[3], A. J. Devall[2], P. Wojtowicz[1], S. Alyas[1], F. Ramos Vasques[1], A. Oumie[4], N. D. James[5], K. K. Cheng[6], M. P. Zeegers[7], N. Deshmukh[2], B. O'Sullivan[8], P. Taniere[8], K. G. Spink[4], D. J. McMullan[1], M. Griffiths[1];*
[1]West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom, [2]Bladder Cancer Prognosis Programme, School of Cancer Sciences, University of Birmingham, Birmingham, United Kingdom, [3]Affymetrix UK Ltd., Wooburn Green, United Kingdom, [4]Affymetrix UK Ltd, Wooburn Green, United Kingdom, [5]Clinical Trials Unit, University of Warwick, Coventry, United Kingdom, [6]School of Population and Health Sciences, University of Birmingham, Birmingham, United Kingdom, [7]Department of Complex Genetics, NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht University Medical Centre+, Maastricht, Netherlands, [8]Department of Histopathology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.

Urothelial bladder cancer (UBC) is the 7th most common cancer in Western societies with a rising global incidence. UBCs are highly heterogeneous in their clinical characteristics, and this is mirrored in the often highly complex genomic profiles observed in formalin-fixed paraffin-embedded (FFPE) tumour material. Identification of such complex genomics and detection of important specific genomic biomarkers in a non-invasive fashion would be highly advantageous for diagnosis, treatment selection and monitoring of disease.
Here we show genomic data from >100 FFPE UBC tumour samples profiled using the OncoScan® FFPE assay kit. The samples were obtained from a well characterised UBC patient cohort with >3 years clinical follow-up. Analysis of this data reveals novel predictive and prognostic genomic biomarkers in UBC. Additionally we show data from concurrent, parallel genomic analyses of 23 UBC patients using DNA extracted from urine cell pellets; cell-free DNA (cfDNA) from urine supernatants, and DNA from FFPE tumour samples. This data illustrates the potential of DNA extracted from the urine for non-invasive genomic profiling of UBC and for the identification of predictive and prognostic biomarkers. Interestingly our data shows increased sensitivity of cfDNA (85%) over DNA from urinary cell pellets (55%) for accurate non-invasive genomic profiling of UBC.

PM15.06
Alteration in the PI3K/AKT signaling pathway in Czech breast cancer patients

B. Kubova[1], *J. Simova[1,2], M. Uvirova[1,2], H. Tomaskova[2], Z. Bravencova[3], S. Pitronova[1], A. Hopenstokova[1], I. Zebrakova[1], R. Ondruššek[1], J. Dvorackova[1,2,4];*

[1]Laboratory of molecular genetics and pathology, CGB laboratory Inc., Ostrava, Czech Republic, [2]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic, [3]Institute of Oncology, Faculty Hospital in Ostrava, Ostrava, Czech Republic, [4]Institute of Pathology, Faculty Hospital in Ostrava, Ostrava, Czech Republic.

Introduction: Breast cancer is the most frequently diagnosed cancer and the leading cause of cancer death in females worldwide. Deregulation of PI3K/AKT signaling pathway has been associated with cancer development and progression and is promising target for breast cancer therapy.
Materials and Methods: DNA samples of breast tumour tissues were tested for presence of selected somatic mutations in PIK3CA and AKT1 genes. Analysis was performed by primer extension method or real-time PCR. Statuses of HER2 gene and ER/PR expression were evaluated by FISH and/or immunohistochemistry methods using FFPE tissue sections. Correlation between PIK3CA mutation status and clinicopathological characteristics were estimated with the chi-squared test (95% CI).
Results: Somatic mutations in PIK3CA gene were detected in 26,1% (63/241). Mutations in the exons 9 and 20 were detected in 36,5% and 57,1%, respectively. Coexistence of mutations (exon 9 and 20) was found in 6,4%. Mutation p.E17K in AKT1 gene was detected in 1,7% (2/115). PIK3CA mutations were signicantly associated with low histopathological grade and ER positive status.
Conclusions: Frequency of PIK3CA and AKT1 gene mutations correlates with published data. Marked differences in distribution of PIK3CA mutations were found among breast cancer subtypes (ER+ , HER2- and triple negative). Alterations involving the PI3K/AKT pathway may have distinct prognostic and predictive impacts on patients. Novel combination of treatment strategies, involving PI3K pathway inhibitors, has a potential to improve clinical benefit of breast cancer patients.

Association of Twist transcription factor expression and chemosensitivity of primary breast tumor samples

S. Ulusal[1], *M. H. Muslumanoğlu*[2], *M. Muslumanoğlu*[3], *S. Başaran*[4], *Z. Z. Çalay*[5], *A. Aydıner*[6], *U. Vogt*[7], *T. Çakır*[8], *S. Artan*[9];
[1]Trakya University Faculty of Medicine Department of Medical Genetics, Edirne, Turkey, [2]Yıldız Technical University Faculty of Science and Literature Department of Molecular Biology and Genetics, Istanbul, Turkey, [3]Bezmialem University Faculty of Medicine Department of General Surgery, Istanbul, Turkey, [4]Istanbul University Faculty of Medicine Department of Medical Genetics, Istanbul, Turkey, [5]Istanbul University Cerrahpaşa Medical Faculty Department of Pathology, Istanbul, Turkey, [6]Istanbul University Faculty of Medicine Department of Medical Oncology, Istanbul, Turkey, [7]European Laboratory Assocation ELA, Ibbenbueren, Germany, [8]Gebze Technical University Faculty of Engineering Department of Bioengineering, Istanbul, Turkey, [9]Eskişehir Osmangazi University Faculty of Medicine Department of Medical Genetics, Eskişehir, Turkey.

Doxorubicin and Docetaxel are anticancer agents which commonly used as a part of breast cancer chemotherapy regimens. TWIST1 (OMIM 601622) gene encodes Twist transcription factor which is a basic-helix-loop-helix protein and regulates the mesoderm formation and differantiation during development. In vitro studies using cancer cell lines sugessted that Twist transcription factor might have a role in resistance to chemotherapeutic agents in some cancer types including breast cancer. We aimed to investigate the association of twist gene expression levels and theraphy response to doxorubicin and docetaxel in primary breast tumor samples. 26 tumor samples were collected from the patients. Chemosensitivity of primary breast tumor samples to doxorubicin and docetaxel have been determined by ATP based tumor chemosensitivity assay. Total RNA was extracted by using RNeasy Mini Kit (Qiagen) from tumor samples. Twist gene expression of tumor samples were determined by Real Time Reverse Transcriptase PCR by using beta actin gene expression as reference. (Real Time Ready Gen Expression Assay, Roche) 9 out of 26 tumors were nonresponsive to doxorubicine whereas only 3 out of 26 tumors were nonrespnsive to docetaxel. Doxorubicine non-responsive breast tumors had higher TWIST1 gene expression levels compared to doxorubicine responsive breast tumors (p=0.041) There were no association of twist gene expression with docetaxel resistance (p=0.3). In conclusion our results support that twist transcription factor might be a candidate biomarker to predict chemoresponse of breast tumors to doxorbicine. Further studies with larger sampe groups are needed to clarify the role of Twist gene expression in resistance to chemotheraphy.

PM15.08

Clinical validation of a NGS based in vitro diagnostic (CE-IVD) kit for targeted detection of actionable gene rearrangements in lung cancer specimens

J. Schageman;
Thermo Fisher Scientific, Austin, TX, United States.

In recent years, advances in next-generation sequencing (NGS) technologies have enabled faster and cheaper methods for uncovering the genetic basis of disease. For cancer, NGS based screening for known tumor subtypes can inform diagnosis and allow the clinician to tailor a specific therapy based on testing outcome. Here we present the validation of one such NGS based kit approved for CE-IVD use to screen for specific chromosomal translocations in non-small cell lung cancer (NSCLC) samples by targeting specific breakpoints in known fusion transcripts.
The kit tested (Oncomine™ Solid Tumor Fusion Transcript Kit) included a single primer pool containing amplicon designs to simultaneously screen for over 75 specific rearrangements involving the receptor tyrosine kinase (RTK) genes ALK, RET and ROS1 as well as NTRK1. The panel was compatible with formalin-fixed paraffin-embedded lung tumor samples and achieved high-sensitivity down to 10 ng of RNA input. In addition, amplicon assays designed at the 5’ and 3’ ends the RTK genes provide non-specific evidence that a translocation exists in a sample by comparing expression imbalance between the two ends.
Validation testing was carried out at three external clinical laboratories (CLIA, CAP, INAB). In addition to positive and negative control samples, each site contributed FFPE lung tumor samples for which ALK fusion status was known prior to NGS library preparation carried out using the Ion AmpliSeq™ workflow. For site-specific samples samples (n=144), high concordance, sensitivity and specificity were measured at 97.2%, 90.5% and 98.4% respectively.

PS15.09

Effect of CYP2D6 genotypes on the pharmacodynamics of carvedilol in healthy korean volunteers

D. Seo, *H. Jeong, F. Jiang, Y. Kim, Y. Hyun, J. Lee, I. Hwang, H. Na, J. Kim;*
National Institute of Food & Drug Safety Evaluation, cheongju-si, Korea, Republic of.

Depending on the variation of genes related with the drug metabolism, a drug may express no effect or cause severe adverse effect. For this reason, MFDS, Korean national drug regulatory authority put great effort to harness pharmacogenomics using genomic information from Korean population.
As a part of this effort, the pharmacodynamic study of carvedilol, a important beta blocker widely used in Korea, has been conducted to find out the effect of CYP2D6 genotype on pharmacodynamic endpoints of carvedilol. After recruiting CYP2D6 genotype-specific subjects(EM, IM1 and IM2), a clinical study was conducted to check pharmacodynamic endpoints.
Heart rate, systolic blood pressure and diastolic blood pressure were decreased by medication of carvedilol in all genotype groups. Isoproterenol sensitivity test (IST) also showed increased CD25 after the medication in all genotype groups like other vital signs.
The mean CD25 value showed no statistically significant change when compared with basal level. But the mean CD25 value between different genotype groups (EM vs IM) revealed some statistic singificance ($p < 0.05$).
The pharmacodynamic study of carvedilol in Korean populations showed that CYP2D6 genotype caused difference in CD25 value of IST but not in major clinical endopoint such as heart rate, systolic blood pressure and diastolic blood pressure. These results inferred that carvedilol does not cause any important clinical difference depending on the CYP2D6 genotype. In conclusion, these results suggested that dose adjustment does not requried for the carvedilol treatment in Korean population.
Acknowledgement: This research was supported by a grant (14181MFDS532) from Ministry of Food And Drug Safety in 2014.

PM15.10

Development and analytical validation of an ADME gene Ion AmpliSeq sequencing assay covering 143 SNP and CNV Pharmacogenetics targets.

T. Chen, M. Manivannan, S. Chen, T. Hartshorne, A. Mongan, **C. Ainli**, *G. Liu, M. Andersen, F. Hyland;*
Thermo Fisher, South San Francisco, CA, United States.

Cytochrome P450 (CYP) enzymes metabolize about 75% of drugs, with UGT enzymes metabolizing about another 15%. Variations in gene sequence or copy number may result in an inactive, defective, unstable, mis-spliced, low expressed, or absent enzyme, an increase in enzyme activity, or an altered affinity for substrates. ADME gene genotypes can predict whether an indi-

vidual is a poor or rapid metabolizer, facilitating dose optimization to avoid adverse or insufficient drug reaction.
We have designed a pharmacogenomics (PGx) Ion Ampliseq panel to detect 143 variants in 37 ADME genes including copy number detection in CYP2D6, covering the common, actionable, interpretable and reimbursable targets in genes encoding drug metabolism enzymes and associated transport proteins, including CYP2D6 and CYP3A4. The panel contains 134 amplicons in an ultrahigh-multiplex PCR in a single pool, followed by Ion Torrent™ semiconductor sequencing; the assay is compatible with FFPE samples as well as non-FFPE samples, requiring as little as 10 ng of input DNA. This panel can be customized, allowing additional targets to be added.
Analytic validity of the panel was established by sequencing 90 annotated cell lines from Coriell, and comparing the Ion AmpliSeq genotypes to gold standard TaqMan OpenArray genotypes. Concordance with TaqMan genotypes was > 99.8%, genotype reproducibility was > 99.9%, and the genotype no-call rate was < 0.15%.
These results demonstrate an ADME genotype assay with high accuracy, which can be used to explore potential pharmacogenomic relationships, including the relationship between copy number and genotype of DME genes on drug tolerability and clinical outcomes.

PS15.11
High frequency and founder effect of the CYP3A4*20 loss-of-function allele in the Spanish population classifies CYP3A4 as a polymorphic enzyme

Grupo de Medicina Xenómica, CIBERER, IDIS, Santiago de Compostela, Spain.*

Cytochrome P450 3A4 (CYP3A4) is a key drug metabolizing enzyme. Loss-of-function variants have been reported as rare events, and the only demonstration of a CYP3A4 protein lacking functional activity is caused by *CYP3A4*20* allele. Here we characterized the world distribution and origin of *CYP3A4*20* mutation. *CYP3A4*20* was determined in more than 4000 individuals representing different populations and haplotype analysis was performed using *CYP3A* polymorphisms and microsatellite markers. *CYP3A4*20* allele was present in 1.2% of the Spanish population (up to 3.8% in specific regions), and all *CYP3A4*20* carriers had a common haplotype. This is compatible with a Spanish founder effect and classifies CYP3A4 as a polymorphic enzyme. This constitutes the first description of a *CYP3A4* loss-of-function variant with high frequency in a population. *CYP3A4*20* results together with the key role of CYP3A4 in drug metabolism, support screening for rare *CYP3A4* functional alleles among subjects with adverse drug events in certain populations. Currently, we are genotyping *CYP3A4*20* allele in Spanish individuals treated with various CYP3A4-substrates to better characterize the pharmacokinetics of *CYP3A4*20* carriers.

PM15.12
Role of pharmacogenetic on deferasirox AUC and efficacy

S. Allegra[1], *J. Cusato[1], S. De Francia[2], D. Massano[3], A. Piga[3], A. D'Avolio[1];*
[1]University Of Turin-Department Of Medical Science, Turin, Italy, [2]University Of Turin-Department Of Biological And Clinical Sciences, Turin, Italy, [3]University Of Turin-Department Of Paediatrics, Turin, Italy.

Deferasirox is a once-daily oral administered iron chelator and its pharmacokinetic significantly correlates with therapy outcome. This drug is metabolized in liver by UDP-glucuronyltransferase (UGT) 1A1 and 1A3, by cytochrome-P450 (CYP) 1A1, 1A2 and 2D6 enzymes, and it is eliminated via biliary-enteric circulation through multidrug resistance protein 2 (MRP2).
We perform a retrospective study of deferasirox pharmacokinetic (AUC, area under the curve) according to single nucleotide polymorphisms (SNPs) in genes involved in this drug metabolism and elimination, in a cohort of adult β-thalassemic patients. Moreover, we define a plasma AUC cut-off value predicting an adequate response to therapy.
Allelic discrimination for SNPs in UGT1A1, UGT1A3, CYP1A1, CYP1A2, CYP2D6, MRP2 and BCRP1 genes is performed by real-time PCR. Drug plasma concentrations are measured by an HPLC-UV validated method. AUC over 24 hours values are determined by the mixed log-linear rule, using Kinetica software.
Sixty patients meet the inclusion criteria. UGT1A1 CT/TT (rs887829), UGT1A3 TT (rs1983023) and AG/GG (rs3806596) SNPs show an influence on the half-life (p=0.029, p=0.043 and p=0.043 respectively); UGT1A3 GG (rs3806596) and CT/TT (rs1983023) SNPs significantly influenced AUC, volume of distribution, maximum serum concentration and time of maximum concentration. According to Chirnomas effectiveness definition, a deferasirox AUC cut-off value of 360 ng/mL/h was identified (ROC-curve, p=0.012). UGT1A1 rs887829 (p=0.008) and ABCG2 rs13120400 (p=0.007) SNPs are factors able to predict concentration above 360 ng/mL/h in the logistic regression analysis. These data contribute to a better management of deferasirox treated patients, suggesting the usefulness of a genetic-based dose personalization.

LDL-cholesterol (LDL-C) reduction effectively reduces risk of coronary artery disease (CAD). However, statins (the most widely prescribed LDL-C lowering drugs) increase type 2 diabetes (T2D) risk. Using public domain data from genome-wide association studies, we conducted genetic epidemiological investigations to identify druggable loci that alter LDL-C and CAD risk without causing dysglycemia. A one standard deviation (SD) increase in LDLC caused an increased odds ratio (OR) for CAD of 1.63 (95% confidence interval [CI]: 1.55, 1.71) and LDL-C/CAD-associated SNPs showed consistent effect directions (binomial P=4.93x10-21). A 1-SD higher LDL-cholesterol was protective of T2D (OR 0.86; 95%CI:
0.81, 0.91), however LDL-C/T2D- ssociated SNPs didn't show consistent effect directions (binomial P=0.08). PCSK9, APOB, LPA, CETP, PLG and ALDH2 were identified as druggable loci that alter LDL-cholesterol and CAD risk without causing dysglycemia, indicating drugs targeting these gene products may reduce CAD risk without increasing T2D risk.

PS15.15
Genomic risk prediction of obesity and related disorders: body mass index vs. waist-to-hip ratio

M. L. Bermingham[1], *R. Pong-Wong[1], M. Perez-Alcantara[1], A. Spiliopoulou[1], C. Hayward[1], I. Rudan[1], H. Campbell[1], A. F. Wright[1], J. F. Wilson[1], F. Agakov[2], P. Navarro[1], C. S. Haley[1];*
[1]College of Medicine and Veterinary Medicine, University of Edinburgh., Edinburgh, United Kingdom, [2]Pharmatics Limited, Edinburgh Bioquarter, Edinburgh, United Kingdom.

Introduction: Waist-to-hip ratio (WHR) has been suggested to be a better predictor of obesity and related disorders than body mass index (BMI). However, it is unclear which of the two are most appropriate for genomic risk stratification. The aim of the study was to test whether predicted genomic values (PGV) for WHR are better than those of BMI in classifying outcomes for obesity and related disorders within a Croatian (N=2,159) and into a UK (N=805) population sample. Materials and Methods: PGV were estimated in the genomic best linear unbiased prediction (GBLUP) and Bayes C framework. The discriminative power of BMI and WHR PGV in classifying outcomes for general (BMI ≥30 kg/m2) and abdominal (WHR >1.0 in men and >0.85 in women) obesity and related disorders (chronic obstructive pulmonary disease, hypertension, peripheral vascular disease and metabolic syndrome) was assessed by the area under the receiver operating characteristic curves (AUC) and bootstrap-derived confidence limits. Results: Performance of GBLUP prediction was similar to that of Bayes C in both populations; suggesting that the genetic architecture of BMI and WHR approximates the infinitesimal model. BMI classified genomic risk of obesity and related disorders as well as or better than WHR. All AUC reported in this study ranged from 0.51 to 0.81; indicating low to moderate discriminatory value. Conclusions: Inclusion of PGV in combination with the traditional risk

factors (age, age2 and sex) in most cases augmented the AUC; indicating that genomic information can be used to supplement traditional risk factors in prediction models.

PM15.16

BRAF mutations in Slovak cohort of patients with gastrointestinal stromal tumors

Z. Lasabová[1], *K. Gemzová*[1,2], *V. Buzalková*[2], *G. Minárik*[3], *A. Štanclová*[2], *P. Szépe*[2], *L. Plank*[2];
[1]*Comenius University in Bratislava, Jessenius Faculty of Medicine, Dept. of Molecular Biology, Martin, Slovakia,* [2]*Comenius University in Bratislava, Jessenius Faculty of Medicine, Department of Pathological Anatomy, Martin, Slovakia,* [3]*Comenius University in Bratislava, Faculty of Medicine, Institute of Molecular Biomedicine, Bratislava, Slovakia.*

Introduction: Gastrointestinal stromal tumors (GISTs) are highly resistant to conventional chemotherapy and radiotherapy, however sensitive against tyrosine kinase (TK) inhibitors. Approximately 10 to 15% of GISTs are lakking the mutations in KIT and PDGFRA and are referred as wildtype GISTs (wtGISTs) which are less sensitive to TK inhibitors. One of the reasons can be the activated RAS-BRAF signaling.
Material and methods: Formalin-fixed paraffin-embedded (FFPE) tissue sections were collected as a part of the National GIST Registry from 705 patients with the diagnosis of GIST in years 2004-2014 and were genetically characterized for KIT and PDGFRA mutations by dideoxysequencing - 150 patients' samples corresponded to wtGISTs and further 100 patients with mutation in KIT or PDGFRA were included in the study. For the detection of BRAF V600E, dideoxysequencing and allele-specific PCR were used.
Results: The proportion of the BRAF-positive patients (V600E and K601N) in the total cohort of patients with GIST analyzed for the mutational status in KIT and PDGFRA genes is 1.42% (10/705), in the wtGIST subset 6.67% (10/150). Only in 5 cases, the BRAF mutation could be confirmed by dideoxysequencing showing the low amount of BRAF positive cells in the tumor mass. Two patients of hundred previously identified as mutated in KIT or PDGFRA have harbored the BRAF mutation too.
Conclusion: BRAF mutations may affect the response to imatinib of wtGIST and KIT imatinib-sensitive mutations representing new mechanisms of primary resistance to targeted therapy in GIST. The BRAF testing in GIST should be taken into account.

University Hospital of Salamanca -USAL-CSIC, Salamanca, Spain,* [3]*Molecular Medicine Unit, Department of Medicine. University of Salamanca, Salamanca, Spain,* [4]*Institute of molecular and cellular biology of cancer (IBMCC). University of Salamanca-CSIC, Salamanca, Spain.*

Introduction: Head and neck cancer represents one of the most common cancers in the developed world. The main risk factors (tobacco, alcohol, etc.) can cause DNA damage as well as cancer treatments. Therefore, polymorphisms in DNA repair genes may alter the ability to repair DNA damage increasing the susceptibility to develop the disease and modifying the response to treatment and survival. In this work we focused on the influence of these polymorphisms on the disease free survival.
Methods: We studied 173 patients with head and neck cancer. *XRCC1* rs25487, *APEX1* rs1130409, *XPD* rs13181, *ERCC1* rs11615 and *XRCC3* rs861539 polymorphisms were genotyped. Statistical analysis was performed according to the different models of inheritance (codominant, dominant, recessive, additive). We stratified the analysis by stages at diagnosis.
Results: We found an increased risk of relapse in patients with minor alleles of *XPD* or *ERCC1* (Table 1) in 78 patients with localized disease (stages I and II). Regarding patients with advanced disease (stages III and IV), we studied a total of 95 patients and we did not find any statistically significant results.
Conclusions: We found an association of *XPD* (rs13181) and *ERCC1* (rs11615) variants with disease free survival depending on the stage at diagnosis. These results support the importance of the nucleotide excision repair pathway in these tumors.

Resequencing of GWAS loci identifies new candidate genes on chromosome 5 for heparin-induced thrombocytopenia

A. Witten[1], *J. Bolbrinker*[2], *A. Barysenka*[1], *F. Rühle*[1], *U. Nowak-Göttl*[3], *E. Garbe*[4], *R. Kreutz*[2], *M. Stoll*[1];
[1]*Institute of Human Genetics, Münster, Germany,* [2]*Institute of Clinical Pharmacology and Toxicology and Pharmacovigilance-Center FAKOS, Berlin, Germany,* [3]*Institute of Clinical Chemistry, Kiel, Germany,* [4]*Department of Clinical Epidemiology, BIPS - Institute for Epidemiology and Prevention Research, Berlin, Germany.*

Treatment with unfractionated (UFH) or low molecular weight heparins (LMWH) represents a mainstay for the prevention and treatment of thrombotic disorders. Heparin-induced thrombocytopenia (HIT) is a potentially deleterious complication of heparin use. To explore whether a genetic predisposition contributes to HIT, we performed a pharmacovigilance study enrolling patients with suspected HIT and corresponding control patients. Subsequently, we selected 182 cases and 182 controls for the pharmacogenetic substudy consisting of a genome-wide association study (96 cases) with replication in additional 86 cases, followed by imputing and overall fine mapping analysis. One single nucleotide polymorphism (SNP, rs1433265) from initially 16 identified SNPs was successfully replicated (P=1.5x10-4) and remained the most strongly associated SNP (P=3.5x10-5) after imputing genotypes on chromosome 5. Fine mapping revealed two significantly associated haplotypes with an odds ratio of 0.63 (95% CI, 0.46-0.88; P=5.6x10-3) and 2.41 (95% CI, 1.64-3.55; P=4.9x10-6).In order to find variants not detected in our GWAS but contributing to the association signals, we applied a NGS-based targeted resequencing approach in a subgroup of 73 HIT patients and 23 controls for the regions with the 16 most strongly HIT-associated SNPs. A C-alpha test was applied to perform a gene-based test for the impact of rare variants in our targeted region and we were able to detect two associated HIT-candidate genes, ICE1 (P = 0.010) and ADAMTS16 (P= 0.005) containing 17 and 23 rare variants, respectively. These results provide a basis for further studies that aim to characterize the genetic predisposition to HIT.

PS15.19

IFNL4 polymorphism is a predictor of hepatitis C treatment efficiency in Ukrainian patients

A. Kucherenko[1], *V. Pampukha*[1], *K. Romanchuk*[2], *S. Chernushyn*[1], *I. Bobrova*[3], *L. Moroz*[2], *L. Livshits*[1];
[1]*Institute of Molecular Biology and Genetics of the National Academy of Sciences of Ukraine, Department of Human Genomics, Kyiv, Ukraine,* [2]*National Pirogov Memorial Medical University, Department of Infectious Diseases with Epidemiology Course, Vinnytsya, Ukraine,* [3]*Ukrainian Treatment and Diagnostic Center, Kyiv, Ukraine.*

The discovery of host genotype impact in combination with virus genotype on chronic hepatitis C (CHC) treatment outcome was a milestone in the development of antiviral therapy strategies. The aim of this study was to examine association between IFNL4 (interferon-lambda 4) gene ss469415590 and treatment efficiency in group of Ukrainian PEG-interferon-treated CHC patients.
Study group was 92 unrelated HCV genotype 1 mono-infected CHC patients. Viral load was detected at weeks 4, 12, 24, 48 and 72. The patients were distributed into: case group - 29 patients with late or absent viralogical response, and control group - 63 patients with sustained viralogical response (SVR). Study material - genomic DNA extracted from peripheral blood. Genotyping for IFNL4 gene ss469415590 was performed using amplification-refractory mutation system PCR. Statistical analysis was performed using GenePop and OpenEpi statistical packages. A P-value of less than 0.05 was

regarded as significant.
Frequency of ss469415590 ΔG carriers was significantly higher in patients without SVR (86.2%) comparing to group with SVR (50.8%). Obtained results imply ss469415590 TT/TT genotype positive association with SVR, whereas ss469415590 ΔG/ΔG genotype is associated with poor virological response. This association fits into additive model of inheritance, ss469415590 ΔG/ΔG homozygotes have 3,6-times higher risk of poor response to PEG-interferon/ribavirin combination therapy (OR=3,62; CI95%: 1.12-11.67).
Our study presents the evidence of ss469415590 being informative pharmacogenetic marker of CHC treatment efficiency in Ukrainian patients.

PM15.20
The plant cytokine kinetin as a potential therapeutic agent to correct CFTR splicing defects

L. Straniero[1,2], *G. Soldà*[3,2], *V. Rimoldi*[2], *R. Asselta*[3,2], *S. Duga*[3,2];
[1]University of Milan, Milan, Italy, [2]Humanitas Clinical and Research Center, Rozzano, Italy, [3]Humanitas University, Rozzano, Italy.

Cystic fibrosis (CF) is a common recessive disorder caused by >1900 mutations in the CF transmembrane conductance regulator (CFTR) gene. About 13% of CFTR mutations are classified as splicing defects. Besides these severe mutations, other variations are known to modulate the correct CFTR splicing, the most important being the polymorphic TG(9-13)T(5,7,9) locus, which influences exon-10 inclusion and has been associated with monosymptomatic forms of CF. Recent advances in CF treatment have demonstrated the efficacy of drugs targeting specific classes of molecular defects, such as potentiators (Ivacaftor, already FDA approved and suitable for about 4% of patients) and correctors (Vx-661 and Vx-809 for F508del), opening a new era of personalized treatment. However, no such therapies are available for patients carrying splicing mutations.
For this reason, we are exploring the possibility to improve exon-10 inclusion in CFTR mRNA using the plant cytokinin kinetin, an FDA-approved drug previously found to correct aberrant splicing in familial dysautonomia and neurofibromatosis.
We tested the effect of kinetin on CFTR splicing in Caco-2 cells, which express high level of CFTR transcript and present a significant amount of exon-10 skipping.
By competitive fluorescent RT-PCR and digital RT-PCR we demonstrated that different concentrations of kinetin determine a dose-response rescue of wild-type CFTR splicing. These results reveal a remarkable impact on splicing fidelity by this small molecule, which may represent a promising therapeutic agent for CF and particularly atypical forms. Moreover, it will be interesting to test whether kinetin treatment can also partially rescue severe splicing mutations in CFTR.

PS15.21
Do metabolic disease genes SNPs affect elite sports performance?

V. Ginevičienė[1], *A. Jakaitienė*[1], *L. Tubelis*[2], *A. Utkus*[1];
[1]Department of Human and Medical Genetics, Vilnius, Lithuania, [2]Lithuanian University of Educational Sciences, Vilnius, Lithuania.

Introduction: Complex metabolic diseases and physical activity levels are closely-related. PPAR family and members of the PGC-1 are key regulators of energy homeostasis and metabolism. We studied the association of PPARGC1A rs8192678, PPARGC1B rs7732671, PPARA rs4253778, PPARD rs2016520, PPARG rs1801282 which have been shown to impact metabolic dysfunction and elite athletic status. We hypothesised the metabolic risk genotype/allele to be underrepresented in elite athletes (n=130, sprint/power and endurance orientated) compared to controls (n=175, healthy unrelated non-athlete Lithuanians). Methods: Genotyping was performed by PCR-RFLP. Results: The genotypes' distribution was in HWE within all groups. For three SNPs the genotype frequencies were significantly different between the total athlete and control group (PPARGC1B CC/CT/TT: 89.2/10.8/0% vs 80.6/19.4/0%; P=0.04; PPARD TT/TC/CC: 88.5/11.5/0% vs 78.9/19.4/1.7%; P=0.05; PPARA GG/GC/CC: 61.5/38.5/0% vs 70.3/26.9/2.9%; P=0.02). PPARA genotype distribution in sprint/power athletes significantly differed from controls (GG51.4; GC48.6; CC0%; P=0.03). The PPARA C allele in the sprint/power athletes (24.3%) was more frequent compared to endurance (17.7%) and controls (16.35%). Having the metabolic risk-related PPARA GC&CC genotypes increases chances by 2.23 times (95%CI, 1.07-4.67) of achieving better results in sprint/power sport. The other SNPs did not show significant differences between the study groups. Conclusions: we found an association between PPARA rs4253778 and athletic status. Sprint/power athletes are more likely to have the metabolic risk allele C of PPARA compared to controls. These results suggest that some SNPs across the human genome have dual effect and may predispose sprint/power athletes to increased risk of developing metabolic morbidities compared with the general population.

PM15.22
NRAS genotyping in patients with metastatic colorectal cancer

G. Gordo[1], *J. Tenorio*[1], *P. Arias*[1], *L. Ostios*[2], *M. Muñoz*[3], *H. Tong*[3], *R. Lubomirov*[3], *J. Miranda*[2], *A. M. Borobia*[3], *J. Feliu*[2], *A. J. Carcas-Sansuán*[3], *N. Rodríguez*[2], *P. Lapunzina*[1];
[1]Institute of Medical and Molecular Genetics-INGEMM. Hospital Universitario La Paz, Madrid, Spain, [2]Medical Oncology Service. Hospital Universitario La Paz, Madrid, Spain, [3]Clinical Farmacology Service. Hospital Universitario La Paz, Madrid, Spain.

Introduction: Metastatic colorectal cancer (mCRC) is the second cause of dead in the world. Development of monoclonal antibodies against Epidermal Growth Factor Receptor (EGFR), Cetuximab and Panitumumab, has increased the survival of patients with mCRC. The efficiency of these drugs depends on the use of genetic biomarkers such as KRAS and, recently, NRAS. It has been found that patients with mutations in these genes have poorer survival rate when they are treated with anti-EGFR therapy. The objective of this study is to perform a mutational analysis of NRAS in patients with mCRC, and correlate the findings with the response to anti-EGFR drugs.
Material and Methods: We performed mutational analysis by pyrosequencing to detect the commonest changes in codons 12, 13, 59, 61, 117 and 146 of NRAS, in tumours samples of 493 patients with mCRC treated with anti-EGFR drugs, and whose KRAS mutational status has been studied previously. We also compared the percentage of mutations detected in the different codons of KRAS and NRAS with previous works.
Results: We have found 15 mutations in NRAS in 15 tumour samples. Fourteen did not have mutations in KRAS. Codon 61 is the most frequently mutated. The percentages obtained in our study are in agreement with previous studies.
Conclusion: This study demonstrates that a percentage of KRAS-negative colorectal tumours has mutations in NRAS, and that this status would be related to the response of anti-EGFR therapy.

PS15.23
The most frequent monogenic disorders in Russian population identified by microarray "Ethnogene"

M. M. Litvinova[1,2], *T. A. Roslova*[2], *M. S. Balashova*[1,2], *F. A. Konovalov*[2], *K. G. Shevchenko*[2], *E. A. Pomerantseva*[2], *K. A. Konduktorov*[2], *Y. V. Kovaleva*[2], *A. A. Isaev*[2];
[1]Sechenov First Moscow State Medical University, Moscow, Russian Federation, [2]Human Stem Cells Institute, Moscow, Russian Federation.

Introduction: It is known that every person has 5-7 pathogenic mutations in genome (mostly in genes of autosomal-recessive disorders). In such cases carrier status does not lead to clinical manifestation however, if both parents have mutations in the same gene, the risk for offspring to develop disease is 25%. In our clinical practice we prophylactically detect carrier status in spouses using genetic screening "Ethnogene" (APEX microarray technology). This screening program can be also used for diagnostic purpose. It is especially important at pre-clinical stage of disorder when there is a chance to prevent disease complications.
Materials and Methods: Microarray "Ethnogene" allows detecting the mutations leading to 60 monogenic disorders most frequent in Russia. In this study we prophylactically analyzed 336 persons including adults and children of different age.
Results: 8.6% of 336 genotyped patients were diagnosed to have monogenic disease (table 1). 70% of examined persons appeared to have 1-3 mutations in carrier status.
Conclusion: Application of microarray screening "Ethnogene" helps to reveal carrier status among couples planning pregnancy and to determine risk for offspring to be affected by certain monogenic disorders. Detection of monogenic diseases in yet asymptomatic patients allows preventing a number of complications by prescribing pathogenic therapy.

Targeted Next-Generation Sequencing (NGS) Of Nine Candidate Genes With Custom Ampliseq In Patients And A Cardiomyopathy Risk Group

A. S. Glotov[1,2], *S. V. Kazakov[3], Elena A. Zhukova, Oleg S. Glotov, Vladimir S. Pakin, Maria M. Danilova, A. V. Alexandrov[3], S. S. Niyazova[4], N. N. Chakova[4], S. M. Komissarova[5], E. A. Kurnikova[6], A. A. Sergushichev[3], A. A. Shalyto[3], V. S. Baranov[1,2];*
[1]Saint-Petersburg State University, St.-Petersburg, Russian Federation, [2]FSBSI „The Research Institute of Obstetrics, Gynecology and Reproductology named after D.O.Ott", St.-Petersburg, Russian Federation, [3]ITMO University, St.-Petersburg, Russian Federation, [4]Institute of Genetics and Cytology of the National Academy of Sciences, Minsk, Belarus, [5]Republican Scientific Practical Center «Cardiology», Minsk, Belarus, [6]Saint Petersburg State Pediatric Medical University, St.-Petersburg, Russian Federation.

Hypertrophic cardiomyopathy is a common genetic cardiac disease. Prevention and early diagnosis of this disease are very important. Because of the large number of causative genes and the high rate of mutations involved in the pathogenesis of this disease, traditional methods of early diagnosis are ineffective. We developed a custom AmpliSeq panel for NGS sequencing of the coding sequences of ACTC1, MYBPC3, MYH7, MYL2, MYL3, TNNI3, TNNT2, TPM1, and CASQ2. A genetic analysis of student cohorts (with and without cardiomyopathy risk in their medical histories) and patients with cardiomyopathies was performed. For the statistical and bioinformatics analysis, Polyphen2, SIFT, SnpSift and PLINK software were used. To select genetic markers in the patients with cardiomyopathy and in the students of the high risk group, four additive models were applied. Our AmpliSeq custom panel allowed us to efficiently explore targeted sequences. Based on the score analysis, we detected three substitutions in the MYBPC3 and CASQ2 genes and six combinations between loci in the MYBPC3, MYH7 and CASQ2 genes that were responsible for cardiomyopathy risk in our cohorts. We also detected substitutions in the TNNT2 gene that can be considered as protective against cardiomyopathy. We used NGS with AmpliSeq libraries and Ion PGM sequencing to develop improved predictive information for patients at risk of cardiomyopathy.

The work was supported by the Russian Science Foundation grant №14-50-00069.

The NR3C1 gene polymorphism in polish IBD patients undergoing glucocorticoids therapy

M. Gabryel[1], **M. Skrzypczak-Zielinska**[2], *A. Komur[3], M. Walczak[3], M. Wieczorek[3], O. Zakerska-Banaszak[2,4], A. Dobrowolska-Zachwieja[1], R. Slomski[2,3];*
[1]Department of Gastroenterology, Human Nutrition and Internal Diseases, University School of Medical Sciences, Poznan, Poland, [2]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland, [3]Department of Biochemistry and Biotechnology, University of Life Sciences, Poznan, Poland, [4]The NanoBioMedical Centre, Adam Mickiewicz University, Poznan, Poland.

Glucocorticoids (GCs) are still drugs of first choice in patients with exacerbation of inflammatory bowel diseases (IBD), although epidemiological studies show, that over 15% of patients would not respond properly to these agents. The glucocorticoid receptor, encoded by NR3C1 gene, is playing crucial role in the effects of GCs. A few of described polymorphism are functionally relevant. The aim of this study was to determine the essential loci: rs6189/rs6190 (p.ER22/23EK), rs56149945 (p.N363S), rs41423247 (BclI, IVS2+646C>G) of the NR3C1 gene and to correlate the obtained genotypes with the observed GCs therapy reaction.

Materials and Method: We analyzed DNA samples from 40 clinically diagnosed IBD patients treated with methylprednisolone and hydrocortisone. Patients were qualified to one of three groups - steroid resistant (6), steroid dependent (8) and steroid sensitive (26). The genotypes were determined using sequencing (p.ER22/23EK, p.N363S) and RFLP analysis (BclI).

Results: The p.E23K and p.N363S variants are not present in steroid resistant and dependent groups compared to 7.69% among steroid sensitive group. The allel G in BclI position was identified with frequency of 71.15 % in steroid sensitive group compared to 68.75 % in steroid dependent and 58.33% in steroid resistance. BclI carriers shown the significant increased sensitivity for GCs compared to rest of investigated patients (OR=0.103, 95% CI=0.008-1.282, p=0.04944).

Conclusions: Our initial studies indicate, that BclI polymorphism could be a useful molecular marker to identify polish IBD patients responsive to GC treatment.

PM15.26

Targeted next generation sequencing to unveil genetic markers of paclitaxel-induced peripheral neuropathy

M. Apellániz-Ruiz[1], *H. Tejero[2], L. Inglada-Pérez[1,3], L. Sánchez-Barroso[1], G. Gutiérrez-Gutiérrez[4], I. Calvo[5,6], L. García-Estévez[6], M. Sereno[7], J. García-Donás[8], A. Cascón[1,3], M. Robledo[1,3], F. Al-Shahrour[2], C. Rodríguez-Antona[1,3];*
[1]Hereditary Endocrine Cancer Group, Spanish National Cancer Research Centre (CNIO), Madrid, Spain, [2]Translational Bioinformatics Unit, Clinical Research Programme,Spanish National Cancer Research Centre (CNIO), Madrid, Spain, [3]ISCIII Center for Biomedical Research on Rare Diseases (CIBERER), Madrid, Spain, [4]Neurology Section, Hospital Universitario Infanta Sofía, Madrid, Spain, [5]Medical Oncology Department, Hospital Montepríncipe, Madrid, Spain, [6]Medical Oncology Department, Centro Integral Oncológico Clara Campal, Madrid, Spain, [7]Medical Oncology Department, Hospital Universitario Infanta Sofía, Madrid, Spain, [8]Gynecological and Genitourinary Tumors Programme, Centro Integral Oncológico Clara Campal, Madrid, Spain.

Introduction: Paclitaxel is a cytotoxic agent widely used in oncology. However, it frequently causes peripheral sensory neuropathy that can seriously impact patients' quality of life. Previous studies suggest an important contribution of genetic factors to the variation in paclitaxel neuropathy susceptibility; however, most part remains unexplained. In this study we aimed to identify genetic markers predictive of paclitaxel-induced neuropathy through candidate gene sequencing.

Materials and Methods: From a series of 380 breast and ovarian cancer patients treated with first-line paclitaxel, 170 cases (73 with low and 97 with high neuropathy) were selected for sequencing. A custom panel including 40 genes involved in paclitaxel pharmacokinetics and pharmacodynamics, and hereditary neuropathies was designed (TruSeq Custom Amplicon, Illumina). Libraries derived from patients' blood were sequenced in the MiSeq system (Illumina).

Results: The analysis pipeline includes selection of high-quality loss-of-function and missense variants and an analysis following two different approaches. First, for common variants a Chi^2 test to compare the number of alternative alleles among the two groups of patients. Second, a variance-component test, aimed to study low frequency variants in a gene basis. We found loss-of-function variants in *DHTKD1*, *EPHA5* and *EPHA8* genes in the high neuropathy group, and a preliminary analysis suggested that rare missense variants were overrepresented in *EPHA6* in the high neuropathy group. Full analysis will be presented in the conference.

Conclusions: Sequencing of candidate genes in well characterized series of patients seems a promising approach to unveil genetic variants associated with complex traits such as paclitaxel-induced neuropathy.

ICLDC Repository- a research platform for development of personalised medicine

H. Daggag, *A. Al Tikriti, M. Barakat;*
Imperial College London Diabetes Centre, Abu Dhabi, United Arab Emirates.

ICLDC Repository is a unique initiative for the storage and management of biological samples linked to clinical data, led by and integrated into Imperial College London Diabetes Centre (ICLDC), Abu Dhabi. The general purpose of the repository is to set up a resource that can support a diverse range of research intended to improve prevention, diagnosis and treatment of illness,

and promotion of health throughout the UAE society. The added benefits of the repository are reflected in the collection of samples and data for genetic analysis. Studying the genetic variation of the UAE population will enable the individualization of healthcare and contribute to disease identification, tailoring therapies and disease management strategies specific for this region.
ICLDC Repository undoubtedly represents a uniquely rich resource for investigating the relevance of a wide range of exposures to various health-related outcomes. More specifically, research conducted using ICLDC Repository genetic samples will facilitate the study of genetic variation that influence individual response to drugs.
ICLDC Repository is a newly developed concept in the UAE, with undeniable scientific value that can be extracted from such facility. The necessity for a better genetic understanding of the Emirati population is growing by the day and facilities such as ICLDC Repository will prove to be vital in accomplishing such an endeavor.

PM15.28
Combined Evaluation Of Genotype And Phenotype Of Thiopurine S-Methyl Transferases (TPMT) As A Profit Tool In The Clinic Management Of Patients In Chronic Therapy With Azathioprine

A. Marocchi[1], *M. Cigoli*[1], *V. Marini*[2], *C. Fucile*[2], *F. Mattioli*[2], *P. Primignani*[1], *G. Gesu*[1], *S. Penco*[1];
[1]*Niguarda Ca' Granda Hospital, Milan, Italy,* [2]*University of Genova, Genova, Italy.*

Occurrence of adverse events (ADR) often occur during treatment with azathioprine (AZA) in patients with chronic autoimmune diseases. The response to AZA is influenced by the activity of thiopurine s-methyl transferases enzyme (TPMT): a low activity leads to accumulation of toxic metabolites, a high activity results in a higher production of methylated metabolite and therefore a lower therapeutic efficacy. To date 3 TPMT gene polymorphisms are associated with reduced enzyme function: 238G/C, 460G/A, 719A/G. Response to AZA can be predicted genetically with the study of polymorphysms and biochemically with the study of the enzyme activity. Integrated evaluation of TPMT genotype/phenotype is a useful tool in the clinical management of patients receiving AZA preventing ADR and/or side effects.
223 patients afferent to Medical Genetics of Niguarda Ca' Granda Hospital (Milan), were genetically analyzed for the 3 TPMT gene polymorphisms. The enzymatic TPMT activity was evaluated with HPLC assay.
199 patients resulted wild type (wt) and have tolerated therapy, 12 were found to be mutated and do not use AZA therapy, 12 patients resulted wt, but have developed ADR.
Genetic analysis of TPMT gene can predict the occurrence of ADR related to treatment with AZA predetermining TPMT activity levels; this text is not influenced by pharmacological and intra-individual variables. Conversely, genetic analysis focus only on three variables explaining about 80% of the altered TPMT activity. The biochemical test predicts dose-dependent ADR but the enzymatic assay suffers from pharmacological and/or individual variables. An integrated genotype/phenotype assessment of TPMT is a useful tool in the clinical management of patients receiving AZA for preventing ADR.

PS15.29
ePGA: an integrated electronic Pharmacogenomics Assistant for Personalized Medicine

K. Lakiotaki[1], *E. Kartsaki*[1], *A. Kanterakis*[1], *T. Katsila*[2], *G. Patrinos*[2], *G. Potamias*[1];
[1]*ICS-FORTH, Heraklion, Greece,* [2]*Department of Pharmacy, University of Patras, Patras, Greece.*

Introduction: Research and Direct to Consumer services increase the flow of genetic data. Interpretation of these data into meaningful information that could lead to clinical applications, requires the development of novel (bio) informatics tools and services. Here, we present an integrated electronic Pharmacogenomics Assistant (ePGA) that provides personalized genotype-to-phenotype translation services, linked to drug recommendations.
Materials and methods: ePGA is a web-service, which combines data from heterogeneous data sources (PharmGKB, dbSNP, Ensembl) and links them to available, up to date, clinical guidelines. ePGA users can query for combinations of genes, drugs and alleles, and browse related clinical guidelines. Moreover, users may upload genotypes in Variant Call Format (VCF) and receive personalized drug recommendations.
Results: To demonstrate ePGA we explored genome data from phase-I 1000 Genomes Project (1kG). Statistical analysis indicates that pharmacogenomics (PGx) profiles differ significantly among 1kG populations in most (~75%) of the studied pharmacogenes. In general, individuals of African ancestry exhibit greater PGx profile variation in most genes among populations, which can be attributed to increased genetic heterogeneity of African population.
Conclusions: The novelty of ePGA rests in its ability to translate genotypes into PGx phenotypes and drug recommendations, based on state-of-the-art pharmacogenomics knowledge. ePGA's acts as a "one stop shop" web portal for clinicians - by supporting them in making informed decisions, and for researchers - by providing a single place with information to understand, document and assess individuals' differences in drug efficacy.
This work was supported by the Greek GSRT in the context of eMoDiA project (11SYN_10_145), "COOPERATION 2011" program.

PM15.30
Modification of lipid spectrum due to pharmacogenetic interaction of prenatal retinoic acid administration with 7-gene-segment of rat chromosome 8

M. Krupkova, *M. Janku, F. Liska, L. Sedova, D. Krenova, V. Kren, O. Seda;*
Intitute of Biology and Medical Genetics First Faculty of Medicine Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic.

Introduction: Polydactylous rat strain (PD/Cub) and spontaneously hypertensive rat (SHR) are two established rodent models of human metabolic syndrome. In PD/Cub predispositions for metabolic syndrome and polydactyly-luxate syndrome colocalize on the rat chromosome 8. Recently we have derived the minimal congenic SHR.PD-(D8Rat42-D8Arb23)/Cub (SHR-Lx) strain carrying only 7 genes of PD origin on SHR background.
Material and methods: Rat dams of SHR and minimal congenic SHR-Lx strains were treated with retinoic acid (atRA, 1 mg/kg at 13 ED) or vehicle. We then contrasted metabolic profiles (incl. oral glucose tolerance test (OGTT) and triglyceride and cholesterol in 20 lipoprotein fractions) of adult male SHR and SHR-Lx offspring under conditions of high sucrose diet with or without prenatal exposition to atRA.
Results: We observed differences in effect of atRA between SHR and SHR-Lx strains reflected by significant two-way ANOVA strain * atRA interactions (S*atRA). SHR-Lx PD5 displayed greater sensitivity to RA-induced metabolic dysregulations compared to SHR, including impairment of glucose tolerance (e.g. S*atRA $p = 0.04$ for glucose at 60 min. of OGTT), a shift towards less favorable distribution of cholesterol and triglycerides into the lipoprotein fractions and differences in size of cholesterol particles (e.g. S*atRA $p = 0.005$ for LDL particle size and $p = 0.004$ for HDL particle size).
Conclusions: We demonstrated that pharmacogenetic interaction of prenatally administered retinoic acid with a 7- gene region of rat chromosome 8 affects the distribution of cholesterol and triglycerides into the lipoprotein fractions along with other features of metabolic syndrome.

PS15.31
Variants in clinical relevant genes among 2628 participants of the Dutch Rotterdam Study

A. J. M. H. Verkerk, *J. G. J. van Rooij, S. C. A. Nouwens, L. Broer, A. Hofman, J. Heeringa, R. M. W. Hofstra, L. H. Hoefsloot, R. Kraaij, A. G. Uitterlinden;*
Erasmus MC, Rotterdam, Netherlands.

Within our Dutch population-based Rotterdam Study we have sequenced the exome of 2628 individuals. In this dataset we have made an inventory of variants present in the by Green et al. previously published 56 „actionable genes" that are important for and used in the clinical diagnosis of classical Mendelian genetic diseases.
We have selected truncating (stopgains, splice, frameshift) and nonsynonymous damaging variants (as predicted by a total of 7-8 prediction tools) and grouped them into 3 different tiers based on their predicted deleteriousness. Tier1 are variants classified as pathogenic or probably pathogenic by the ClinVar database (40 variants); Tier2 are variants classified as untested or probably non-pathogenic by the ClinVar database but annotated as truncating or loss of function variants (as predicted by 7-8 damaging prediction tools) (27 variants with 15 unreported in dbSNP138) and Tier3 are nonsynonymous and indel variants without a known clinical classification but nevertheless predicted to be truncating or damaging (by 7-8 damaging prediction tools) (30 variants with 18 unreported in dbSNP138). Initial analysis shows i.e. 2 novel variants (4 and 8 allele counts) predicted to be damaging in MSH2.
As participants in the Rotterdam Study are extensively phenotyped, novel variants from disease related „actionable genes" will be analyzed in relation to relevant phenotypes. Furthermore we are testing the presence of known clinical pathogenic variants in our exome data. This will add to the discussion on how to handle these kind of findings in population based studies, especially on whether or not to report back these findings to participants in the study and under which conditions.

PM15.32

Gene expression analysis of clozapine treatment in whole blood of patients with treatment resistant schizophrenia

R. N. S. Harrison[1], *S. de Jong[1], L. Sang Hyuck[1], R. M. Murray[2], J. Paya Cano[1], D. Dempster[1], C. Curtis[1], D. Dima[1], F. Gaughran[3], G. Breen[1];*
[1]SGDP, King's College London, London, United Kingdom, [2]3. Department of Psychosis Studies, Institute of Psychiatry Psychology and Neuroscience, King's College London, London, United Kingdom, [3]Department of Psychosis Studies, Institute of Psychiatry Psychology and Neuroscience, King's College London, London, United Kingdom.

Objectives:
Clozapine is an atypical antipsychotic with a unique effect in treatment-resistant schizophrenia (TRS). We tested the effect of clozapine versus other drug treatments on peripheral blood gene expression in a sample of schizophrenia patients from the United Kingdom.
Methods: Blood samples from individuals receiving treatment for established schizophrenia were analysed for gene expression using on Illumina HumanHT-12.v4 BeadChips. After standard quality control procedures, 152 samples remained, including 55 from individuals receiving clozapine. Weighted Gene Correlation Network Analysis (WGCNA) was used to identify modules of co-expressed genes. The influence of the mood-stabilisers, lithium carbonate/ lithium citrate and sodium valproate, was studied to identify their possible roles as confounders.
Results
No significant change in gene expression was found for clozapine versus other antipsychotic medication at the individual gene or network level. Sensitivity analyses for lithium demonstrated an association with one gene co-expression module at the network level, and thus this was corrected for in the clozapine analyses.
Conclusions
Overall, this study finds no significant distinction between the effects of clozapine on gene expression in human whole blood samples versus that of other antipsychotic drugs at the individual gene or the network level. This study had limited power due to a small sample size and use of non-primary tissue but does
suggest that clozapine has similar effects on blood gene expression as other common antipsychotic treatments for schizophrenia.

PS15.33

Association of polymorphisms of genes involved in metabolism of oseltamivir with adverse drug reactions in a Mexican population

M. A. Bermudez de Leon[1], *R. Gonzalez-Rios[1], R. A. Leya-Parra[1], E. Gonzalez-Gonzalez[1], A. Alvarado-Diaz[1], O. E. Vazquez-Monsivais[1], V. L. Mata-Tijerina[1], B. L. Escobedo-Guajardo[1], M. Curras-Tuala[1], M. E. Aguado-Barrera[1], B. Silva-Ramírez[1], J. Alcocer-González[2], A. Salinas-Martinez[1], C. Becerril-Esquivel[1], P. E. Lopez-Salas[1];*
[1]Mexican Social Security Institute, Monterrey, Mexico, [2]Autonomous University of Nuevo Leon, Monterrey, Mexico.

Oseltamivir is a neuraminidase inhibitor extensively used in influenza outbreaks to prevent the release of progeny virions and thereby limit the spread of infection. There are reports about deaths and neuropsychiatric events in other populations with the use of oseltamivir, suggesting that this drug could inhibit also to human sialidases in a similar way that virus. Oseltamivir phosphate is a prodrug that is absorbed by Peptide transporter PEPT1 and effluxed by P-glycoprotein. Once inside of the cell, oseltavimir phosphate is converted by human carboxilesterase-1 to oseltamivir carboxilate, which is the active form to inhibit influenza virus neuraminidase. However, oseltamivir also has an inhibitory effect on human sialidases, which are important in various cellular functions including lysosomal catabolism. The aim of this study was to determine the single nucleotide polymorphisms (SNPs) for PEPT1(SLC15A1 gene), P-glycoprotein (ABCB1 gene), carboxilesterase-1 (CES1 gene) and sialidase (NEU2 gene) in >700 Mexican patients with oseltamivir therapy, and these data were correlated with side effects reported between 2010-2012. The SNPs evaluated were Gly185Val(rs1128501), Ser893Thr/Ala(rs2032582) and Ile1145Ile(rs1045642) for ABCB1 gene; Ser117Asn(rs2297322) for SLC15A1 gene; Gly143Glu and Arg199His (rs71647871 and rs2307243, respectively) for CES1 gene; and Arg41Gln(rs2233385) for NEU2 gene. Clinical data of patients were obtained from institutional electronic files. This work was approved by the Ethics Committee of Mexican Social Security Institute. We found that eight percent of patients showed side effects as depression, anxiety, seizures, and hallucinations among others. Genetic and allelic frequencies are presented and associated with the side effects of oseltamivir in a Mexican population. The authors thank CONACyT-Mexico for financial support (Grant number SALUD-2011-1-162243).

PM15.34

No impact of SLCO1B1 521T>C, and 388A>G polymorphisms on statin induced myopathy in the Hungarian population

V. Remenyi, *T. Szilasi, Z. Grosz, P. Balicza, A. Gal, M. J. Molnar;*
Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary.

The first choice treatment of hypercholesterolemia and hyperlipidemia are the HMG-CoA reductase inhibitors (statins). One of the side effects of statins is the statin-induced myopathy (SIM) which occurs in 5-15% of patients. In the genetic background of SIM the *SLCO1B1* gene c. 521 T> C (p.Val174Ala, rs4149056) variation with the most significance association was described. The aim of our investigation was the analysis of the two commonly SIM associated *SLCO1B1* SNP's - c.521 T> C and c.388 A> G (p.Asn130Asp, rs2306283) - in Hungarian statin treated patients with SIM and without any side effects.
Sixty patients with SIM (male 23, female 37; mean age 64.3 ± 9.9 years) and 30 statin treated patients without SIM (male 11, female 19; mean age 53.2 ± 8.2 years) has been investigated. Specific TaqMan SNP Assays were used for the real-time PCR (ABI StepOnePlus System).
The allele frequency of the mutant C allele (rs4149056) was 81.7% in the SIM cohort (homozygous: 39 cases, heterozygous: 20 cases) and 81.6% in the group without SIM (homozygous: 19 cases, heterozygous: 11 cases). The allele frequency of the mutant G allele (rs2306283) was 45.8%, in the SIM group (homozygous: 9 cases, heterozygous: 37 cases) and 40% in the group without SIM (homozygous: 5 cases, heterozygous: 14 cases).
The presence of rs4149056 and rs2306283 major variants of *SLCO1B1* gene did not show any significant association to SIM in Hungarian patients. Analyses of larger cohorts, and SNP's of further genes, like *KIF6, COQ2 ATP2B1* are in progress.
Grant: Hungarian Brain Research Program - Grant, No. KTIA_13_NAP-A-III/6.

PS15.35

P53 tumor suppressor gene codon 72 polymorphism in patients with oral lichen planus - a pilot study

E. Galimova[1], *G. Akmalova[2], E. Khusnutdinova[1];*
[1]Institute of Biochemistry ang Genetics, Ufa Scientific Center of Russian Academy of Sciences, Ufa, Russian Federation, [2]Department of Therapeutic Dentistry, Bashkir State Medical University, Russian Ministry of Health, Ufa, Russian Federation.

Oral lichen planus (OLP) is a T-cell mediated autoimmune disease in which autocytotoxic CD8+ T cells (CTLs) trigger apoptosis of oral epithelial cells. Activated CTLs can produce Fas ligand and by binding to Fas lead to apoptosis. This Fas pathway and the action of p53 tumour suppressor gene are important in producing apoptosis. Current data demonstrate a link between these two factors at the transcriptional level. TP53 encodes a tumor suppressor protein, which plays multiple roles in apoptosis, cell-cycle control, and DNA repair. The TP53 codon 72 polymorphism produces variant with G/C, and the variant lead to an amino acid change in the protein product (Arg→Pro). The objective of this study was to assess the association of the TP53 codon 72 polymorphism with OLP. 93 Russian patients of European descent with OLP and 163 healthy donors were studied. Genotyping was performed by RT-PCR. The frequencies of TP53 C allele (P = 0.0008) and CC genotype (P = 0.004) in patients with erosive OLP were significantly greater than the corresponding values in the control group. The OR (95% CI) of erosive type of OLP cases with C as susceptibility allele was 2.25(1.38-3.64). Our study suggests that PRO at SNP P53 codon 72 is one of the genetic risk factors for OLP and that this polymorphism may be useful as one of the genetic markers for predicting the occurrence of this disease. Moreover, our data may provide genetic evidence to support the importance of P53 protein in OLP development. This research was funded by the RFBR grants 13-04-01489 and 14-04-97026.

PM15.36

Rationale for pretreatment genetic testing for VKORC1*2 polymorphism in vulnerable patients groups

N. Lojo-Kadric[1], *E. Alavac[2], J. Ramic[1], L. Pojskic[1];*
[1]Institute for genetic engineering and biotechnology, Sarajevo, Bosnia and Herzegovina, [2]Department of Biology, Faculty of Science, University of Sarajevo, Sarajevo, Bosnia and Herzegovina.

Vitamin K epoxide reductase complex, subunit 1 (VKORC1) has major role of vitamin K pathway in metabolic of warfarin (anticoagulation drug). Genotyping of VKORC1 most common polymorphism VKORC1*2 (rs9923231) is currently used in pharmacogenomics personalized therapy for warfarin treatment since it is linked to possibly serious adverse events in treated patients.

The main aim of this experiment was to assess the variation of VKORC1 in two typical subsets of patients subjected to anticoagulant treatment in order to estimate the actual need for genotyping prior to anticoagulant (warfarin) treatment.
First patient cohort was consisted of patients that had at least one thrombo-embolitic episode in their lifetime; second patient cohort was consisted of women that had recurrent spontaneous abortions. Healthy volunteers which did not have any thrombo-embolitic episode or family history of thromboembolism represented third cohort. VKORC1*2 polymorphism was genotyped by ARMS PCR method. Statistic tests used for genetic association analysis were: test of genetic association, adjusted for smaller sample size – Fisher Exact test (CI 95%); allele and genotype frequencies comparison among smaller subsets-exact P-value; odds ratio and relative risk ratio.
As a result of this experiment, no statistically significant allele association for VKORC1 with either investigated disorder was observed (p>0,05). Also, there was no observable difference in allelic distribution of VKORC1 as marker between thromboembolism-group and general population. Main conclusions are that in this retrospective analysis, we were unable to confirm that pretreatment genetic testing for VKORC1 polymorphism is justified in addition to standard precautionary measures related to anticoagulant treatment.

PS16.01
SeqPurge: highly-sensitive adapter trimming for paired-end short read data

M. Sturm, *C. Schroeder, P. Bauer;*
Institute of Medical Genetics and Applied Genomics, University Hospital Tübingen, Germany, Tübingen, Germany.

Trimming adapter sequences from short read data is a common preprocessing step in most DNA/RNA sequence analysis pipelines. For amplicon-based approaches, which are mostly used in clinical diagnostics, sensitive adapter trimming is of special importance. Untrimmed adapters can be located at same genomic position and can lead to spurious variant calls. Shotgun approaches are more robust towards adapter contamination. Untrimmed adapters are randomly distributed over the target region which reduces the probability of spurious variant calls.
When performing paired-end sequencing, the overlap between forward and reverse read can be used to identify excess adapter sequences. This is exploited by several published adapter trimming tools. However, in our evaluations on amplicon-based paired-end data we found that these tools fail to remove all adapter sequences and that adapter contamination can even cause spurious variant calls.
Here we present SeqPurge, a highly-sensitive adapter trimmer that uses a probabilistic approach to detect the overlap between forward and reverse reads of paired-end Illumina sequencing data. The overlap information is then used to remove adapter sequences - even if only one base long. Compared to other adapter trimmers specifically designed for paired-end data, we found that SeqPurge achieves a higher sensitivity. The number of remaining adapters after trimming is reduced by 40-75%, depending on the compared tool. The specificity of SeqPurge is comparable to that of the compared other tools. In addition to adapter trimming, SeqPurge can also perform trimming based on quality and based on no-call (N) stretches.

PM16.02
Gene expression profiles in generalized aggressive periodontitis

D. Sunnetci-Akkoyunlu[1], *E. Guzeldemir-Akcakanat*[2], *N. Cine*[1], *B. Orucguney*[2], *B. Kan*[3], *E. Yilmaz*[1], *H. Savli*[1];
[1]*Kocaeli University Medical Genetics Department, Kocaeli, Turkey,* [2]*Kocaeli University Department of Periodontology, Kocaeli, Turkey,* [3]*Kocaeli University Department of Oral and Maxillofacial Surgery, Kocaeli, Turkey.*

Introduction: Aggressive periodontitis (AgP) is an inflammatory periodontal disease which is complex, multifactorial and destructive.High susceptibility for periodontal destruction and the relationship between inflammatory changes, and genetic factors remain unclear.In this study, we investigated molecular biomarkers which play role in the development of generalized aggressive periodontitis (GAgP) using gingival tissue samples through omics-based whole-genome transcriptomic while using healthy individuals as background controls.
Materials and Methods: Gingival tissue biopsies from 23 patients with GAgP and 25 healthy individuals were analyzed using gene expression microarrays with network and pathway analyses to identify gene expression patterns. To substantiate the results of the microarray studies, Q-RT-PCR was performed to assess the mRNA expression of MZB1 and DSC1.
Results: As a result of gene expression microarray studies, 5 significant gene networks were identified. The most up-regulated genes were found as MZB1, TNFRSF17, PNOC, FCRL5, LAX1, BMS1P20, IGLL5, MMP7, SPAG4, MEI1; the most down-regulated genes were found as LOR, LAMB4, AADACL2, MAPT, ARG1, NPR3, AADAC, DSC1, LRRC4, CHP2.
Functions of the identified genes that involved in gene networks were cellular development, cell growth and proliferation, cellular movement, cell-cell signaling and interaction, humoral immune response, protein synthesis, cell death and survival, cell population and organization, organismal injury and abnormalities, molecular transport, small molecule biochemistry.
The microarrays and real-time PCR resulted in similar gene expression changes, confirming the reliability of our microarray results at mRNA level.
Conclusion: Gingival tissue transcriptomes provide a valuable scientific tool for further hypothesis-driven studies of the pathobiology of periodontitis.

PS16.03
The effect of genetic variability on gene expression in human brain using whole transcriptome sequencing

M. S. Guelfi[1,2], *K. D'Sa*[1,2], *J. Vandrovcova*[1,2], *J. Botía*[1,2], *V. Varghese*[2], *M. Matarin*[1], *D. Trabzuni*[1], *A. Ramasamy*[1,2,3], *P. Forabosco*[2,4], *T. (UKBEC)*[1], *C. Smith*[5], *J. A. Hardy*[1], *M. Ryten*[1,2], *M. E. Weale*[2];
[1]*Department of Molecular Neuroscience, Institute of Neurology (UCL), London, United Kingdom,* [2]*Department of Medical & Molecular Genetics, King's College, London, United Kingdom,* [3]*Jenner Institute, University of Oxford, Oxford, United Kingdom,* [4]*Istituto di Ricerca Genetica e Biomedica, Cittadella Universitaria di Cagliari, Cagliari, Italy,* [5]*MRC Sudden Death Brain Bank Project, University of Edinburgh, Department of Neuropathology, Edinburgh,, United Kingdom.*

Expression quantitative trait locus (eQTL) analysis allows the identification of common DNA variants that regulate gene expression.
As part of the UKBEC project, we performed eQTL analysis on whole transcriptome RNA sequencing (RNA-seq) data from 134 neuropathologically normal post-mortem human brains (180 samples from two separate regions: putamen and substantia nigra). After standard quality control steps, the RNA-seq data were combined with SNP genotype data from the Illumina Omni-1M and Immunochip arrays and then imputed to the 1000-Genomes resource, before genome-by-transcriptome association analysis using the MatrixEQTL package.
We identified eQTLs at both the whole-gene and exon levels. We detected 1883 independent eQTL signals in putamen and 1072 in substantia nigra at the whole-gene level and 3523, 1848 respectively at the exon level. We found strong evidence for region-specific eQTLs both at the gene and exon-level . We also report high overlap (73%,47%) with our previous eQTL study using microarray data. Finally, we compared our eQTL signals with signals obtained for common, consistent Allele Specific Expression (ASE) signals. We found evidence for (1) ASE signals that converted to eQTL signals in a „chromosome-independent" manner; (2) ASE signals that converted to eQTL signals but in a manner suggestive of chromosome-dependence; (3) consistent ASE signals which did not convert into eQTL signals. These patterns reveal the complexity of genetic regulation as reflected in eQTL and ASE signals.
Our dataset provides a valuable resource for the neuroscience community and all results will be made publicly available through our portal (www.braineac.org).

HumanMine: An integrated data resource for Human Genomics and Proteomics.

R. Lyne, D. Butano, S. Contrino, J. Heimbach, F. Hu, A. Kalderimis, M. Lyne, R. Smith, R. Stěpán, J. Sullivan, **G. Micklem**;
University of Cambridge, Cambridge, United Kingdom.

HumanMine (www.humanmine.org) is a new integrated database of human genomics and proteomics data built using the InterMine data warehouse system. Datasets incorporated include SNPs, GWAS studies, pathway and interaction data, protein localisation and expression studies, disease and phenotype data as well as genome annotation and sequences with plans to increase utility in disease studies.
HumanMine is designed for integrative analysis and can be accessed through a user-friendly web interface. For bioinformaticians, extensive web services as well as programming interfaces for most common scripting languages support access to all features.
The web interface includes a useful identifier look-up system, and both simple and sophisticated search options. Interactive results tables enable exploration, and data can be filtered, summarised, browsed and exported as well as transmitted for external analysis in Galaxy and GenomeSpace. A set of graphical analysis tools provide a rich environment for data exploration including statistical enrichment of sets of genes or other entities.

HumanMine complements other InterMine-based data analysis platforms that are available for mouse (www.mousemine.org), rat (ratmine.mcw.edu), budding yeast (yeastmine.yeastgenome.org), plants (www.araport.org/thalemine), nematode (www.wormbase.org/tools/wormmine), fly (www.flymine.org) and zebrafish (www.zebrafishmine.org). Through InterMine we aim to make it easier for users to navigate between databases, and facilitate cross-organism analysis. All of the above InterMine databases are freely available resources run by members of the academic research community.

PS16.05
Bayesian methods for assessing shared genetic effects in auto-immune disease

H. Trochet[1], *L. Jostins*[1], *M. Pirinen*[1,2], *C. Spencer*[1];
[1]*Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [2]*Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland.*

Genome-wide association studies (GWAS) have linked many single nucleotide polymorphisms (SNPs) to many phenotypes. Often, one SNP will show associations with multiple diseases, which may point to a shared genetic architecture, and thus common underlying etiological pathways. New methods are needed to help formally detect and assess pleiotropy in a way that can be applied genome-wide. We have developed an approach using Bayesian inference and applied it to published data on the evidence of association at 107 SNPs, in 7 different auto-immune diseases, published by Cotsapas et al. Our method makes use of readily available summary statistics of genetics association, and we use simulations to explore power to detect pleiotropic associations. As the approach is based on summary statistics we can easily obtain a probabilistic assessment of each of the possible 2^7 models of pleiotropy. The complete posterior probability distribution not only allows us to determine the „best" model, but also to see by how much it improves on the null model of no association with any phenotypes, as well as all other possible models. We highlight its use in helping assess the genetic similarity between disease phenotypes.

PM16.06
Single molecule BCR-ABL1 fusion transcript sequencing in routine screening of CML patients

A. Ameur, *N. Cahill, W. Schaal, O. Spjuth, U. Olsson-Strömberg, H. Monica, L. Cavelier;*
Science for Life Laboratory, Uppsala University, Sweden.

By long-read Pacific Biosciences (PacBio) sequencing we are developing workflow for detection of BCR-ABL1 tyrosine kinase inhibitor (TKI) resistance mutations in patients with chronic myeloid leukemia (CML). Our assay enables rapid sequencing of a ~1.6kb BCR-ABL1 cDNA amplicon without the need of a nested PCR. This results in a collection of highly accurate full-length sequences that represent the diversity of BCR-ABL1 molecules in a given sample. Mutations down to a level of 0.5% are clearly detected using this approach. Moreover, the long PacBio reads makes it possible to resolve the mutational composition of all different clones present in CML patient samples. Since compound mutations might confer cross-resistance to multiple TKIs, the information provided by our assay can directly influence the choice of therapy. Our results also show the presence of multiple splice isoforms of BCR-ABL1 in several of the samples. However, we have at present no indications that these splice isoforms play any role in the development of TKI resistance.
To evaluate if our method is ready for introduction into clinical routine we are now conducting a pilot project, where CML patient samples screened by Sanger sequencing are analysed in parallel with the PacBio assay. A streamlined workflow has been developed both for the sample preparations and bioinformatic analyses. Also, a web based reporting system has been constructed to communicate mutation results to the clinicians. Our preliminary results show that the PacBio workflow gives a fast turn around time and a higher sensitivity for mutation screening as compared to Sanger sequencing.

PS16.07
TidyVar: fast and accurate variant caller

B. Noyvert, *G. Elgar;*
National Institute for Medical Research, London, United Kingdom.

We present a novel approach to calling variants (SNPs and short indels) in DNA sequencing data from multiple individuals. The new algorithm is fundamentally different form the existing methods. It uses string matching and pattern recognition to discover and genotype variant alleles. The algorithm implementation (TidyVar) outperforms the current state of the art variant calling software (GATK) in accuracy and speed. In particular it excels in discovery and genotyping of insertions and deletions. Moreover unlike GATK and other Bayesian variant callers TidyVar can call variants in small targeted genome regions. We describe the basic principles of the new algorithm and compare the variant calls by TidyVar and GATK on an example dataset.

PM16.08
Detection of new genomic regions related to celiac disease based on genetic ancestry

K. Garcia-Etxebarria, *J. Bilbao;*
BioCruces Health Research Institute/University of the Basque Country, Leioa, Spain.

Celiac disease, an autoimmune disease that is developed in presence of gliadine, has a complex genetic basis. The most important genetic factors are located in the HLA region, explaining the 40% of the genetic component. In addition, various genomic regions that could be related to the disease have been identified but these regions could vary among populations.
With the aim of finding unknown genomic regions related to celiac disease, we designed a new approach based on the ancestry of subpopulations and used it to reanalyze the data from a case/control study of celiac disease genotyped using the Immunochip platform. First, we defined blocks of haplotypes to choose unrelated SNPs, in total 8537 blocks. Then, we analyzed the ancestry of individuals to define subpopulations and the optimal number of ancestries was 30. Finally, each subpopulation was analyzed using association analyses.
The results of association analysis in each subpopulation were slightly different. Although the HLA region was the most significant, the rest of genomic regions that could be related to the disease were mostly different in each subpopulation. 370 out 381 SNPs with a p-value<10-4 were located in genomic regions that were not previously related to celiac disease. Thus, the approach we developed could be useful to detect genomic regions that were not previously known to be related to celiac disease and to determine new genomic components that modulate risk to celiac disease.

PS16.09
BioExpress: Cloud service for massive bio data using hybrid cluster which can run Hadoop and general Linux programs

P. Kim, *G. Ko, J. Yoon;*
Korean Bioinformation Center, KRIBB, Daejeon, Korea, Republic of.

Owing to the exponential growth of biological data since the introduction of next generation sequencing technology, analysis of massive bio data became a more complicated and difficult problem. To find out meaningful information from these massive data, researchers need IT skills to compose and run complicated bioinformatics analysis process which is constituted many opensource programs. IT infra such as computing servers, network devices, and storage is also essential to run pipelines. Consequently small research groups without IT facility have a big problem to analyze massive bio data. The research groups with IT facility have also a difficulty in maintenance of IT facility. To address this problem, we developed cloud service for massive bio data (BioExpress). BioExpress consists of two modules: OpenBio and Closha. OpenBio is hybrid cluster system which can run Hadoop and Linux programs. It is based on HDFS which can run Hadoop programs and disk caching, the technique which transfers a file in HDFS into general Linux file system in each request, enables the executing of Linux program. It is economic than general cluster system with shared storage because it is based on HDFS which is cheaper than shared storage. BioExpress has also parallel processing feature using MapReduce in Hadoop. Closha is an automatic workflow modeling system that researchers can represent the process of bio-data analysis as a workflow which is composed of a sequence of analysis tools by connecting the output of preceding tool and the input of following tool in sequence, with same formats. Users can easily analysis the complicated and massive bio-data through Closha.

PM16.10
CNV calling and association with body mass index in adults: benchmarking and meta-analysis.

A. Macé[1,2], *K. Männik*[3,4], *A. Teumer*[5], *R. Mägi*[4], *U. Völker*[6], *M. Nõukas*[4], *E. Salvi*[7], *D. Cusi*[7,8], *H. Völzke*[5], *A. Metspalu*[4], *J. S. Beckmann*[2], *S. Jacquemont*[9], *A. Reymond*[3], *Z. Kutalik*[10,2];
[1]*Department of Medical Genetics, University of Lausanne, Lausanne, Switzerland,* [2]*Swiss Institute of Bioinformatics, University of Lausanne, Lausanne, Switzerland,* [3]*Center of Integrative Genomics, University of Lausanne, Lausanne, Switzerland,* [4]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [5]*Institute for Community Medicine, University Medicine Greifswald, Greifswald, Germany,* [6]*Interfaculty Institute for Genetics and Functional Genomics, University Medicine Greifswald, Greifswald, Germany,*

[7]Dept of Health Sciences, University of Milano, Milano, Italy, [8]Institute of Biomedical Technologies, Italian National Research Council, Milano, Italy, [9]Service de Génétique Médicale, Centre Universitaire Hospitalier Vaudois, Lausanne, Switzerland, [10]Institut universitaire de médecine sociale et préventive, Lausanne, Switzerland.

Many SNPs influence common disease susceptibility, but explain only part of the heritability (<3% for BMI). We have shown that the rare variants, like the 16p11.2 rearrangement, can have substantial impact on BMI. To search for more such examples genome-wide, we use CNV calls from genotyping arrays of very large number of cohorts in order to identify new rare CNVs associated with BMI.
As genechip-based CNV calling has high false positive rate, we first developed a novel quality score (QS) to estimate the probability of a CNV call being true. To derive this QS we called CNVs for five cohorts (N=6'628) using PennCNV, QuantiSNP and CNVpartition. A CNV is considered to be true if at least 70% of its length is detected by all software. To predict which PennCNV calls are true, we built a predictive model using different CNV- and sample-related quality metrics. We termed this continuous predictor of true CNV status as QS. We simulated traits associated with true CNV status and ran associations between these traits and PennCNV calls. Results showed that our QS-based association can yield up to 5–fold increase in power compared to classical filtering approaches, in particular for low frequency (<10%) and low quality CNV calls.
Using our QS-based association we performed a pilot CNV association for BMI (N=4'381). First results show trends of association for a CNV located 277kb upstream of *SH2B1* (P-value=0.00336). In collaboration with the GIANT consortium we expect to scale up to 100'000 samples within the next four months.
ZK received financial support from the SNSF (31003A-143914, 51RTP0_151019).

PS16.11

OneSeq enables simultaneous detection of genome-wide copy-number-changes, cnLOH, indels, and low frequency multi allelic gene mutations

A. Ashutosh, *A. Vadapalli, D. Joshi, K. S. Jeong, D. Roberts, J. Ghosh; Agilent Technologies, Santa Clara, CA, United States.*

Agilent's OneSeq is a revolutionary all-in-one SureSelect target enrichment assay with accompanying SureCall software that detects genome-wide copy-number-changes (CNCs), copy-neutral loss-of-heterozygosity (cnLOH), indels, and point mutations. The assay comprises a set of backbone probes for CNV and cnLOH, plus user selectable mutation detection probes. Clinical researchers will benefit from the lower costs of a single OneSeq assay compared to using different assays to detect each type of variation. In particular, low-pass WGS cannot detect cnLOH; while focused target enrichment panels are not effective at measuring genome-wide CNCs.
OneSeq backbone probes are optimized to detect CNC and cnLOH by capturing high minor allele frequency SNPs. Specificity is ensured via consideration of Shannon-Weiner sequence complexity, DUST score, GC content and mappability. A novel algorithm has been developed and implemented in SureCall to best analyze OneSeq data. The algorithm streams sample and reference data to generate log-ratios of sequencing counts. Chromosomal break points are detected from the log-ratios using an un-decimated wavelet transform. False discovery rate (FDR) is controlled; the breakpoints passing the FDR control are scored for statistical significance. The aberrant intervals are then assigned copy numbers by examining the median values at different wavelet scales. In parallel, SNPs are called using the SNPPET algorithm, which facilitates calling of cnLOH.
OneSeq detects known aberrations of sizes as small as 150 kB, and 2 MB cnLOH, while allowing simultaneous measurement of indels, and point mutations. OneSeq offers a practical solution by converging genetic technologies while maintaining cost-effectiveness and throughput in one comprehensive assay.

PM16.12

How good is my run? Whole genome resequencing and Targeted panel sequencing enrichment coverage analysis

P. Antoniou[1], *P. Bignell*[2], *J. Mason*[1,2], *A. Schuh*[1,2]; *[1]University of Oxford, Oxford, United Kingdom, [2]Oxford Molecular Diagnostic Centre, Oxford, United Kingdom.*

Introduction: With the rapid advancement of Next Generation Sequencing (NGS) and the parallel development of bioinformatics tools to analyse the data whole genome re-sequencing (WGS) is now becoming feasible in medium sized labs. Furthermore, targeted panel sequencing (TPS) is already used as a diagnostic medium at many medical centres. We describe a versatile tool that provides coverage information for WGS and TPS runs to assess whether the sequencing data has covered the genome and all the targets sufficiently for downstream analysis including variant calling.
Materials and Methods: We bring together the forces of open source software including R, bedtools, samtools, and circos to provide coverage statistics and quality plots for assessing the quality of the run.
Results: For WGS we provide tables and plots describing among others: per chromosome coverage statistics, duplicate read percentage, repeat regions, segmental duplication, known copy number and structural variation coverage, translocations, average gene coverage and clinically actionable exon coverage.
For targeted panel the user defines the panel manifest, the targeted transcripts, the level of coverage required and optionally a set of expected targeted variants. The tool summarises the coverage in all targets focusing on the exons and the expected variants, reporting all regions not sufficiently covered as a first indication of the suitability of the run for clinical diagnosis.
Conclusions: As NGS moves from research to clinic, this tool for assessing the quality and coverage of a run can be an integral part of the analysis pipeline.

PS16.13

Genome-wide association study of 41 circulating cytokines

A. V. Ahola-Olli[1], *J. Kettunen*[2], *P. Würtz*[3], *N. Pitkänen*[4], *K. Aalto*[1], *M. Salmi*[1], *A. Havulinna*[1], *V. Salomaa*[5], *T. Lehtimäki*[6], *S. Jalkanen*[1], *O. Raitakari*[1]; *[1]University of Turku, Turku, Finland, [2]University of Oulu, Oulu, Finland, [3]University of Oulu, Oulu, Finland, [4]University of Eastern Finland, Kuopio, Finland, [5]Finland National Institute for Health & Welfare, Helsinki, Finland, [6]University of Tampere, Tampere, Finland.*

Introduction**:** Cytokines have essential roles in regulation of immune response. Dysregulation of immune system have been linked to various autoimmune diseases such as inflammatory bowel diseases and rheumatoid arthritis. The purpose of this study is to shed light to yet unknown biology behind immune system regulation and pathogenetic mechanisms behind autoimmune diseases.
Materials and Methods: Both the genotype and cytokine data were available from three Finnish population based cohorts: The Cardiovascular Risk in Young Finns Study, Finrisk97 and Finrisk02. Total of 8153 subjects were included in this study. Cytokine measurements have been performed with Bio-Rad's premixed Bio-Plex Pro Human Cytokine 27-plex Assay and 21-plex Assay. The amount of bound cytokine was detected using streptavidin-phycoerythrin conjugate. 1000 genomes imputation panel was used to impute genotypes. Snptest software was used to conduct genome-wide scans. Meta-analyses were performed with METAL software. Following filters were applied to data: info > 0.7, minor allele count > 10 and association test info > 0.7. Cis eQTL analyses were performed for lead SNPs.
Results: We identified 14 new loci previously not associated with cytokines, hsCRP or white blood cell count. Six of these loci are located near a SNP previously associated with an autoimmune disease. Total of 29 loci had genome-wide significant association with the concentration of at least one cytokine.
Conclusions**:** This study have provided important insights to development of autoimmune diseases and identified cytokines that probably have important role in development of these diseases.
The study was supported by Juho Vainio Foundation.

PM16.14

SEDAN: A cloud enabled platform for analyzing and storing sequencing experiments within a clinical context

S. Pabinger[1], *R. Kreuzhuber*[2,3], *K. Vierlinger*[1], *A. Kriegner*[2]; *[1]AIT Austrian Institute of Technology, Health & Environment Department, Molecular Diagnostics, Vienna, Austria, [2]Platomics GmbH, Vienna, Austria, [3]European Molecular Biology Laboratory, European Bioinformatics Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, United Kingdom.*

The rapid advances of high-throughput sequencing technologies have been revolutionizing the way we study the human genome. To use and validate these new technologies in a clinical setting, a standardized analysis workflow is needed tailored to sensitivity, specificity, safety, and usability requirements.
Based on these prerequisites, we have been developing a cloud enabled sequence data analysis pipeline (SEDAN) covering the complete analysis workflow: data cleaning, read mapping, variant calling, annotation, and decision support. SEDAN has been designed as a multistep application supporting the execution of the whole pipeline or only specific parts of the workflow. In addition, it performs on the fly transformation of coordinates to different reference sequences (e.g., hg19 - Refseq).
The pipeline is centered on proven open source tools and is able to deal with

data generated by all widely-used sequencing platforms (NGS and Sanger). It provides predefined parameter sets and can be used without previous knowledge of informatics. Results are output as spreadsheets and in standardized formats. In addition, they are displayed in a graphically interactive way together with meta-information. The pipeline is tightly integrated into the web-based Platomics platform, providing data management capabilities, user authentication, and a graphical user interface. Each analysis run, including used parameters and result files, is automatically stored and can be easily queried and compared.
The analysis pipeline and platform are actively used in a clinical setting and have been rigorously validated. Together, they provide a straight forward and easy to use solution for analyzing sequencing data in a clinical context.

PS16.15
Orphanet: a database of genes with clinical significance in rare diseases

C. Gonthier, A. Olry, **S. Janmaat**, *M. Hanauer, S. Gérard, A. Rath;*
INSERM, US14 - Orphanet, Paris, France.

Sequencing the whole human genome and the advances made in NGS techniques allow a number of genetic variants to be detected, although their functional impact is still largely unknown. To harness this information, it is necessary to characterise a complete list of human disease genes.
To contribute to this goal, Orphanet maintains a database of genes, loci and non-coding RNA of clinical significance in rare diseases (RD). Gene-disease relationships are described as: causative mutation (germinal/somatic, loss-of-function/gain-of-function), modifier gene, major susceptibility gene, gene playing a major role in the phenotype of a chromosomal anomaly. Candidate genes tested in the clinical setting are included. Genes are linked to a clinical, poly-hierarchical classification of RD, and aligned with OMIM, HGNC, UniProtKB, Genatlas, ensembl, Reactome and IUPHAR, allowing for interoperability with mutation databases. Data are captured from literature and databases surveys, manually curated and expert-assessed. They are visible on the Orphanet website (www.orpha.net), downloadable in Orphadata (www.orphadata.org) and in the Orphanet Rare Diseases Ontology -ORDO- (http://bioportal.bioontology.org/ontologies/ORDO). The database includes 3376 genes and is updated monthly.
The added-value of the Orphanet database of genes lies in the relationships provided to clinically defined conditions, which are unique whatever the number of genes involved and stable in time; in the possibility to cluster genes by disease groups, or RD by genes; and in its expert curation. The database can be used as a reference to compare new genetic information with state-of-art knowledge on RD genes.
This work is supported by „RD-Action", a Joint Action receiving funding from the European Union in the framework of the Health Programme.

PM16.16
Deciphering Developmental Disorders: Clinical review and reporting in practice

S. Clayton, *P. Jones, J. McRae, T. W. Fitzgerald, A. R. Tivey, C. F. Wright, M. E. Hurles, H. V. Firth, on behalf of the DDD study;*
Wellcome Trust Sanger Institute, Hinxton, United Kingdom.

The Deciphering Developmental Disorders study is on course to analyze the exomes of 12,000 children with developmental disorders, recruited from the 24 regional genetics services across the U.K. and Republic of Ireland. The DDD study is a collaboration between the Wellcome Trust Sanger Institute and the U.K. Department of Health and aims to research the causes of developmental disorders and to diagnose patients where standard genetic testing has proved unrevealing. Here I describe a software tool for converting genetic findings into a diagnosis as part of a population scale solution.
To achieve high-throughput the tool enables fully automatic rule based, and user driven delivery of reports, variants, evidence and comments to our collaborators in the regional genetics services. Both modes are required as not all genetic findings are relevant to the patient and complex cases must be manually reviewed.
To support efficient manual review users can set their own filters and prioritize patients for later sessions. The DDD study is also a research project so the tool is designed to support reinterpretation of patients if new variants are discovered or if the variant consequence or inheritance has changed.
To help interpret the variant the tool provides an integrated display of patient and family information as well as views of the raw data. The tool helps to create a valuable resource for research into variant prioritization by recording pathogenicity and relevance to the patients phenotype.

PS16.17
How to find the second patient

P. M. Krawitz;
Charite, Berlin, Germany.

In recent years disease causing genes were identified for many monogenic disorders in high-throughput sequencing studies for exomes and whole genomes. Usually such approaches were successful, if a case group with several phenotypically similar patients was available. The analysis of such cohorts was relatively simple from a statistical point of view and is often referred to as filtering by overlap.
However, for all the cases that did not yield conclusive results more sophisticated approaches are now required, that is finding similar patients and searching for significant gene associations. We designed an online platform that assists in matching patients on a phenotypic as well as on the genotypic level. This will result in a case groups for which we test whether one gene bears a significant burden of rare variants. If a significant association is detected all users who contributed a case to this phenotypic cohort will be informed so that they can join in working up the identified candidate mutations. We demonstrate use cases in which the status of variants of unknown clinical significance could effectively be resolved by a community driven effort.
Currently more than 1000 expert users are registered on the platform and participate in illucidating Mendelian disorders.

PM16.18
DIDA: the first digenic disease database

D. Daneels[1,2], *A. Gazzo*[3], *M. Bonduelle*[1,2], *E. Celia*[4], *T. Lenaerts*[4], *G. Smits*[5], *S. Van Dooren*[1,2];
[1]*Center for Medical Genetics, UZ Brussel, Vrije Universiteit Brussel (VUB), Brussels, Belgium,* [2]*Research Group Reproduction and Genetics, Vrije Universiteit Brussel (VUB), Brussels, Belgium,* [3]*Interuniversity Institute of Bioinformatics in Brussels, VUB-ULB, Brussels, Belgium,* [4]*Machine Learning Group, ULB, Brussels, Belgium,* [5]*HUDERF, ULB, Brussels, Belgium.*

Although there exist many human disease-related genetic variant databases (e.g. HGMD, SwissVar), no public effort has been made to organize these data so that one can investigate the oligo- and polygenic nature of their disease-of-interest. However, it has been shown that many disorders, classically considered as monogenic, may be better explained by more complex inheritance mechanisms. One example can be found in those diseases with imperfect genotype-phenotype correlations, which might, in a monogenic context, be considered as showing reduced penetrance, but could in fact also be explained by a digenic inheritance model. This example pinpoints the need to develop new databases and services focused on complex inheritance models.
Here we present DIDA (DIgenic DAtabase): a manually curated database collecting human digenic disease instances. DIDA was created by collecting all digenic disease data published in scientific literature until December 2014. We manually screened the literature to ensure the high quality of this ex novo digenic database. For every publication describing patients with a disease explained by a digenic inheritance model, we annotated causative variant-pairs and enriched every instance with different features. These features include variant- and gene information with genomic-, cDNA- and protein coordinates, information regarding the functional effects of the variants, disease name and OMIM-id, clinical symptoms with HPO-terms and a digenic effect category (influence on the presence, severity, age-of-onset or symptoms of the disease). As such, this database forms a basis for understanding how the interplay and weight of variants leads to disease, which in turn may provide novel insights into diseases classically considered as monogenic.

PS16.19
Integrating data sources in druggability analysis of genes implicated in dilated cardiomyopathy

G. Kummeling[1], *V. Tragante*[1], *F. W. Asselbergs*[1], **D. Hemerich**[1,2];
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*CAPES Foundation, Ministry of Education of Brazil, Brasília, Brazil.*

Introduction: Dilated cardiomyopathy (DCM) is characterized by systolic dysfunction and dilation of the left ventricle of the heart, with a 5-year mortality estimated in 50%, and is the main indication for heart transplantation. Current treatments primarily work by slowing down disease progression. Treatments targeting genetic factors may potentially prolong survival and reduce side effects. A literature search identified 110 genes implicated in DCM. We analyzed the druggability properties of these genes and related genes in pathways. A list of gene-drug interactions was generated based on bioinformatics techniques, and we aim at identifying drugs that can be repurposed for DCM treatment, using information on indications and side

effects of these drugs.
Materials and Methods: We identified 343 drugs that act on DCM-related genes, using DGIdb [1], chEMBL [2] and DrugBank [3]. We developed a Python script to identify synonyms of each drug, based on definitions from STITCH [4], and integrated these drugs with indications and side effects from SIDER [5].
Results: From the 343 drugs mapped for the genes of interest, 114 were found by the algorithm in the aliases database. The search returned 14589 synonyms for the original names, a list of side effects for each drug listed (10359 in total) as well as their indications (934 in total).
Conclusions: Integrating data sources is a necessary step towards more complex analyses that may lead to better and faster translation to health care.

Transcriptome analysis of mouse ES cells carrying a human chromosome 21

A. Letourneau[1], J. Groet[2], F. Santoni[1], C. Gehrig[1,3], M. Guipponi[1,3], C. Borel[1], V. L. J. Tybulewicz[4], E. M. C. Fisher[5], D. Nizetic[2,6], **S. E. Antonarakis**[1,3,7]*;*
[1]Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva, Switzerland, [2]The Blizard Institute, Barts and The London School of Medicine, Queen Mary University of London, London, United Kingdom, [3]University Hospitals of Geneva, Geneva, Switzerland, [4]Medical Research Council, National Institute for Medical Research, London, United Kingdom, [5]Department of Neurodegenerative Disease, UCL Institute of Neurology, Queen Square London, London, United Kingdom, [6]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore, [7]iGE3, Institute of Genetics and Genomics of Geneva, Geneva, Switzerland.

Down syndrome is most likely the result of a gene dosage alteration. In order to further characterize this dosage imbalance, we investigated the transcriptional changes occurring in tranchromosomic mouse ES cells carrying an additional human chromosome 21 (HSA21) (Hernandez et al. 1999). By adding a whole freely segregating human chromosome, this model properly recapitulates the trisomy 21 conditions and offers a way to examine the expression of human genes in a mouse genomic context.
We used mRNA-sequencing to determine the transcriptome profile of these transchromosomic cells, using the parental wild-type mES cells as controls. Four replicates of each group were sequenced on the Illumina HiSeq. Reads were mapped with TopHat against a hybrid reference containing both the mouse genome and the HSA21 sequences.
A preliminary differential expression analysis (EdgeR) revealed 8'101 protein-coding genes dysregulated in the transchromosomic cells (Bonferroni<0.01), suggesting that the presence of a HSA21 can extensively disturb the mouse transcriptome.
Additionally, we compared the expression level (RPKM) of each HSA21 gene (present in 1 copy) and its corresponding ortholog in the mouse genome (2 copies). Interestingly, very few genes showed the expected 1:2 expression ratio between the 2 species. Whereas some genes were exclusively expressed from HSA21, others were on the contrary completely silenced. Further analyses will help to understand the regulatory network controlling the expression of these human genes in this unrelated mouse genomic context. The model will also contribute to the understanding of evolution of the regulatory landscape in mammals.

PS16.21
European Genome-phenome Archive (EGA): a secure archive for genomic and phenotypic data

J. Almeida-King[1], *J. E. Paschall[1], I. Lappalainen[1], A. Senf[1], J. D. Spalding[1], S. Rehman[1], G. Saunders[1], P. Flicek[1], J. Rambla[2], O. Martinez-Llobet[2], M. Sitges-Puy[2], M. Alberich[2], S. Torre[2], A. Navarro[2];*
[1]European Molecular Biology Laboratory, European Bioinformatics Institute (EMBL-EBI), Cambridge, United Kingdom, [2]Centre for Genomic Regulation, Barcelona, Spain.

The European Genome-phenome Archive (EGA) facilitates the secure storage and controlled distribution of genetic and phenotypic data, for the purpose of biomedical research.
Our collections include major reference data for rare and common diseases, including data derived from the UK10K project, Blueprint and the International Cancer Genome Consortium (ICGC), as well as control sets for use in addition to the public reference panels, such as the 1000 Genomes project.
As of January 2015, the EGA securely stores ~1.6 petabytes of data derived from ~600K unique samples across ~1300 distributable datasets.
The EGA have implemented fundamental changes to facilitate data discovery and improve data dissemination to enhance the user experience of EGA users.
The new 'Data Mart' webpage enables a user to sort, filter and select files based on 'Study', 'Dataset' or 'Sample' centric criteria before initiating a download.
We have also introduced a data streaming service to disseminate data files. The service provides robust, reliable and flexible downloading capabilities, enabling the user to download files direct from the EGA website or using the command line.
The new services also enable the user to query all EGA public metadata through a REST API, as well as downloading metadata from the EGA website.
Future plans include providing the user with the facility to generate 'BAM slices' for viewing in a genome browser.
The EGA is maintained by European Bioinformatics Institute (EMBL-EBI) and the Center for Genomic regulation (CRG) and is available at both www.ebi.ac.uk/ega/ and https://ega.crg.eu/.

PM16.22
A tool for rapid aggregation of eQTLs in human cells

S. Hofer, *M. Samwald;*
Medical University of Vienna, Wien, Austria.

While genetic variation in the coding regions of genes can drive disease, it has been shown that SNPs associated with complex disorders and some pharmacologic phenotypes are enriched for expression quantitative trait loci (eQTLs): polymorphisms that influence the expression of these genes. Despite the efforts of researchers, eQTLs that have been identified in existing studies are often „locked up" in the supplementary methods and difficult to obtain from the published material. Existing tools for browsing these SNPs are often time intensive and difficult to use. This issue is further complicated by the fact that data scientists and researchers looking for statistically significant relationships between eQTLs, genes and disorders often lack disease-centric knowledge that would be needed to identify the potentially important single nucleotide polymorphisms (SNPs). To this end, we have implemented a software tool that gives easy and unified access to eQTLs described in published studies and quickly arrive at a list of SNPs that could be relevant for a disease or gene. We have currently included results from four studies that have identified eQTLs in human cells: 1 based on blood-, 1 on intestine-, and 2 on liver-cells. By distributing the software as an IPython notebook, scientists can examine and extend the existing code to include data from other sources as well. Additionally, this approach simplifies the subsequent analysis, as the resulting SNP list can be further refined and explored using the extensive Python codebase for artificial intelligence, machine learning and other algorithms, resulting in rapid knowledge discovery.

PS16.23
A pipeline for eQTL-analysis using Illumina microarray data

T. Kätzel[1], *H. Schulz[2], S. Heilmann-Heimbach[1], L. Hochfeld[1], S. Herms[3,1], P. Hoffmann[3,1], J. Becker[1], T. Hess[1], J. Schumacher[1], A. Hofmann[1], M. Nöthen[1];*
[1]University of Bonn, Bonn, Germany, [2]University of Cologne, Cologne, Germany, [3]Universitätsspital Basel, Basel, Switzerland.

Throughout the last decade GWAS have identified numerous SNP-disease-associations. However, a majority of these SNPs are located in non-coding regions, which necessitates a comprehensive functional annotation. Here, expression quantitative trait loci (eQTL) analyses which enable the identification of SNPs that affect gene-expression in a tissue and context-dependent manner have gained major attention. Therefore, we aimed at establishing an automated workflow for identification of eQTLs from high-throughput genomic and transcriptomic data. Genome-wide genotype and expression data was generated using Illumina's Omni-Family and HumanHT-12 bead arrays. Subsequent imputation of genotypes (1000Genomes) ensures comparability of the eQTL-findings across studies and enables integration with GWAS data. Robustness of the workflow is guaranteed by application of different filter steps, i.e. removal of non-expressed, ambiguous and low-confidence transcripts from expression data and filtering of genotypes according to standard QC parameters. eQTLs are identified via linear regression using *MatrixEQTL*. Inclusion of covariates in the regression analysis ensures controlling for confounding effects in the data and leads to an improved and highly reliable identification of eQTLs. The pipeline was successfully applied to identify tissue-specific eQTLs from stomach, hair and hippocampus. Here, we found more than 10,000 eQTLs in the investigated tissues, ~35% being tissue-specific. The data has been used to functionally annotate GWAS data for Barrett's esophagus, male pattern baldness and psychiatric disorders. Thus, our pipeline presents a fast, standardized and easily applicable me-

thod for identification of functional genetic variance derived from microarray and RNAseq data and can help to elucidate biological mechanisms at known disease risk loci.

PM16.24
OpEx: an exome analysis pipeline optimised for sensitive and specific indel detection

E. Ruark[1], *M. Münz*[2], *A. Renwick*[1], *G. Lunter*[1], *N. Rahman*[1,3];
[1]*Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom,* [2]*Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [3]*Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom.*

Exome sequencing is being used by increasing numbers of research and clinical laboratories. However, simple, user-friendly exome analytical pipelines are not readily available. In particular, detection of insertion/deletion (indel) variants has proved challenging in NGS data, particularly for rare indels. It is essential for research and clinical disease genetics that indels are robustly detected because of the prevalence of this variant class as a pathogenic mutational mechanism.
To enable rapid, automated and robust analysis of exome sequencing data optimised for indel detection, we created the OpEx pipeline. OpEx uses Stampy for alignment, Platypus for variant calling, CAVA for variant annotation and provides useful additional information such as coverage metrics. OpEx is easy to use, requiring a single command and input FASTQ files to return a tab-separated file containing clinically annotated substitution and indel variants in an individual. We evaluated OpEx performance with a set of orthogonal validation data, including 730 Sanger sequencing evaluations. Importantly, OpEx is both sensitive and specific for indels, with ~95% of positive and negative sites correctly identified, and a low false positive rate of 3%. OpEx is run independently at the sample level, providing similar performance for any number of samples and thus allowing analysis to keep pace with sequencing output. Due to its excellent performance and suitability for the clinical and lab settings, OpEx is our standard exome analysis pipeline, used to analyse over 12,000 exomes to date. We are now making the OpEx pipeline freely available for others to use (by April 2015).

PS16.25
Functional annotation of obesity SNPs underlying potential parent of origin effects

X. Liu[1,2], *A. Tönjes*[3], *M. Stumvoll*[1,3], *P. F. Stadler*[2,4,5], *Y. Böttcher*[1];
[1]*IFB AdiposityDiseases, Leipzig, Germany,* [2]*Bioinformatics Group, Department of Computer Science, University of Leipzig, Leipzig, Germany,* [3]*Department of Medicine, University of Leipzig, Leipzig, Germany,* [4]*Institute for Theoretical Chemistry, University of Vienna, Vienna, Austria,* [5]*Sante Fe Institute, Sante Fe, NM, United States.*

Genome-Wide Association Studies (GWAS) were successfully applied to discover genetic variants associated with obesity, however some heritability were unexplained. Analyses of potential parent of origin effects (POE) may provide further insights into genetic mechanisms of obesity. The aim of study was to identify novel functional SNPs/regions which would contribute to obesity.
Genome-wide genotypes from Sorbs (N=525), a German self-contained population, were phased using AlphaImpute. Three different GWAS were applied in PLINK: (i) standard association, (ii) considering paternal and (iii) maternal alleles. Ten top tagging SNPs from paternal and maternal GWAS were selected respectively. An R package FunciSNP was used to identify correlated SNPs.
Totally,109 SNPs and 180 SNPs correlated with tagging SNPs underlying paternal and maternal POE respectively. Two transcription factors SF1 (steroidogenic factor 1) and LRH1 (liver receptor homolog-1) putatively bound at rs1204880 underlying paternal POE. SF1 involves in determining sex and differentiation while LRH1 affects bile acid metabolism and glucose homeostasis. Rs1204880 was highly correlated (r2 =1) to tagging SNP rs942459 and located within the putative promoter of PADI6 (Peptidyl Arginine Deiminase, Type VI) which may associate with reorganizing cytoskeletal in egg and during early embryo development. MicroRNA binding sites were identified at rs11180547 and rs4562666 underlying maternal POE.
Incorporating high-throughput epigenetic data, variants from 1000 Genomes and various genomic databases into POE specific GWAS may reveal novel putative SNPs located in potentially functional regions and maybe involve in obesity.
This work was supported by German Research Foundation, German Diabetes Association, DDS Foundation and IFB AdiposityDiseases.

PM16.26
Integrated Genome Mapping in Nanochannel Arrays and Sequencing for Better Human Genome Assembly and Structural Variation Detection

A. Pang, A. Hastie, P. Sheth, T. Anantharaman, Z. Dzakula, H. Cao, **L. Scott**;
BioNano Genomics, San Diego, CA, United States.

De novo genome assemblies using purely short sequence reads are generally fragmented due to complexities such as repeats found in most genomes. These characteristics can hinder short-read assemblies and alignments, and that limits our ability to study genomes.
The BioNano Genomics Irys System linearizes long DNA molecules, thus yielding single-molecules containing long-range information. These hundreds of kilobases molecules can capture structural information that may be missed by other sequencing platforms. The assembled genome maps from these molecules can scaffold sequencing contigs to validate the accuracy of the sequences, and to anchor the adjacent sequences into the proper order and orientation. The long-range hybrid scaffolds can identify novel chromosomal rearrangements recalcitrant to short-read alignment or reference-guided assembly approaches.
We present a comprehensive analysis of a human genome by combining single molecule genome mapping with one of the most annotated sequence assemblies, the HuRef assembly. Overall, we found that the assemblies of two technologies correspond well, and the resulting hybrid scaffolds are highly contiguous, with a N50 of >35Mb, a value typically unachievable by short-read sequencing. In addition, we compared the structural variation with calls previously detected in the HuRef assembly, and found multiple novel variants spanning over hundreds of kilobases in size. Some of these variants reside in areas where the sequence assembly was poorly covered or was highly fragmented; yet these variants encompass numerous genes, and can be of functional importance. Finally, we identified genome maps that span over the remaining reference gaps, and maps that resolve and measure long tandem repeats.

PS16.27
Structural Variation Discovery by De Novo Assembly Using Extremely Long Single-Molecules in Human Disease and Non-Disease State Genomes

A. Hastie, *E. Lam, T. Liang, A. W. C. Pang, S. Chan, Z. Džakula, H. Cao;*
BioNano Genomics, San Diego, CA, United States.

Structural variation analysis (SVA) of human genomes is usually a reference based process and therefore biased and incomplete. In order to have a comprehensive analysis of structural variation, a de novo approach is needed. As a result of limitations of DNA sequencing methods, it is not feasible to create high quality de novo assemblies for detecting and interpreting structural variation that are refractory to high throughput or short-read technologies. Using a single molecule genome analysis system (Irys®), we produced high resolution genome maps that were assembled de novo, these maps preserve long-range structural information necessary for structural variation detection. Dozens of human genomes have been de novo assembled by Irys to date. Structural variation analysis reveals insertions, deletions, inversions and translocations. We have generated genome maps for two trios. From these genome maps, we detect hundreds of structural variants, including large deletions in genes in the mother and son from the AJ trio. We have also investigated the amylase locus in both trios as well as ~20 other individuals and have found at least 15 different structural variants. Human amylase genes have variable copy number and this variation is believed to have been evolved to adapt to increase starch intake. We were able to identify multiple copy neutral variants, i.e. inversions, for each for the same copy number variants. Each genome shows many megabases of variation within genomic regions not included in the hg19, underscoring the need for more de novo approaches to genome analysis.

PM16.28
Analysis of ciliome protein interaction networks to identify novel disease genes in a cohort of ciliopathy patients

H. J. Williams, *M. Schmidts, H. Mitchison, P. Beales;*
UCL Institute of Child Health, London, United Kingdom.

Ciliopathies represent a class of disorders caused by defects in the formation or function of the cilium. They result in a diverse yet overlapping range of phenotypes which are often chronically disabling and sometimes life threatening. Through previous large collaborative efforts, the proteins that comprise the cilia, the basal body and those that play a role in normal function have been identified and their interactions mapped, the so called ciliome. Although mutations in specific genes from within the ciliome have

been shown to give rise to specific ciliopathies, there are still a number of patients where no genetic mutations have been identified. We have sought to identify novel ciliopathy related genes in these patients through the analysis of exome data from a cohort of ciliopathy patients through the application of network analysis. We have used the known ciliome proteins and performed protein interaction analyses to explore novel, related networks of proteins whose cognate genes can be interrogated for causal mutations. This work has led to the identification of potentially novel findings.

PS16.29
Statistical procedure for pathway-guided GWAS analysis

S. Biswas, S. Pal, **S. Bhattacharjee***;*
National Institute of BioMedical Genomics, Kalyani, India.

Genome-wide Association (GWA) studies have discovered thousands of polymorphisms affecting the risk of various complex traits. For most of these traits, exploration of the identified polymorphisms has revealed that the variants tend to be clustered near genes involved in few biological pathways. It therefore appears naïve to perform an unbiased GWA scan without taking pathway/network information into account. Post-hoc enrichment analysis only helps in interpretation of already discovered variants; it does not improve the power for novel discovery. It is now recognized that typical GWAS are under-powered to detect all associated variants due to a huge multiple-testing burden. This is particularly true for variants that are relatively less common and/or those with weaker effects that could have been missed in GWA studies conducted thus far. Pathway/network information, if properly harnessed, has the potential to improve the power of GWAS drastically. Here we propose a generic statistical procedure that can utilize pathway information a-priori while conducting a GWA scan. It automatically enhances the power to discover associated variants that are clustered in pathways. We demonstrate that, our procedure adapts to the data to maintain correct type-1 error (even if the pathway information is irrelevant). At the same time it can give huge power gains if the associated variants indeed cluster in pathways. Our method is fast and easy to implement even with summary-level data (p-values and odds ratios) from previous GWA studies. We also illustrate the performance of the procedure using published GWAS data from the Collaborative Association Study of Psoriasis.

PM16.30
Human Gene Family Resources at genenames.org

R. L. Seal[1]*, K. A. Gray*[1]*, S. Tweedie*[1]*, M. W. Wright*[2]*, E. A. Bruford*[1]*;*
[1]*HGNC, European Bioinformatics Institute (EMBL-EBI), Hinxton, United Kingdom,* [2]*National Center for Biotechnology Information, National Library of Medicine, National Institutes of Health, Bethesda, MD, United States.*

The HUGO Gene Nomenclature Committee (HGNC) has assigned unique approved gene symbols and names to over 39,000 human loci to date. Approximately 19,000 of these are protein coding genes, but we also name pseudogenes and non-coding RNAs. Our website, genenames.org, is a searchable repository of HGNC approved nomenclature and associated resources. Approved gene symbols are based on names describing structure, function or homology, and where possible these are organised into gene groupings and families, many of which have specialist advisors who are experts in that particular area of biology. We are continually adding new gene families and currently have over 600 gene family pages. We have recently improved the display and content of these pages and sorted many of the families into hierarchies which allow genes to be browsed and downloaded at either a top level such as "G protein-coupled receptors", or at a more specific level, such as "Melanocortin receptors". The new gene family pages include family aliases, a family hierarchy map, a family text description, a graphical representation of protein domains for an example family member, and links to publications and relevant external resources. The gene families are fully searchable via the Search tool found at the top of each page at genenames.org and there is also a gene family index where users can browse through the full list of families. If you know of a gene family that you think we should include or update, please contact us via hgnc@genenames.org or talk to us during this meeting.

PS16.31
How far shall we go? Preliminary test on imputation of Italian isolated populations using an internal whole-genome reference panel

M. Cocca[1]*, M. Traglia*[2]*, C. Barbieri*[1,2]*, C. Sala*[2]*, P. D'adamo*[1]*, S. Ulivi*[1]*, D. Toniolo*[2]*, N. Soranzo*[3]*, P. Gasparini*[4,1]*;*
[1]*Department of Medical, Surgical and Health Sciences, University of Trieste, Trieste, Italy,* [2]*Division of Genetics and Cell Biology, San Raffaele Research Institute, Milan, Italy,* [3]*Human Genetics Wellcome Trust Sanger Institute Genome Campus, Hinxton, United Kingdom,* [4]*Medical Genetics, Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy.*

The usefulness of isolated populations as models in large-scale GWAS studies is well known and their contribution helped unravelling the interaction between genetic variation and complex traits. The imputation approach based on reference panels led to new findings and to better insights in the range of low-frequency (<=5% MAF) variants thanks to the analysis of a complete scaffold of mixed populations haplotypes.
To exploit the peculiar characteristics of isolates and the advantages introduced by imputation, a subset of 987 individuals from three Italian Isolated Populations from INGI network was selected for Low Coverage Whole Genome Sequencing to draw an Italian specific reference panel.
The aim is to maximize imputation quality of Italian isolated cohorts and general populations (INCIPE , University of Verona) and provide a scaffold of low frequency variants haplotypes to complete the spectrum of South European human variation covered by the current standard reference panel.
Here is the first set of variants characterization based on a preliminary release of imputation panel collecting a batch of 568 samples: on average 36% of the total variations has frequencies < 1% whereas the comparison with outbred populations such as 1000G1 and UK10K2 highlighted an average of 15% of private variants. Accordingly, we expect to definitely power the genetic association studies on the large set of risk factors for common diseases.

PM16.32
Application of RNA-Seq for gene fusion identification in leukaemia

M. Knut[1]*, W. Tapper*[1]*, S. Ennis*[1]*, N. Cross*[1,2]*;*
[1]*University of Southampton, Southampton, United Kingdom,* [2]*Wessex Regional Genetics Laboratory, Salisbury, United Kingdom.*

The development of Next Generation Sequencing (NGS) revolutionised different fields of science. RNA-Seq, a variety of NGS, is a method of transcriptome investigation, and a valuable tool in aberrant transcript identification. As such, it can be used to identify gene fusions in various types of cancers, regardless whether they are the underlying cause of cancer or the result of it. Gene fusions are associated with many types of leukaemia. We present gene fusion identification from RNA-Seq of samples taken from leukaemia patients, where more traditional methods of gene fusion identification, such as FISH, failed to identify correct translocations. We have found and confirmed with RT-PCR BCR-JAK2 fusion, molecularly similar to Philadelphia chromosome, in a patient with complex cariotype, and RAB20-ING1 fusion in another patient.

PS16.33
Linked data approach: some results and considerations from the first RD-Connect Bring Your Own Data meeting in Rome

C. Carta[1]*, M. Roos*[2]*, S. Gainotti*[1]*, P. Lopes*[3]*, M. Thompson*[2]*, R. Kaliyaperumal*[2]*, E. van der Horst*[2]*, N. Queralt Rosinach*[4]*, R. Thompson*[5]*, D. Taruscio*[1]*;*
[1]*National Center for Rare Diseases Istituto Superiore di Sanità, Rome, Italy,* [2]*Human Genetics department, Leiden University Medical Center, Leiden, Netherlands,* [3]*DETI/IEETA, Universidade de Aveiro Campus Universitario de Santiago, Aveiro, Portugal,* [4]*Integrative Biomedical Informatics Group, Research Program on Biomedical Informatics, IMIM Hospital del Mar Research Institute, Barcelona, DCEXS Universitat Pompeu Fabra, Barcelona, Spain,* [5]*Institute of Genetic Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom.*

Patient registries, biobanks and bioinformatic data represent key resources for Rare Diseases (RD) to increase the chances of a timely and accurate diagnosis, improve patient management, tailor treatments and facilitate clinical trials. Unfortunately most RD registries and biobanks still keep their data "siloed" slowing down the process of discovery and development in RD research. Here we report some results and considerations of the Bring Your Own Data (BYOD) meeting, held in Rome in November 2014, in order to explore the potential of the "linked data approach" in RD research. The BYOD was co-organised by RD-Connect Linked Data (LD) and ontology task force, National Center for Rare Diseases Istituto Superiore di Sanità, Leiden University Medical Center, University of Aveiro, DTL/Elixir, BioMedBridges. The meeting brought together in particular LD experts and the members of RD-Connect, a six year project funded by the European Union but uniting researchers across the world. Participants were split into four groups and answered some cross-resource questions. Each group produced their first linked data to accomplish their objectives and managed to link data sets that were converted to resource description framework. LD technologies provi-

de a promising approach to connect registries and between registries, biobanks and bioinformatics data allows researchers to get more rapid responses to cross-resource questions improving the use of available information on RD. This prospect is slowed down by scepticism towards sharing data. We thank participants and contributors to the BYOD. BYOD was sponsored by RD-Connect and DTL/Elixir. CC, MR, SG equally contributed to the work.

PM16.34
Comparison of SOLiD sequencing data analysis pipelines

T. Rančelis, *E. Pranckevičienė, A. Pranculis, V. Kučinskas;*
Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

Background. Software tools designed for the *Illumina* next generation sequencing (NGS) platforms are most documented. Alternatively, pipelines related to Life Technologies SOLiD platform, which use colour-space encoding, are not widely discussed in scientific literature. We applied several computational and variant calling pipelines for analysis of sequenced exomes of trios obtained by ABI SOLiD 5500 system. Using the same data sequenced by SOLiD we investigated proprietary *LifeScope's* pipeline and several other color-space competent mapping programs: *MAQ*, *SHRiMP* and *BFAST* coupled with *Genome Analysis Tool Kit* (GATK) for variant calling. *Annovar* program was used to annotate identified genomic variants.
Results. All methods covered 97% of the targeted regions. *LifeScope* and *SHRiMP* produced more mapped reads than *MAQ* and *BFAST*. To verify that called variants were not random we used transition/transversion (Ti/Tv) ratio. Ti/Tv ratio in all used pipelines was around 2.2 - 2.7. We compared how many known harmful variants from ClinVar and COSMIC databases were identified among called variants with at least x15 coverage by each investigated pipeline. *Lifescope* found the highest amount of known variants in these databases, while *MAQ* and *BFAST* pipelines called the least. Variants called by SHRiMP pipeline had lower mapping quality scores than other mapping programs.
Conclusion. Our comparison showed that *Lifescope's* pipeline is superior in analysing the SOLiD data. However, using several pipelines is encouraged because each pipeline creates a different view of the same variant data. This study is part of the LITGEN Project (VP1-3.1-MM-07-K-01-013) funded by the European Social Fund under the Global Grant Measure.

PM16.36
Clinical metabolomic profiling for the diagnosis of inborn errors of metabolism & undifferentiated genetic phenotypes

P. S. Atwal[1], *M. Miller*[1], *T. Donti*[1], *A. D. Kennedy*[2], *A. D. Eckhart*[2], *J. E. Wulff*[2], *M. V. Milburn*[2], *J. A. Ryals*[2], *A. L. Beaudet*[1], *Q. Sun*[1], *V. R. Sutton*[1], *S. H. Elsea*[1];
[1]*Baylor College of Medicine, Houston, TX, United States,* [2]*Metabolon, Research Triangle Park, NC, United States.*

Introduction: Clinical metabolomic profiling is a novel platform that allows for parallel testing of hundreds of metabolites in a single plasma specimen. We have validated this platform for common metabolic conditions compared with standard tests, including amino acid, organic acid, fatty acid oxidation, vitamin cofactor, pyrimidine biosynthesis, creatine biosynthesis, and urea cycle disorders.
Materials & Methods: A state-of-the-art mass spectrometry platform was utilized, and the resulting spectra were compared against a library of ~2,500 human metabolites. The analytes detected encompass numerous classes of important small molecule biomarkers, including fatty acids, amino acids, nucleotides, and other molecules sized 50-1500 Da. Validation samples and exome confirmatory samples were included.
Results: For the majority of IEM samples, classic pathognomonic analytes were among the most significantly elevated analytes detected; however, to achieve similar diagnostic outcomes with standard methods, many different biochemical tests are traditionally required. We found biochemical perturbations in pathways with no available clinical analyte testing such as citrate transporter deficiency. We were able to diagnose aromatic l-amino acid decarboxylase deficiency using plasma analytes (3-methoxytyrosine), which typically requires CSF neurotransmitter analysis. In a patient where exome revealed two VUS in the GABA transaminase deficiency gene (ABAT), metabolomic profiling was diagnostic revealing significantly elevated 2-pyrrolidinone, confirming the VUS as pathogenic.
Conclusion: Global metabolomic profiling is a novel test able to: (1) screen for common metabolic conditions in undifferentiated phenotypes, (2) reveal biochemical perturbations in pathways with no available clinical analyte testing, (3) diagnose disorders using plasma analytes that were heretofore only detectable in CSF, and (4) aid in interpretation of exome data.

PS16.37
MLPA 2.0 - Multiplex Ligation-dependent Probe Amplification on Illumina NGS platforms using a 600+ probe assay

J. Schouten, *K. de Groot, L. Atanesyan, M. Loden;*
MRC-Holland, Amsterdam, Netherlands.

Introduction: MLPA, the multiplex PCR-based technique that has now become the standard in copy number variation, was developed by MRC-Holland in 2002. Although the method is used worldwide for the detection of copy number and methylation changes in human DNA, traditional MLPA has its limitations: an MLPA assay can contain a maximum of 60 probes and requires a minimum of 20-50 ng sample DNA of good quality.
We now introduce MLPA 2.0: a NGS-based MLPA variant enabling the use of 600 probes in a single reaction, with less stringent requirements regarding both sample DNA quantity and quality. This newly developed MLPA variant enables the creation of assays that screen a much larger proportion of the human genome. MLPA 2.0 assays can be used on all Illumina NGS platforms. As NGS-based sequence analysis still has its limitations when it comes to reliable detection of copy number variants, MLPA2.0 fulfills a yet unmet need. In this poster, we show the results of an MLPA 2.0 assay designed to complement sequence analysis for finding the cause of a hereditary predisposition to cancer. The assay contains probes for each exon of 26 genes involved in breast, colon, gastric and prostate cancer and melanomas, including BRCA1, BRCA2, MLH1 and MSH2.
Other MLPA 2.0 products that are currently in development include assays for newborn screening and the analysis of tumour-derived DNA.

PM16.38
The Human-Mouse: Disease Connection: a versatile tool for translational research discovery

A. V. Anagnostopoulos, *S. M. Bello, C. L. Smith, J. A. Kadin, J. E. Richardson, J. T. Eppig, the Mouse Genome Informatics Staff;*
The Jackson Laboratory, Bar Harbor, ME, United States.

The mouse is a premier model system for investigating etiopathogenetic mechanisms and therapeutics for human disease. Mouse Genome Informatics (MGI, www.informatics.jax.org) offers a new translational tool, the Human-Mouse: Disease Connection (HMDC, www.diseasemodel.org), granting free, concurrent access to human-mouse genomic, phenotypic, and genetic disease information. Researchers can readily explore phenotypes and disease correlations, examine candidate genes, and evaluate experimentally defined mouse genotypes modeling a spectrum of clinically-relevant phenotypes. The HMDC portal empowers users to search from a human or mouse standpoint, using (1) genes or gene IDs for either species, (2) genome locations from either species, and (3) mouse phenotype or human disease (OMIM) terms. Alternatively, data can be uploaded from human or mouse VCF files. Users can input one or more genes, a region for QTL, multiple deletion regions, or enter phenotype/disease terms of interest (e.g., "CHARGE Syndrome", or "lymphopenia") using the optional autocomplete feature. Boolean searches are supported. Initial search results display in an interactive grid for visual comparison of phenotypes and diseases across multiple genes, phenotypes, and diseases. The grid employs color cues that reflect depth of human and mouse annotations, and grid cells are dynamically linked to underlying MGI data, including phenotypic detail, model-relevant publications, and global availability of mouse resources via IMSR (www.findmice.org). Alternate HMDC views include gene- and disease-centric information presented in tabular format. We present current content, optimized search and filter options, and integrated data mining approaches to effectively prioritize candidate genes and locate mouse models of preclinical value. Supported by NIH grant HG000330.

PS16.39
Discovery of novel markers for neural differentiation with Next-Generation Sequencing.

Y. Ku, *Y. Sun, D. Piper, S. Jackson;*
Thermo Fisher Scientific, South San Francisco, CA, United States.

Human neural stem cells (NSCs) are pluripotent cells that give rise to neurons, astrocytes and oligodendrocytes in the nervous system. They hold promise for treatment of brain and spinal injuries and diseases. However, very little is known about their regulatory mechanisms. Here we used Next-Generation Sequencing (NGS) to define the temporal transcriptome signatures of human NSCs. Cultured human embryonic stem cells (H9) were compared to induced NSCs at days 0, 7 and 14. Total RNAs were extracted and Ion AmpliSeq™ Transcriptome libraries were created for sequencing. The transcriptome profiles of H9 cells differed little between days 0, 7, and 14

while NSCs induced from H9 cells showed remarkable differences from day 0 to days 7 and 14 during differentiation. Hierarchical clustering also showed more robust sample classification for NSCs than H9 cells. Comparing the expression profiles of NSCs versus H9 cells, a total of 4001 and 4768 were differentially expressed at day 7 and day 14 respectively. We further clustered their expressions into 24 groups by Self-Organizing Map. A total of ~250 genes showed similar expression patterns to known NSC markers including NES, SOX1 and PAX6. These genes are enriched for neural differentiation related pathways and are potential candidates for novel NSC markers. Their expressions will be further validated by qPCR. In summary, we used NGS to construct a temporal transcriptome database of H9 cells and NSCs. We also developed an analysis pipeline to systematically identify potential novel NSC makers.
For Research Use Only. Not for use in diagnostic procedures.

PM16.40
Speeding up NGS analysis through local and remote computing resources

B. Wolf[1,2], *P. Kuonen*[1], *T. Dandekar*[2], *D. Atlan*[3];
[1]*University of applied sciences and arts western switzerland, Fribourg, Switzerland,* [2]*University of Würzburg, Würzburg, Germany,* [3]*Phenosystems, Wallonia, Belgium.*

Over recent years the explosion of NGS data and the need for ever faster computers to analyze them has pushed smaller laboratories to their limits. We previously presented a way for users of GensearchNGS to combine all their locally available computer resources to speed up the alignment process, by allowing multiple computers in the laboratory to work together. We now expanded this possibility for cases where the locally available computer resources are not sufficient. This has been done by including the possibility to use a remote cloud, such as the amazon cloud, to speed up the alignment process. If requested by the user, remote computing instances are dynamically created at the beginning of the alignment process and destroyed again once it ends, all transparently for the user. This gives the users the choice to align NGS data on his own computer, on all the computers in his local network or using the resources of a remote cloud. By providing the possibility to combine any of those 3 computing resources the user has the flexibility needed, particularly for smaller laboratories, to choose the optimal solution for their particular needs, be it in terms of required analysis speed or privacy data privacy policies. Possible solutions and approaches to the issue of privacy when sending data to the cloud are explored as well, such as the combination of raw sequencing data of multiple samples to obfuscate the data of the samples to be analysed.

PS16.41
Managing NGS Bioinformatics pipelines with bpipe and bpipe-config.

D. Rambaldi, *D. Cittaro;*
Center for Translational Genomics and Bioinformatics, Ospedale San Raffaele, Milano, Italy.

Managing NGS Sequencing projects on large computation infrastructures can be challenging, especially if pipelines are managed with shell scripts: when a shell script fail, it is difficult to track where it failed and is even harder to restart the pipeline from the point of failure. Bpipe (Sadedin S et al., 2012), a platform for running big bioinformatics jobs that consist of a series of processing stages, tries to tackle these problems providing a framework to manage and launch bioinformatics pipelines in a controlled environment.
Herein we introduce bpipe-config, a software to generate pipelines ready for execution in bpipe, with a focus on Illumina sequencing environment.
The program bpipe-config make some check on the input files, generate a configuration file to launch bpipe on a cluster and create a pipeline using a generic template and the information stored in the SampleSheet file (i.e. reference genome, project name, sample name). When multiple samples are available, bpipe-config is able to generate a list of the input files that will be used for each sample.
As an example, we show our implementations for exome alignment, variant calling, variant annotation and WES project report. Each pipeline includes quality control steps (coverage, % unmapped reads, depth of coverage of variants) as well as a reporting infrastructure. The WES project report pipeline uses bpipe, R and the knitr R library to generate a complete report from a Whole Exome Sequencing project.

CAVA: a variant annotation tool optimised for the clinical setting

M. Münz[1], *E. Ruark*[2], *A. Renwick*[2], *S. Mahamdallie*[2], *M. Clarke*[2], *V. Cloke*[3], *S. Seal*[2,3], *G. Lunter*[1], *N. Rahman*[2,3,4];
[1]*Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [2]*Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom,* [3]*TGLclinical, Institute of Cancer Research, London, United Kingdom,* [4]*Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom.*

Next-generation sequencing (NGS) offers unprecedented opportunities to expand clinical genomics but also presents challenges, particularly in the annotation of indels, a highly important variant class in clinical genomics. Annotation in relation to a reference genome sequence, gene transcripts on different DNA strands and potential alternative variant representations has not been well addressed.
To address these challenges we developed CAVA (Clinical Annotation of VAriants) which is written in Python. CAVA is a fast, lightweight tool that can be easily incorporated into NGS pipelines. CAVA allows transcript specification, appropriately accommodates the strand of a gene transcript, which is crucial for consistent indel annotation, and flags variants with alternative annotations to facilitate clinical interpretation.
We evaluated CAVA in exome data and a clinical BRCA1/BRCA2 gene testing pipeline. CAVA annotated the ICR1000 exomes in 6.5 hours. Evaluation of 25,503 different indels revealed 79% had alternative representations in left-aligned and right-aligned data. Annotation of left-aligned data, as performed by many annotation tools would thus give clinically discrepant annotation for the 9,543 (37%) indels in genes transcribed from the forward DNA strand. By contrast, CAVA provided the correct clinical annotation for all indels. CAVA also flagged 9,177 indels with alternative representations of a different functional class, which may profoundly influence clinical interpretation. Finally, annotation of 50 BRCA1/BRCA2 gene mutations from a clinical testing pipeline gave 100% concordance with Sanger data; only 8/25 BRCA2 mutations were correctly clinically annotated by other tools.
CAVA is freely available from well.ox.ac.uk/cava. This work was funded by the Wellcome Trust Grant 098518/Z/12/Z.

Bioinformatic analysis of genes expressed in fetal cells circulating in maternal blood

M. Korabecna[1,2], *M. Jirkovska*[1];
[1]*First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic,* [2]*General University Hospital, Prague, Czech Republic.*

Fetal cells circulating in maternal blood are regarded as the main source of fetal cell-free DNA in maternal plasma which is examined in non-invasive prenatal diagnostics (NIPD). Understanding of biological processes associated with their release, viability and possibilities of their detection in maternal blood are therefore of interest for further development of NIPD.
In order to contribute to biological characterization of circulating fetal cells (CFC) we performed bioinformatic analysis of published gene set expressed in CFS and obtained the results documenting striking relationship between circulating fetal cells and endothelial cells. The results are in good agreement with the facts describing trophoblast deportation during pregnancy and its function as the fetal structure directly facing maternal blood.
Although there is the evidence of molecular similarity between circulating fetal cells and endothelial cells, the biological behavior of adult vascular endothelium practically excludes the presence of maternal endothelial cells in circulation. The situation is complicated by the presence of endothelial progenitor cells in circulation. Such incompletely described cells can undergo hematopoietic to endothelial transition and to regenerate vascular epithelium, therefore the spectrum of their molecular markers may overlap significantly with markers detected in blood cells, endothelial cells and circulating fetal cells.
It seems that a set of markers for effective CFC study in maternal blood for NIPD purposes could contain well known endothelial markers whose expression in CFC highly exceeds the expression in other blood cells.

The Orphanet Rare Disease Ontology (ORDO): data modelling for rare diseases and genes

A. Olry[1], *D. Vasant*[2], *J. Malone*[2], *C. Gonthier*[1], *S. Arunachalam*[1], *M. Hanauer*[1], *H. Parkinson*[2], **A. Rath**[1];
[1]*INSERM, US14 - Orphanet, Paris, France,* [2]*European Bioinformatics Institute, Hinxton, United Kingdom.*

As genetic knowledge becomes increasingly complex, there is an increasingly urgent need for reference tools that gather and integrate scattered phenotypic data in clinical databases and multiple medical terminologies in a normalised fashion, so as to improve their accessibility for health information systems and researchers.
Since 1997, Orphanet maintains a multilingual database of rare diseases (RD), based on the available
literature and on expert advice. Manually curated, Orphanet's data is comprised of a nosology (classification of RD), relationships (genes-diseases, epidemiological data, orphan drugs) and cross-references with other terminologies (MeSH, UMLS), databases (OMIM) or classifications (ICD10) in use. Genes are cross-referenced with other scientific databases (HGNC, OMIM, UniProtKB, Genatlas, Reactome, ensembl, IUPHAR). Orphanet's data is already freely available for download via the OrphaData platform (www.orphadata.org).
Data also needs to be made available to researchers in a machine-readable format, ready to be integrated with any technical environment. To address this need, Orphanet set up a collaboration with the European Bioinformatics Institute (EBI, Hinxton, UK) in order to produce the Orphanet Rare Diseases Ontology (ORDO), which provides a robust and consistent modeling of data and their semantic relationships, as well as interoperability standards with other scientific resources in use in both research and in public health. The Orphanet Rare Diseases Ontology is available on BioPortal (http://bioportal.bioontology.org/ontologies/ORDO) and Orphadata (www.orphadata.org).

Testing alternative methods to single-SNP GWAS analysis in family-based studies

R. Nagy[1], *P. Navarro*[1], *C. Hayward*[1], *J. F. Wilson*[1,2], *C. S. Haley*[1,3], *V. Vitart*[1];
[1]MRC Human Genetics Unit, Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom, [2]Centre for Population Health Sciences, University of Edinburgh, Edinburgh, United Kingdom, [3]Roslin Institute and Royal (Dick) School of Veterinary Studies, Edinburgh, United Kingdom.

Genome-wide association studies (GWAS) have identified many single-nucleotide polymorphisms (SNPs) affecting complex traits. These SNPs often explain only a small amount of the total trait heritability, warranting the development of methods to find this ‚missing heritability'. The success of GWAS depends on strong linkage disequilibrium at the population level between individual SNPs and trait variants. Regional heritability mapping takes into account the associations of causative variants with all SNPs in a region, allowing the identification of regions affecting the trait where individual SNP effects are small and would be missed by single-SNP GWAS. Linkage analyses utilise associations between SNPs and trait variants within families and not at the population level. Linkage analyses have been successful in identifying regions associated with monogenic traits, but less so when analysing polygenic traits in the GWAS age.
Here, we performed in parallel variance components linkage analysis, regional heritability analysis and GWAS on about 50 quantitative traits of public health importance (e.g. blood biochemical traits, anthropometric traits) in several isolated and cosmopolitan family-based populations.
We identified promising linkage peaks (LOD scores of 4-6) for several traits, in individual populations, with little overlap with known single SNP GWAS regions. Regional heritability frequently flagged regions picked up by GWAS, but also identified novel regions that lie within, or near, genes that are good candidates (based on function) for affecting a trait.
Replication and meta-analysis results across studies are being examined and the most promising regions will be followed-up using haplotype analyses and exome- and whole-genome sequencing data.
Funded by MRC PhD studentship.

CliMGuiDeS: online platform to develop clinical management guidelines for rare conditions

I. Gomez-Paramio[1,2], *G. Nenadic*[3], *J. Clayton-Smith*[4];
[1]Faculty of Life Sciences, The University of Manchester, Manchester, United Kingdom, [2]Institute of Human Development, The University of Manchester, Manchester, United Kingdom, [3]School of Computer Science, The University of Manchester, Manchester, United Kingdom, [4]Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.

Rare diseases, defined as occurring at a frequency lower than 5 per 10,000 people, will affect 1 in 17 people at some point in their life. Thus, although individually are rare, collectively are very important. There are around 6000 rare disease, many are life threatening and/or require continuous care.
Their optimum management, achievable with specialised clinical management guidelines, improves quality of life, and has financial benefits for the individual, their family and society. However, because of their rarity, the evidence base for some of their therapies and treatments is poor. Thus, guidelines need to be carefully drawn up, based on available evidence and expert consensus opinion and ensure that those with intimate knowledge of the natural history of the disorders are engaged in the process.
Unfortunately, its development is a costly process, requiring expert knowledge and time, as the Dyscerne project demonstrated previously.
CliMGuiDeS aims to create an all-in-one solution to streamline the development of management clinical guidelines for rare conditions, through the establishment of an online platform providing user-friendly environment with detailed information and tools to facilitate the completion of each step during this complex process. This platform will be globally accessible, and free to establish and sustain; it will not require specific (bio)informatics knowledge, operative-system, server, data-storage, or payable software. Further, to prove that effective work and innovative approaches can provide solutions even under the most challenging situations, this platform will be developed within just three months by one student.

PS16.47
Cafe Variome: Comprehensive Data Discovery for Rare Disease Diagnostic Networks and Research Consortia

O. Lancaster, *T. Beck, R. Dalgleish, A. J. Brookes;*
University of Leicester, Leicester, United Kingdom.

Vast amounts of useful mutation and phenotype data are not being openly shared - often for good legal, ethical or competitive reasons. The full value of these data is therefore never realised, and this fundamental ‚data sharing' roadblock cannot be solved by any technical wizardry that emphasises sharing.
Instead, the Cafe Variome approach changes the nature of the problem to one of enabling data discovery - i.e., making the ‚existence' rather than the ‚substance' of the data accessible. All records in the system can be made discoverable to help users comprehensively establish what useful content exists. The software facilitates the subsequent supply of these discovery 'hits' depending on who the data requestor and the data owner are.
The main use case being supported involves networks of rare disease diagnostic laboratories or research consortia within which members share an interest in certain causative genes/diseases, know/trust each other to different degrees, and wish to have a full picture of what records exists across the collaborating network. The first of these federations (for cardiovascular disease) has recently gone live and a number of other groups are currently trialling the software.
The development is lead by the University of Leicester, UK. The team and the concept are contributing to a number of major international initiatives focussed on maximising data use. To be compatible with these and other future initiatives all aspects of the Cafe Variome software are designed to be maximally flexible, enabling any data fields, ontologies, federation architecture, discovery search options, and data complexity to be handled.

Creation of ‚IRDiRC Recommended', a label to be used to highlight tools, standards and guidelines contributing to IRDiRC objectives

A. Mills, L. Lau, **S. Aymé**, *and the International Rare Disease Research Consortium;*
IRDiRC, Paris, France.

Following intense brainstorming exercises conducted by the International Rare Disease Research Consortium (IRDiRC), the Executive Committee decided to establish a label to highlight tools, standards and guidelines contributing to IRDiRC's objectives, namely to deliver 200 new therapies to the market by 2020 and the tools to diagnose most rare diseases.
The 'IRDiRC Recommended' label is a quality indicator, based on specific criteria. Any tool/standard/guideline compliant with the required criteria is entitled to receive the label. 'IRDiRC Recommended' is a public label which could, and should, be made visible on and by the resource, giving users an assured guarantee of its quality/appropriateness. The selected tool/standard/guideline must be fundamental to the rare diseases research and development community.
To receive the label, the tool/standard/guideline must fall within IRDiRC's focus, mission and requirements. It should have a development and maintenance team, and be functional and accessible with minimal downtime. It must be well-documented with clear terms-of-use and licence policies, and should adhere to all relevant ethical and privacy policies. The tool/standard/guideline should have implemented quality control and life cycle management processes, be financially viable for three years following its label accreditation and provide documented evidence of its core impacts (e.g. number of users, number of visits). Moreover, the tool/standard/guideline

should be freely available and must not be a commercial product.
Applications for the label will be peer-reviewed and submitted for approval by the IRDiRC's Executive Committee. Applications will be received and reviewed on an ongoing basis.
FP7/2007-2013, grant agreement n° 305207 "Support for international rare disease research to serve the IRDiRC objectives (SUPPORT-IRDiRC)".

Genomic, transcriptomic and miRNomic integrative analysis of recombinant inbred rat models of metabolic syndrome

B. Chylikova, *M. Hodulova, L. Sedova, M. Krupkova, F. Liska, D. Krenova, V. Kren, O. Seda; Intitute of Biology and Medical Genetics First Faculty of Medicine Charles University in Prague and, Prague, Czech Republic.*

We have previously established a genetically designed set of recombinant inbred rat strains PXO as a model of metabolic syndrome. Aim of this study was to compare, on genomic, transcriptomic and miRNomic levels, two PXO strains showing highest contrast in metabolic syndrome parameters.
At genomic level we have compared > 20,000 SNPs between PXO3-1 and PXO3-2. Both RNA and miRNA were isolated from liver, visceral adipose tissue and muscle (m. soleus) of adult males of both strains and its integrity was checked by Agilent 2000 BioAnalyzer. The transcriptomic and miRNomic assays were run using Affymetrix® Rat Gene 2.1 ST Array Strip and Affymetrix® miRNA 4.1 Array Strip, validated by qPCR. Resulting data were subjected to systems biology-level analyses using Partek Genomics Suite and Ingenuity Pathways Analysis.
PXO3-2 showed impaired glucose tolerance, higher TG and HDL-cholesterol together with lower adiposity compared to PXO3-1. On the genomic level, we have identified polymorphic regions on chromosomes 1, 3, 5, 8, 12, 16 and 19 totalling at 3.2% of genome. After correction for multiple comparisons, there were 1133, 236 and 29 differentially expressed transcripts between PXO3-1 and PXO3-2 in liver, visceral adipose tissue and muscle, respectively. Integrative pathway analysis revealed networks likely to underlie the observed metabolic differences including Ppara, Ppard, Insig2, Por a Srebf2 genes as their major nodes.
Using integrative approach of genomic, transcriptomic and miRNomic analysis in, we have identified major biological networks contributing to the pathophysiology of several aspects of metabolic syndrome in the recombinant inbred model set.

Introduction: Some common variants potentially involved in rheumatoid arthritis (RA) have been identified by genome wide association analysis. However, the genetic component of RA is not fully defined, and the identification of rare variants could help us to characterize a part of the missing heritability.
Materials and Methods: To identify rare RA-associated variants, we have analysed exome sequences from 30 individuals belonging to multiplex families in order to enrich the genetic component: 16 individuals (11 affected and 5 unaffected) from five families with at least four cases of RA (RA_fam); and 14 individuals (11 affected and 3 unaffected) from four families with at least four cases either of RA or other autoimmune diseases (RA_AID_fam).
Results: Exonic DNAs were captured with Agilent SureSelect Human All Exon V5 kit and sequenced with an Illumina HiSeq2000 sequencer. After alignment, quality filtering, targeting of captured regions and genome annotations to select variants according to their minor allele frequency (less than 1% or absent in databases) and their in silico predicted risk, we identified some rare variants present in all RA cases in one RA_fam but absent in unaffected relatives and in other individuals from both types of families. Familial and inter-familial analysis of these variants is currently ongoing.
Conclusions: Selected variants will be further validated by genotyping extended to all available members of each family in order to perform segregation analysis.
This work was supported by Fondation ARTHRITIS.

Large Scale Metabolomics identifies Dysregulated Metabolic Pathways in Rheumatoid Arthritis and Its Sub-types

N. A. Yousri[1], *W. G. Alhaq*[1], *S. Al Emadi*[2], *M. Hammoudeh*[2], *H. Halabi*[3], *B. Masri*[4], *H. Badsha*[5], *I. Uthman*[6], *R. Plenge*[7], *R. Saxena*[7], *K. Suhre*[1], *T. Arayssi*[1];
[1]*Weill Cornell Medical College- Qatar, Doha, Qatar,* [2]*Hamad Medical Corporation, Doha, Qatar,* [3]*King Faisal Medical and Research Center, Jeddah, Saudi Arabia,* [4]*Jordan Hospital, Amman, Jordan,* [5]*HBMC, Dubai, United Arab Emirates,* [6]*American University of Beirut, Beirut, Lebanon,* [7]*Broad Institute, Boston, MA, United States.*

Background
Rheumatoid Arthritis (RA) is a systemic chornic inflammatory disease of unknown etiology predominantly affecting the synovial joints. Although antibodies are now helpful in making early diagnosis of RA, novel diagnostic and prognostic markers are still needed to improve both diagnosis and treatment. Previous studies indicated the importance of metabolic profiling in uncovering details of pathomechanisms of RA. Untargeted metabolomics approach, together with metabolic networks, allows a deeper investigation of pathways associated with RA.
Objectives
Using an untargeted metabolomics approach, we investigate metabolic dysregulation in RA cases versus controls and in the sero positive and sero negative sub-types versus controls. Metabolic networks are further constructed using correlations between metabolites, to explore metabolic mechanisms underlying RA.
Materials and Methods
Blood and serum samples from 236 subjects of Arab ancestry were collected. Metabolic profiles were identified using the untargeted approach by Metabolon Inc.. Regression models, that correct for covariates were used for identifying metabolites associated with RA, as well as those differentiating sero positive from sero negative cases. Metabolic networks are then constructed and overlaid on identified metabolites.
Results
Several steroids showed significant decrease in RA patients, among which DHEAS has been previously reported. Other steroids which were not reported before in relation to RA were also identified and were found in the DHEAS metabolic subnetwork. Sero positive and sero negative RA cases further stratified the RA associated metabolites into two subsets.
Funding
This study is funded by Biomedical Research funds at Qatar Foundation.

PM16.52
RNA-Seq data analysis pipeline

T. Schwarzmayr[1], *T. Wieland*[1], *E. Graf*[1], *T. Meitinger*[1,2], *T. M. Strom*[1,2];
[1]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany,* [2]*Institute of Human Genetics, Technische Universität München, Munich, Germany.*

Next-generation sequencing has become the main technique for investigating the transcriptome. Although microarrays have been successfully used over years they have several limitations and the decreasing costs of NGS have led to a shift from microarrays to RNA sequencing (RNA-Seq).
We developed a pipeline to analyze RNA-Seq data and a database to store important metrics. The pipeline is a combination of Perl scripts and public available software packages (i.e. GEMmapper, HTSeq, DESeq2). It was integrated in an already existing exome sequencing data anlysis pipeline and its flexible and modular structure allows for an easy integration of new features which is important to cope with emerging issues in the constantly enhancing field of Next-generation sequencing.
As a standard feature, the pipeline performs split read alignment for each RNA-Seq sample and counts the number of reads within annotated features. To enable the detection of unwanted bias we calculate numerous quality metrics like amount of sequence, mapping rate, duplication rate, inter- vs. intragenic rate or rRNA rate. Subsequently, depending on the experimental design and possibly detected biases one can adapt parameters for downstream analysis such as differential gene expression or pathway enrichment analysis.
Overall, we applied the analysis pipeline to more than 700 RNA-Seq samples. On average, over 6 Gb of sequence was generated per sample resulting in more than 60M reads. We yield an overall mapping rate of about 99% and approximately 82% of the reads map within annotated exons. The rRNA rates are consistently below 1%. Furthermore, duplication rates vary considerably between standard (~20%) and low-input (~35%) RNA-Seq protocols.

FEATURES OF THE FIRST REFERENCE SEQUENCE OF SAUDI

I. Alabdulkareem, *W. Alharbi, Maryam Maryam Ballow, Yazid Alhaidan, AbdulkareemAlAbdulrahman, Zaki Rabhan, Mohammed Aljumah, M. Albalwi; KAIMRC, Riyadh, Saudi Arabia.*

A total of 2311051 unique variants were detected in the reference subjects that use for establishment of Saudi reference
sequence. however; the Alignment of the genomics data of the targeted subject was performed against human genome (hg19) by
hybrid approach. it was noticed that more than 10000 unique indels and almost 16000 structural variants were detected the
reference subjects
Our previous data that showed more than 14% of the SNPs were unique among 32 subjects was also present at our proposed
reference . A de novo assembly of 9,894 contigs sequences was not represented in NCBI reference genome.
Conclusion: De novo assembled and analyzed full Saudi Arabian individual genome of showed more than 231K
polymorphisms that is sole compare to the reference sequence.

PM16.54
A Micro-fabricated Single Cell Isolation System To Process 1000s Of Individual Cells For Genomics Applications

I. Mann[1], S. Nasarabadi[1], H. Shapiro[1], P. Lin[1], R. Acob[1], M. Slater[1], S. Husain[1], A. Mir[1], T. Schaal[1], M. Soumillion[2], T. Mikkelsen[2], **M. Srinivasan**[1]*;*
[1]WaferGen BioSystems, Fremont, CA, United States, [2]Broad Institute, Cambridge, MA, United States.

Understanding biological heterogeneity at a single-cell level requires new technologies that miniaturize and automate the isolation of thousands of individual cells and process these individual cells for downstream applications such as NGS or qPCR. Microfluidic technologies have streamlined single cell genomics applications but can do at best 96 individual cells at a time and costs over $20/cell. Droplet-based technologies have been shown to process thousands of cells but also hold several productizing challenges including handling emulsion oils and optimizing reaction efficiencies at picoliter volumes. In its first product version, WaferGen aims to increase throughput ~50 fold while simultaneously decrease cost at least 10-fold by engineering a simple device based on its proprietary, scalable, micro-fabricated chip, SmartChip, which contains an array of 5184 individual polymer-coated nanoliter wells drilled into a metal alloy substrate. The SmartChip platform has been used successfully for qPCR, genotyping and targeted sequencing applications and is proven for its flexibility in processing multiple samples in a single chip using the MultiSample NanoDispenser (MSND), a microsolenoid controlled reagent dispenser that can dispense volumes as low as 40 nl into the SmartChip wells. We will present data to support the reproducible dispensing of individual cells at a >80% occupancy rate (~4000 cells) and barcoding individual cells with unique molecular identifiers by adapting SCRB-seq, a Single Cell RNA Barcoding and Sequencing strategy to estimate 3' differential gene expression (http://dx.doi.org/10.1101/003236).

PS16.55
The functional annotation of genetic sequence variants using FATHMM-MKL

M. F. Rogers[1], *H. A. Shihab[1], J. Gough[1], M. Mort[2], D. N. Cooper[2], I. N. M. Day[1], T. R. Gaunt[1], C. Campbell[1];*
[1]University of Bristol, Bristol, United Kingdom, [2]University of Cardiff, Cardiff, United Kingdom.

We propose a novel approach for predicting whether single nucleotide variants (SNVs) are functional in human disease. We use an integrative classifier that weights component data-types according to their relative informativeness, and assigns a confidence measure to each predicted class label. We evaluated our approach using pathogenic germ-line SNVs from the Human Gene Mutation Database, and neutral SNVs from the 1,000 Genomes Project. The majority of disease-associated sequence variants lie in non-coding regions, but currently only two other recently proposed predictors exist for these variants. Using a weighted combination of four data sources, our method significantly outperforms both competing methods, and is currently state-of-the-art. The most highly weighted data source is sequence conservation across species: a variant in a highly conserved region has a higher probability of disease association than variants in regions of high variability. If we focus on examples with a confidence measure above 90%, the classifier achieves 96% test accuracy while making predictions on nearly 40% of examples; at a 95% confidence cutoff, accuracy increases to 98% with predictions for nearly 16% of examples. In coding regions, our model uses a weighted combination of 10 sources of data and is as accurate as the top competing algorithms. We have also devised disease-specific predictors and provide a web-browser for visualising the results from these studies.

PM16.56
Improved Detection of Low Level Sequence Variants by Sanger Sequencing using New Variant Caller Software

E. Schreiber, *H. Leong, S. Schneider, J. Marks, S. Berosik, M. Wenz; Thermo Fisher Scientific, South San Francisco, CA, United States.*

Sanger sequencing using capillary electrophoresis (CE) has been considered gold standard for identifying disease-causing mutations due to its robustness, low error rate, ease of use, visual display of the electropherogram, and low cost per sample and target. Homozygous and heterozygous germline mutations are reliably detected using DNA sequencing analysis software such as the Applied Biosystems Variant Reporter™ software. However, somatic variants with an allelic proportion of 25 % or less are often not „called" by the software and thus escape awareness if not detected by careful visual inspection of the electropherogram. With the rapid adoption of next generation sequencing technology (NGS) and its use for characterization of specific and discrete mutations in tumor samples, a need has emerged to establish an orthogonal technology for reliable and sensitive detection of somatic mutations which may occur at proportions of 10% or lower compared to the normal allele. To this end, we have developed innovative algorithms, software, and a protocol that specialize in the detection of minor mutations by Sanger sequencing. Using panels of prepared mixtures of minor alleles in the range of 2.5%, 5%, 10% and 20 %, we have achieved 92% sensitivity and 98.5 % specificity for detection of mutations present at the 5 % level with high quality data. In conclusion, we have demonstrated that standard protocols for fluorescent dye terminator Sanger sequencing in conjunction with the new Variant Caller may enable identification of de novo somatic mutations to a level of 5% which will also be useful for the confirmation of minor variants identified by NGS platforms.

PS16.57
The protein-protein interaction network of the human spliceosome

E. Galliopoulou[1,2], A. Gioutlakis[2,3], Z. Mamuris[1], M. Klapa[3], N. Moschonas[2], **T. Sarafidou**[1]*;*
[1]Department of Biochemistry and Biotechnology, University of Thessaly, Larissa, Greece, [2]Department of General Biology, School of Medicine, University of Patras, Patras, Greece, [3]Metabolic Engineering and Systems Biology Laboratory, FORTH/ICE-HT, Patras, Greece.

Splicing decisions are controlled by two major determinants, the pre-mRNA sequence and its inherent signals as well as the protein complement of the spliceosome. A major difficulty concerning the spliceosomal functional analysis arises from the large number of proteins involved and their dynamic interactions within spliceosomal sub-complexes. The aim of this study is the in silico reconstruction of the protein-protein interaction (PPI) network of the human spliceosome.
We identified the proteins that have been isolated as subunits of the human spliceosome and/or its subcomplexes, based on all the relevant publications. Direct PPIs between spliceosomal components were retrieved from the human interactome knowledge base, PICKLE_DB augmented with PPIs for the D. melanogaster and C. elegans orthologous to human spliceosomal proteins from the DroID and Worm Interactome Database. A thorough manual curation of the acquired data and the supporting publications ensured a final set of confidently direct PPIs.
The proteome of the human spliceosome comprises 630 proteins, 60% of which can be assigned to specific spliceosomal sub-complexes. The reconstructed spliceosomal PPI network, which follows the power law distribution, consists of 457 nodes and approximately 1600 edges. Approximately 25% of the proteins-nodes have been associated with genetic diseases, making the reconstructed network a valuable platform for suggesting documented functional relationships between genes, diseases and the topological structure of the interactome.

Hadoop-based NGS Analyzer for Predicting Genomic Structure Variations

G. Ko, *P. Kim, S. Park;*
Korean Bioinformation Center, KRIBB, Daejeon, Korea, Republic of.

It is almost impossible to store or analyze such large scale NGS data with a traditional method on a commodity server. Hadoop is an alternative to this requirement. We aim to address the issues involved in the large scale data analysis on the cloud in bioinformatics. Accordingly, we propose a Hadoop-based algorithm HAVS for predicting genomic variations at least 1000 bp and related to diseases.
Our algorithm consists of 3 steps in MapReduce workflow. The first step is to classify the sequences as normal sequences, of which the direction of paired-end reads is correct and in which the mapping distance belongs to the range of ±2.7SD standard deviation of the mean fragment size of the reads, and the sequences that do not belong to the range as variation. The second analysis process is to compute the mean insert size of sequences by structural variation types for only the sequences regarded as structural variation. The third analysis step is to cluster the structural variation sequences on the basis of the information computed in the above analysis process, and to predict a breakpoint in which structural variation occurred.The algorithm covers the structural variation types such as segmental duplication, copy number variation, translocation, inversion, insertion, and deletion. The experiments are performed on Hadoop clusters with the proposed algorithm and the YRI sequencing data provided by the 1000 Genome Project. The experimental results show that our proposed algorithm based on Hadoop is more accurate, efficient, and applicable to the prediction of genome structural variations.

Resolving Complex Structural Genomic Rearrangements using a Randomized Approach

X. Zhao, *S. B. Emery, J. M. Kidd, R. E. Mills;*
University of Michigan, Ann Arbor, MI, United States.

Structural variants (SVs), defined as the rearrangement or removal of genomic regions, are major sources of genetic diversity in human populations and directly responsible for the pathogenesis of numerous diseases. Many studies have been conducted in the past decade to discover and analyze SVs, however these have predominantly focused on unbalanced (copy number variant) events involving only one or two breakpoints. In contrast, more complex rearrangements resulting from multi-step or overlapping events involving three or more breakpoints have received considerably less attention or have been incorrectly interpreted. We have developed an algorithm, SVelter, which accurately identifies and resolves both simple and complex rearrangements using whole genome, paired-end sequencing data. This method first detects regions of the genome that are suspected to involve a structural variant by clustering sets of candidate breakpoints using aberrant read pair and split read mappings. The resulting segments are then iteratively rearranged in a randomized fashion and scored against null models of expectation based on library insert length, read orientation, sequence depth, and spanning coverage. We applied our algorithm to simulated genomes containing both simple and complex events and show a comparable accuracy for simple deletions, duplications and inversions, as compared to modern SV calling methods. However, SVelter outperforms these approaches on more complex rearrangements, showing a higher sensitivity without significant loss of specificity across different levels of sequence coverage as assessed using individual haplotype structures. We have also reexamined well-characterized genomes from the 1000 Genome Project (1KGP) that have been deeply sequenced and compared our results to the reported structural variants in these samples.

Sexpression analysis of >1,700 Finnish individuals reveals sex-dependent transcriptional differences in whole blood for immune system processes, response to stress and lipid metabolism

A. Joensuu[1,2], *M. Nuotio*[1,2], *V. Salomaa*[2], *T. Lehtimäki*[3], *O. Raitakari*[4,5], *M. Perola*[2,1,6], *J. Kettunen*[7,2,8];
[1]*Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland,* [2]*Department of Health, National Institute for Health and Welfare, Helsinki, Finland,* [3]*Department of Clinical Chemistry, Fimlab Laboratories and School of Medicine, University of Tampere, Tampere, Finland,* [4]*Research Centre of Applied and Preventive Cardiovascular Medicine, University of Turku, Turku, Finland,* [5]*Turku University Hospital, Turku, Finland,* [6]*University of Tartu, Tartu, Estonia,* [7]*Computational Medicine, Institute of Health Sciences, University of Oulu, Oulu, Finland,* [8]*NMR Metabolomics Laboratory, School of Pharmacy, University of Eastern Finland, Kuopio, Finland.*

Background: Sex-differences in gene transcription levels have been studied in specific diseases and specific tissues. It is important to identify normal sex-dependent differences in transcription levels, which can only be studied in population cohorts of large enough size.
Methods: We studied differences in autosomal gene expression levels between males and females in two Finnish population cohorts, the Young Finns Study (YFS, N=1255) and DILGOM (N=518), having genome-wide transcriptional coverage (>30,000 transcripts) from whole blood detected with Illumina HumanHT-12 BeadChips. The cohorts were analyzed separately using linear regression and meta-analyzed with random-effects meta-analysis. Covariates included age, BMI and smoking, and women using contraceptive pills or pregnant were excluded from the analyses.
Results: After correction for multiple testing, 992 autosomal transcripts (3.5%) in 949 genes showed differential expression between sexes. Gene enrichment analysis revealed significant enrichment of six Gene Ontology (GO) Terms including immune system process (p-value=4.9e-25) and response to stress(p-value=9.8e-6). Altogether 77 genes with GO terms related to lipids or lipoproteins showed differential expression in males and females. Interestingly, the Lipase A (LIPA) gene showed higher expression levels in males (0.54 increments in SD), with p-value 5.34e-28. This gene encodes lysosomal acid lipase, an essential enzyme for the hydrolysis of triglycerides and cholesteryl esters in lysosomes.
Conclusions: A high number of genes show different levels of expression between sexes when studied in a population cohort setting. These analyses can potentially pinpoint complex disease risk factor genes (e.g. LIPA) that may have a differential effect to the risk factor between males and females.

PS16.61

Variant data from more than 100,000 samples at the European Variation Archive

G. I. Saunders, *J. D. Spalding, I. M. Castello, C. Y. Gonzalez, J. Kandasamy, F. Lopez, I. Lappalainen, J. C. Moragón, J. M. M. López, J. Paschall;*
European Molecular Biology Laboratory, European Bioinformatics Institute (EMBL-EBI), Wellcome Trust Genome Campus, Cambridge, United Kingdom.

The European Variation Archive (EVA; www.ebi.ac.uk/eva) at EMBL-EBI is a one-stop-shop for variant data from all species. EVA contains more than 300 million variants from over 100,000 samples and our resource is growing at an increasing rate month on month due to submission of data from researchers interested in our service and the in-house addition of high-value datasets.
EVA data is annotated using a variety of methods, including VEP, for both the complete and basic GENCODE genesets. Data statistics are calculated both intra and inter study, and we also permit views of submitter provided annotations. We shall present the ways in which users can mine these data using filters on the website to construct both study-centric and global queries, filtering on any combination of species, methodology, variant type, phenotype, consequence or allele frequency and how results from these queries can be downloaded in a variety of formats. Additionally, EVA provides a comprehensive RESTful web-service, to allow programmatic access, and hence the integration of these data with other resources such as Ensembl Variation and Uniprot, and this shall also be presented.
Data submitted to EVA is brokered to NCBI (dbSNP or dbVar) as appropriate. Additionally, EVA has imported all dbSNP human variants and is continuing to load other species. Finally we shall present how EVA, supported by our close integration with ClinVar, accepts submission of clinically relevant data and describe the tools we offer that allow queries to be constructed against the complete clinical dataset of more than 100,000 variants.
Please send all questions, comments and/or submissions to eva-helpdesk@ebi.ac.uk

Human Variation Database in Japanese Integrated Database Project

K. Tokunaga[1], *A. Koike*[2], *H. Sawai*[1], *I. Inoue*[3], *S. Tsuji*[1];
[1]*University of Tokyo, Tokyo, Japan,* [2]*Cent Res Lab, Hitachi Ltd, Tokyo, Japan,* [3]*Natl Inst Genet, Mishima, Japan.*

We have established the Human Variation Database (http://gwas.biosciencedbc.jp/cgi-bin/hvdb/hv_top.cgi) in order to achieve continuous and intensive management of Japanese GWAS data, CNV data and variations identified by NGS and other experimental methods. The scope of the registry includes not only single gene disease causing variations and multifactorial disease associated variations, but also variations associated with drug responses and infectious susceptibilities. Since some phenotype-related variations are recognized to be different among populations, the reference genomes have been built for different populations. Variations include short/long insertions and deletion and structural variations as well as SNP/SNV.

Since vast amount of knowledge about variation-phenotype relationships are varied in the scientific literature, these data have been extracted by manual curation to organize the phenotype-related variations and improve our understanding of disease mechanisms and disease-disease relationships. More than 30,000 disease-related variation entries are currently registered. Since many characteristics of the HLA regions are different from other genomic regions, HLA-DB has also been constructed. Although only variations in germ-line cells are targeted in the database, it also provides links to driver mutations archived in the widely used databases such as COSMIC in order to clarify the relationships between the driver mutations in various cancers and germ-line mutations. Furthermore, pathway data are also provided to facilitate the understanding of epistasis and relationships between related diseases.

Acknowledgement: This work was supported by the contract research fund „Database Integration Program" from the Japan Science and Technology Agency.

PS16.63
Likelihood-based inference of relationship for family exome data

V. Heinrich;
Charité Universitätsmedizin Berlin, Berlin, Germany.

Whole exome sequencing (WES) analysis has become a powerful strategy to search for causal variants underlying rare Mendelian disorders. However, the identification of the disease-causing mutation among thousands of potentially functional sites can be challenging and often starts with linkage analysis to identify the chromosomal location of the potential disease gene. This strategy depends completely on correct pedigree information and may lead to false discoveries in a case of sample swaps or label mix-ups.
However, detailed knowledge about relatedness is not only a prerequisite for linkage analysis but is also becoming more and more important for genome wide association studies. While a sample mix-up is severely corrupting any linkage analysis, the inclusion of loosely related individuals in a case-control group scenario may result in spurious associations.
We created a strategy that combines two approaches to detect population substructure and predict complex pedigrees from genomic data. On the one hand we developed an algorithm based on likelihood ratios to discriminate different orders of relatedness between sample pairs of WES family data (e.g. siblings, parent-child, unrelated). On the other hand we applied a similarity metric on a collection of individuals to characterize their genetic population substructure on a group level by comparing each sample to genotype data provided by the 1000 genomes project.
By this means we are able to predict the correct pedigrees from exome samples of multiple generations as well as to detect cryptic relatedness in a cohort of an exome study.

PS17.01
Hair e-QTLs - delineating the genetic basis of gene-expression in human hair follicle

S. Heilmann-Heimbach[1,2], *T. Kätzel[1,2], A. Hofmann[1,2], L. M. Hochfeld[1,2], H. Schulz[3], F. Degenhardt[1,2], N. Karbalai[4], A. M. Hillmer[5], F. F. Brockschmidt[1,2], S. Herms[1,2,6], P. Hoffmann[1,2,6], B. Müller-Myhsok[4], M. M. Nöthen[1,2];*
[1]Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany, [2]Institute of Human Genetics, University of Bonn, Bonn, Germany, [3]Cologne Center for Genomics (CCG), University Cologne, Cologne, Germany, [4]Max-Planck-Institute of Psychiatry, Munich, Germany, [5]Genome Technology and Biology; Genome Institute of Singapore, Singapore, Singapore, [6]Division of Medical Genetics; Department of Biomedicine, Basel, Switzerland.

Human scalp hair plays an important role in our social and cultural life and its undesirable loss is often perceived as psychologically stressful. This has provoked many studies on the identification of genetic risk factors that predispose to hair loss disorders such as alopecia areata and male-pattern baldness. However, the biological context in which these genetic risk factors exert their biological effect is often unknown. Here, the analysis of genetic variants that influence gene expression (eQTLs) has gained major importance. The aim of our present study was to systematically map eQTLs in human hair-follicle that can be used to functionally annotate genetic risk factors for hair-related traits. Genome-wide genotyping of blood-DNA and transcriptome profiling of hair-follicle-RNA was performed on Illumina's OmniExpress- and HT12v4-arrays. After imputation of genotypes and quality control, a total of 6,593,881 SNPs and 14,687 expression-probes from 97 individuals remained for analysis. The genome-wide eQTL-analysis identified 2,883 independent cis- and 224 trans-eQTLs. A comparison with published eQTL-data from peripheral blood and brain revealed hair-follicle-specificity for about ~40% of the cis-eQTLs (N=1,159). The strongest hair-specific effects were observed for SNHG8, MRPL43 and XYLT1. IPA-pathway-based analysis revealed an enrichment for hair-eQTL-genes in several pathways. Among the top findings are the androgen- and prolactin-signaling-pathway which have been implicated in hair growth (de)regulation and the melanocyte development and pigmentation signaling. It is hoped that integration of the present data with GWAS-findings will help to pinpoint novel candidate genes and pathways and to further elucidate the biological mechanisms that contribute to the development of hair loss disorders and hair-related phenotypes.

PM17.02
C9orf72 epigenetic modifications in Italian amyotrophic lateral sclerosis patients

D. Calini[1,2], *C. Tiloca[1], D. Gentilini[3], E. Onesto[1], F. Verde[1,2], A. Ratti[1,2], V. Silani[1,2];*
[1]Department of Neurology and Laboratory of Neuroscience IRCCS Istituto Auxologico Italiano, Cusano Milanino, Italy, [2]Dipartimento di Fisiopatologia Medico-Chirurgica e dei Trapianti, "Dino Ferrari" Center, Università degli Studi di Milano, Milano, Italy, [3]IRCCS Istituto Auxologico Italiano, Cusano Milanino, Italy.

The hexanucleotide repeat expansions (REs) in the non-coding region of *C9orf72* are by far the most frequent cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia, accounting for a large proportion of both familial and sporadic cases. The basis for *C9orf72* carriers clinical heterogeneity remains unknown. Recently the association between *C9orf72* promoter methylation and histone trimethylation with its transcriptional silencing and with decreased accumulation of RNA foci and dipeptide repeat protein aggregates suggested that epigenetic modification of *C9orf72* could mitigate disease pathogenesis.
To consolidate this hypothesis we studied *C9orf72* promoter methylation in 44 *C9orf72*-positive and 22 *C9orf72*-negative ALS patients using bisulfite conversion coupled with next generation sequencing (NGS). When possible, we also performed quantitative PCR on RNA isolated from blood to determine *C9orf72* expression.
As a result from BS-sequencing, 91% of *C9orf72*-negative patients were unmethylated, while 32% of carriers had more than three methylated CpG sites. Performing NGS, we estimated with accuracy the percentage of methylation at each CpG site; this allowed us to refine the previous classification, dividing the samples in five different classes and concluding that only 27% of carriers had medium or high degree of methylation. While methylation levels didn't correlate with age at onset, they were mild correlated with disease duration and were inversely associated with repeats length. Quantitative PCR confirmed the correlation between *C9orf72* promoter methylation and lower levels of *C9orf72* RNA. Hence our data support the hypothesis that epigenetic silencing of mutant *C9orf72* and its subsequent diminished expression are associated with less aggressive disease.

PS17.03
Monozygotic female twins discordant for Beckwith-Wiedemann syndrome

S. E. Boonen[1], *F. Kasper[2], A. Skytte[1];*
[1]Aarhus University Hospital, Aarhus, Denmark, [2]Regional Hospital West Jutland, Herning, Denmark.

We present a case of monozygotic, monochorionic female twins discordant for Beckwith-Wiedemann syndrome (BWS) with detailed clinical description and DNA methylation analyses in order to provide further clinical and molecular data to the understanding of the mechanisms leading to this phenomenon.
The twins were born at gestational week 36+6 after a planned caesarean sectio due to an estimated weight difference of 1 kg between them.
Twin A was clinically unaffected with a birth weight of 2,739 g, while twin B had clinically BWS with a birth weight of 3,542 g, an enlarged tongue, nevus flammeus, bilateral ear pits, an umbilical hernia and neonatal hypoglycaemia
DNA extracted from peripheral blood, and buccal swabs of both twins, were analysed at a number of differentially methylated regions (DMRs) including DMR2 (KvDMR1) of the BWS region at chromosome 11p15.5. Partial loss of methylation (LOM) of the maternal allele of DMR2 in DNA extracted from blood from both the clinically affected as well as the phenotypic normal twin was identified. On the other hand, partial LOM of DMR2 in DNA from buccal swab was only identified in the clinically affected twin but not in the clinically unaffected twin.
Clinical follow-up at 1½ year of age and results of the extensive molecular analyses including the methylation profile of other imprinted loci will be presented.

PM17.04

Detection of 11p15 imprinting defects in patients with Beckwith-Wiedemann and Russell-Silver syndrome by Methylation-Specific Multiplex Ligation-dependent Probe Amplification method

I. Sansović, *I. Barišić;*
Children's Hospital Zagreb, Zagreb, Croatia.

Beckwith-Wiedemann syndrome (BWS) and Russell-Silver syndrome (RSS) are clinically heterogeneous disorders associated with overgrowth and growth retardation respectively. These conditions are caused by genetic or epigenetic changes that modify expression of genes in the imprinted region of chromosome 11p15.5. Approximately 60-70% of the patients have imprinting abnormalities at one of two imprinted domains H19DMR (imprinting center 1, IC1) or KvDMR (imprinting center 2, IC2). Loss of methylation at IC2 on the maternal chromosome is found in 50% of persons with BWS. Hypomethylation at IC1 on the paternal chromosome is identified in 35%-50% of individuals with RSS. Other causes of BWS and RSS are uniparental disomy (UPD) of chromosome 11p15.5 (BWS) and 7 (RSS), deletion/duplication, inversion and translocation of 11p15.5 and mutations in the CDKN1C gene.

Methylation-Specific Multiplex Ligation-dependent Probe Amplification (MS-MLPA) method enables detection of aberrant methylation of the KvDMR and H19DMR domains in the 11p15 BWS/RSS region. Also, it can be used to detect deletions/duplications in the same region.

We have analyzed six patients with BWS and four patients with RSS by MS-MLPA method. MS-MLPA analysis has shown hypomethylation pattern in gene KCNQ1OT1 in all subjects with BWS. In subject with RSS, MS MLPA revealed hypomethylation pattern in gene H19.

MS-MLPA provides robust and simple detection of epigenetic and genomic alterations at 11p15.5 as it detects copy number changes and DNA methylation alterations including those resulting from UPD. Therefore, MS-MLPA analysis should be offered in all cases of BWS/RSS as a first line test.

PS17.05

Integrating genome-wide methylation and genetic data for understanding biomarker regulation

A. Lind-Thomsen, **M. Ahsan**, *S. Enroth, U. Gyllensten, W. Ek, Å. Johansson;*
Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden.

An important aspect of modern medicine is the use of biomarkers to estimate disease risk. A better understanding of the importance of genetic and epigenetic factors in the regulation of biomarker expression, is crucial for discerning the role of biomarkers in diseases as well as the causes of interperson variation of biomarker levels.

In this study, genetic and epigenetic data are integrated to study factors that influence circulating levels of 144, well-established and exploratory, protein biomarkers for cancer and cardiovascular diseases. An epigenome-wide association study (EWAS) was performed using DNA methylation data from >470K CpG sites in 729 individuals and a genome-wide association study (GWAS) was performed using >8 million genotyped and imputed SNPs in 1033 individuals from a population-based cohort.

Results revealed EWAS significant CpG sites and GWAS significant SNPs (Bonferroni adjusted p-values <0.05) for 45 and 36 biomarkers respectively. In total 189 CpG sites, distributed over 130 loci and 4361 SNPs at 31 loci were identified. Many SNPs are located within or close to (<1Mb) the gene encoding the respective biomarker. A subset of the EWAS and GWAS signals overlap, suggesting that these represent the same underlying regulatory factor, while other signals characterize different regulatory factors. Some CpG sites are associated with multiple biomarkers, e.g. one in the inflammatory gene NLRC5.

Integrating GWAS and EWAS data gives a unique possibility to study their respective roles in regulating protein biomarkers. This knowledge is important in order to better understand the role of biomarkers in disease development and progression.

Potential of CDH1 promoter hypermethylation as a biomarker in early detection of cervical cancer

V. Holubekova[1], *A. Mendelova*[1], *S. Mersakova*[1,2], *I. Svecova*[2], *I. Kapustova*[2], *A. Vanochova*[1], *P. Zubor*[2], *J. Danko*[2], *Z. Lasabova*[1];
[1]*Department of molecular biology, Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Martin, Slovakia,* [2]*Department of Gynecology and Obstetrics, Jessenius Faculty of Medicine in Martin, Comenius University in Bratislava, Martin, Slovakia.*

E-cadherin is a transmembrane glycoprotein encoded by CDH1 gene and plays a pivotal role in cell-cell adhesion, suppression of tumour invasion, metastasis and participates in cell signaling. Intensive studies of many types of human cancer found reduced or lost expression of E-cadherin that might be also linked to the epithelial-mesenchymal transition (EMT) whereby epithelial cells can convert to mesenchymal cells via a multiple-step process. Our hypothesis was based on the fact whether the methylation of CDH1 gene is detectable in cervical swabs and has potential in cervical cancer screening. We studied CDH1 promoter hypermethylation in a spectrum of cervical specimens including normal cervix (n=47), low-grade (LSIL, n=34) and high-grade squamous intraepithelial lesions (HSIL, n=46) and invasive cervical cancer (n=13). The presence of CDH1 promoter hypermethylation was investigated by methylation-specific PCR (MSP-PCR) and its effect on CDH1 gene transcription was evaluated by relative quantification. We found out the presence of CDH1 hypermethylation in 20.6% (7/34) of LSIL, 21.7% (10/46) of HSIL and 46.2% (6/13) of cancers. We confirmed that the presence of CDH1 promoter hypermethylation was significantly associated with formation of cervical lesion resp. cancer (p=0.0005) and its expression was significantly decreased in samples with methylated CDH1 promoter (p=0.048). These data suggest that E-cadherin could be relevant biomarker for early and specific diagnosis and may improve cervical cancer management.

Epigenome-wide Association study of coffee and tea consumption

W. E. Ek[1], *A. Lind-Thomson*[1], *M. Ashan*[1], *U. Gyllensten*[1], *S. Enroth*[1], *S. A. Kyrtopoulos*[2], *P. Georgiadis*[2], *E. Ponzi*[3], *P. Vineis*[4], *J. A. Flanagan*[5], *Å. Johansson*[1], *The Epigenome-Wide Association Study Consortium;*
[1]*Department of Immunology, Genetics and Pathology, Uppsala, Sweden,* [2]*National Hellenic Research Foundation, Institute of Biology, Medicinal Chemistry and Biotechnology, Athens, Greece,* [3]*HuGeF, Human Genetics Foundation, Torino, Italy,* [4]*School of Public Health, Imperial College London, London, United Kingdom,* [5]*Dept of Surgery and Cancer,Imperial College London, London, United Kingdom.*

Exposure to chemicals and toxic agents can alter DNA methylation. One common exposure in most human populations is coffee and tea consumption. Coffee has been suggested to play an important role in risk of disease in humans by suppressing tumour progression, decreasing inflammation and influencing estrogen metabolism.

We performed a genome-wide DNA methylation study for coffee and tea consumption in 718 individuals from the northern Sweden. DNA methylation was measured, in white blood cells, at more than 470,000 sites distributed throughout the genome.

We identified one genome-wide significant CpG site (cg12934382, P-value = 2.7x10-8) associated with coffee consumption, and no sites associated with tea. Cg12934382 is located close to the transcription-starting site of the Glutamate Receptor 2 gene (GRM2). Glutamate receptors are used as therapeutic targets for Parkinson's disease, and GRM2 has also been associated with Schizophrenia. Interestingly, it has been shown that high caffeine consumption is associated with increased symptoms in Schizophrenia patients and that hypermethylation of GRM2 decrease the risk of Schizophrenia. Oppositely, for neurodegenerative diseases such as Parkinson's and Alzheimer's disease, coffee consumption is associated with reduced risk.

In summary, we have identified that DNA methylation in GRM2 is associated with coffee consumption. The link between Glutamate receptor genes and diseases that have been linked to coffee consumption suggests that GRM2 might be mediating this effect. As a continuation we will replicate our findings in a set of independent study cohorts, and meta-analyse genome-wide methylation data from almost 3000 samples, as part of the EWAC consortium.

PM17.08

The CRC-predicting diet induced expression changes in normal colon mucosa

M. Pussila[1], *S. Katayama*[2], *E. Einarsdottir*[3], *M. Nyström*[1];
[1]*University of Helsinki, Helsinki, Finland,* [2]*Karolinska Institutet, Huddinge, Sweden,* [3]*Karolinska Intsitutet, Huddinge, Sweden.*

Colorectal cancer (CRC) is the second most common cause of cancer related deaths in the Western world and interactions between genetic and environmental factors, including diet, play a critical role in its etiology. We conducted long-term feeding experiment in a mouse to address expression changes arising in normal colonic mucosa and their functional consequences as putative cancer-predisposing events available for early detection. Previously the expression of 94 growth-regulatory genes linked to human CRC and aber-

rant hypermethylation was studied for 5 weeks and 12 Months old Mlh1+/- mice analogous to human Lynch syndrome (LS) and wild type littermates, fed either by Western-style diet (WD) or control diet. Histologically normal proximal colonic mucosa, the predominant site of cancer formation in LS, exhibited a significant diet/genotype induced expression decrease in numerous CRC related tumor suppressor genes e.g. Cdh1, Dkk1, Slc5a8, and Socs1. The reduced expression was associated with age-related promoter hypermethylation.
Study continues with whole transcriptome RNA-sequencing to check the status of the previously found affected genes, affected pathways, and new CRC candidate genes in 18 and 21 Months old mice. The link from expression changes to cancer is studied from colonic tumors, from which the protein expression of susceptibility gene Mlh1 and beta-catenin was studied with immunohistochemistry. None of the tumors were found to be Mlh1 negative or to express nuclear beta-catenin. Therefore, the molecular reason behind tumorigenesis in our mouse series still remains to be elucidated. Yet, the role of WD in carcinogenesis is underscored by the fact that over 80 % of tumors were found in mice fed with WD.

PS17.09

Genomic/epigenomic defects associated with surprisingly detected parental consanguinity uncovered by molecular karyotyping with SNP arrays

M. A. Zelenova[1,2,3], *S. G. Vorsanova*[1,2,3], *Y. B. Yurov*[1,2,3], *S. A. Korostelev*[4], *I. Y. Iourov*[1,2,5];
[1]*Mental Health Research Center, RAMS, Moscow, Russian Federation,* [2]*Research and Clinical Institute for Pediatrics at the Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*The State Educational Institution of Professional Training under the Federal Agency of Health Care and Social Development, Moscow, Russian Federation,* [5]*Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.*

Parental consanguinity is generally accepted to be a risk factor for hereditary diseases. However, parents may not know about their consanguinity. As a result, clinical genetic evaluation is unable to provide a preliminary diagnosis for performing targeted molecular genetic diagnosis. Fortunately, there do exist whole-genome scanning techniques making possible to detect not only genomic but also epigenomic variations (i.e. segmental loss of heterozygosity or SLOH) for evaluating levels of consanguinity. Here, we have analyzed genomes of 188 children with intellectual disability, autism, epilepsy and/or congenital malformations using SNP/oligonucleotide molecular karyotyping (Affymetrix) and an original bioinformatic technology for addressing phenotypic, cellular and molecular consequences of genomic/epigenomic variations. SLOH, specific to clinical manifestations in these children, were found in 6 cases (3.2%). It is to note that parental consanguinity was not initially reported in all these cases. In one child, Meier-Gorlin syndrome was diagnosed. Other cases were also associated with hereditary diseases. Two cases of SLOH indirectly related to the phenotype were associated with microdeletions in 14q22.1 and 15q15.2, respectively. Parental consanguinity has long been considered as a source of knowledge about origins of hereditary diseases. In the present study, the possibility of genetic analyses of children born in consanguineous marriages has been extended by whole-genome and bioinformatic analyses. Actually, it has been shown that surprisingly detected consanguinity can be relatively common and molecular diagnosis using SNP arrays and bioinformatics can be useful for revealing of mechanisms of genetic and epigenetic diseases. Supported by Russian Science Foundation (Grant: №14-15-00411).

PM17.10

Identification of trisomy 21 specific biomarkers based on transcription level characteristics

S. Kyriakou[1], *E. Papageorgiou*[2], *C. Strati*[2], *P. C. Patsalis*[1,3];
[1]*The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus,* [2]*NIPD Genetics LTD, Nicosia, Cyprus,* [3]*The Ministry of Health, Nicosia, Cyprus.*

Non-invasiveprenatal diagnosis has been one of the most challenging fields in the past two decades. The discovery of fetal nucleic acids in the maternal circulation encouraged several groups to work on the identification of fetal specific biomarkers. In order to expand the
panel of fetal biomarkers, we targeted the whole transcriptome to identify differentially expressed genes (DEGs) among the trisomy 21 and normal fetuses from their mothers. The majority of the studies, working on biomarker discovery, focused on chromosome 21 but the phenotypic characteristics of Down syndrome (DS) suggest that can be related to genes located on other chromosomes as well. Expression microarrays covering the whole transcriptome were applied to four normal and two trisomy 21 chorionic villi (CVS) RNA samples together with their matching maternal RNA (white blood cells). Association studies of identified DEGs with Down syndrome phenotype were performed. Multiple trisomy 21 specific DEGs, 175 in number, were identified and found to be located across the whole genome. Nine of them were directly associated with the DS phenotype. Furthermore, many of the remaining DEGs were indirectly associated through pathological conditions occurring in DS. Findings of this study strongly support the hypothesis that DS phenotype is expressed from the disruption of the whole genome and not only chromosome 21 encoded genes. DEGs could eventually be used as fetal specific biomarkers for the identification of trisomy 21 from normal fetuses. Due to the transcription level variability among individuals, a large-scale study is needed in order to confirm our findings.

PS17.11

Epigenetic modifiers of cystic fibrosis

E. Kvaratskhelia[1], *N. Dabrundashvili*[1], *E. Maisuradze*[1], *M. Gagua*[1], *T. Topuria*[1], *L. Margvelashvili*[2], *T. Tkemaladze*[3], *E. Abzianidze*[3];
[1]*Tbilisi State Medical University, Bakhutashvili Institute of Medical Biotechnology, Tbilisi, Georgia,* [2]*Hospital „New Life", Department of Medical Genetics and Diagnostics, Tbilisi, Georgia,* [3]*Tbilisi State Medical University, Dept. of Molecular and Medical Genetics, Tbilisi, Georgia.*

Cystic Fibrosis (CF) is caused by mutations in the CFTR gene. T-lymphocytes from patients with CF are characterized by reduced expression of anti-inflammatory cytokines, such as IL-10 and elevated level of pro-inflammatory cytokines (e.g.IL-8). Epigenetic factors such as DNA methylation or histone modifications might contribute in cytokine dysregulation during CF. DNA methylation is catalyzed by DNA-methyltransferase enzymes (DNMTs).
In this study the correlations between levels of DNMT1, DNMT3a and IL-10 were investigated in T-lymphocytes derived from CF patients and healthy subjects. T-lymphocytes were isolated by ficoll gradient centrifugation with subsequent purification and cultured in RPMI 1640 medium supplemented with 5% L-glutamine and 10% FCS, with presence or absence of 5-azacytidine (5-AzaC; Sigma- Aldrich), a DNA methyltransferase inhibitor, for 24h. T-cells were activated with ionomycin (250 ng/ml) and PMA (20ng/ml). Levels of DNMT1 and DNMT3a were measured in nuclear extracts using DNMTs assay kits (Abcam, UK). IL-10 amount from supernatant of T-cell culture was quantified by ELISA kit (Abcam, UK).
We have found that T-lymphocytes from CF patients express elevated level of DNMT3a (40%), while no significant changes was observed at levels of DNMT1 compared to healthy subjects. In presence of the high dose of 5-AzaC (6μmol/L) the level of DNMT3a was decreased which was accompanied by an increased amount of IL-10.
These findings show the immunomodulatory effect of 5-azaC in CF T- lymphocytes. Since aberrant epigenetic modifications are potentially reversible epigenetic drugs might represent targets for Cystic Fibrosis therapy. Further work will involve evaluation of a promoter methylation status of cytokine genes in CF T- cells .

Epigenetic alterations in genes, connected to stress and toxicity, in the course of type 2 diabetes

S. Karachanak-Yankova[1], *D. Nesheva*[1], *R. Dimova*[2], *T. Tankova*[2], *B. Rukova*[1], *Z. Hammoudeh*[1], *O. Antonova*[1], *V. Damyanova*[1], *D. Toncheva*[1], *I. Dimova*[1];
[1]*Department of Medical Genetics, Medical Faculty, Medical University of Sofia, Sofia, Bulgaria,* [2]*University Specialized Hospital for Active Treatment of Endocrinology "Academician Ivan Penchev", Sofia, Bulgaria.*

Type 2 diabetes (DM2) is a chronic metabolic disease resulting from genetic, epigenetic and environmental factors. Its pathogenesis and progression are related with chronic oxidative stress-an important mechanism for glucose toxicity.
The aim of our study was to define the epigenetic alterations in DM2. First, we have determined mRNA expression levels of methyl-CpG binding domain protein 2 (MBD2) in 16 patients and 12 controls. Then, we have analyzed DNA methylation status of 22 genes, connected to stress and toxicity, in four DNA pools of: 20 healthy controls; 20 initial DM2 patients; 20 patients with DM2 for less and 20 patients with DM2 for more than five years. The expression analysis and methylation status survey were performed by Real-Time PCR, preceded by reverse transcription and restriction with methylation-sensitive and methylation-dependent enzymes, respectively.
Our results show that MBD2 has increased expression in DM2 (more than 4 times). From the genes analyzed for promoter methylation, four show increasing methylated fraction with the course of DM2: BRCA1 (0% in healthy controls; 5.9% in initial DM2; 0.5% in DM2 for less than 5 years and 47.8% in DM2 for more than 5 years), CCND1 (0%, 13.6%, 14.7% and 34.1%, respectively), SCARA3 (3.5%, 8.1%, 20.2% and 23.3%, respectively) and Prdx2 (7.3%, 22.3%, 22.4% and 32%, respectively).

In conclusion, the increased MBD2 expression in DM2 seems to be related to DNA methylation. This involves genes for DNA repair and cell cycle regulation (BRCA1 and CCND1) and genes with antioxidant protective role (SCARA3 and Prdx2).

Role of the genetic background in epigenetic response to phtalate exposure on a genome wide scale

A. Paoloni-Giacobino, *L. Stenz, C. Stouder, A. Dayer, J. Prados;*
Geneva University Medical School, Geneva, Switzerland.

Di-(2-ethylhexyl)phtalate (DEHP) is a plasticizer with endocrine disrupting properties found ubiquitously in the environment. Studies in rodents and in humans revealed that it is an aggressive reproductive system toxicant.
The possible impact of DEHP exposure during pregnancy in mice was assessed on sperm count and on DNA methylation by MBD-sequencing in the F1 male generation using two different genetic backgrounds, C57BL6 and FVB mice. DEHP exposure induced a C57BL6 strain-dependent statistically significant reduction in sperm counts (p = 8.7x10-4) with no detectable impacts in the other strain tested (FVB mice, p= 0.9). In the sperm of DEHP exposed F1 mice, MBD-sequencing analysis taking in account the strain and the DEHP exposure revealed statistically significant DNA methylation enrichments in promoters of four genes: Tmem125, Piwil2, Fkbp1a and Smim8. Among them, Piwil2 was previously shown to be hyper-methylated in the testicular samples of human infertile males, whereas Fkbp1a stimulates sperm motility. Piwil2 and piwil4 were the two most significant and recurrent candidates identified in the approach targeting genes involved in reproduction according to Go terms. Transcription level of a subset of targets was tested by RT-qPCR on sperm RNA. Results showed that promoter methylation was globally inversely correlated with gene expression. Finally, functional genetic variations between both mice strains were localized on some of the targets identified by MBD-sequencing.
This study reveals an important strain-dependent impact of DEHP exposure during pregnancy on the production of sperm cells. It was associated with epigenetic dysregulation occurring in genes involved in the reproduction process.

We are analyzed the biochemical, immunological, echocardiography and electrocardiogram markers of the stress response when performing exercise testing student-athletes. The study of gene expression, biochemical and immunological analyses were performed to exercise testing and immediately afterwards. All subjects gave their written informed consent to the experiment. Created a collection of microRNAs from the blood using a set of reagents „RNeasy Protect Animal Blood Kit („Quigen, USA). Quantitative and qualitative assessment of selected microRNAs were performed on the 2200 TapeStation Instrument (Agilent technologies, USA) and „Qubit“ („Invitrogen, USA). Sequencing was performed using a set of reagents „Ion PGM™ Sequencing 300 Kit and a microchip „Ion 314™ Chip“ („Life technologies, USA). The data analysis sequencing was performed by aligning the nucleotide sequences against a reference genome HG19 using the resource Alignment v3.6.56201“, and generate the required file format (*.bam *.vcf) using Torrent Server according to the instructions, Torrent Suite 3.4.1“ („Life technologies, USA). Annotating and filtering of variants was performed using the Internet resource „Gene Talk‘ (http://www.gene-talk.de). So using the resource for data analysis NGS sequencing microRNA - omiRas were identified changes in the expression for hsa-mir-185 (differ before and after load). MicroRNA hsa-mir-185 is associated with the regulation of the following genes: PPARG, VEGFA. The products of these genes are associated with the physical performance. Obtained preliminary results allow us to speak about the role of microRNAs in the stress response of athletes on physical activity. However, requires verification of the received data using realtime PCR.

Analysis of histone modifications in Familial Mediterranean Fever patients

B. Fidan[1], *I. Karacan*[1], *H. Ozdogan*[2], *S. Ugurlu*[2], *E. Seyahi*[2], *E. Tahir Turanli*[1,3];
[1]*Graduate School of Science Engineering and Technology, Department of Molecular Biology Genetics and Biotechnology, Istanbul Technical University, Dr. Orhan Ocalgiray Molecular Biology and Genetics Research Centre, Istanbul, Turkey,* [2]*Department of Rheumatology, Istanbul University Cerrahpasa Medical Faculty and Hospital, Istanbul, Turkey,* [3]*Molecular Biology and Genetics Department, Istanbul Technical University, Istanbul, Turkey.*

Introduction: Familial Mediterranean Fever (FMF) mostly exhibiting autosomal recessive inheritance (1:1000 in Turkey) is the most common autoinflammatory disease. More than 200 FMF-associated variations have been reported in the MEFV gene. MEFV gene expression levels are generally low in FMF patients compared to healthy controls, and further decrease has been observed during attacks which appears to be associated with inflammation, Furthermore, methylation level of exon 2 of MEFV was found to be higher in FMF patients which reversely correlates with expression. In this study, in addition to the link between DNA and histone lysine methylation, we wanted to explore heterochromatin and euchromatin modifications in FMF patients during the attack and attack-free period in order to assess whether the modifications are related to inflammation.
Materials and Methods: This study included 10 FMF patients during the attack and attack-free period and 10 age-gender matched healthy controls. Modification-specific antibodies (trimethylation(me) of H3K9 and H3K4) are used for chromatin immunoprecipitation(ChIP) experiments to enrich modified regions in Peripheral Blood Mononuclear Cells (PBMCs) isolated from peripheral blood. ChIP experiment was combined with sequencing (ChIP-seq) and was performed on one Illumina Hiseq 2500 lane, 177,447,268 bases in total.
Results: We detected H3K4me3 modification on many genes mostly localized in chromosome 11, 12 and 16 which harbours candidate genes for inflammation.
Conclusions: Although bioinformatic analyses are still ongoing in depth, we currently searching promising candidates with H3K9me3 modification. Further studies will be conducted to determine whether these modifications are associated with MEFV and/or other components of inflammatory pathway.

PM17.16
Investigating the regulatory landscape of the human fibrinogen gene cluster

C. N. Espitia[1,2], *R. J. Fish*[1,2], *S. W. Lukowski*[1,2], *M. Neerman-Arbez*[1,2];
[1]*University of Geneva, Geneva, Switzerland,* [2]*Institute of Genetics and Genomics in Geneva (iGE3), Geneva, Switzerland.*

Introduction: The coagulation factor fibrinogen is expressed and secreted by hepatocytes and its circulating concentration is associated with cardiovascular disease (CVD) risk. Three clustered genes (*FGA, FGB* and *FGG*) encode the three polypeptide components of fibrinogen. They are coordinately regulated and we previously identified two intergenic enhancer elements. Our aim is to uncover further regulatory elements and understand how local chromatin architecture influences fibrinogen expression.
Materials and Methods: A luciferase reporter assay in fibrinogen-expressing (HepG2) and non-expressing (HEK-293T) cells and a transgenic zebrafish assay were used to demonstrate liver enhancer activity for predicted regulatory sequences near the fibrinogen locus. Chromatin interactions will be assessed by chromatin conformation capture and their role in the regulation of fibrinogen expression studied using CRISPR-Cas9 editing.
Results: We identified two enhancers flanking the fibrinogen locus. Each sequence enhances reporter gene activity in HepG2 cells irrespective of orientation and position with respect to a fibrinogen promoter, and one drives liver transgene expression in zebrafish larvae. ENCODE chromatin immunoprecipitation-sequencing data demonstrate that each enhancer is bordered by CTCF and RAD21 interaction sites, suggesting that the extremities of the gene cluster may be looped together. We are investigating the functional importance of these potential interactions.
Conclusions: The fibrinogen locus is flanked by liver enhancers and may adopt a looped conformation. Demonstrating functional importance of this looping in the regulation of fibrinogen expression could link chromatin interactions to circulating fibrinogen levels, and ultimately to CVD risk.

Reactivation of the FMR1 gene in fragile X lymphoblastoid cells by 5-aza-2-deoxycytydine does not cause random genomic DNA demethylation.

G. Mancano[1], *E. Tabolacci*[1], *S. Lanni*[1], *F. Palumbo*[1], *M. Goracci*[1], *F. Ferrè*[2], *M. Helmer-Citterich*[2], *P. Chiurazzi*[1], *G. Neri*[1];
[1]*Institute of Medical Genetics-Catholic University, Rome, Italy,* [2]*Centre for Molecular Bioinformatics- Department of Biology-University of Tor Vergata, Rome, Italy.*

Fragile X syndrome (FXS) is caused by CGG expansion over 200 repeats at the 5' UTR of the FMR1 gene and subsequent DNA methylation of both the expanded sequence and the CpGs of the promoter region. This epigenetic change causes transcriptional silencing of the gene. We have previously demonstrated that 5-aza-2-deoxycytydine (5-azadC) treatment of FXS lymphoblastoid cells reactivates the silent gene, allowing CpG sites demethylation, increased acetylation of histones H3 and H4 and methylation of lysine 4 on histone 3. Recently we observed that reactivation of FMR1 transcription is long lasting, up to a month after a 7-days treatment with 5-azadC, and that maximum level of transcription are reached 10-15 days after 5-azadC last administration. In order to check the specificity of the 5-azadC-induced DNA demethylation, we performed bisulphite sequencing of the entire methylation boundary upstream the FMR1 promoter region, which is preserved in WT cells [Naumann et al., 2009]. We did not observe any modification of the methylation boundary after treatment. Furthermore, methylation analysis by MS-MLPA of PWS/AS and BWS/SRS loci demonstrated that 5-azadC treatment has no demethylating effect on these regions. Methylation analysis through Infinium 450K (Illumina) revealed no significant changes in differentially methylated regions after treatment. Taken together these data show that 5-azadC has a long lasting reactivating effect on the mutant FMR1 gene and that its demethylating effect on genomic DNA is not random but rather restricted to specific regions. These findings may open new perspectives for a drug-based epigenetic therapy of FXS.

Supported by Telethon Onlus, FRAXA Foundation and Italian Association for fragile X syndrome.

PM17.18

FSHD 1 and 2 testing - a clinical diagnostic service perspective

D. Smith[1], *R. Whittington*[1], *P. Lunt*[2], *T. Evangelista*[3], *H. Lochmuller*[4], *M. Williams*[1];
[1]*Bristol Genetics Laboratory, Bristol, United Kingdom,* [2]*Bristol University, Honorary Research Fellow, Medical Faculty, Bristol, United Kingdom,* [3]*3The Newcastle University, John Walton Muscular Dystrophy Research Centre, MRC Centre for Neuromuscular Diseases at Newcastle, Newcastle, United Kingdom,* [4]*The Newcastle University, John Walton Muscular Dystrophy Research Centre. MRC Centre for Neuromuscular Diseases at Newcastle, Newcastle, United Kingdom.*

FSHD (affecting ~1 in 20,000 individuals) is an autosomal dominant epigenetically regulated disorder, with characteristic pattern of progressive muscle involvement commencing in the face and shoulder-girdle. Two clinically indistinguishable forms differ in molecular basis of epigenetic regulation, but are underpinned by hypomethylation of 4q35, causing aberrant DUX4 expression (toxic transcription factor). FSHD1 (OMIM158900) (95% cases) caused by contraction of D4Z4 repeats, results in allele-specific hypomethylation. FSHD2 (OMIM158901) (~3% of cases), contraction independent, is caused by mutations in SMCHD1, encoding a chromatin-modulating enzyme, resulting in global hypomethylation and chromatin relaxation of D4Z4 arrays. A permissive haplotype at 4q35 is required for clinical expression of FSHD1 and 2, necessitating digenic inheritance for FSHD2.

BGL provides a UKGTN specialist diagnostic service for FSHD processing >500 UK/international referrals annually. Clinically typical (assessed by clinical proforma) deletion negative patients (4.8% referrals) are tested for FSHD2 by 4q35 methylation quantification (pyrosequencing) followed by SMCHD1 sequencing of hypomethylated patients.

A diagnosis of FSHD2 has been confirmed in 15/45 cases, with 12/15 novelSMCHD1 mutations (the remainder are deletions of intron/exon 25 boundary, the first 'hotspot' identified in SMCHD1). We have compared the clinical severity of FSHD2 and age/sex matched FSHD1 patients.

FSHD2 shows digenic inheritance with risk to offspring between 25 and 50%, depending on the haplotypes of the wider family. Family testing has been undertaken for 3 cases.

We present the clinical and genetic data of the FSHD2 cohort, and interesting cases highlighting the clinical utility of genetic testing, and the complexity of counselling family risks associated with digenic disease.

PS17.19

Integration of the PPP1R26P1 human pseudogene sequence does not induce imprinting of Rb1 in the mouse

V. Tasiou, M. Hiber, **L. Steenpass**;
Institute of Human Genetics, Essen, Germany.

The human RB1 gene is imprinted, carrying a differential methylation mark at an intronic CpG island (CpG85) on the maternal chromosome and showing biased expression of full-length RB1 in favor of the maternal allele. On the unmethylated paternal allele, CpG85 serves as promoter for an alternative RB1 transcript, which starts at a novel exon 2B and possibly interferes with expression of the RB1 gene from the main promoter. CpG85 is part of the PPP1R26P1 pseudogene, which integrated into intron 2 of the RB1 gene by retrotransposition. To study if integration of a pseudogene sequence per se is sufficient to induce differential methylation and imprinting, we generated a knock-in mouse, carrying human PPP1R26P1 in intron 2 of the mouse Rb1 gene.

Using next-generation bisulfite amplicon sequencing, we analyzed acquisition of DNA methylation at CpG85 in several tissues in male and female heterozygous mice after either maternal or paternal transmission of PPP1R26P1. We observed a tissue-specific pattern of DNA methylation with high levels in neuroectodermal tissue, like brain and eye, but low levels in all other tissues tested. This pattern was observed independent of parental transmission, indicating that CpG85 in the human pseudogene does not act as stable gametic DMR in the mouse. Preliminary analysis of CpG85 methylation in germ cells showed that it is unmethylated in sperm and in oocytes. This indicates that the integration of a foreign pseudogene sequence is not sufficient for establishment of differential methylation at CpG85 in the mouse germline.

The project is funded by the Deutsche Forschungsgemeinschaft, Grant STE1987/4-1.

PM17.20

Prediction of imprinted genes based on the genome-wide methylation analysis

N. Pervjakova;
Estonian Genome Center University of Tartu, Tartu, Estonia.

Genomic imprinting is an epigenetic gene-marking phenomenon that occurs in the germline and results in monoallelic expression according to parental origin. Our hypothesis is that imprinted genes in humans can be predicted by the methylation level of CpG sites within that gene region. We also expect that the variability of beta values is smaller within imprinted genes as they have more semi methylated probes and therefore more medium beta values.

For this study 17 tissues from 4 individuals were collected during autopsy. DNA methylation analysis was performed with the Illumina Infinium HumanMethylation450 BeadChip in Estonian Genome Centre.

As a result, all imprinted genes (n=77) demonstrated less variability in the methylation level ($p < 0.01$) across all 17 tissues when compared to non-imprinted genes. We visualized the CpG patterns of known imprinted genes across all tissues. The visualized CpG patterns confirmed tissue-specific nature of imprinted genes. We found a tissue-specific switch of imprinted status across somatic tissues for two genes - MKRN3 and KCNQ1DN. CpG patterns also showed expression-specific patterns of genes, such as bi-allelic, monoallelic or combined expression. We also found that methylation pattern remains stable not depending on a gene being expressed or not. Based on this approach, we selected 50 potentially imprinted genes for further studies, 2 of which were already known as imprinted and 1 was predicted by another study.

Our method can be used as an efficient tool to clarify the nature of the already established imprinted genes as well as to discover new imprinted genes across the whole human genome.

PS17.21

Mining novel candidate imprinted genes by using high resolution DNA methylation microarrays in multiple human tissues

A. Bonaldi[1], *L. Vasques*[1], *A. Y. Kashiwabara*[2], *E. S. S. Araujo*[3], *A. R. Paschoal*[2], *M. Andosia*[1], *D. Villela*[1], *C. K. Suemoto*[4,5], *C. A. Pasqualucci*[6,5], *L. T. Grinberg*[7,5], *C. Rosenberg*[1], *A. M. Vianna-Morgante*[1], *D. Carraro*[3], *A. C. Krepischi*[1];
[1]*Department of Genetics and Evolutionary Biology, Institute of Biosciences, University of São Paulo, São Paulo, Brazil,* [2]*Department of Computation, Federal Technological University, Curitiba, Brazil,* [3]*International Center of Research and Training (CIPE), A. C. Camargo Hospital, São Paulo, Brazil,* [4]*Department of Internal Medicine, University of São Paulo Medical School, São Paulo, Brazil,* [5]*Brazilian Aging Brain Study Group, Department of Pathology, University of São Paulo Medical School, São Paulo, Brazil,* [6]*Department of Pathology, University of São Paulo Medical School, São Paulo, Brazil,* [7]*Memory and Aging Center, Department of Neurology, University of California, San Francisco, CA, United States.*

Different strategies have been recently applied in the search for novel imprinted genes (IG) in humans, either focusing on monoallelic expression or epigenetic signature. Aiming at revealing novel IGs, we generated genomic

methylation data for 67 samples from six different human tissues (leukocyte, brain, liver, breast, melanocyte, chorionic villus), using the Illumina HM450K platform. CpG sites mapped at gene promoters harboring CpG islands in the beta-value range of 0.38-0.65 were applied to call hemimethylated CpG sites potentially associated with IGs. CpGs common to at least three different tissues were selected. About 30% of known IGs were recovered, and 170 candidate IGs were identified. Among these, 27 were shown to have at least three CpG probes shared by three or more tissues. Differentially methylated CpGs have been previously reported for seven of them, thus supporting the hypothesis of these genes being imprinted: PLEC, PTCHD3, ZNF331, KIAA2013, SYCE1, HTR5A and ZNF232. Among our 27 top candidates, PLEC, TONSL and VPS28 are neighbor genes mapped to a 665 Kb segment at 8q24.3, and might constitute a novel imprinted cluster. Interestingly, 39 members of protocadherin (PCDH) clusters on 5q31.3 were found to have hemimethylated CpGs at promoter regions in multiple human tissues; Pcdh non-imprinted monoallelic and randomic isoform expression have been previously demonstrated in mice, and this might be the case in human. Our approach based on the methylation pattern in multiple tissues was successful to reveal hemimethylated CpG sites potentially associated with novel IGs or non-imprinted monoallelic expressed genes in humans.

PM17.22
A retrospective analysis of the prevalence of imprinting disorders in Estonia

M. Yakoreva[1,2], **T. Kahre**[1,2]*, E. Õiglane-Shlik[2,3], M. Vals[1,2,3], P. Mee[4], K. Õunap[1,2];*
[1]Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia, [2]Department of Pediatrics, Faculty of Medicine, University of Tartu, Tartu, Estonia, [3]Children´s Clinic, Tartu University Hospital, Tartu, Estonia, [4]United Laboratories, Tartu University Hospital, Tartu, Estonia.

Introduction: Imprinting disorders (IDs) are a group of rare congenital diseases affecting growth, development and metabolism. The cause of IDs is an aberrant expression of imprinted genes due to genetic or epigenetic abnormalities. At present, there are eight clinically well-recognized IDs. Because of high variability of clinical phenotype and molecular alterations, the exact prevalence of IDs is not known.
Methods: In this study we retrospectively reviewed records of all Estonian patients with molecularly confirmed ID diagnosis during the period 1998-2014.
Results: A total of 52 individuals with IDs were identified. 46% (24) of them had Prader-Willi syndrome (PWS), 23% (12) Angelman syndrome (AS), 13%(7) Beckwith-Wiedemann syndrome (BWS), 12% (6) Silver-Russell syndrome (SRS), 2% (1) Temple syndrome (TS), 2% (1) pseudohypoparathyroidism Ib (PHP-Ib) and 2% (1) transient neonatal diabetes mellitus (TNDM). No cases of Kagami-Ogata syndrome have been found. The age of diagnosis varied between 0.03 and 83 years. All cases of TS, PHP-Ib, TNDM and the most cases of SRS and BWS were diagnosed in the last 4 years due to new diagnostic tests. During the period 2004-2014 birth prevalence of PWS in Estonia was 1/13,634 live births (~1/18,000 worldwide), AS 1/32,722 (~1/16,000), BWS 1/40,903 (~1/13,000) and SRS 1/54,537 (~1/70,000). Thus the total prevalence of IDs in Estonia is 4/100,000.
Conclusions: The introduction of new diagnostic methods allows todiscover cases of rare and atypical IDs. Further studies are needed to determine the exact prevalence and etiological mechanisms of IDs. This work was supported by the Estonian Research Council grant PUT355.

PS17.23
Strategies to correct the epigenetic path KDM5C-H3K4me3 damaged in XLID/Epilepsy diseases

L. Poeta[1]*, S. Zucchelli[2], A. Padula[1], A. Ranieri[1], S. Filosa[3,4], P. Collombat[5], M. B. Lioi[6], L. Altucci[1,7], S. Gustincich[2], M. G. Miano[1];*
[1]IGB-CNR, Naples, Italy, [2]SISSA, Trieste, Italy, [3]IBBR-CNR, Naples, Italy, [4]Neuromed, Pozzilli, Italy, [5]Inserm, Nice, France, [6]University of Basilicata, Potenza, Italy, [7]SUN, Naples, Italy.

Mis-steps in histone methylation-demethylation rounds have been directly involved in several forms of Intellectual Disability (ID) with Epilepsy. Lysine-specific demethylase 5C (KDM5C) is an X-linked gene which encodes a chromatin JmjC eraser with H3K4me2/3 demethylase activity. It is mutated in a spectrum of XLID and/or malignant Epilepsy and functions as a transcriptional repressor interacting with REST/NSRF, a master epigenetic hub critical for transition of neural progenitors to neurons. Noteworthy, a defective KDM5C-H3K4me3 path has been found in association with a mis-regulation of XLID/Epilepsy effector genes.
We report here methods to correct KDM5C fault by testing epi-drugs and RNA-based technology to target KDM5C-H3K4me3 axis. To this end, we used neuronally-differentiated Arx KO/Kdm5c-depleted ES cells, which show GABAergic abnormalities in association with a global increase of H3K4me3 signal. We have undertaken an in vitro analysis of a number chromatin compounds aiming of modifying the accessibility of the KDM5C transcription machinery. A strong up-regulation of Kdm5C/KDM5C has been obtained in presence of an inhibitor of HDAC at different points of in vitro differentiation, both in WT and Kdm5C-defective cells.
In addition, we generated synthetic lncRNAs antisense to KDM5C. In transfected cell lines, HEK293T and P19, we obtained increased levels of endogenous KDM5C protein. Given the H3K4 demethylase activity of KDM5C, we therefore tested the level of H3K4me3 and verified that the increase amount of KDM5C inversely correlates with a decrease in H3K4me3 signal. However, the snapshot of this captivating stratagems may become more well-defined once we will decipher the downstream effect of KDM5C upregulation in Arx KO/Kdm5C-depleted ES cell line.

PM17.24
Key regulatory transcription factors shaping the DNA methylome of breast cancer molecular subtypes

N. Fernandez-Jimenez*, V. Cahais, D. Degli Esposti, S. Ecsedi, H. Hernandez-Vargas, Z. Herceg;*
IARC, Lyon, France.

Lowly methylated regions (LMRs), non-CpG island *loci* that usually contain specific transcription factor (TF) binding sites, have been suggested to act as regulatory elements that define cellular identity. To date, LMRs have not been reported in breast cancer (BC). In this study, we aimed to identify the key subtype-specific TFs that shape the breast cancer methylome. We selected subtype-specific LMRs using whole bisulfitome data available at TCGA. Differentially methylated regions (DMRs) within the BC subtype-specific LMRs were selected by comparing tumors and normal tissues in a larger TCGA cohort assessed by Illumina 450K arrays. Finally, we performed TF enrichment analyses in the identified DMRs and calculated Pearson's correlations between the methylation levels of the *loci* presenting subtype-specific TF motifs and the expression of the nearest genes. We found 4,409 and 4,711 differentially hypomethylated positions for basal and luminal subtypes, respectively, among which 1,062 positions were shared by both subtypes. These positions could be grouped into 1,185 and 1,358 DMRs, respectively. In addition, basal LMRs were depleted on *FOXD3* and enriched on *EBF1* motifs, which had previously been associated to basal BC. The methylation levels of the regions containing *EBF1* motifs showed a strong negative correlation with the expression of 719 genes, including *BTS2*, *CD74*, *CDCP1* and *SLPI*, putative oncogenes known to be specific for basal type and/or poor outcome BC cases. Together, our results establish a link between master TFs and cancer-specific DNA methylation profiles and highlight our workflow as a powerful strategy in the search of subtype-specific therapeutic targets.

PS17.25
Analysis of a potential interaction between the WNT10A- and the EBF1-risk loci for male pattern baldness

L. M. Hochfeld[1]*, A. Woitecki[2], K. Pernhorst[2], B. F. Basmanav[1], S. Schoch[2], R. C. Betz[1], M. M. Nöthen[1], S. Heilmann-Heimbach[1];*
[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]Department of Neuropathology, University of Bonn Medical Center, Bonn, Germany.

Molecular genetic studies have identified at total of twelve genetic risk loci for male-pattern baldness (MPB). Among them two loci on chromosomes 2q35 and 5q33.3 located intronically within WNT10A and EBF1, respectively. Expression analyses indicated an allele-specific regulatory effect of the lead-SNP rs7349332 at the 2q35-locus on WNT10A-expression (Heilmann et al, 2013). Database research revealed that rs7349332 is in strong linkage disequilibrium with rs3856551. Interestingly, this variant is located within a binding site for the transcription factor EBF1, which suggests a potential functional interaction between the two loci. Here, we hypothesized the MPB-risk variant rs3856551 causes an allele-specific difference in the binding affinity of EBF1 to its target site at 2q35 that result in the observed differences in WNT10A-mRNA-expression.
To functionally prove this interaction, we performed in vitro luciferase assays in human keratinocytes by co-transfecting a luciferase construct containing the computationally predicted WNT10A promoter sequence, the 2q35-EBF1 binding site with either the C- or the T-allele for rs3856551, and an EBF1-expression vector. Our experiments indicate that EBF1 is able to activate the WNT10A promoter and point towards a significantly weaker activation for the rs3856551 C-allele. Our results therefore suggest a so far unknown functional interaction between the two MPB risk loci on 2q35 and 5q33.3. Additional experiments are ongoing to further prove this functional interaction. This may eventually help to elucidate the underlying molecular

mechanisms at these two MPB risk loci.

PM17.26

An investigation into the variation of mitochondrial methylation across different regions of post-mortem human brain.

M. A. M. Devall[1], *M. Weedon*[1], *J. Burrage*[1], *J. Mill*[1,2], *K. Lunnon*[1];
[1]*University of Exeter, Exeter, United Kingdom,* [2]*King's College, London, United Kingdom.*

Mitochondrial dysfunction has been implicated in Alzheimer's disease. We recently demonstrated that epigenetic dysfunction is seen in the nuclear genome in Alzheimer's disease brain and blood. Mitochondria are a unique cellular organelle in that they possess their own unique genome of ~16kb and encode for 37 genes. We hypothesise that mitochondrial dysfunction in Alzheimer's disease may be driven by epigenetic changes in the mitochondrial genome. As no study has previously investigated this phenomenon in human post-mortem tissue, we investigated whether differences can be seen in mitochondrial DNA methylation between different anatomical regions of the brain using sequencing approaches. We identified 16 significantly differentially methylated regions (DMRs) ($p<0.05$) in 9 of the 37 mitochondrial-encoded genes between the cortex and the cerebellum. As over evolution, regions of the mitochondrial genome have inserted themselves into the nuclear genome (nuclear-mitochondrial pseudogenes (NUMTs)) we decided to bioinformatically account for these in our analyses, leading to dramatic changes in DMR calling (13 from 9 genes). This data highlights the importance to correct for NUMTs not only in mitochondrial genetic studies but also in epigenetic studies. Further, the data is the first to our knowledge to identify DMRs using these methods in the mitochondrial epigenome between different brain regions.

DNA methylome profiling of human tissues reveals global and tissue-specific methylation patterns

N. Tõnisson[1,2], *K. Lokk*[1,2], *V. Modhukur*[3], *B. Rajashekar*[3], *K. Märtens*[3], *R. Mägi*[1], *R. Kolde*[3], *M. Koltsina*[4], *T. K. NIlsson*[5], *J. Vilo*[3], *A. Salumets*[6,7,8];

Background
DNA epigenetic modifications, such as methylation, are important regulators of tissue differentiation, contributing to processes of both development and cancer. Profiling the tissue-specific DNA methylome patterns will provide novel insights into normal and pathogenic mechanisms, as well as help in future epigenetic therapies. In this study, 17 somatic tissues from four autopsied humans were subjected to functional genome analysis using Illumina's Infinium HumanMethylation450 BeadChips that cover above 486,000 CpG sites.
Results
Only 2% of the CpGs analyzed are hypermethylated in all 17 tissue specimens; these permanently methylated CpG sites are located predominantly in gene-body regions. In contrast, 15% of the CpGs are hypomethylated in all specimens and are primarily located in regions proximal to transcription start sites. A vast number of tissue-specific differentially methylated regions are identified and considered likely mediators of tissue-specific gene regulatory mechanisms since the hypomethylated regions are closely related to known functions of the corresponding tissue. Finally, a clear inverse correlation is observed between promoter methylation within CpG islands and gene expression data obtained from publicly available databases.
Conclusions
This genome-wide methylation profiling study identified tissue-specific differentially methylated regions in 17 human somatic tissues. Many of the genes corresponding to these differentially methylated regions contribute to tissue-specific functions. Future studies may use these data as a reference to identify markers of perturbed differentiation and disease-related pathogenic mechanisms.

Combined overexpression of 3 microRNAs leading to autophagy dysfunction as a new pathophysiological mechanism in Hutchinson-Gilford Progeria Syndrome

E. KASPI[1,2,3], *M. MONDOLONI*[1,2], *S. PERRIN*[1,2], *A. ROBAGLIA-SCHLUPP*[1,2,3], *J. ENRICH-BENGOA*[1,2], *N. BANZET*[3], *D. SALGADO*[1,2], *D. DEPETRIS*[1,2], *C. NAVARRO*[1,2], *N. LEVY*[1,2,3], *A. DE SANDRE-GIOVANNOLI*[1,2,3], *P. CAU*[1,2,3], **P. ROLL**[1,2,3];

The Hutchinson-Gilford Progeria Syndrome (HGPS) is a rare genetic disease with accelerated aging, due to the accumulation in nucleus of a toxic protein called progerin, leading to abnormal gene expression and potential microRNA (miRNA) deregulation. To evaluate the role of miRNAs in HGPS, we conducted an in vitro miRNome analysis on dermal fibroblasts by studying 5 patients and 5 healthy individuals of different ages at early (P12+/-2) and late passages (P22+/-2). We identified 29 deregulated microRNAs in more than 50% of patients (15 overexpressed, 14 underexpressed) with different deregulation profiles depending on their age and passage in vitro. We identified 4 interesting potential targeted pathways linked to aging/Progeria: cell cycle and proliferation, senescence, inflammation and autophagy for which 3 microRNAs target central actors of this pathway. No significant difference between patients and controls was detected for 3 autophagy makers on western blotting. However, using flow cytometry, allowing quantification of autophagy level cell by cell, we observed in a 14 yo patient exhibiting the most miRNA deregulated profile, a majority of cells having no autophagy. Our hypothesis is that the overexpression of the 3 autophagy inhibitor miRNAs act as a "brake" on autophagy, leading to a decrease of progerin degradation, and finally to a pathophysiological vicious cycle. We will now confirm this hypothesis by transfecting antagomirs on cellular model. We will also evaluate this mechanism in our HGPS LAKI mouse model and in the context of physiological aging, during which progerin is also produced.

Introduction: Neural tube defects (NTDs) are severe congenital malformations that arise from the failure of neurulation during embryonic development. Though family- and population-based studies have confirmed a genetic component, responsible genes for NTDs in humans are still largely unknown. Based on the hypothesis that folic acid prevents NTDs by stimulating methylation reactions, epigenetic factors, such as DNA methylation, are predicted to be involved in NTDs.
Materials and Methods: Methylome analysis using the 450K array was performed using leukocyte DNA of 10 myelomeningocele (MMC) patients and 6 controls. A case-control validation study with the Sequenom Epityper analyzed selected candidate loci with altered methylation in larger cohorts (83 MMC and 30 controls). Gene overexpression studies and phenotype analysis in a zebrafish model of neural tube formation are ongoing.
Results: First, analysis of methylome data using a candidate pathway approach identified *HOXB7* as risk factor for NTDs. Interestingly, *HOXB7* hypomethylation was confirmed in the validation study and *HOXB7* overexpression in zebrafish resulted in NTDs. Secondly, genome wide analysis of the methylome data showed significant hypomethylation of 7 candidate loci that could also be validated with the EpiTYPER. Third, gene prioritization analysis based on functional protein associations, discovered interesting candidate loci.
Conclusions: Our data implicate DNA hypomethylation as risk factor for NTDs with at least 8 novel candidate genes underlying NTDs.

DNA 5-Hydroxymethylation in human adipose tissue differs between subcutaneous and visceral adipose tissue depots

K. Rohde[1], *M. Keller*[1], *M. Stumvoll*[1,2], *A. Dietrich*[1,3], *M. Blüher*[2], *Y. Böttcher*[1];
[1]*IFB Adiposity Diseases, University of Leipzig, Leipzig, Germany,* [2]*Department of Medicine, University of Leipzig, Leipzig, Germany,* [3]*Department of Surgery, University of Leipzig, Leipzig, Germany.*

Background: Epigenetic mechanisms such as DNA methylation at the 5-carbon of cytosine (5-mC) were shown to have tissue specific patterns and play a role in post-transcriptional regulation of gene expression. While 5-mC is well studied, the discovery of a stable intermediate during DNA de-methylation (5-hydroxymethylcytosin (5-hmC)) raises questions about its function and distribution. The aim of this study was to test whether 5-hmC exists in human subcutaneous (SAT) and visceral adipose tissue (VAT) and correlates with anthropometric and metabolic parameters.

Materials and methods: We used a sample set of 81 subjects (42 women and 39 men) to measure the % 5-hmC content in both SAT and VAT by using ELISA technology. To test for associations with anthropometric and metabolic parameters we used paired students t-tests, bivariate correlation analyses and linear regression models.
Results: We observed an average 5-hmC content of 0.47 % ± 0.093 in SAT, while VAT (0.51% ± 0.122) is significantly higher hydroxymethylated (P = 0.005). In the total cohort we observed a positive association of % 5-hmC in VAT with age (P = 0.034). Furthermore, we identified a significantly negative relationship between % 5-hmC in VAT and LDL cholesterol levels which withstands adjustment for covariates and remains significant after correction for multiple testing (P = 0.008).
Conclusion: Our data suggest adipose tissue depot specific 5-hmC levels with significantly higher levels in VAT.

Hyperactive Rho-kinase signalling due to Oligophrenin-1 loss of function induces nuclear import of class IIa Histone Deacetylase (HDAC7) and downregulation of orphan nuclear factor NR4A1.

C. Compagnucci, S. Barresi, S. Petrini, E. Bertini, **G. Zanni**;
Bambino Gesù Children's Hospital, IRCCS, Rome, Italy.

Rho-kinase (ROCK) has been well documented to play a key role in RhoA-induced actin remodeling. ROCK activation results in Myosin light chain (MLC) phosphorylation either by direct action on MLC kinase (MLCK) or by inhibition of MLC phosphatase (MLCP), modulating actin-myosin contraction. We found that inhibition of the ROCK pathway in induced pluripotent stem cells, leads to nuclear export of HDAC7 and transcriptional activation of the orphan nuclear receptor NR4A1 while in cells with constitutive ROCK hyperactivity due to loss of function of the RhoGTPase activating protein Oligophrenin-1 (OPHN1), the orphan nuclear receptor NR4A1 is downregulated. Our study identify a new target of ROCK signaling via Myosin Phosphatase Subunit (MYPT1) and Histone Deacetylase (HDAC7) at the nuclear level and provide new insights in the cellular functions of ROCK.

PM17.32

Cardiovascular GWAS PEAR1 SNP stimulates its intronic enhancer activity via DNA methylation

B. Izzi[1], *M. Pistoni*[2], *M. Criel*[1], *K. Cludts*[1], *C. Verfaillie*[2], *P. Verhamme*[1], *K. Freson*[1], *M. F. Hoylaerts*[1];
[1]*Department of Cardiovascular Sciences, Center for Molecular and Vascular Biology-KULeuven, Leuven, Belgium,* [2]*Department Development and Regeneration, Stem Cell Institute, University of Leuven, Leuven, Belgium.*

Platelet Endothelial Aggregation Receptor-1 (PEAR1) is a cell-cell contact protein mainly expressed in platelets and endothelial cells. A common genetic variant in PEAR1 (rs12041331) influenced platelet aggregation in aspirin-treated high-risk CVD patients. Reduced PEAR1 expression and decreased blood platelet function have been associated with the minor A-allele of this SNP (G>A) that is located in intron 1 of PEAR1. We aimed to unravel the mechanism by which this non-coding SNP leads to changes in PEAR1 expression.
Luciferase assays in HEK293 cells transfected with the pGL3-promoter vector showed that the intronic region containing the G allele possesses significantly higher transcriptional activity compared to the A allele ($p<0.05$). The G allele induces a potential CpG unit in this intronic region that can be methylated. Bisulfite-sequencing of rs12041331 in leukocyte DNA samples from 10 G/G healthy individuals showed that the cytosine at this position is indeed fully methylated. EMSA experiments showed that the rs12041331 region (chr1:156869698-156869731) containing the methylated G allele strongly interacts with EAHY926 endothelial cells nuclear proteins compared to the presence of the non-methylated G allele or the A allele.
ChIP experiments using DNA from EAHY926 endothelial cells and CHRF megakaryocytic (platelet progenitor) cells showed a significant enrichment of the active enhancer-specific histone mark H3K4me1 for the rs12041331 region.
In conclusion, we have found evidence that the rs12041331 SNP containing intronic PEAR1 region functions as transcriptional enhancer. Moreover, the methylated G-allele is associated with increased enhancer activity, which could explain the association of this SNP with changes in platelet reactivity important for CVD.

Transcriptome analysis by next-generation sequencing (RNA-seq) allows a deep investigation of RNA expression and could be a powerful approach to identify networks of genes that play a role in disease. We investigate the transcriptome using HiSeq 2500 platform (Illumina) followed by differential gene expression analysis of samples derived from two patients affected by Bloom's syndrome and three unaffected controls. The raw data were processed and analyzed using two different methodologies: Bowtie2 and EdgeR programs with filtering and the Rsubread and DESeq2 programs without filtering. The genes found differentially expressed underwent a functional enrichment analysis by DAVID. The analysis showed a highly complex transcriptional setting with upregulated differentially expressed genes associated to activation and regulation of immune pathways. Our results suggest that immune responses can be most active in these patients in order to compensate for a probable post transcriptional imbalance leading to genomic instability in patients with Bloom's Syndrome.

Systemic Sclerosis (SSc) is a complex autoimmune disease of unknown etiology. The SSc is characterized by vascular dysfunction and excessive accumulation of extracellular matrix, resulting in progressive fibrosis leading to the failure of the affected organs. Previous studies identified specific deregulation of miRNAs involved in autoimmune, vascular or fibrotic processes in skin samples from patients with SSc. Moreover, a specific miRNA profile is expected to be found also in blood samples from SSc patients that might be useful as biomarkers for diagnosis prognosis or disease severity. We obtained the transcriptional profiling of 17 PBMC from SS patients and 10 control samples using the methodology of massive sequencing of miRNAs by the small RNA-Seq Illumina technology. Illumina sequencing unaligned reads data were aligned to the human subset of miRBase21 with novoalign (novocraftv3). Known miRNAs had a broad range of expression level. There were aprox. 330 mature miRNAs with more than 10 sequence reads and 32 miRNAs with more than 10.000 sequence reads. Differential expression analysis revealed 17 miRNAs significantly different between peripheral blood samples from SSc patients comparing to controls. 12 of them were found downregulated in SSc samples. Among these miRNAs, we detected miR-29a, miR-29b, miR-150, let-7g, miR-145, and miR-31 which were also found deregulated in the skin of patients with SSc. Other miRNAs not yet associated with the disease were also found. Analysis of blood cells miRNA expression may be useful to characterize the differential expression affecting immune cells, and to identify novel differentially expressed miRNAs associated with SSc.

Introduction: Binding of transcription factors (TFs) to specific DNA sequences is essential for regulating the spatial and temporal expression of

genes. Approximately 10 % of known genes code for TFs, and with the FANTOM5 project TF expression profiles have been firmly linked to gene expression profiles in multiple tissues and cell types. Studies indicate that common variants have low likelihood of falling within transcription factor binding sites (TFBSs), indicating purifying selection. Though tools like FunSeq2 have been developed that can predict breaking or conserving effects of variants on TFBSs, the genome-wide impact of known variants on TFBS activity remain largely unexplored.
Materials and Methods: A high quality catalogue of human variation obtained by sequencing, including more than 80 million variants, from 2504 individuals and 26 populations, available from the 1000genomes project were used for the analysis. Characteristics of genetic variants and their effects of TF binding scores, calculated using position weight matrices, were annotated using a custom script interacting with the ENSEMBL database.
Results: We defined different classes of genetic variants, based on their impact on binding scores, and identify the most functionally relevant category, by performing enrichment analyses with variant sets from genome-wide association studies and different categories of diseases.
Discussion: Our work provides a more comprehensive genome-wide picture of the impact of genetic variation on TFBSs. The identification of rare variants, more likely to play a role in different pathologies, through the activity of TFs, will help better annotation and understanding of the results of future sequencing studies.

PS17.37
Exposure to ultraviolet radiation B has an acute effect on gene expression in blood

M. Bustamante[1,2,3], *C. Hernandez[1,3,4], A. Tewari[5], G. I. Harrison[5], Y. Sarria[2,3,4], P. Dadvand[1,3,4], X. Estivill[2,3,4], J. R. Gonzalez[1,3,4], A. R. Young[5], M. Nieuwenhuijsen[1,3,4];*
[1]Centre for Environmental Epidemiology, Barcelona, Spain, [2]Centre for Genomic Regulation, Barcelona, Spain, [3]Pompeu Fabra University, Barcelona, Spain, [4]CIBER Epidemiología y Salud Pública, Barcelona, Spain, [5]King's College London, London, United Kingdom.

Introduction: Ultraviolet B (UVB) radiation, representing 5% of total solar UVR, is responsible for vitamin D production and suppresses the immune system locally and systemically, with potential beneficial effects for autoimmune diseases. We studied the effects of UVB on the whole blood transcriptome at different time points after exposure.
Material and Methods: Nine Caucasian males with skin type II and mean age 25 years were exposed to sub-erythemal UVB [whole body exposure of 2.5 standard erythema doses (SED)]. Blood samples were collected in PAXGene tubes before exposure (0h) and after 6h, 24h and 48h of exposure. RNA was extracted and mRNA libraries were prepared with the Illumina TruSeq mRNA Sample Preparation kit and sequenced in a HiSeq2000 equipment (100 nt, single reads).
Results: An average of 17.3 M reads per sample (SD: 4.6, min: 9.8M, max: 28.7M) were mapped on the human genome and approximately 22% of them represented globin genes. At 6h post exposure, 9 downregulated and 1 upregulated gene were detected at a False Discovery Rate (FDR) of 5%. The most relevant genes are: FLT3, a class III tyrosine kinase regulating hematopoiesis and involved in acute myeloid and lymphoblastic leukemia; CPM, a carboxypeptidase that participates in monocyte and macrophage differentiation; and FKBP5, a member of the immunophilin family, which plays a role in immunoregulation. No significant changes were identified at 24h or 48h, indicating a short-lived acute effect.
Conclusions: Exposure to UVB decreases expression of genes involved in immunoregulation in blood at 6h post exposure.

PS18.01
Admixture Analyses of phenotypes related to the metabolic syndrome in a Brazilian population

M. d. Andrade[1], *L. Xe[2], J. M. P. Soler[3];*
[1]Mayo Clinic, Rochester, MN, United States, [2]Boston University, Boston, MA, United States, [3]University of Sao Paulo, Sao Paulo, Brazil.

Background: We conducted admixture analyses of metabolic syndrome in the Baependi family study from the state of Minas Gerais, Brazil to better understand the basis of ethnic differences in the metabolic syndrome. Methods: The Baependi family study consists of 80 families and 1,109 subjects with complete clinical information and genotype data from Affymetrix 6.0 SNP chip. Genome-wide admixture analysis was performed to test whether local ancestry in this data was associated with any of the phenotypes in the metabolic syndrome using a mixed linear model adjusted for age, sex, principal components 1 and 2 and taking into account the family structure. Results: Admixture analysis was performed using PCAdmix, a principal components based algorithm for determining ancestry along each chromosome from a high-density genome-wide set of phased single nucleotide polymorphism (SNP) genotypes of admixed individuals. It returns a local ancestry estimate for haplotypes for each reference population. We used HapMap Phase 3 CEU and YRI samples and the HGDP Native American (NA) samples as the reference for PCAdmix. We observed an average local ancestry to be 0.69/ 0.13/ 0.18 across the genome for CEU/ YRI/ NA, respectively. We observed a peak on chr2p due to African ancestry for systolic blood pressure, on chr3 due to Native American ancestry for diastolic blood pressure, and on chrs 2q and5q due to African ancestry for truncal obesity. Conclusions: In summary, by performing association analysis using local ancestry help to understand the ethnic differences in phenotypes related to the metabolic syndrome better than the standard association analysis.

PM18.02
A candidate gene association study identifies DAPL1 as a female-specific susceptibility locus for age-related macular degeneration (AMD)

F. Grassmann, *B. H. F. Weber;*
Institute of Human Genetics, University of Regensburg, Regensburg, Germany.

Age-related macular degeneration (AMD) is the leading cause of blindness among white caucasians over the age of 50 years with a prevalence rate expected to increase markedly with an anticipated increase in the life span of the world population. To further expand our knowledge of the genetic architecture of the disease, we pursued a candidate gene approach assessing 25 genes and a total of 109 variants. Of these, synonymous single nucleotide polymorphism (SNP) rs17810398 located in DAPL1 (death associated protein-like 1) was found to be associated with AMD in a joint analysis of 3,229 cases and 2,835 controls from five studies (combined P = 1.15×10-6, OR=1.332 [1.187-1.496]). This association was characterised by a highly significant sex difference (Pdiff = 0.0032) in that it was clearly confined to females with genome wide significance (PADJ = 2.62×10-8, OR = 1.541 [1.324-1.796]; males: PADJ = 0.382, OR = 1.084 [0.905-1.298]). By targeted resequencing of risk and non-risk associated haplotypes in the DAPL1 locus, we identified additional potentially functional risk variants, namely a common 897bp deletion and a SNP predicted to affect a putative binding site of an exonic splicing enhancer. We show that the risk haplotype correlates with a reduced retinal transcript level of two, less frequent, non-canoncical DAPL1 isoforms. DAPL1 plays a role in epithelial differentiation and may be involved in apoptotic processes thereby suggesting a possible novel pathway in AMD pathogenesis.

PS18.03
Further analysis of human salivary and pancreatic amylase gene CNVs

N. Shwan, *J. A. L. Armour;*
University of Nottingham, Nottingham, United Kingdom.

The human amylase gene cluster is a highly copy number variable region. Salivary amylase (*AMY1*) copy number variation (CNV) has been correlated with the protein level, and high *AMY1* copy number appears to result from adaptation to a high starch diet[1]. Additionally, *AMY1* CNV has also recently been associated with body mass index (BMI)[2]. In the present study, we developed two PCR ratio assays to explore the pancreatic amylase (*AMY2*) variation, and a paralogue ratio test (PRT) for measuring *AMY1* copy number. Combining our results with previous PRTs and read depth analysis, we observed variation in the *AMY2* genes in the form of deletion or duplication of *AMY2A* and duplication of *AMY2A/AMY2B*.The frequency of these variations was different between the studied populations, in most of which *AMY2* CNV showed associations with *AMY1* copy number. The *AMY2* genes exhibit less extensive variation than the salivary amylase genes; most individuals have two copies of *AMY2A* and *AMY2B*. However, segregation analysis in African family trios revealed new arrangements of the pancreatic amylase genes. Some haplotypes harbour higher order duplication of *AMY2A/AMY2B*, extending to quintuplication of *AMY2A/AMY2B*. Furthermore, our results suggest that the PRT we developed is a simple, accurate and high throughput method for measuring *AMY1* copy number in a large set of samples.

Apolipoprotein E gene polymorphisms and lipid levels in patients with T1D

T. Hovnik[1], *G. Klančar*[1,2], *A. Švigelj*[1], *N. Bratina*[2], *K. Trebušak Podkrajšek*[1], *T. Battelino*[2,3];
[1]*Unit for Special Laboratory Diagnostics, University Children's Hospital, UMC Ljubljana, Vrazov trg 1, Ljubljana, Slovenia, Ljubljana, Slovenia,* [2]*Department of Endocrinology, Diabetes and Metabolic Diseases, University Children's Hospital, UMC Ljubljana, Bohoričeva 20, Ljubljana, Slovenia, Ljubljana, Slovenia,* [3]*Department of Paediatrics, Faculty of Medicine, University of Ljubljana, Bohoričeva 20, Ljubljana, Slovenia, Ljubljana, Slovenia.*

Introduction: Apolipoprotein E (APOE) genetic variants have a major influence on lipid metabolism and represent a risk factor for development of cardiovascular disease in type 1 diabetes (T1D) patients. The c.334T>C (rs429358) and c.472C>T (rs7412) genetic variants in gene encoding APOE determine 3 major alleles: e2, e3, e4 and 6 corresponding genotype combinations: e2/e2, e2/e3, e2/e4, e3/e3, e3/e4, e4/e4. The aim of this study was to determine the influence of APOE genetic variants on serum concentrations of total cholesterol (TC) and triglycerides (TG) in T1D patients.
Methods: The study population consisted of 260 unrelated T1D patients (137 male and 123 female, median age 17.8±4.4). Based on recommended limit lipid levels for T1D, the patients were divided into 2 groups with TC>4.4 mmol/L or TG>1.7 mmol/L and a group with normal TC≤4.4 mmol/L or TG≤1.7 mmol/L. APOE genotyping was performed using TaqMan genotyping assays. Independent t-test was used to compare the continuous parameters and chi-squared test to determine differences in allelic and genotype frequencies among patients.
Results: Patients with elevated TC or TG levels had higher body mass index and poor glycemic control (HbA1c). Additionally patients with elevated TC levels had higher body weight and increased diastolic blood pressure. Most common allele was e3 (84.8%) and most common genotype was e3/e3 (71.5%). Carriers of genotype combination e3/e4 (OR=2.31, 95%CI=1.18-4.49, P=0.012) or E4 allele (OR=2.42, 95%CI=1.25-4.69, P=0.008) have higher TC concentration.
Conclusion: In conclusion, serum lipid levels in T1D patients are significantly influenced by genetic background and not only the environmental factors.

Many genes contributing to asthma heritability remain undiscovered besides the firm susceptibility genes exposed to date. Most genome-wide association studies (GWAS) for the trait have been performed in northern European populations and have analyzed the genetic variation provided by HapMap. As genetic risks varies among populations, here we have performed a three stage GWAS with unrelated Spanish subjects, which harbors 4-20% North African admixture. By leveraging the information provided by The 1000 Genomes Project, we analyzed ~6.5 million common variants (MAF>5%, Rsq>0.3) in 380 asthma cases and 552 population-based controls, using the Axiom Genome-Wide CEU array (Affymetrix). We performed a prioritization of 18 loci associated at suggestive significance (p≤5x10-5) that were followed up in a second sample of 482 cases and 1209 controls and a third sample of 346 cases and 137 controls, genotyped using iPLEX Gold assays (Sequenom). Two loci (2q33.2, 3p14.1) were nominally associated in the second sample, while only 3p14.1 achieved nominal significance in the third sample as well. A fixed effects meta-analysis of the 3,106 individuals confirmed the association of 3p14.1 with asthma (OR=0.49, 95% CI=0.38-0.64, p=1.28x10-7). To our knowledge, this is the first GWAS of asthma in the Spanish population, allowing to identify a new susceptibility locus.

Glutathione S Transferase M1and T1 gene variants increases risk of asthma in Indian children: A case control study

P. Dixit, *S. Awasthi;*
King George`s Medical University, Lucknow, India.

Abstract
Background- Asthma is a complex genetic disorder. Glutathione S-transferases (GST) gene plays a major role in the detoxification of metabolites of oxidative stress resulting in inflammation leads to asthma. Therefore, the hypothesis that GSTT1 and GSTM1 gene variants are associated with asthma was examined.
Material and methods- Hospital based case-control study, 150 cases and 150 age and sex matched controls, aged 1 year -15 years were recruited. Cases included were those children presenting symptoms of asthma according to EPR 2007 and excluded were children with other respiratory diseases. Children with no present and past history of asthma were enrolled as controls. Spirometry was done in cases age ≥ 6 years. Binary logistic regression and chi square test are used to find out the association.
Results- Of 150 cases and 150 controls, GSTT1 null allele was found more prevalent in asthmatics (36 %) than in the controls (17.3 %), which yielded a nearly thrice fold risk towards asthma (OR=3.17, 95 %CI =1.86-5.42, p = 0.000). Increased risk of asthma was also found in individuals having GSTM1 null allele in asthma patients (46.6 %) than in controls (39.4 %) (OR=2.25, 95 %CI =1.39-3.63, p = 0.003). Value of FEV1/FVC ratio was significantly lower in asthmatics having GST gene variants (P value< 0.05).
Conclusions- GST gene variants increases asthma risk and also associated with decline lung function growth in Indian children.
Funding- Indian Council of Medical Research, India

The unique evolutionary signature of autism genes

E. Tsur, M. Friger, **I. Menashe***;*
Ben-Gurion University of the Negev, Beer Sheva, Israel.

Autism spectrum disorder (ASD) is a prevalent heritable neurodevelopmental disorder, characterized by social, and communication disabilities that greatly reduce reproductive fitness. The maintenance of such heritable and low-reproductive trait in the human population is an evolutionary enigma that likely left a signature in ASD genes. To test this hypothesis, we studied the allelic characteristics of 441 ASD genes and 15,144 non-ASD genes in a whole-exome sequencing dataset, which included data on 503,481 single-nucleotide variants (SNVs) in 1351 European Americans, and 1088 African Americans individuals. We discovered that ASD genes were significantly longer, and less variable than non-ASD genes (2684 vs. 1632 bp, and nucleotide diversity $\pi = 0.036$ vs. $\pi = 0.046$ respectively; $P<0.001$). The mutational dearth in ASD genes was particularly eminent when considering only SNVs with functional consequences, a possible effect of negative selection. Interestingly, ASD genes also showed signs of positive selection, but these were less evident ($P<0.09$). We used these genomic characteristics to generate a multivariate model that classified ASD from non-ASD genes with 72% accuracy. These finding suggest that ASD genes have a unique evolutionary signature that could be used to identify new candidate genes for this condition.

Identifying susceptibility variants for multifactorial human traits can be complicated depending on the understanding of the genetic background on which it arises. This is especially difficult in small, under-studied populations without readily-available control cohorts. In such populations, low-penetrance variants in complex disease can be challenging to confidently identify when normal variation and allele frequencies are uncharacterised. We present an investigation of biliary atresia (BA), a usually sporadic malformation of the biliary tree. Worldwide, BA leads to half of all paediatric liver transplants, and is always fatal without major surgical intervention. The causes of BA remain unknown; autoimmune processes and genetic background may both play a part. In *Māori* and Polynesian populations the incidence is elevated three-fold compared to Europeans. We have identified a large Maori family (iwi) exhibiting an extremely elevated incidence of BA (1:100–300). To circumvent some of the problems in studying complex traits in Maori we

have adopted a non-parametric, family-based approach to localise a presumptive genetic factor conferring this susceptibility. Assuming a single, segregating susceptibility factor contributes to BA in our family cohort, we have used the software Beagle, Germline and in-house methods to examine haplotype sharing between affected pairs across this family. We have constructed maps of long, Identical-By-State (IBS) segments across the collective genomes of affected individuals without reliance on pre-existing assumptions about allele frequencies, a definitive inheritance model or exclusion of unidentified phenocopies. Further work aims to integrate rare variation from next generation sequencing data to further resolve shared haplotypes and define candidate regions in which a susceptibility variant could lie.

PM18.10

Evaluating the association between candidate gene and disease status in genome-wide association studies: An enhanced version of Cochran-Armitage trend test

Z. Ghodsi, *M. Ghodsi, H. Hassani, K. McGhee;*
Bournemouth University, Bournemouth, United Kingdom.

Introduction: In genome-wide association (GWA) studies the evaluation of the association between candidate gene and disease status is widely carried out using Cochran-Armitage trend test. However, only a small number of research papers have evaluated the distribution of p-values for the Cochran-Armitage trend test. In this paper we explore the genetic association for case-control design that draw the inference of the equality of the genotype frequencies in case and control and thus introducing an enhanced version of Cochran-Armitage trend test.
Materials and Methods: simulation studies have been applied to demonstrate the validity of the proposed methods for the inference of trend test. In order to study the finite sample properties of them, Monte Carlo experiments are used. The proposed methods are simultaneously based on the same simulated data in order to provide a meaningful comparison of various algorithms. The simulations are done based on the 5000 iterations. In order to make a comparative evaluation of the procedures, we seek the certain desirable features such as the actual significance level.
Results: Both simulation studies and real data studies have been used to validate the theoretical results. The QQplot of the p-value of the proposed tests shows that the p-value using the introduced method fits more with the uniform distribution that admits this method can be nominated to draw the inference.
Conclusions: Based on achieved results it is concluded that the proposed method which needs less assumption in comparison with the conventional method can be successfully used to test the genetic association.

To date, the c.-23+1G>A (IVS1+1G>A) splice site mutation is one of frequent mutations in the GJB2 gene (MIM 121011, 13q11-q12) in patients with congenital deafness in certain populations of Eastern Europe, Caucasus, Middle East, Central Asia, Southern and Eastern Siberia. Previously, it was shown that this mutation is widespread in Yakutia (Eastern Siberia) due to founder effect. For reconstruction of haplotypes with mutation c.-23+1G>A and for comparative analysis with other populations of Eurasia (Mongolia and Turkey) 9 SNPs flanking the GJB2 gene and previously reported in (Tekin et al., 2010) have been used. Total sample was represented by 126 individuals homozygous for the c.-23+1G>A mutation: Yakuts (n=111), Tuvinians (n=6), Mongolians (n=4), Turks (n=3), Evenk (n=1), and Russian (n=1). Five different haplotypes were identified with variety among the Mongolians (4 haplotypes) and Yakuts (3 haplotypes). The reconstruction of haplotypes with a c.-23+1G>A mutation revealed common SNP-haplotype C-A-G-A-C-C-A-T-G, which is present in most of studied chromosomes of patients homozygous for this mutation: 100% for Tuvinians, Turks, Russian, and Evenk, 99% - for Yakuts, and 67% - for Mongolians. The results suggest that the c.-23+1G>A mutation in the GJB2 gene has a common origin in Eurasia.
Study was supported by the RFBR grants (14-04-01741_a, 15-44-05106-r_vostok_a, 14-04-90010_Bel_a.), Governmental contract # 6.656.2014/K, SBRAS Integration project #92, and grant of the Head of the Republic of Sakha (Yakutia) for young scientists, experts and students for 2015 (RG#76 from 02.06.2015).

Funded access to large prospective cohorts in Europe through the biobanking infrastructure BBMRI-LPC

O. Törnwall[1], *M. Johansson*[2], *B. Simell*[1], *P. Brennan*[2], *G. J. van Ommen*[3], *M. Perola*[4,5];
[1]*Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland,* [2]*International Agency for Research on Cancer, Lyon, France,* [3]*Leiden University Medical Centre, Leiden, Netherlands,* [4]*The National Institute for Health and Welfare, Helsinki, Finland,* [5]*Institute for Molecular Medicine Finland, Helsinki, Finland.*

Most of the present knowledge on diagnostics, diseases and drugs was obtained by careful investigation of human biospecimens and related medical data. Central for such investigations are biobanks that systematically collect and store biological samples with information of study individuals before and up to the onset of disease and beyond. A critical factor for success is facilitation of structured access to biobanked materials in an ethically- and privacy-compliant manner. In 2013, an EU-funded multinational BBMRI-LPC-project (Biobanking and Biomolecular Resources Research Infrastructure - Large Prospective Cohorts) was established in mission to facilitate 'free-of-charge' access to samples and health data across country borders through open scientific calls. BBMRI-LPC unites prospective study sets from 17 countries with 22 different cohorts involving over 1 million study participants.
The 1st BBMRI-LPC scientific call, released in July 2014, resulted in 9 proposals. Four of these, applying innovative technologies, notably metabolomics, to early discovery of various cancers and cardiovascular diseases, were approved. The proposals involved in total 18 prospective cohorts of which 11 are now active in their access procedures. In order to map the access steps and potential bottlenecks, BBMRI-LPC records the versatile procedures. Following the successful 1st call, BBMRI-LPC launches its 2nd call in March 2015 inviting researchers in EU-member and associated states to submit their cutting edge proposals on common chronic diseases. The poster describes the current records on 1st call access, and presents the specifics of the 2nd call, through which the unique prospective collections in Europe can yet again be harnessed for innovative research initiatives.

PS18.13

Evaluation of CVD genetic risk in the Lithuanian population

I. Domarkienė[1], *I. Uktverytė*[1], *L. Ambrozaitytė*[1], *R. Meškienė*[1], *N. Burokienė*[2], *V. Kasiulevičius*[2], *Z. A. Kučinskienė*[3], *V. Kučinskas*[1];
[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Clinics of Internal Diseases, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [3]*Department of Physiology, Biochemistry, Microbiology and Laboratory Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.*

According to Perk J et al., 2012 Lithuania is among the countries of very high cardiovascular disease (CVD) risk. Common CVD risk algorithms are non-universal and either overestimate or underestimate the risk. It is important to evaluate genetic risk factors in order to create an algorithm as a measure of an accurate CVD risk evaluation of local patients.
Lithuanian population is represented as 253 unrelated individuals (127 women and 126 men) recruited from the ethnolinguistic regions - Žemaitija (113) and Aukštaitija (140). DNA samples were extracted from venous blood either by phenol-chloroform or magnetic beads isolation methods. Genotyping was performed using the Illumina HumanOmniExpress-12 v1.1 assay. Sixty CVD-associated SNPs were selected for the analysis. The R v3.0.3 was used for statistical analysis.
The number of risk alleles per person in the population and intra-population groups (men and women, Aukštaičiai and Žemaičiai) was determined. The mean value was 55.81, median 56, mode 59, minimum value was 39 and maximum - 74. No statistically significant differences among intra-population groups were found. All individuals were divided into the groups by the number of risk alleles (39-50 (small); 51-62 (medium); 63-74 (large)). 68% of individuals fell into the medium and 13% into the large group. Risk alleles of SNPs have a small effect size and regarding their additive effect it can be

concluded that majority of the Lithuanian population individuals are at an average CVD genetic risk.

LITGEN project (VP1-3.1-ŠMM-07-K-01-013) is funded by the European Social Fund under the Global Grant measure.

Within the GABRIEL consortium we identified 17q21 as the major childhood asthma susceptibility locus. Here, numerous single nucleotide polymorphisms (SNPs) in high linkage disequilibrium spread across seven genes, covering 238 kb.

While the finding was widely replicated, it is yet unclear whether one or more causal SNPs exist in the region and to which genes the signal annotates. Therefore, we fine mapped the locus and evaluated how certain alleles influence disease susceptibility and genes expression.

Data was acquired for 1,454 children (763 asthmatics) from the German MAGIC and ISAAC II studies, using Illumina Chip and MALDI-TOF MS genotyping, direct sequencing, and imputation. Allele-specific *cis*-effects on the 17q21 genes expression were determined in peripheral blood mononuclear cells (PBMC) for selected asthma-associated SNPs in 50 adult non-asthmatics.

The initial genome-wide dataset provided information for only 36 SNPs from the 17q21 locus. We substantially increased the number of genotyped (n=68) and analyzed (n=156, 88 imputed) polymorphisms for their relation with asthma. Eighty-five of them showed disease associations (58 with $p<10^{-5}$). The major signals derive from five distinct tagging bins comprising *GSDMB-GSDMA* region, with rs8079416 being the top hit ($p=6.08*10^{-8}$). Association data was also available for variants of the recently validated *LRRC3C*. Polymorphisms (rs12603332, rs4795405 and rs8079416) located in a cluster, representing three highest association peaks, influence *ORMDL3* and *GSDMA* levels in PBMC [non-stimulated and cells, stimulated with allergens (PHA, Derp1, LpA and Ppg)] in an allele-specific manner.

Multiple 17q21 childhood asthma signals exist. The major peaks originate from the *GSDMB-ORMDL3-LRRC3C-GSDMA* region, suggesting that these genes could functionally underlie those associations.

PS18.15

Development of a comprehensive next-generation sequencing panel for UMOD and association analyses of SNPs and methylation in UMOD, UMODL1, and UMODL1-AS1 genes for kidney disease in multiple populations.

C. Y. Bailie[1], *A. P. Maxwell*[1,2], *A. McKnight*[1];

[1]*Queens University Belfast, Belfast, United Kingdom,* [2]*Regional Nephrology Unit, Belfast City Hospital, Belfast, United Kingdom.*

Chronic kidney disease (CKD) is a major problem worldwide, leading to end-stage renal disease (ESRD), with associated cardiovascular disease and premature mortality. *UMOD* encodes uromodulin (Tamm-Horsfall glycoprotein) which is protective against kidney disease and is associated with Mendelian and multi-factorial CKD.

Using www.ampliseq.com we designed a next-generation-sequencing panel to comprehensively sequence 23,928 bp extending ~2 kb up and downstream of *UMOD* on chromosome 16p12.3. There is 96.4% coverage of the entire region with 100% coverage of exons using 89 amplicons (125-375 bp) sequenced on an Ion Torrent Personal Genome Machine (PGM™) generating >900M aligned bases per 318 chip. Linkage disequilibrium was established for identified SNPs and common tag SNPs genotyped in 2,000 individuals using a case-control approach. A comprehensive literature review was conducted for *UMOD* to facilitate meta-analysis for SNPs that were present in more than three studies with similar kidney phenotypes.

Quantitative methylation data was available for 255 cases with CKD compared to 152 controls without kidney disease from three independent studies. Following stringent quality control, and adjustment for multiple testing, five CpG sites were associated in *UMOD*, with subgroup analysis for diabetic nephropathy revealing cg03140788 as the most significant with P=0.00000000037. We also considered *UMODL1* and overlapping *UMODL1-AS1*, revealing twenty-four associated CpG sites, with $P_{max}=2.9x10^{-32}$ (cg16624482) for non-diabetic ESRD.

We have developed a cost-effective approach for genotyping individuals or larger population-based cohorts using 20 ng of input DNA. Genes were characterised for SNPs and CpG sites. Strong association was observed for CKD, which was supported by independent replication.

PM18.16

Association between three gene polymorphisms and chronic periodontitis among Romanian population

C. Cristescu[1], *M. Niculescu*[1], *A. M. Craciun*[2], *D. Stefan*[2], *C. Serafinceanu*[2], *L. M. Berca*[3], *S. Spandole*[4], *I. Radu*[4], *A. Tudor*[4], *D. Cimponeriu*[4];

[1]*Titu Maiorescu University, School of Medicine and Pharmacy, Bucharest, Romania,* [2]*NIDNMD N. Paulescu, Bucharest, Romania,* [3]*National Institute of Research and Development for Food Bioresources, Bucharest, Romania,* [4]*Department of Genetics, University of Bucharest, Bucharest, Romania.*

Introduction: Chronic periodontitis (CP) is a multifactorial disease. The TGFb, IL6 and SELL gene polymorphisms may be involved in the aetiology of CP. The aim of this study was to analyze the association between chronic periodontitis and TGFb C-509T, IL6 G-174C and SELL C605T genetic polymorphisms in the Romanian population.

Materials and Methods: A total of 330 unrelated individuals, with at least 20 teeth in the oral cavity, were enrolled in the study. One hundred sixty five chronic periodontitis patients and 165 healthy controls were selected. The subjects were 44±3.8 (34-60) years old. Control subjects had no evidence of clinical attachment loss and they were age and gender matched with patients. The diagnosis of CP was made on the basis of standardized clinical criteria. The polymorphisms were genotyped using polymerase chain reaction-based methods.

Results: The distribution of the investigated polymorphisms in both groups was in Hardy-Weinberg equilibrium. When the polymorphisms were considered independently, only the TGFb C-509T was associated with CP ($p<0.05$). Additional factors seem to influence this association. The risk for CP was also increases by the association between TGFb and gender (risk was higher in women) or SELL 605T variant (p=0.001) and by the presence of IL6 -174C variant in smokers (p=0.05).

Conclusion: TGFb considered individually, or in association with gender and SELL 605T or IL6 -174C variants in smokers, was associated with CP in the Romanian population.

Susceptibility to colorectal cancer is influenced by interaction between genetic variants and plasma vitamin D level

M. N. TIMOFEEVA[1], *L. Zgaga*[1,2], *L. Ooi*[1], *P. Vaughan-Shaw*[1], *E. Theodoratou*[3], *M. Walker*[1], *A. Tenesa*[4], *S. Farrington*[1], *H. Campbell*[3], *M. Dunlop*[1];

[1]*Institute of Genetics and Molecular Medicine, University of Edinburgh and MRC Human Genetics Unit, W, Edinburgh, United Kingdom,* [2]*Trinity College Dublin, Dublin, Ireland,* [3]*Centre for Population Health Sciences, University of Edinburgh, Edinburgh, United Kingdom,* [4]*Roslin Institute, University of Edinburgh, Edinburgh, United Kingdom.*

Introduction: Vitamin D deficiency is associated with risk of colorectal cancer (CRC), however causality remains questionable. We investigated the possible role of gene-environment (GxE) interactions between genetic variants and plasma vitamin D levels on colorectal cancer risk.

Material and Methods: 3114 CRC cases and 2939 population based controls were collected as a part of Study of Colorectal Cancer in Scotland (SOCCS). Plasma was assayed for 25-OHD by liquid chromatography-tandem mass spectrometry. All sample were genotyped using Illumina HumanHap 240K/300K array (675 cases and 896 controls), Omni5M (131 cases), OmniExomeExpress array (1379 cases) or custom 50K Illumina Array (929 cases and 2043 controls). Logistic regression models with genotype-vitamin D interaction terms were adjusted for sampling month, age and gender. 115 normal colorectal mucosa samples with available Illumina HT12 expression

array were used to explore co-expression of vitamin D receptor (VDR) gene and the genes identified through GxE analysis.
Results: Initial scan for GxE interaction in the subset of 24,471 variants overlapping between different platforms identified variant at 19q13.41 reaching significance level after correction for multiple testing. When we constrained analysis to the subset of genes correlated with VDR expression level in normal mucosa ($p<0.05$, n=2932), an increase in genomic inflation factor ($\lambda=1.10$ vs $\lambda=1.02$ for overall analysis) was observed, suggesting enrichment for GxE interactions.
Conclusion: Preliminary GxE analysis identified a new candidate locus associated with the CRC risk. We observed enrichment for GxE interaction within genes correlated with VDR expression, suggesting a causal relationship between vitamin D and risk.
The work was funded by a CRUK Programme Grant (C348/A12076).

Genetic trace of postglacial and Neolithic movements in Southeast Asia

A. Brandão[1,2,3], *M. B. Richards*[3,4], *P. Soares*[1,5], *L. Pereira*[1,6];
[1]*Instituto de Investigação e Inovação em Saúde, Instituto de Patologia e Imunologia Molecular da Universidade do Porto (IPATIMUP), Porto, Portugal,* [2]*Instituto de Ciências Biomédicas da Universidade do Porto (ICBAS), Porto, Portugal,* [3]*Department of Biological Sciences, School of Applied Sciences, University of Huddersfield, Huddersfield, United Kingdom,* [4]*School of Biology, Faculty of Biological Sciences, University of Leeds, Leeds, United Kingdom,* [5]*Centre of Molecular and Environmental Biology (CBMA), Department of Biology, University of Minho, Braga, Portugal,* [6]*Faculdade de Medicina da Universidade do Porto, Porto, Portugal.*

Island Southeast Asia (ISEA) is still one of the less genetically characterized region in the world, and it is often absent from ancestry studies of the Pacific even though it is a key location for understanding the population history of that region. Recent genetic studies suggest that the simplistic and most widely accepted model of an Australo-Melanesian first settlement ~60 ka followed by an Austronesian expansion around 4.5 ka does not fully capture the complexity of ISEA demographic history. To clarify the main dispersal routes and their impact in ISEA population prehistory, we performed a comprehensive study with a total of 114 newly complete mtDNA genomes affiliated in haplogroups previously associated with several demographic events in SEA. The most-parsimonious phylogenetic trees were reconstructed including all published data. The statistical analyses included ρ statistics and maximum likelihood (ML) to estimate the coalescence times of clades, and Bayesian methods to evaluate changes in effective population size through time. Our results show two main demographic events contributing to the gene pool of ISEA populations. One was the result of climatic changes and subsequent landscape alterations which lead to the postglacial dispersal of mtDNA lineages N9a6a, R9ab1a1a, B4c1b2a2, B5b1c, F3b1 and possibly R9c1a from both Mainland and ISEA, representing the major signal in ISEA. However dispersal of Austronesian-speaking Neolithic populations from Taiwan towards insular SEA were detected introducing mtDNA lineages D5b1c1, B4b1a2, F1a4a and Y2a1, that together with previously analysed M7c3c, correspond to ~20% of ISEA lineages.

PS18.19
Candidate gene association study of chronic obstructive pulmonary disease using targeted high throughput sequencing

H. Matsson[1], *C. Söderhäll*[1], *H. Backman*[2], *A. Lindberg*[2], *E. Rönmark*[2], *B. Lundbäck*[3], *N. Dahl*[4], *J. Klar*[4];
[1]*Biosciences and Nutrition, and Center for Innovative Medicine, Karolinska Institutet, Huddinge, Sweden,* [2]*The OLIN studies, Sunderby Hospital of Norrbotten, Luleå, Sweden,* [3]*Krefting Research Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden,* [4]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden.*

Chronic obstructive pulmonary disease (COPD) is a relatively common lung disease in Sweden with severe impact on health and quality of life. Smoking is an important risk factor. Not all smokers develop COPD and non-smokers can be in elevated risk for COPD, suggesting genetic factors modulating lifetime risk. Today, little is known about the impact of genetic variation on COPD susceptibility, progress and severity.
Our aim is to investigate candidate genes, with emphasis on those important for lung development, for single nucleotide variants (SNVs) predisposing to COPD.
We captured and sequenced 22 genes implicated in lung development and 71 genes and regions previously associated with COPD. Subjects with COPD and controls without COPD were retrieved from the Swedish Obstructive Lung Disease in Norrbotten (OLIN) sample. Both groups were matched for age, gender, weight and height, and contain the same number of smokers.
We found 75 SNVs in significant association with COPD and all showed a strong effect size as either low or high odds ratios (0.2-8.1). These variants are mainly in genes that cluster in pathways associated with cell proliferation, which includes genes in branching morphogenesis of the lung pathways involved in lung development and damage repair.
Our results confirm previous findings but with higher effect sizes of associated variants compared to similar studies, most likely attributable to the genetic background in our study population. These findings support the idea that genetic variants affecting lung developmental genes are important determinants of adult lung function.

PM18.20
Common CNVs in a population-based cohort reveal several associations in the transcriptome and consecutive changes in the metabolome

H. Mattsson[1,2], *A. Joensuu*[1,2], *V. Salomaa*[1], *A. J. Kangas*[3], *P. Soininen*[3,4], *M. Ala-Korpela*[4,5,6], *J. Kettunen*[1,3,4], *M. Perola*[1,2,7];
[1]*National Institute for Health and Welfare, Helsinki, Finland,* [2]*University of Helsinki, Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland,* [3]*Computational Medicine, Institute of Health Sciences, University of Oulu, Oulu, Finland,* [4]*NMR Metabolomics Laboratory, School of Pharmacy, University of Eastern Finland, Kuopio, Finland,* [5]*Computational Medicine, Institute of Health Sciences, University of Oulu and Oulu University Hospital, Oulu, Finland,* [6]*Computational Medicine, School of Social and Community Medicine & Medical Research Council Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom,* [7]*University of Tartu, Estonian Genome Center, Tartu, Estonia.*

Copy-number variations (CNVs) are widespread structural changes in the genome having a global impact on the transcriptome, and also recognized risk factors for complex diseases. However, the functional contribution of CNVs to human health is still not well understood. The variability of gene expression is not explained by genetic diversity alone, therefore integration of systems-level information, omics data, will provide a better understanding of human biology and disease etiology.
To assess cis-effects of common CNVs on gene expression and on complex phenotypes in the Finnish population-based cohort DILGOM (N=510), we performed association analyses of CNVs to both the peripheral blood leucocyte transcriptome and nuclear magnetic resonance (NMR) spectroscopy -measured serum metabolome . We used linear regression to estimate the associations between 685 CNVs and expression levels of 37, 022 transcripts. A similar model was used for the serum metabolome, consisting of 31 lipid and lipoprotein-related metabolite measures.
After correction for multiple testing, 38 CNVs showed associations ($p<2.28e-06$) with gene expression levels and 14 of these CNVs showed further association ($p<0.05$) with metabolite levels. As an interesting example, a CNV in region 17q12 associated with SLFN13 and the ratio between apolipoproteins apoB and apoA1 in women ($p=2.12e-04$). Furthermore, the DILGOM sample seven-year-follow-up of transcriptomic and metabolomic profiles will soon allow us to perform an intra-cohort replication.
Our results suggest that integration of omics data is a powerful approach to reveal novel connections between phenotypic variation and genomic diversity.

PS18.21
Genomic diversity and distribution of CNVs in Lithuanian population

A. Urnikyte, *I. Domarkiene, I. Uktveryte, L. Ambrozaityte, R. Meskiene, V. Kučinskas; Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.*

Although copy number variation (CNV) has received much attention, the knowledge about CNV's characteristics as occurrence rate, distribution in genome among populations and within the same population is still insufficient. In this study, we used *Illumina 770K HumanOmniExpress-12v1.0* (and *v1.1*) arrays to examine diversity and distribution of CNVs in 286 healthy individuals of two main ethnolinguistic groups of Lithuanian population (Aukštaičiai, Žemaičiai) . For primary data analysis we employed *Illumina GenomeStudio™ Genotyping Module v1.9* and two algorithms, *cnvPartition 3.2.0* and *QauntiSNP 2.0* for high-confidence CNVs identification. In total, 478 autosomal CNVs were detected by both algorithms and those were clustered in 87 copy number variation regions (CNVRs), spanning ~12.5 Mb of genome (Table 1). At least 8.6% CNVRs were unique and had not been reported in the *Database of Genomic Variants*. Most of CNVRs (57.5%) were rare with frequency ≤1%, whereas common CNVRs with at least 5% frequency comprised only 1.1% of all CNVRs. About 30% of CNVRs were shared among Aukštaičiai and Žemaičiai and the remaining CNVRs were specific to each group. Many of the detected CNVs (66.3%) overlapped with known *UCSC* gene regions. CNV distribution analysis between ethnolinguistic groups showed the differences in CNV occurrence and frequency both in the indi-

vidual level and at the population level, however there were no statistically significant differences found (p-value 0.9585, α= 0.05).
Work supported by LITGEN project - European Social Fund under Global Grant Measure (VP1-3.1-ŠMM-07-K-01-013).

Analysis of genomic regions associated with Coronary Artery Disease reveals continental-specific risk SNPs in North African populations.

D. Zanetti, *M. Via, R. Carreras-Torres, E. Esther, M. Àlvarez, C. Ros-Surrá, P. Moral;*
University of Barcelona, Barcelona, Spain.

Coronary artery disease (CAD) is a complex disease and the leading cause of death in the world. Populations of different ancestry do not always share the same risk markers. In recent years, several genomic regions have been robustly associated with CAD in different genome-wide association studies mainly conducted on people of European descent. These kinds of data are lacking in African populations even though heart diseases are currently an important cause of premature death and disability.
In this study, 384 single nucleotide polymorphisms (SNP) located in four genomic regions associated with CAD (1p13, 1q41, 9p21 and 10q11) were analysed in a novel set of 274 case-control samples from Morocco and Tunisia with the aim of analyse for the first time if the associations found in European populations could be transferable also to North Africa.
The results indicated that the variation in these four genetic regions had an important role for CAD predisposition also in North Africa. However, the individual SNPs associated with CAD in Africa were different from those identified in Europe in most cases (1p13, 1q41, and 9p21). In addition, significant differences in the haplotype blocks and in the linkage disequilibrium patterns among North Africa and Europe were detected.
The disparity in markers associated to CAD susceptibility between North Africa and Europe is probably due to the significant population differences found in the chromosomal architecture of these 4 CAD risk regions.
This research was supported by the Ministerio de Ciencia e Innovación (CGL2011-27866).

PS18.23

Exome-sequencing in a large family-based and population-based study identifies a large-effect missense variant associated with depression

N. Amin, *F. de Vrij, R. Brouwer, J. van Rooij, A. G. Uitterlinden, W. F. J. van IJcken, S. Kushner, H. Tiemeier, C. M. van Duijn;*
Erasmus MC, Rotterdam, Netherlands.

Depression is a prevalent psychiatric disorder with a strong genetic component (40-50%). Efforts to uncover common genetic variation underlying depression have so far failed. Here we explored whether relatively large-effect-rare variants influence the risk of depression. To investigate high-risk genetic variants associated with depression, we adopted a step-wise approach. Within the Erasmus Rucphen Family (ERF) study, we identified families and individuals informative for the segregation of large-effect-rare variants using linkage and haplotype analyses with a sparse genome-wide genotyping array. We then used exome-sequence data of these individuals and the filtering approach to identify potentially high-risk variants. Next we associated the identified variants with depressive symptoms
in the ERF study (N=1,327). Finally, we replicated the findings in the population-based Rotterdam study (RS, N=2,356). We identified a missense C>T variant on chromosome 9p24 shared by affected haplotype carriers in the family. The variant was conserved and characterized as a damaging variant. The frequency of this variant was increased ~10 times (1.4%) in ERF compared to the general population (1000Genomes=0.16%). Carriers (N=51) were distributed across 5 generations. Significant association was observed with depressive symptoms (p-value=$9*10^{-04}$) giving an increase of depressive symptoms by 2.47 per-allele. The variant explained ~5% of the genetic variance of depressive symptoms in ERF. Significant association (p-value=0.032) and a large effect (effect=3.60) was observed on depressive symptoms in RS (N(carriers)=23). The gene harboring the C>T variant is a novel gene for depression. Functional studies are required to ascertain the mechanisms through which the variant influences the risk for depression.

Association analysis of thirty DNA sequence polymorphisms with diabetic retinopathy in Pakistan

M. Azam[1], *R. Qamar*[1], *N. K. Waheed*[2], *A. Azam*[3], *S. I. Maqsood*[4], *S. Bashir*[1], *COMSATS genomic research group;*
[1]*COMSATS Institute of Information Technology, Islamabad, Pakistan,* [2]*Tufts University Medical School, Boston, USA, Boston, MA, United States,* [3]*Institute of Ophthalmology, Mayo Hospital, Lahore, Pakistan,* [4]*Royal College of Ophthalmologists, Mersey Deanery, London, United Kingdom.*

Introduction: Polymorphic single nucleotide DNA sequence variations in components of different regulatory and metabolic pathways have been reported to be associated with diabetes and its related complications worldwide. In the present study we assessed the role of 30 such DNA polymorphisms in the onset of diabetes-induced retinopathy (DR) development in Pakistani type 2 diabetic subjects.
Materials and Methods: A total of 570 age and gender-matched individuals that included diabetic retinopathy (177=99 non-proliferative DR+78 proliferative DR), diabetic non-retinopathy (DNR; 193) and controls (200) were genetically screened for polymorphisms in *ACE*, *PAI-1*, *SDH*, *eNOS*, *PON1*, *GSTT1*, *GSTM1*, *GSTP*, *VEGF*, *RAGE*, *TNF-α*, *ATF6*, *HSP70*, *MTHFR* and *MMP9*. The genotyping techniques included allele specific PCR, RFLP and Sanger sequencing. Statistical comparisons were carried out by gender and subclinical class adjusted logistic regression analysis.
Results: Out of thirty SNPs studied, significant associations (p<0.05) were observed for *HSP70* with diabetes, DNR, DR and non-proliferative DR; *MTHFR* (rs1801133) with DNR; *SDH* (rs2055858) with DR and proliferative DR, *SDH* rs3759890 and rs2055858 were also found to have synergistic role in disease development; *VEGF* (rs1570360) with proliferative DR; *TNF-α* and *GSTT1M0* with proliferative and non-proliferative DR; *ACE* with non-proliferative DR.
Conclusions: This study of genetics of diabetic retinopathy in Pakistan revealed that there is significant associations with the disease of 7 polymorphisms, which are components of folate and homocysteine metabolism, angiogensis, polyol pathway, renin-angiotensin system, antioxidant pathway and heat shock protein, with different studied sub-classes of Pakistani type 2 diabetic subjects.

PS18.25

A case-control association study of diabetic retinopathy in Edinburgh Type 2 Diabetes Study

E. Sandoval-Garcia, *S. McLachlan, M. Strachan, J. F. Wilson, J. Price;*
Centre for Population Health Sciences, University of Edinburgh, Edinburgh, United Kingdom.

Background: Type 2 diabetes (T2D) is a serious public health concern resulting in a number of macrovascular and microvascular complications. Diabetic retinopathy (DR) is an important microvascular complication and a leading cause of blindness worldwide. DR is a complex trait, dependant on number of factors (e.g. glycaemic exposure, blood pressure), and increasing evidence suggests that genetic variation may also influence the susceptibility to DR. Previously published genome-wide association studies (GWAS) have identified loci underlying DR within the regions of 1q13-42, 2q31-47, 6q22-27 and 13q14-32. However, these loci have not been replicated yet and studies used different grading schemes which confound interpretation of results. We aimed to explore the data from the Edinburgh Type 2 Diabetes Study (ET2DS) to identify potential association of genetic variants with DR in T2D patients.
Methods: A case-control association study was performed in 299 diabetic cases with DR and 640 diabetic controls. Cases were characterised according to Early Treatment Diabetic Retinopathy Study (ETDRS) classification. Genotype data obtained by the Illumina MetaboChip® array was used for association analysis using PLINK. We used logistic regression analysis adjusted for sex, duration of diabetes, systolic and diastolic blood pressure and glycosylated haemoglobin.
Results: Despite being one the largest study of its kind to date in Caucasians, no significant associations between genetic variants and DR were found.
Conclusions: Further studies with an increased sample size are needed to identify loci associated with DR. The identification of new loci will reveal a better understanding of the aetiology of DR and could help to identify environmental factors contributing to the disease development.

PM18.26

Supporting human genetics research for 30 years, and into the future

A. Hiscott, *D. Blick, C. Phelps, J. Cooper;*
Public Health England, Salisbury, United Kingdom.

Public Health England's secure site at Porton Down this year celebrates 30 years of supporting human genetic research. In this time the European Collection of Cell Cultures (ECACC), has processed human blood samples, from tens of thousands of individuals and their family members, cryopreserving, storing and distributing, viable primary lymphocytes, cell lines and nucleic acids, to scientific researchers involved in the study of hundreds of genetic diseases. Originally established to support the Human Genome Mapping Project (HGMP) the service has evolved, and continues to enable the MRC DNA banking Network, the Wellcome Trust and dozens of industrial and academic groups and charity funded projects to achieve their goals. The service accurately processes thousands of samples in a high throughput manner with quality assurance supported by barcode tracking, testing of samples for sterility, and STR profiling to ensure that genetic identity is maintained from blood through to cell line and extracted nucleic acids. Cells are optimally cryopreserved and stored, in liquid nitrogen tanks in a dedicated warehouse, where samples can be confidently retrieved, even decades after storage. We show how our data management, human tissue authority (HTA), quality compliance systems, and infrastructure have adapted and developed over the last 30 years. The significant challenges of maintaining and developing this high quality system, in a not-for-profit organisation, adapting this infrastructure to help serve the emerging field of personalised medicine, and the development of large cohort induced pluripotent stem (iPS) cell banks are explained.

PS18.27

Epidemiology of Elis van Creveld syndrome in Europe: a registry based study

I. Barisic[1], *L. Boban*[1], *M. Loane*[2], *E. Garne*[3], *D. Wellesley*[4], *E. Calzolari*[5], *EUROCAT working group;*
[1]*Childrens University Hospital Zagreb, Zagreb, Croatia,* [2]*University of Ulster, Newtownabbey, United Kingdom,* [3]*Hospital Lillebaelt, Kolding, Denmark,* [4]*Wessex Clinical Genetics Service, Princess Anne Hospital, Southampton, United Kingdom,* [5]*Registro IMER, Azienda Ospedaliero-Universitaria di Ferrara, Ferrara, Italy.*

Ellis-van Creveld syndrome or chondroectodermal dysplasia (EVC, MIM 225500) is a rare autosomal recessive skeletal dysplasia characterized by short limbs and ribs, postaxial polydactyly, dysplastic nails and teeth and congenital heart defects. We present the largest population-based epidemiological study to date using data provided by the European Surveillance of Congenital Anomalies (EUROCAT) network of congenital anomaly registries. The study population consisted of 42 cases of EVC identified between January 1990 and December 2012 in 34 European registries. The mean prevalence of EVC was 0.53 per 100 000 births. There were 25 (59.5%) terminations of pregnancy after prenatal diagnosis, 2 (4.7%) fetal deaths, and 15 (35.7%) live births. The most common anomaly was polydactyly (27; 87.1%). Congenital heart anomalies, mostly septal defects, were present in 20 (64.5%) cases. Most cases (85.7%) are suspected prenatally at 18.8±4.2 (range 12-33) gestational weeks. The ultrasound examination usually reveals shortening of long bones, narrow thorax, hexadactyly and cardiac defects. Pregnancies are mainly (25/30, 83.3%) terminated at 20.1±4.6 gestational weeks, reducing the number of live births to one third of the total prevalence rate (0.19 per 100 000 births, or 1 in 528 044). In conclusion, EVC is a very rare disease affecting 1 in 188587 births. Early diagnosis is important for timely counselling of couples and multidisciplinary management of affected children. The study is part of the EUROCAT Joint Action funded by the EC, under the framework of EU Health Programme 2008-2013, Grant Agreement 20102204 (Executive Agency for Health & Consumers).

Genetic and Epigenetic Analysis of ELMO1 for Association with Kidney Disease

L. J. Smyth[1], *J. A. McCaughan*[1,2], *A. P. Maxwell*[1,2], *A. McKnight*[1];
[1]*Queen's University of Belfast, Belfast, United Kingdom,* [2]*Regional Nephrology Unit, Belfast City Hospital, Belfast, United Kingdom.*

End stage kidney disease (ESKD) is the most severe stage of chronic kidney disease (CKD). In 2011, the incidence of renal replacement therapy for ESKD in Europe was 117 per million population, creating substantial healthcare costs. Selected SNPs and differential methylation, with corresponding changes to gene expression of ELMO1, have been associated with CKD leading to dysregulation of extracellular matrix proteins. We sought to evaluate SNPs and CpG sites in ELMO1, performing a meta-analysis of independent studies and exploring relevant methylation quantitative trait loci (meQTLs).

A comprehensive literature review conducted for ELMO1 facilitated meta-analysis for SNPs that were present in greater than three studies with similar kidney phenotypes. The Infinium® methylation 450K BeadChip array (Illumina, Inc, USA) was used to analyse DNA methylation across the methylome in 255 CKD cases and 152 controls without kidney disease. Following stringent quality control, significant CpG sites in ELMO1 were identified. The top ranked CpG site for this gene was cg05642546 (P=4.8x10-27). Genome-wide SNP data (n=561,233 SNPs; 372 individuals) from the Illumina 660K array was analysed in PLINK with methylation data from CpG sites in the ELMO1 gene to identify meQTLs associated with ESKD and healthy individuals. No genome-wide significant cis-meQTLs were identified for ELMO1, however genome-wide significant results for trans-meQTLs appear to affect ELMO1 through regulatory effects.
We have provided a genomic map of ELMO1 that combines published and novel data to help resolve conflicting association data and suggest a mechanism of how ELMO1 influences kidney disease.

PS18.29

Exome analysis of rare and common variants within the NOD receptor pathway

G. Andreoletti[1], *T. Coelho*[1,2], *Y. Gao*[3], *N. Afzal*[2], *A. Batra*[2], *A. Williams*[3], *R. Beattie*[2], *S. Ennis*[1];
[1]*University of Southampton-Human Genetic & Genomics Medicine, Southampton, United Kingdom,* [2]*Southampton Children's Hospital, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom,* [3]*Cancer Sciences Division, Faculty of Medicine, University of Southampton, Southampton, United Kingdom.*

Background: Pediatric inflammatory bowel disease (PIBD) is a chronic gastrointestinal autoimmune disorder in which genetic predisposition plays a more substantial role. Rare and private mutations may have a stronger impact in the susceptibility of PIBD compared to common variants. This study looks at the burden of any coding mutation in PIBD patients within genes of the NOD2 pathway using data derived from exome sequencing.
Methods: Cases and controls were recruited through tertiary referral clinics at University Hospital Southampton. For all exomed patients, genomic DNA was extracted using the salting out method and the samples were exome sequenced at the Wellcome Trust Centre in Oxford. Data were aligned and tested for quality control by using the in-house pipeline and customised scripts. Association testing was conducted between disease status and population control using the SKAT-O test.
Results: 10 genes within the NOD2 pathway have been previously implicated in IBD by GWAS. We observed mutations in 39 of 40 genes comprising this pathway. Despite the small sample size (143 cases and 88 controls), SKAT-O test identified four genes associated with disease status ($p<0.05$). The evidence contributing to the association signal for these genes is primarily driven by rare variants that would not have been assessed in GWAS.
Conclusion: Within our small cohort SKAT-O showed a significant excess of burden of mutation in 4 genes: association was significant for two known IBD genes (NOD2 and IL6) and for two previously unreported genes (BIRC2 and BIRC3). Burden of mutations suggests the possible implication of BIRC2 and BIRC3 in PIBD.

PM18.30

Familial aggregation of late-onset FAP ATTR V30M: looking into asymptomatic carriers

C. Lemos[1,2], *T. Coelho*[3], *M. Alves-Ferreira*[1,2], *D. Santos*[1,2], *J. Sequeiros*[1,2], *A. Sousa*[1,2];
[1]*Instituto de Investigação e Inovação em Saúde (I3S); and UnIGENe, IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal,* [2]*ICBAS, Porto, Portugal,* [3]*Unidade Clínica de Paramiloidose, Centro Hospitalar do Porto (CHP), Porto, Portugal.*

Introduction: Familial Amyloid Polyneuropathy (FAP ATTRV30M) is an AD systemic amyloidosis, due to a point mutation in the transthyretin (TTR) gene. A wider age-at-onset (AO) variability was uncovered although in Portugal the disease has been characterized by its early onset (<40yrs). However, more and more late-onset (≥50yrs) cases are being ascertained, often matched with older asymptomatic parents. Our aim now was to look into aged-asymptomatic carriers group in order to unravel familial aggregation of late-onset.
Methods: From the largest registry worldwide we analyzed a group of 222 asymptomatic carriers on regular follow-up, aged ≥40 at last observation and their first-degree relatives, belonging to 122 families, using descriptive analysis and the Student's t-test.
Results: Age-at-last-observation varies between 40 and 49 for 103 subjects and was ≥ 50 for 119 of them. Mean age-at-last-observation was 54.06 (SD: 12.2; range: 40-89) and no gender differences were found. We were able to identify 92 transmitting-parents (59 fathers, 33 mothers) with AO. Their mean AO was 56.91 (SD: 12.8; range: 25-80) and no differences in AO were

found between parent's gender. Also, we found a mean AO close to 40 years for siblings of these asymptomatic carriers (mean: 39.91; SD: 8.89; range: 24-65).
Discussion: We confirmed familial aggregation of late-onset cases. We also found that for late-onset cases no gender differences are observed. Due to different clinical aspects of FAP in late-onset patients it is crucial to explore mechanisms that can be related with aging and protective factors that can lead to new therapeutic strategies.

PS18.31
Late-onset cases of FAP ATTR V30M may provide insights on genetic modifiers of age-at-onset (AO)

A. Sousa[1,2], *T. Coelho*[3], *M. Alves-Ferreira*[1,2], *D. Santos*[1,2], *J. Sequeiros*[1,2], *C. Lemos*[1,2];
[1]*Instituto de Investigação e Inovação em Saúde (I3S); and UnIGENe, IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal,* [2]*ICBAS, University of Porto, Porto, Portugal,* [3]*Unidade Clínica de Paramiloidose, Centro Hospitalar do Porto (CHP), Porto, Portugal.*

Introduction: Familial amyloid polyneuropathy (FAPATTRV30M) is an autosomal dominant systemic amyloidosis, due to a point mutation in the transthyretin (TTR) gene (chr18q12.1). Our registry in Porto (Portugal) has data on 2754 patients (678 families). Although mean AO is 35.3, an important group of late-onset cases (AO≥50) has been diagnosed in more recent years.
Our aim now was to study this group and its differences with early-onset cases.
Methods: Our analysis of 326 late-onset cases (133 families) comprised gender and also their transmitting parent. Descriptive analysis and Student's t-test were used.
Results: Age-at-onset was 60.03 for men and 59.25 for women (NS), as opposed to the general sample where women had a later onset (37.6) than men (33.4). Familial aggregation of late-onset cases is apparent, with some families having up to 11 late-onset cases. Out of 678 probands, ~40% had no affected parent at time of diagnosis, this figure being 86% (115/133) among late-onset probands. These parents had died with no signs of the disease mostly at old-age. No one had an affected parent with early-onset of the disease.
Discussion: While most of FAP probands had one affected parent (as expected in an AD disease), a significant number has a late-onset and no affected parent at time of diagnosis. The study of these families which are protected from the devastating effects of early-onset may provide important clues to disease mechanism and possible genetic modifiers.

PM18.32
Can up-regulation of ERK1/2 and MEK1/2 genes be associated with age-at-onset variability in familial amyloid polyneuropathy (FAP) ATTRV30M?

D. Santos[1,2], *T. Coelho*[3], *M. Alves-Ferreira*[1,2], *J. Sequeiros*[1,2], *I. Alonso*[1,2], *C. Lemos*[1,2], *A. Sousa*[1,2];
[1]*Instituto de Investigação e Inovação em Saúde (I3S); and UnIGENe, IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal,* [2]*ICBAS, Instituto Ciências Biomédicas Abel Salazar, Univ. Porto, Porto, Portugal,* [3]*Unidade Corino de Andrade (UCA), Centro Hospitalar do Porto (CHP), Porto, Portugal.*

Familial amyloid polyneuropathy (FAP ATTRV30M) is an autosomal dominant systemic amyloidosis, due to a point mutation in the transthyretin (TTR) gene. Among Portuguese families, FAP shows a wide variation in age-at-onset (AO) [19-82 yrs] and is characterized by extracellular amyloid deposits of fibrillary TTR and degeneration of peripheral nerves. Extracellular signal-regulated kinases 1/2 (ERK1/2) increase activation in salivary glands and nerves. ERK1/2 kinases (MEK1/2) activation was also up-regulated in peripheral nerves, with phosphorylation of ERK1/2. Therefore, this may represent an early signalling cascade leading to cytotoxic effects of TTR aggregates, resulting in earlier-onset.
Our aim was to study four candidate-genes in this pathway as genetic modifiers of AO in Portuguese FAP ATTRV30M families.
We collected a sample of 106 FAP families with 316 patients. We selected 37 tagging SNPs, genotyped by SNaPshot, sequencing and RFLP. Results were analyzed with the GeneMapper™ v.4.0 software.
We found four significant SNPs in MEK1 gene: rs8039880 (CC), rs11630608 (CC and CT) and rs745796 (GG), genotypes associated with earlier-onset; whereas the GA genotype of rs16949939 was significantly associated with later-onset. For MEK2 gene, only the TT genotype of rs1823059 was significantly related with later AO. For ERK1/2 gene, we did not find significant results.
This study reinforced the role of MEK1/2 genes in FAP signalling mechanism and AO variability. These findings may have important implications in genetic counselling and therapeutic strategies.

PS18.33
The frequency of the MEFV gene mutations and MEFV SNPs haplotypes determined with next generation sequencing technique in FMF patients

D. Aydin, *N. Sertdemir, N. Cine, B. Bilgen, P. Canbaz, H. Savli;*
Kocaeli University, Faculty of Medicine, Medical Genetic Department, Kocaeli, Turkey.

Familial Mediterranean Fever is an autosomal recessive disorder characterized by recurrent attacks of fever, abdominal pain, arthralgias, arthritis and development of amyloidosis over time. In our study, 735 patients who were send to Medical Genetics Department of Kocaeli University, between September 2012-June 2014 for routine diagnosis taken part. We aimed to determine the mutation and SNPs haplotype frequency of the patients MEFV gene who were scanned with the Next Generation DNA Sequencing technique and relationship between diagnostic criteria and detected mutations.
Among 735 patients, mutations were detected in 325 (%44), no mutations were detected in 410 (%56). M694V, E148Q, M680I G/C, V726A, K695R, R761H mutations with the ratio of %41, %17, %13, %8, %2, %2 were detected frequently in our patients respectively. The most frequent symptoms were; abdominal pain, arthritis, fever, chest pain, oral aphthae and erythema were detected with the ratio of %76, %72, %53, %40, %34, %23 respectively among MEFV mutated patients. R202Q alterations were detected in 307 (%42) patients.
Also we analysed MEFV SNPs haplotype among mutated patients. We detected 5 SNPs haplotype group among D102D, G138G, A165A and R202Q polymorphisms and 3 SNPs haplotype group among R314R, E474E, Q476Q, D510D polymorphisms.
Diagnostic power is thought to be increased with the scanning of whole gene with detection of rare mutations and polymorphisms together in FMF disease.
Using this technique in large number of patients are considered to be more meaningful in mutations frequency of the Turkish society studies and constitute a very important place in literature.

PM18.34
Consanguinity and founder effect for Gaucher disease mutation G377S in a population from Tabuleiro do Norte, Northeastern Brazil

R. G. Chaves[1,2], *L. V. Peireira*[3], *F. T. Araújo*[3], *R. Rozenberg*[3], *J. C. Coelho*[4], *K. Michelin-Tirelli*[5], *M. D. F. Carvalho*[6], *M. F. Chaves*[7], *G. B. Cavalcanti Jr.*[8];

ABSTRACT

INTRODUCTION: Gaucher's Disease (GD) is caused by a β-glucocerebrosidase (GCase) deficiency leading to the accumulation of glucocerebroside in the reticuloendothelial system. The prevalence of GD in Tabuleiro do Norte (TN) (1:4,000) is the highest in Brazil. The purpose of this study was to present evidence of consanguinity and founder effect for the G377S mutation (c.1246G>A) among GD patients in TN based on enzyme, molecular and genealogical studies. **METHODS**: Between March 2009 and December 2010, 131 subjects at risk for GD (GC in dried blood ≤2.19 nmol/h/mL) and 5 confirmed GD patients from the same community were submitted to molecular analysis to characterize the genetic profile of the population. **RESULTS:** Based on the enzymatic and molecular analysis, the subjects were classified into 3 categories: affected (n=5), carrier (n=20), and non-carrier (n=111). All carriers were (G377S/wt). Affected subjects were homozygous (G377S/G377S).
CONCLUSION: The identification of a single type of mutation in carriers and homozygotes from different generations, the history of the community and the genealogy study suggest that the high prevalence of GD in this population may be due to a combination of consanguinity and founder effect for the G377S mutation.

Table 1: Affected subjects, carriers and non-carriers of mutations for Gaucher's disease according to gender, age and enzyme activity (GCase activity in leukocytes and chitotriosidase activity in plasma).

Variables	Subjects according to genetic status			Total	*p*-value
	Non-carrier	Carrier G377S/wt	Affected G377S/G377S

Incidence of fragile X syndrome in Ireland - an all-Ireland study

J. J. O'Byrne[1], *M. Sweeney*[1], *D. E. Donnelly*[2], *D. Lambert*[1,3], *D. Beattie*[2], *C. M. Gervin*[2], *C. A. Graham*[2], *D. E. Barton*[1], *S. A. Lynch*[1];
[1]*Department of Clinical Genetics, Our Lady's Children's Hospital, Crumlin, Dublin, Ireland,* [2]*Northern Ireland Regional Genetics Centre, Belfast Health and Social Care Trust/City Hospital, Belfast, United Kingdom,* [3]*The Children's University Hospital, Temple Street, Dublin, Ireland.*

AIMS:
To determine the observed incidence of Fragile X Syndrome (FXS) in the Republic of Ireland (ROI) and Northern Ireland (NI) separately and combined. To compare these observed incidences to estimated worldwide incidences of FXS.
METHOD:
A retrospective clinical and lab database review of positive FXS cases, born between years 2000-2009 inclusive, in both ROI and in NI.
Inclusion criteria: i) Birth place: ROI/NI, ii) Birth year: 2000-2009, iii) FXS confirmed on clinical examination, iv) Full mutation allele (>200 CGG repeats), v) molecular test performed 2000-2014.
RESULTS:
The observed incidence of FXS in males and females, in both the ROI and NI, is ~1:11,000 and ~1:40,000-50,000 respectively. The analysis rate of FXS in ROI and NI is 0.8% and 1.3% of live births respectively however the male: female analysis rate ratio in both ROI and NI was determined to be ~4: 1.
CONCLUSIONS:
The all-Ireland study does not support the commonly held view that FXS is the most common single gene cause of inherited intellectual disability. This first report of the observed incidence of FXS in ROI/NI is approximately 2.5 - 3 times less than the estimated worldwide incidence in males and less for females. The low incidence in males is not due to under-testing as the analysis rates are comparable to international standards. The very low incidence in females is probably exaggerated by lower than expected female analysis rates in both ROI and NI which indicates a need for sex specific criteria to guide clinicians when testing for FXS.

PM18.36
Using Ion Torrent Next Generation Sequencing to identify mutations and alleles spectrum in Glucose 6-phosphate dehydrogenase (G6PD) deficiency among Saudi neonates

M. A. Al Balwi[1,2], *M. Alotaibi*[2], *W. AlHarbi*[2], *M. Ballow*[2], *S. AlSaif*[3], *I. AlAbdulkareem*[2];
[1]*King Abdulaziz Medical City, Riyadh, Saudi Arabia,* [2]*Medical Genomics Research Department, King Abdullah International Medical Research Center, Ministry of National Guard, Riyadh, Saudi Arabia,* [3]*Division of Neonatology, Department of Pediatrics, King Abdulaziz Medical City, Ministry of National Guard, Riyadh, Saudi Arabia.*

Glucose 6-phosphate dehydrogenase (G6PD) is the most common inherited human enzyme deficiency and estimated to affect more than 400 million people worldwide. G6PD deficiency is an X-linked recessive hereditary condition that causes destruction of red blood cells. Males are more affected than females and the condition is common in African, Mediterranean, and Asiatic populations (i.e. malaria-endemic regions). In the Middle East, the prevalence estimate of G6PD deficiency is the second highest in the world at 6%, the first being Sub Saharan Africa. Saudi Arabia is one of the most affected countries where G6PD deficiency is considered an endemic and all previous studies have been conducted using biochemical analysis. Such analysis limited to disease carries without measuring the severity of the G6PD deficiency of identifying the patient genetic makeup. To date, there are no molecular analysis studies of G6PD gene in Saudi Arabia. Using Ion Torrent next generation sequencing technology; we identify several novel mutations, SNPs and indels and there frequency among 120 neonates patients representing from different population across Saudi Arabia. In this study, we correlated neonate's clinical presentation with their biochemical enzymatic finding and their mutations spectrum finding within G6PD gene. The resultant conclusion can be employed for designing a pre-marital test to reduce the incidence of the disease in our population.

PM18.38
Regional analysis provides insight into the genetic architecture of general cognitive ability

W. D. Hill[1,2], *G. Davies*[1,2], *R. E. Marioni*[1,3,4], *D. J. Porteous*[1,3], *Generation Scotland, I. J. Deary*[1,2];
[1]*Centre for Cognitive Ageing and Cognitive Epidemiology, University of Edinburgh, Edinburgh, UK, Edinburgh, United Kingdom,* [2]*Department of Psychology, University of Edinburgh, Edinburgh, United Kingdom,* [3]*Medical Genetics Section, Centre for Genomic and Experimental Medicine, Institute of Genetics & Molecular Medicine, University of Edinburgh, Western General Hospital, Edinburgh, United Kingdom,* [4]*Queensland Brain Institute, The University of Queensland, Brisbane, Australia.*

General cognitive ability is substantially heritable and is predictive of both social and health outcomes. Molecular genetic studies estimate that common SNPs tag around 30% of the phenotypic variation. Here, using 594,756 single nucleotide polymorphisms (SNPs) genotyped in a sample of 6,610 unrelated individuals, the genome wide heritability estimate was decomposed into biologically informative groups with the aim of showing where in the genome the greatest proportion of the polygenic signal lies. The results indicate that the amount of phenotypic variance captured by a chromosome is proportional to its length and that SNPs within genes explain a greater proportion of phenotypic variance than SNPs found outside of genes. A chromosome by chromosome analysis is also provided and for the first time the contribution of common SNPs found on the X chromosome is quantified. Together these results provide further evidence that general cognitive ability is a highly polygenic trait with significant contributions arising in both genic and intergenic regions but with a greater proportion of variation being tagged by SNPs in genes. This unequal distribution of the polygenic signal justifies the use of gene-set analysis methodology to genome wide association study data sets as well as indicates that methods aimed at exploring regions between genes can also identify regions harbouring variants making significant contributions to general cognitive ability.

[1]*Institute of Sport, Exercise and Active Living (ISEAL), Victoria UniversityVictoria University, Melbourne, Australia,* [2]*School of Doctorate Studies and Research, Universidad Europea de Madrid, Madrid, Spain,* [3]*Centre for Sport and Exercise Science and Medicine (SESAME), University of Brighton, Brighton, United Kingdom,* [4]*Ural State University of Physical Culture, Chelyabinsk, Russian Federation,* [5]*School of Physical Education and Sport, University of Sao Paulo, Sao Paulo, Brazil,* [6]*Department of Human and Medical Genetics, Vilnius University, Vilnius, Lithuania,* [7]*Academy of Physical Education and Sport, Department of Tourism and Recreation, Gdansk, Poland,* [8]*Faculty of Physical Activity, Universidad Europea de Madrid, Madrid, Spain,* [9]*Department of Genetics, Development and Molecular Biology, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [10]*Department of Life and Environmental Sciences, University of Cagliari, Cagliari, Italy,* [11]*Murdoch Childrens Research Institute, Melbourne, Australia,* [12]*3Centre for Sport and Exercise Science and Medicine (SESAME), University of Brighton, Brighton, United Kingdom,* [13]*12Department of Basic Medical Sciences, University of West Indies, Kingston, Jamaica,* [14]*13University of Technology, Kingston, Jamaica,* [15]*Research Institute of Physical Culture, St Petersburg, Russian Federation,* [16]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation,* [17]*Institute of Sport, Exercise and Active Living (ISEAL), Victoria University, Melbourne, Australia.*

To date, case:control studies investigating the association between the *ACTN3* R577X and the *ACE* I/D gene variants and elite sprint/power performance have been limited by small sample size, the inclusion of sprint and power athletes from mixed sport disciplines, and lack of quantitative measure of performance.
Using a new quantitative approach, we examined the association between the *ACTN3* R577X and the *ACE* ID variants with a total of 527 best personal 100-, 200-, and 400-m times of 349 elite pure sprinters from Australia, Brazil, Greece, Jamaica, Italy, Poland, Russia, Lithuania, Spain, and US. Genotyping of the sprinters was performed using various methods of PCR.
On average, male Caucasian sprinters with the *ACTN3* 577RR or the *ACE* DD genotype had faster best 200-m sprint time than their 577XX (21.19±0.53 vs. 21.86±0.54 sec, p=0.016) and *ACE* II (21.33±0.56 vs. 21.93±0.67 sec, p=0.004) counterparts, respectively. A trend towards a faster best 200-m was noted in the 577RR African sprinters compared to their 577RX counterparts (20.44±0.63 vs. 21.05±0.73, p=0.07). Furthermore, both *ACTN3* 577RR and *ACE* DD sprinters' best personal times were closer to the world record than their 577XX and ACE II counterparts.In conclusion, the *ACTN3* R577X polymorphism individually and in combination with the *ACE* ID polymorphism influence 200- m performance time of elite sprinters, and it is unlikely that athletes with either *ACTN3* 577XX or *ACE* II genotypes will achieve the speeds required for victory in Olympic sprint events.

Analysis of homozygous and compound heterozygous loss-of-function mutations in Finnish exomes in relevance to cardiovascular disorders

A. Wennerström[1,2], *P. Salo*[1,2], *M. Perola*[1,2];
[1]*National Institute for Health and Welfare (THL), Helsinki, Finland,* [2]*University of Helsinki The Institute for Molecular Medicine Finland (FIMM) Biomedicum, Helsinki, Finland.*

Sequencing Initiative Suomi (SISu) Project recently published the frequencies of loss of function variants (LoF) in 3,000 Finns and showed that the average Finn has more rare loss-of-function variants than other Europeans. To better understand the role of homozygous or compound heterozygous LoF in apparently healthy individuals and study the medial impact and expression profile of the variants, we have studied the +500 -subsample of the FINRISK/DILGOM -study. The baseline of the DILGOM-study was performed in 2007 and all the individuals were re-invited for a follow-up study in 2014.
152 exomes were analyzed with the Illumina GAIIx platform and an Agilent SureSelect All Exon kit. Variants were called together with the SISU project and annotated using Essembl Variant Effect Predictor. We identified a total of 6978 LoF variants in the current sample. Nonsense SNPs were the most frequent variant category (n=3997). Splice site variants (n=2115), initiator codon variants (n= 483), and variants affecting the stop codon (n=383) were also observed. Homozygous or compound heterozygous LoF variants were detected in different 509 transcripts in 259 different autosomal genes.
The variants were reviewed using various databases e.g., Ensembl, OMIM, GWAS catalog, Genecard, NCBI, the 1000 Genomes Project and GEUVADIS to identify potential causative variants that have impact on cardiovascular disorders and their risk factors
Next, our aim is to analyze the effects of the homozygous and compound heterozygous LoF variants on gene expression using RNA sequencing data from the +500 cohort and validate the positive signals in larger FINRISK cohorts (n~40 000).

PS18.41
Genetic polymorphism regulating the accumulation of soluble inflammatory mediators in platelet components (PCs)

C. ALOUI[1,2], *A. Prigent*[1,2], *C. Sut*[1,2], *J. Fagan*[2], *S. Tariket*[1,2], *T. Chakroun*[3], *F. Cognasse*[1,2], *O. Garraud*[1,4], *S. Laradi*[1,2];
[1]*1GIMAP - EA3064, Faculté de médecine, Université de Lyon, Saint-Etienne, France,* [2]*EFS - Etablissement Français du Sang Auvergne-Loire, Saint-Etienne, France,* [3]*CRTS - Centre régional de transfusion sanguine, Sousse, Tunisia,* [4]*INTS - Institut National de la Transfusion Sanguine, Paris, France.*

Introduction: Blood platelets destined for transfusion release panoply of inflammatory molecules during preparation and storage. The rationale of this study is to identify regulatory genetic polymorphisms that induce high levels of inflammatory molecules in PCs.
Methods: Supernatant from non-leukodepleted PCs was sampled from 150 PCs prepared for transfusion purpose. Luminex® technique was performed for measuring levels of sCD62P, RANTES, sCD40L, IL8, IL1β and TNFα (MILLIPLEX® MAP Kit Millipore). In parallel, Genomic DNA was extracted from every blood donor, after written consent, using FlexiGene® DNA kit (Qiagen, Paris, France).
Candidate polymorphisms were chosen from the HGMD® professional data base (http://www.hgmd.org/) and genotyped using Tetra-primer ARMS-PCR and RFLP-PCR. All of them were involved in transcription regulation.
Studied polymorphisms were as follow: rs6127 and rs6136 for SELP (CD62P gene); rs3092952 for CD40L; rs1126647 and rs4073 for IL-8; rs2280788 for RANTES; rs1799964 for TNFα and rs1143627 for IL-1β.
Results: We studied the evolution of the amount accumulated during the storage of each inflammatory molecule, depending on the genotype. Levels of sCD62P and IL-1β were genotype associated (p=0.04 and p=0.015, respectively). The G allele of rs6136 for SELP upregulated the concentration of sCD62P and the C allele of rs1143627 of IL-1β gene upregulated the concentration of IL-1β.
Conclusion: If confirmed in a larger study, we suggest using these polymorphisms to prioritize distribution of PCs in order to give products with lower concentration of inflammatory molecules. Exploring these polymorphisms could prevent adverse reactions for patients who previously developed transfusion inflammatory reactions.

PM18.42
The influence of the genetic background on the causality of variants

B. Reiz, *M. Kleinecke, J. Erdmann, I. Brænne;*
Institute for Integrative and Experimental Genomics, Luebeck, Germany.

Next generation sequencing has revolutionized the identification of genetic variants. To be useful in a clinical setting, we need to distinguish causal from genuine variants. One can easily collect convincing but statistically poor evidence that supports the link between a variant and a disease, even if the variant has no true effect on the disease at all. The effect is even worse if a genetic diagnosis is independent of a current phenotype, as it is the case for the so-called incidental findings.
The genetic background has an influence on the pathogenicity of variants. Hence, we aim to assess the population specific patterns for disease-causing variants and the clinical relevance of variants that differ between populations.
We compared the distribution of reported disease-causing variants in the publicly available 1000 Genomes dataset. Principal component analysis on all variants listed in HGMD, ClinVar and based on the ACMG guidelines demonstrates strong population structure. We find variants that are causal across all populations; presumably only disease-causing in one population; and likely to be false positive.
Our work highlights several aspects. To assess the functional impact of a variant, we need to carefully match the ethnicity of the patient with the population in which the variant is reported. This is, however, difficult in admixed populations. We need to carefully evaluate each variant even if reported as causal. How reliable is the pathogenicity flag of a rare variant that is common in another population? How can we assess the causality if no functional data is available?

PS18.43
Regional variation in health-related traits in Scotland: genes or environment?

C. Amador[1], *A. Spiliopoulou*[1], *J. Huffman*[1], *A. Campbell*[1], *D. Porteous*[1], *G. Scotland*[2], *N. Hastie*[1], *V. Vitart*[1], *C. Hayward*[1], *P. Navarro*[1], *C. S. Haley*[1,3];
[1]*MRC IGMM, Edinburgh, United Kingdom,* [2]*A collaboration between the University Medical Schools and NHS in Aberdeen, Dundee, Edinburgh and Glasgow, Scotland, United Kingdom,* [3]*Roslin Institute and Royal (Dick) School of Veterinary Studies, Edinburgh, United Kingdom.*

Patterns of genetic variation provide valuable information for research on disease and epidemiological traits. Geography shapes genetic structure across European populations and geographic associations with health-related traits are known. Substantial disparities in health outcomes including lifespan exist within Scotland but evidence that genomic variation underpins these is limited. We analysed geographic stratification using Generation Scotland's Scottish Family Health Study (GS:SFHS), a cohort designed for study of complex traits and diseases. Principal component analysis of ~200K SNPs in approximate linkage equilibrium from a subset of 6909 unrelated individuals identified a significant correlation between genomic structure and the geographic origin of the individuals. Using information of the geographic origin of the four grandparents of each individual, we could predict more precisely the genomic origin of other individuals, providing an accurate map of Scotland. Traits including cholesterol and high-density lipoprotein had significant mean differences between regions in the GS:SFHS data. We utilised a linear mixed model including a genomic relationship matrix to separate the population's genomic structure from environmental effects of region of residence. The effects of region of residence on the traits remained

significant and largely unchanged by the inclusion of genetic relationships and genomic origin of individuals suggesting that the regional effects are of environmental, rather than genetic, origin. These results show the importance of including genetics in a linear mixed model context to disentangle the environmental effects, and point out the importance of the environment in health-related traits.

Introduction: In Western countries the principal causes of childhood gastroenteritis are Rotavirus and Noravirus infections. Infection peak age is between 6 months and 2y. The heritability for gastroenteritis has been estimated in 54%. We performed a genome-wide association meta-analysis (GWAMA) to identify genetic variants for gastroenteritis susceptibility during first years of life.

Material and Methods: Six thousand children from 5 European cohorts from The EArly Genetics and Lifecourse Epidemiology (EAGLE) Consortium participated in the discovery phase. Gastroenteritis was defined based on questionnaire data or medical records at ages 1y and 2y. Gastroenteritis with or without clinical diagnosis were used as outcomes and followed in enrichment pathway analysis (MAGENTA-KEGG). Top signals from the discovery step will be replicated in additional 4,000 children from the consortium.

Results: Genetic variants near FUT2 gene were associated with gastroenteritis at age 1y (P<1.1E-09), yet some heterogeneity was observed among cohorts (P het= 0.03). FUT2 codes for a glycosyltransferase that participates in the histo-blood antigen production and is associated to infection susceptibility (including Rotavirus and Noravirus). Suggestive associated variants (P< 1E-05) mapped near A4GALT (histo-blood antigen), NPPA-NPPB (blood pressure), RYR2 genes (similarity to rotaviral VP6 protein), or close to GWAS signals for inflammatory bowel disease (PTER and IL17REL). Nominally associated pathways as Vibrio Cholerae infection, T cell receptor signaling, NOD like receptor signaling, glycosphingolipid biosynthesis and cell adhesion, among others, were identified.

Conclusions: Overall, sixty-four suggestive polymorphisms, including FUT2 locus, were identified in the discovery step and will be followed in additional samples.

PS18.45

Influence of genetic variants on heart failure occurrence and outcomes in an Italian population

S. Pileggi, *V. Milani, S. Barlera, E. Nicolis, L. Crociati, S. Pietri, M. G. Franzosi;*
IRCCS - Istituto di Ricerche Farmacologiche, Milan, Italy.

Introduction: Genetic factors can modify severity and progression of heart failure (HF). The CHARGE Consortium GWAS reported that the loci 15q22 and 3p22 are associated with occurrence and with risk of death in HF patients, respectively. Furthermore, a recent European GWAS tested the association of Dilated Cardiomyopathy (DCM) with 517,382 SNPs finding significant associations for rs2234962 and rs10927875. We focused on these conditions in order to replicate these results in an Italian population.

Materials and Methods: Our case-control study included 2535 HF patients from GISSI-HF study (728 have DCM phenotype) and 1196 healthy controls recruited among blood donors. All samples have been genotyped for rs12638540, rs10519210, rs2234962 and rs10927875 polymorphisms. Multivariable logistic regression analyses of the case-control were adjusted for age and sex whereas the association of the SNPs with study endpoints was adjusted for all the baseline variables associated with the outcome of interest.

Results: Association with a decreased risk of HF was obtained for rs10519210 G allele (p=0.03), rs10927875 T allele (p=0.002) and rs2234962 C allele (p=0.04). rs10927875 T and rs2234962 C alleles resulted associated with a decreased risk of DCM (p=0.006 and p=<0.0001, respectively). None of the SNPs provided association with ischemic aetiology of HF. As to the rs12638540 G allele, we confirmed its association with the combined endpoint of mortality and cardiovascular hospitalization (p=0.018), but not for all-cause mortality (p=0.42).

Conclusions: These data confirm that the genetic variants identified by the GWASs can affect the occurrence of HF as well as the outcome of HF patients

PM18.46

Genetic findings in babies whose meconium and colostrum samples containing heavy metals: an example from Kocaeli in Turkey

N. Cine[1], *D. Sunnetci-Akkoyunlu[1], M. Yavuz[2], G. Turker[3], H. Savli[1], O. Hamzaoglu[4];*
[1]Kocaeli University Medical Genetics Department, Kocaeli, Turkey, [2]Istanbul Public Health Administrative, İstanbul, Turkey, [3]Kocaeli University Neonatology Division, Kocaeli, Turkey, [4]Kocaeli University Public Health Department, Kocaeli, Turkey.

Introduction: Exposure to air pollution and particulate matter with 10 micron diameters or less threat human lives significantly. Atmospheric deposits of heavy metals like Arsenic (As), Aluminum (Al), Cadmium (Cd), Copper (Cu), Mercury (Hg), Lead (Pb) and Zinc (Zn) could damage DNA and this damage results in chromosomal aberrations frequently. Heavy metals exposed mothers can transfer these metals to their babies through breastfeeding and circulating blood.

Materials and Methods: We investigated the presence of genetic alterations using array CGH analysis in 32 babies whose meconium and colostrum samples are containing heavy metals. Mothers of 24 babies were living in the industrial town, Dilovası and mothers of 8 babies were living in nonindustrial town, Kandıra.

Results: We found increased risks of genomic changes in heavy metal exposed mothers' babies compared to unexposed mothers' babies both in colostrum and in meconium. For the meconium samples, exposure to As and Zn increased the risk of aberrations (1.3-fold), and exposure to Al, Cd and Hg increased the presence of CNV (Al: 2.7-fold, Cd:1.4-fold, and Hg: 2.0-fold). In colostrum samples, exposure to Al, Cu, Cd and Pb increased the risk of the presence of aberrations (Al: 1.3-fold, Cd: 1.3-fold,Cu: 1.1-fold, and Pb: 3.6-fold), and the exposure to Cd and Zn increased the risk of the presence of CNV (Cd: 2.2-fold, Zn: 1.5-fold).

Conclusion: Our findings indicate that exposure to heavy metals investigated in the scope of this study can result in genomic variation either in the form of aberration or CNV.

PS18.47

Phenotypic expression of haemophilia B in patients with six novel F9 gene mutations

E. P. Sukarova Stefanovska[1], *G. Bozinovski[1], Z. Trajkova-Antevska[2], V. Dejanova-Ilijevska[3], G. Petkov[4], D. Plaseska-Karanfilska[1];*
[1]Research Center for Genetic Engineering and Biotechnology "Georgi D. Efremov", Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of, [2]Hematology Unit, Pediatric Clinic, Medical faculty, Skopje, Macedonia, The Former Yugoslav Republic of, [3]Institute for Transfusion Medicine, Clinical Center, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic of, [4]Pediatric Clinic, Medical faculty, Stara Zagora, Bulgaria.

Hemophilia B, X-linked recessive bleeding disorder, is caused by a wide range of mutations in the *F9* gene. It is characterized by deficiency in factor IX clotting activity. The disease is classified as severe, moderate or mild, and the phenotype severity is related to the type and position of the mutation in the *F9* gene.

During molecular characterization of hemophilia B in Macedonia six unique and unreported changes in the *F9* gene were revealed, confirming the high heterogeneity of molecular defects leading to disease. All mutations occurred in exons coding for the mature FIX domains. Three were missense mutations: c.536G>C,p.Gly179Ala; c.875A>C,p.Gln292Pro and c.1215T>G,p.Asp405Glu, while three were small deletions/insertions: c.230_231delTTinsA, p.Val77Asp*fs**27; delTA deletion affecting nucleotides c.849_850 leading to

Ile284*fs*, and c.1095delA or p.Ser365Ser*fs**3. Each novel missense mutation occurred at a highly conserved region. Prediction of the functional effects of the nucleotide changes was performed using in silico analysis.
All patients were severely affected with FIX<1%, and different episodes of bleeding into joints and muscles. Only the patient with c.875A>C,p.Gln292-Pro missense mutation had moderate form of disease (fIX 3%).
High titer of inhibitors, were registered only in the patient with deletion c.230_231delTTinsA. He was diagnosed at two years of age after thung injury, and since then more than 20 episodes of spontaneous bleeding, were registered. He developed high titer of inhibitors (20U), soon after starting prophylactic therapy.
In summary, these mutations may contribute for more precise identification of the structure-function relationship and understanding the nature of the factor IX molecule.

PM18.48
Heritability estimation from summary statistics using generalized estimating equations

J. Hecker[1,2], *D. Prokopenko*[1,2], *C. Lange*[1,3,4], *H. Loehlein Fier*[1,2];
[1]*Institute of Genomic Mathematics, University of Bonn, Bonn, Germany,* [2]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [3]*Channing Laboratory, Brigham and Women's Hospital, Boston, MA, United States,* [4]*Department of Biostatistics, Harvard School of Public Health, Boston, MA, United States.*

Introduction: In a recently published work, Bulik-Sullivan et al. (Nature Genetics, 2015) provide a methodological approach to differentiate between an inflation of test statistics in genome-wide association studies resulting from a polygenic architecture and from cryptic relatedness. This makes it also possible to estimate the heritability from summary statistics without requiring genotype data.
The approach of Bulik-Sullivan et al. estimates LD Scores from a reference panel and utilizes these quantities as covariates in a weighted linear regression of the squared test statistics. Since the test statistics are not independent of each other, a bootstrap method is applied to obtain robust standard errors.
Material and Methods: Building on the same mean model, our objective is to incorporate more useful extern information into the estimation in order to improve the efficiency of the estimation. In particular, we divide the genomic region into blocks of moderate size. For these blocks, the correlation structure between test statistics can be approximated by LD information from reference panels. Our estimation procedure is based on generalized estimating equations (GEE). We use the LD information to set up the working-correlation matrices for each block, whereas we do not require that nearby blocks are independent.
Results: We show that the GEE-related asymptotic results are still valid under reasonable assumptions. It is important to note that the working-correlation matrices are not required to be exactly the true correlation matrices in order to obtain consistent estimates and correct standard errors.
Conclusion: These results imply that our approach improves the heritability estimation framework.

PS18.49
The genetic ancestry of the Sherpa people

A. Cole[1], *S. Cox*[2], *C. Jeong*[3], *P. Robbins*[4], *H. Montgomery*[2], *P. Gasparini*[5], *Y. Droma*[6], *M. Hanaoka*[6], *M. Ota*[7], *A. Di Rienzo*[3], *G. Cavalleri*[1];
[1]*Department of Molecular and Cellular Therapeutics, Royal College of Surgeons in Ireland, Dublin 8, Ireland,* [2]*Institute for Human Health and Performance, University College London, London, United Kingdom,* [3]*Department of Human Genetics, University of Chicago, Chicago, IL, United States,* [4]*Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, United Kingdom,* [5]*University of Triests, Italy, Triest, Italy,* [6]*First Department of Medicine, Shinshu University School of Medicine, Matsumoto, Japan,* [7]*Department of Legal Medicine, Shinshu University School of Medicine, Matsumoto, Japan.*

Introduction: The Sherpa are an indigenous ethnic group of the Himalayas that display a remarkable ability to function at high altitude. Historical records suggest that the Sherpa migrated from Eastern Tibet to the Solu-Khumbu region of Nepal approximately 500 years ago. We set out to shed further light on the history of the Sherpa and other indigenous high altitude populations of the Himalayas through analysis of dense genomic data.
Methods: We had access to dense genotype data for 115 Sherpa from eight Sherpa-villages in the Khumbu region of Eastern Nepal. We also included 76 Nepalese individuals of seven different ethnicities and 91 individuals from two regions of Tibet; Lhasa and Yunnan. We complemented this dataset with 701 samples from neighbouring populations of the greater Himalayan region including individuals along the Silk Road; Kazakistan, Kirgykistan, Tajikistan and Uzbekistan, India, Pakistan and China. We conducted principal component, admixture and homozygosity analysis on this dataset.
Discussion and Conclusion: Our results suggest the Sherpa are a remarkably isolated, homogenous high altitude population. We confirmed the presence of an ancestral component that appears specific to high altitude populations of the Himalayas and is enriched in the Nepalese Sherpa, with particularly high proportions identified in individuals from a specific Sherpa village in the Khumbu valley of Nepal. Other indigenous populations of Nepal show varying degrees of admixture between southern (Indian), northern (Han) and Himalayan ancestry. Analysis of homozygosity in the Sherpa also indicate recent consanguinity within the population.
This research was supported by an investigators programme grant from SFI (12/IP/1727)

PM18.50
GENETICS OF THE SPHINGOLIPID METABOLISM IN HYPERTENSION

M. Fenger[1], *A. Linneberg*[2], *J. Jeppesen*[2];
[1]*University of Copenhagen, Hvidovre, Denmark,* [2]*University of Copenhagen, Glostrup, Denmark.*

Essential hypertension refers to hypertension with no known cause accounting for 90-95% of all hypertensive subjects and is a major risk factor for stroke, heart disease, and end-stage renal disease. Hypertension is a polygenic disease and as such is supposed to harbour several genetic defects as the causative agents, but so far only a few potential genes have been identified. The major reasons for this modest progress are the unresolved physiologically heterogeneity of the disease and the prevailing monogenic approach to identify genes of importance. The physiologically heterogeneity was resolved by partition of the study population by combined latent class analysis and structural equation modelling into an ensemble of physiological more homogeneous subpopulations. Two-gene interactions were evaluated by variance decomposition and a new weighted mutual information score. The latter analytical approach considerably reduced the number of significant interactions detected by variance decomposition. It was established that the sphingolipid metabolic network is of significant importance in regulating the blood pressure.
In particular, acid ceramidase and sphingosine kinase 1 are the hubs collating the genetic information of blood pressure regulation.

PS18.51
Population Structure of the Island of Hvar - Maternal and Paternal Perspective

T. Saric[1], *J. Sarac*[1], *N. Jeran*[2], *D. Havaš Auguštin*[1], *N. Novokmet*[1], *S. Rootsi*[3], *E. Metspalu*[3], *S. Missoni*[1], *R. Deka*[4], *R. Villems*[3], *P. Rudan*[5];

Island of Hvar is situated in the central Eastern Adriatic, and its relatively small rural population has been reproductively isolated throughout history. Therefore, founder effects, genetic drift and inbreeding have had a significant role in the shaping of the current genetic diversity of Hvar Islanders. Island isolates are among the most suitable populations for theoretical analyses of microevolutionary processes and population differentiation. In this context, mitochondrial DNA (mtDNA) an Y chromosome studies are used to reveal demographic history, migrations, population origins and genetic structure of a population. We analyzed SNP markers of 161 mtDNAs and of 412 Y chromosomes from the island of Hvar, including STRs of 20 male islanders. Results showed a much higher number of mtDNA haplogroups (34) than Y chromosome ones (15). Haplotype diversity analysis showed low gene diversity among both mtDNAs and Y chromosomes on the island, while haplogroup distribution points to a significant population differentiation between the eastern and western part of the island. This substructure effect stems from different representation of subhaplogroups, as well as from differences between haplotypes within the same subhaplogroups and is based on specific demographic processes which occurred on Hvar during its history. When put in a wider context, haplogroups of both uniparental markers placed Hvar in the context of South-Eastern Europe, but the frequencies and the distribution of certain haplogroups significantly deviate from other SEE populations.

Isolated populations have population genetic characteristics that can boost power in genetic association studies of complex traits. Leveraging these advantageous characteristics requires an understanding of their population genetic parameters, such as effective population size, population split time and migration rate, which have shaped their sequence variation. Here, we perform a comprehensive investigation of these parameters using low-depth (4-8x) whole genome sequencing across multiple isolates: Orkney (n=399) from the UK, Friuli-Venezia Giulia (n=250) and Val Borbera (n=225) from Italy, Kuusamo (n=377) from Finland and HELIC-MANOLIS (n=249) from Greece. We compare these isolates to their nearest general populations; UK10K (n=3,781), TSI from the 1000 Genomes Project (n=108), SiSu cohorts (n=1,564, Finland) and TEENAGE (n=100, Greece). We find that all isolates are genetically close to their nearest general population, but have lower genetic diversity, longer LD blocks and a higher proportion of haplotype matching within individuals (runs of homozygosity), as expected because of genetic drift. We investigate the contribution of different population genetic parameters to these characteristics and construct an 'isolation index', which we show can also be calculated reliably from SNP genotype data. Populations with the highest isolation index scores have the greatest overall depletion of rare functional variants, but enrichment of relatively common ones; they also provide examples of positive selection with potential biological relevance. On this basis, candidate isolated populations can be evaluated for their informativeness in association studies.

PS18.53

The *KLOTHO* gene polymorphisms are associated with hypertension in the Chinese population of Matsu islands: a population-based follow-up study

S. Lin[1], *W. Y. Wu[1], L. Chen[2], A. M. Yen[2], H. Chen[3], M. Lin[1,4];*
[1]Institute of Public Health, National Yang-Ming University, Taipei, Taiwan, [2]School of Oral Hygiene, College of Oral Medicine, Taipei Medical University, Taipei, Taiwan, [3]Institute of Epidemiology and Preventative Medicine, National Taiwan University, Taipei, Taiwan, [4]Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan.

Introduction: Hypertension is a major risk factor for cardiovascular diseases, stroke, and end-stage renal disease. Hypertension has been ranked at the top ten leading causes of death in Matsu. The genetic contribution to blood pressure variation is estimated ranging from 30-50%. The *KLOTHO* gene was identified as an aging-suppressor gene and can regulate oxidative stress as well as protect vascular endothelial function, thus attenuate the progression of hypertension. To investigate the role of *KLOTHO* gene polymorphisms on hypertension, we conducted a community-based follow-up study in the Matsu islands of Taiwan.
Methods: From 2002 to 2009, 3707 subjects had participated in the Matsu Community-Based Integrated Health Screening project. We included 1955 Chinese subjects with DNA sample available and selected 6 SNPs on the *KLOTHO* gene (rs1207568, rs571118, rs577912, rs3752472, rs564481 and rs650439) for genotyping.
Results: We found the CT genotype carriers of rs564481 had a significantly higher risk of hypertension than CC carriers (OR = 1.40, 95% CI = 1.02-1.91) and the GGACTA carriers had a higher risk of hypertension than non-carriers (OR = 1.68, 95% CI = 1.16-2.43). We also found that the TT genotype carriers of rs564481 will significantly increase both SBP and DBP than the CC carriers over the study period. Besides, the SBP of the GGACTA haplotype carriers were significantly increased by 1.85 mmHg compared with their counterparts (p = 0.022) during the follow-up period.
Conclusion: Our findings provide evidence that the *KLOTHO* gene may play an important role on hypertension in Chinese population resident in Matsu.

Johansson[4], S. Sauer[5], D. J. Porteous[1], R. M. Fraser[1], C. Drake[1], V. Vitart[1], C. Hayward[1], C. A. Semple[1], **J. F. Wilson**[1];
[1]University of Edinburgh, Edinburgh, United Kingdom, [2]University of Split, Split, Croatia, [3]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [4]Uppsala University, Uppsala, Sweden, [5]Max-Planck-Institute for Molecular Genetics, Berlin, Germany.

Homozygous Loss of Function (HLOF) variants provide a valuable window on gene function in humans, as well as an inventory of the human genes that are not essential for survival and reproduction. All humans carry at least a few HLOF variants, but the exact number of inactivated genes that can be tolerated is currently unknown - as are the phenotypic effects of losing function for most human genes. Here, we make use of 1,432 whole exome sequences from five European populations to expand the catalogue of known human HLOF mutations; after stringent filtering of variants in our dataset, we identify a total of 173 HLOF mutations, 76 (44%) of which have not been observed previously. We find that population isolates are particularly well suited to surveys of novel HLOF genes because individuals in such populations carry extensive runs of homozygosity, which we show are enriched for novel, rare HLOF variants. Further, we make use of extensive phenotypic data to show that most HLOFs, ascertained in population-based samples, appear to have little detectable effect on the phenotype. On the contrary, we document several genes directly implicated in disease that seem to tolerate HLOF variants. Overall HLOF genes are enriched for olfactory receptor function and are expressed in testes more often than expected, consistent with reduced purifying selection and incipient pseudogenisation.

PS18.55

Molecular variation of three SNPs in LIN28B, related to developmental timing traits, in 24 Mediterranean populations

M. M. Álvarez, *R. Carreras-Torres, D. Zanetti, P. Moral;*
University of Barcelona, Barcelona, Spain.

The aim of this study is to screen, for the first time, the variation of the *LIN28B* gene in the whole Mediterranean region, through the analysis of the allele distribution of three single nucleotide polymorphisms (SNPs), namely rs7759938, rs314277 and rs221639, in 24 populations. These SNPs have been recently related to the age at menarche, pubertal height growth, peripubertal body mass index, levels of prenatal testosterone exposure and cancer survival. 1197 DNA samples were genotyped. The allele and haplotype frequencies were used to determine the relationships between populations, using also data from the 1000 Genomes Project for external comparisons. The genotype distributions and the population structure between populations and groups of populations were determined. The population results indicate a significant degree of variation (F_{ST}=0.043, p<0.0001). Allele and haplotype frequencies show significant differences among populations. A hierarchical variance analysis is consistent with a main differentiation between the populations on the two North and South coasts of the Mediterranean. This difference is especially evident in the unexpected distribution of the SNP rs221639, which shows one of the highest F_{ST} (11.5%, p<0.0001) values described so far in the Mediterranean region. The population differentiation and the structuring of the genetic variance, in agreement with other previous studies, indicate that the SNPs studied are good tools for the study of human populations, even at a microgeographic level.
This study was supported by the research project CGL2011-27866 of the Ministry of Science and Innovation of Spain.

PM18.56

Whole genome sequences are required to fully resolve the linkage disequilibrium structure of human populations

R. J. Pengelly, *William Tapper, Andrew Collins, Sarah Ennis;*
University of Southampton, Southampton, United Kingdom.

An understanding of linkage disequilibrium (LD) structures in the human genome underpins much of medical genetics, and provides a basis for disease gene mapping investigating biological mechanisms such as recombination and selection. Whole genome sequencing (WGS) provides the opportunity to determine LD structures at maximal resolution. We compare LD maps produced utilising WGS data with LD maps produced utilising the HapMap dataset, for representative European and African populations. Maps derived from the WGS data achieve much greater resolution of LD structure (~ 5 fold), which translates to improved utility. The absence of ascertainment bias in variant genotyping improves the population representativeness of

the maps, and highlights the extent of uncaptured variation present in African populations using array genotyping methodologies. Given the extended time to an effective population bottleneck for African populations, larger sample sizes and higher marker densities are required to fully resolve the LD structure. Whole genome LD maps will provide a rich resource for medical genetics, as well as for recombination biology.
This work is funded under the UK Biotechnology and Biological Sciences Research Council (BBSRC) 'Excellence with Impact' scheme.

PS18.57
The influence of lipoprotein lipase gene polymorphisms on postprandial lipoprotein metabolism

I. Shatwan[1,2], *A. Minihane*[1,3], *J. Lovegrove*[1,2], *C. Williams*[2], *K. Jackson*[1,2], *K. Vimaleswaran*[1,2];
[1]*Hugh Sinclair Unit of Human Nutrition, Department of Food and Nutritional Sciences, University of Reading, Reading, United Kingdom,* [2]*Institute for Cardiovascular and Metabolic Research (ICMR), University of Reading, Reading, United Kingdom,* [3]*Department of Nutrition, Norwich Medical School, University of East Anglia,, Norwich, United Kingdom.*

Lipoprotein lipase (LPL) is a key rate-limiting enzyme for the hydrolysis of triacylglycerol (TAG) in chylomicrons and VLDL. Polymorphisms in the LPL gene have been previously demonstrated in association with several lipid phenotypes; however, the findings have been inconsistent. Given that postprandial assessment of lipoprotein metabolism may provide a more physiological perspective of disturbances in lipoprotein homeostasis compared to assessment in the fasting state, we have investigated the influence of three LPL polymorphisms (rs268, 291S; rs320, HindIII; rs328, S447) on postprandial TAG, non-esterified fatty acid (NEFA), glucose and insulin in 261 participants using a sequential meal challenge consisting of a mixed breakfast (0 min; 49g fat) and lunch (330 min; 29g fat). Blood samples were taken at 60 min intervals until 480 min after the test breakfast. At baseline, LPL S477 allele carriers had higher TAG (P=0.05) and lower HDL-C (P=0.02). Following the sequential meal challenge, there was an association of LPL S447 polymorphism with postprandial TAG and glucose, where S477 allele carriers had 12% and 8.4% higher TAG area under the curve (AUC) (P=0.04) and glucose AUC (P=0.006), respectively. In addition, a borderline association was observed between S477 and postprandial NEFA levels (P=0.05). With LPL 291N polymorphism, those who were homozygous for N allele had higher fasting NEFA (P=0.038) and postprandial NEFA response (P=0.003). In conclusion, our data suggest that carriers of 291S and S447 polymorphisms have an abnormal postprandial response to sequential meal challenge and provide further in vivo evidence as to the functional nature of LPL polymorphisms.

Previous studies showed gradient of genetic diversity of mtDNA and Y chromosome genetic markers within the population of Lithuania. Further, genetic diversity of autosomal genetic markers has been analyzed.
Venous blood samples and written consent forms were collected across six ethno-linguistic groups of Lithuania (North, South, West Žemaitija and East, South, West Aukštaitija). 253 samples were genotyped using the HumanOmniExpress-12v1.1 arrays (719,666 SNPs). After a systematic primary and secondary QC of the generated data, 590,665 autosomal SNPs and 188 samples remained for the subsequent analyses.
An MDS analysis and PCA based on 105,387 autosomal SNPs (pairwise LD r2<0.2) were performed. No obvious sets of clusters were seen in the scatter plot of MDS of all six ethno-linguistic groups of Lithuania. Though two clearly apparent clusters were detected in the scatter plot of MDS analysis when only samples from North Žemaitija and South Aukštaitija were included. No apparent clusters were seen in the scatter plot of MDS analysis including samples from Žemaitija only. Samples from South Aukštaitija, East or West Aukštaitija and North Žemaitija in the scatter plot of MDS analysis were positioned according to their North-South locations in the territory of Lithuania.
PC1 explained 0.61% (Tracy-Widom test, P<0.05) and PC2 - 0.59% of genetic variation among 188 samples of the Lithuanian population. According to the scatter plot of PCA, the greatest differentiation was detected among samples from the northwest and southeast of the population of Lithuania.
LITGEN project (VP1-3.1-ŠMM-07-K-01-013) is funded by the European Social Fund under the Global Grant measure.

Introduction: Hereditary non polyposis colorectal cancer is an inherited disease with deleterious germline mutations in the DNA mismatch genes causing the development of colon cancer and other malignancies.
Purpose: This study aimed to characterise the mutation profile of MLH1 and MSH2 in Moroccan colorectal cancer cohort. This is the first study in Morocco screening the population of our colorectal cancer patients in order to identify the prevalence of the disease.
Methods: From January 2010, 214 newly diagnosed colorectal cancer tumors received immunohistochemical staining for MLH1 and MSH2. If any stain was absent, the medical genetics service were alerted for a genetic consultation, and a Sequencing of corresponding MMR genes (mlh1 and msh2) was performed using the sanger method.
Results: There were 21 (9.8%) cases with abnormal immunohistochemical results. Genetics was able to contact 19 (90.4%) of these patients, only 16 (76.1%) of them made an appointment. All the cases underwent the genetic testing of mlh1 and msh2 genes, wich was informative in four (25%) of the patients. The diagnosis of lynch syndrome were confirmed among two (0.9%) patients harbouring deleterious mutations, however, the other two cases were found to have mutations with uncertain significance.
Conclusion: This study attempted to define the frequency of lynch syndrome among Moroccan population. The preliminary results of the study showed that 0.9% were found to carry germline mutations of the mlh1 msh2 genes.

Human coding variants in 2,628 Dutch individuals; the Rotterdam Study

J. van Rooij[1], *M. Jhamai*[1], *P. Arp*[1], *S. Nouwens*[1], *M. Verkerk*[1], *A. Hofman*[2], *A. Verkerk*[1], *J. van Meurs*[1], *F. Rivadeneira*[1,2], *A. Uitterlinden*[1,2], *R. Kraaij*[1];
[1]*Erasmus Medical Centre, Department of Internal medicine, Rotterdam, Netherlands,* [2]*Erasmus Medical Centre, Department of Epidemiology, Rotterdam, Netherlands.*

We performed whole-exome sequencing (Nimblegen v2, Illumina sequencing to mean depth of 55x) of a random sample of 3,000 Dutch Caucasian elderly men and women. Single nucleotide variants (SNVs) and small insertions and deletions (Indels) were called using the Genome Analysis Toolkit's (GATK) HaplotypeCaller and after QC and filtering a final dataset of 2,628 individuals was created. We detected 258,702 SNVs and 15,230 Indels with >2 alleles. Approximately 70% of SNVs and 50% of Indels were found reported in the ESP6500 database, with high concordance in minor allele frequency (MAF) (correlation of 0.97 and 0.91, respectively). 475 novel SNVs with MAF>20% were identified, which have not been described in any public database (1000G, ESP, GoNL & UK10K). Pathway analysis of these novel common SNVs showed significant enrichment for olfactory (p=1.4E-05) and taste transduction pathways (p=1.6E-03). As compared to the mean variant density of the genome (1 SNV in 448 nucleotides of coding sequence), we observed 18 enriched pathways among the 500 genes with the lowest SNV density, most of which were signaling or cancer pathways. Noticeably, MAPK1 (1 SNV in 1,400), PIK3CB (1 SNV in 1,305) and PIK3R1 (1 in 1,761) were involved in many pathways, suggesting key regulatory functions for these genes. Because of broad and deep longitudinal phenotyping of the Rotterdam Study cohort, this dataset is currently explored for rare genetic variants in relation to complex traits and diseases as well as known variants in typical Mendelian diseases, and is accessible as a control dataset.

Italy, [3]Basilicata Referral Center for Transplantation Hospital of Matera, Cosenza, Italy.

INTRODUCTION

The medullary cystic kidney disease type II (MCKD2) is an autosomal dominant disorder characterized by early onset of hyperuricemia, decreased fractional renal urate excretion and progressive interstitial nephropathy leading to end-stage renal disease. MCKD2 is caused by mutations in the UMOD gene, which encodes Uromodulin, a glycosylphosphatidylinositol-anchored protein that is expressed in the thick ascending limb of the loop of Henle and excreted in the urine. Over 90% of UMOD mutations are missense, and 62% alter a cysteine residue, implicating a role for protein misfolding in the disease. In this study we investigated the presence of mutations in UMOD gene in four members of Italian family showing the phenotype of MCKD2.

METHODS: Genomic DNA was extracted from peripheral blood leukocytes by using the Wizard Genomic DNA Purification kit following the manufacturer's instructions. Mutation analysis of the UMOD gene was performed by polymerase chain reaction and direct sequencing. A mutant UMOD construct, containing the identify mutation was created by in vitro mutagenesis. Transient transfection studies were performed in human embryonic kidney cells. Expression was evaluated by reverse transcription polymerase chain reaction (RT-PCR), western blot and immunofluorescence.

RESULTS: Sequence analysis revealed a heterozygous missense variation (c.187T>C; p.Cys63Arg) in exon 3 that altered an evolutionary conserved residue in the UMOD. Functional studies showed that the mutant protein was retained in the endoplasmic reticulum and was not excreted to the cell medium, as opposed to the wild-type protein.

CONCLUSIONS: Collectively, our results suggested that the variant may be the causative mutation in this family.

Effect of ACE I/D polymorphism on childhood obesity

C. Duicu, *O. Marginean, A. M. Pitea, F. Tripon, A. Crauciuc, C. Banescu;*
University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.

Obesity is a multifactorial disease influenced by genetic and environmental factors. The common insertion/deletion polymorphism (I/D) in the gene for angiotensin-converting enzyme (ACE) was previously associated with obesity, both in preschoolers, adolescents and adults. ACE I/D polymorphism might play a role in the development of the obesity and the hypertension, which are closely linked to cardiovascular risk factors

The aim of this study was to investigate the associations of obesity and ACE polymorphisms in patients with overweight and obesity. We enrolled 80 consecutive patients and 100 healthy subjects in the study. Both the obese cases and the normal-weight controls underwent the identical subset of standardized examinations. ACE insertion (I)/deletion (D) genotype was determined by PCR. The most common genotype in the obesity group was ID, with a lower percentage of DD and II (46%, 38.9% and 15.10% respectively). We did not find any difference between gender and genotypes in obese and control group. We found that 40% of children with moderate obesity have ID genotypes, while II genotype was most frequent (34%) in the severe obese subgroup. Children carrying I allele had a higher risk of obesity than those with allele D compared with the control group ($p<0.05$). These data suggest that ACE gene polymorphisms may influence the development of weight gain.

Suggestive linkage to chromosomal regions 13q13.3 and 21q22.2 in families with Multiple Sclerosis

E. Everest[1], *T. Avsar*[1], *A. Siva*[2], *U. Uygunoglu*[2], *M. Tutuncu*[2], *S. Saip*[2], *I. Karacan*[1], *E. Tahir Turanli*[1,3];
[1]*Graduate School of Science Engineering and Technology, Department of Molecular Biology Genetics and Biotechnology, Istanbul Technical University, Dr. Orhan Öcalgiray Molecular Biology and Genetics Research Centre, Istanbul, Turkey,* [2]*Department of Neurology, Istanbul University Cerrahpasa Medical Faculty and Hospital, Istanbul, Turkey,* [3]*Moleular Biology and Genetics Department, Istanbul Technical University, Istanbul, Turkey.*

Introduction: Multiple Sclerosis (MS) is an immune-mediated, inflammatory, demyelinating and neurodegenerative disease of the central nervous system with a proven, yet not fully established heritability. The objective of this study is to investigate the genetic basis of familial MS in Turkish population using a genome-wide linkage analysis in 10 multiply affected MS families from Turkey.

Materials and methods: Here we investigated linkage with MS across the genome using single nucleotide polymorphism (SNP) genotyping on the Illumina CytoSNP 300K array in 35 individuals from 10 MS families. Non-parametric linkage (NPL) scores were calculated for each of 3118 SNP markers spaced at an average of 1 cM intervals using SimWalk multipoint NPL analysis. Subsequent fine mapping of regions showing higher NPL scores was performed.

Results: The 10 families in which one or more individuals had MS showed suggestive evidence of linkage (NPL scores above 1.7) to chromosomal regions of 13q12.2-14.11 and 21q22.12-22.3. Fine mapping of these regions revealed that the most promising loci for linkage were mapped to 13q13.3 and 21q22.2, with NPL scores of 1.82 and 1.85, respectively. Inflammation or neurodegeneration associated genes some of which previously implicated in MS including HMGB1, POSTN, OLIG1, IFNAR1, IFNAR2 genes and also promising novel genes yet to be identified like N4BP2L2 and TRPC4 were found within the suggestive regions.

Conclusions: Although there was no significant evidence for linkage, our suggestive linkage results provide a framework for deep sequencing to identify new susceptibility genes and novel variants associated with risk of MS.

Genetic evidence for an origin of the Armenians from Bronze Age mixing of multiple populations

M. Mezzavilla[1,2], *M. Haber*[2], *Y. Xue*[2], *D. Comas*[3], *P. Gasparini*[1], *P. Zalloua*[4], *C. Tyler-Smith*[2];
[1]*Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy,* [2]*The Wellcome Trust Sanger Institute, Cambridge, United Kingdom,* [3]*Universitat Pompeu Fabra, Barcelona, Spain,* [4]*The Lebanese American University, Beirut, Lebanon.*

The Armenians are a culturally isolated population who historically inhabited a region in the Near East bounded by the Mediterranean and Black seas and the Caucasus, but remain underrepresented in genetic studies and have a complex history including a major geographic displacement during World War One. Here, we analyse genome-wide variation in 173 Armenians and compare them to 78 other worldwide populations. We find that Armenians form a distinctive cluster linking the Near East, Europe, and the Caucasus. We show that Armenian diversity can be explained by several mixtures of Eurasian populations that occurred between ~3,000 and ~2,000 BCE, a period characterized by major population migrations after the domestication of the horse, appearance of chariots, and the rise of advanced civilizations in the Near East. However, genetic signals of population mixture cease after ~1,200 BCE when Bronze Age civilizations in the Eastern Mediterranean world suddenly and violently collapsed. Armenians have since remained isolated and genetic structure within the population developed ~500 years ago when Armenia was divided between the Ottomans and the Safavid Empire in Iran. Finally, we show that Armenians have higher genetic affinity to Neolithic Europeans than other present-day Near Easterners, and that 29% of the Armenian ancestry may originate from an ancestral population best represented by Neolithic Europeans. These results illustrate the benefits of combining genetic and archaeological information for understanding present-day populations.

PM18.66

Nitric oxide synthase genes and cardiovascular risk in Spain

C. Ros-Surrá, *R. Carreras-Torres, D. Zanetti, P. Moral;*
University of Barcelona, Barcelona, Spain.

This is a case-control study of genetic association between the molecular variation in the nitric oxide synthase (NOS) genes and susceptibility to cardiovascular disease in Spanish population. Nitric oxide (NO) is an important physiological messenger synthesized by the three NOS isozymes, the neuronal NOS (NOS1), the inducible NOS (NOS2) and the endothelial NOS (NOS3). Potential genetic associations were assessed for different polymorphisms: 67 single nucleotide polymorphisms (SNP), 10 short tandem repeat polymorphisms (STRP) and 6 haplotypes on areas that showed high linkage disequilibrium, on all three NOS genes. These analyses were performed in a total of 903 samples: 408 heart disease patients and 495 non-affected, coming from two different sample designs, nuclear families (trios) and case-control. The association analysis was implemented by using the LAMP software which carries out the analysis combining case-control and trio familiy samples.

No haplotype significant association was found. The SNP results showed some significant associations, however when multiple testing correction (Bonferroni) was applied, all these associations became non-significant. The STRP results showed 7 out the 10 polymorphisms analysed significantly associated to heart disease. After multiple testing corrections 5 of them still showed significant associations. Most significantly associated polymorphisms were located on regulatory regions on the NOS1 and NOS2.

In conclusion only the variability in NOS1 and NOS2 genes appears to be significantly associated to heart disease in the Spanish population.

This study was supported by the research project CGL2011-27866 of the Ministry of Science and Innovation of Spain.

PS18.67

Population variation of NOS genomic regions and coronary incidence differences in Europe

P. Moral, *M. Via, D. Zanetti, E. Esteban, C. Ros-Surrá, M. Álvarez, R. Carreras-Torres; University of Barcelona, Barcelona, Spain.*

Nitric Oxide Synthases (NOS) genes encode for key enzymes on nitric oxide (NO) availability, a substance involved in several cardiovascular processes. Although the variation in the NOS genes has been repeatedly tested in epidemiological studies, it has not systematically analyzed at population level. Population distribution of NOS markers and its relationship with population coronary incidence can shed light on the demographic processes that shape both the population distribution of cardiovascular-related genetic regions and coronary incidence variation among populations. In this study, 114 single nucleotide polymorphisms (SNP) and 17 tandem repeat polymorphisms (TRP) from NOS regions were determined in 1321 individuals from 31 populations from Europe, North Africa and the Middle East. The found variation was tested for selection, used to obtain inferences of population structure, and correlated with coronary mortality in 11 of these European populations. Our results on NOS variation support i) the absence of clear signs of selection for genetic variants elsewhere associated with cardiovascular diseases, and ii) the presence of a continuous genetic pattern among European and North African populations without a Mediterranean barrier for gene flow. The population structure NOS correlated with CAD mortality, explaining a remarkable proportion of coronary event rates (39-98%) among European populations. These results reinforce the hypothesis that genetic bases of cardiovascular diseases shows a geographical distribution mainly associated with random and/or demographic processes.

This research was supported by the Ministerio de Ciencia e Innovación (CGL2011-27866).

Evolution of nuclear mitochondrial insertions in the genomes of primates

G. Dayama[1], *J. Prado*[2], *J. M. Kidd*[1], *T. Marques-Bonet*[2], *R. E. Mills*[1];
[1]*University of Michigan, Ann Arbor, MI, United States,* [2]*Universitat Pompeu Fabra/CSIC, Barcelona, Spain.*

The transfer of mitochondrial genetic material into the nuclear genomes of eukaryotes is a well-established, ongoing phenomenon. The recent advancement of high throughput sequencing technologies has enabled the interrogation of genomic variation from whole genome sequence data at a fine scale and allowed for the identification of other classes of structural variation that had been previously difficult to ascertain, including polymorphic nuclear mitochondrial insertions (numts). We have developed an approach to discover and genotype these numts using paired-end, next generation sequencing data and have previously described its application to human populations. Here, we extend our analysis to the whole genomes of 77 non-human primates consisting of chimpanzees, bonobos, gorillas and orang-utans. We report the identification of 476 novel numt insertions that segregate within each species, the majority of which were discovered in chimpanzees. We characterized and where possible have assembled their underlying sequences, and further examined these variants for biases in sequence context at insertion sites and their potential for functional effects. In addition, we also examined the patterns and origin of these insertions and have estimated their age. We investigated whether there are species-specific preferences for both polymorphic and fixed numt insertions and whether these are associated with the difference in the mutational load of numts observed between chimpanzees and the other species, including humans. To our knowledge, this is the first study to look at polymorphic numt insertions in non-human primates and we believe this research will help clarify to what extent that numts play a role in hominoid diversification and phenotypic variability.

The study of the FTO rs9939609 and ADRB3 rs4994 gene polymorphisms in association with obesity in a Romanian cohort of obese subjects

R. Ursu[1], *C. Bohîlțea*[1], *G. Ursu*[2], *I. Craciunescu*[2], *C. Arsene*[3], *L. Alexandrescu*[4], *M. Puiu*[5], *E. Severin*[6], *N. Cucu*[7];
[1]*"Carol Davila" University of Medicine and Pharmacy, Department of Medical Genetics, Faculty of General Medicine, Bucharest, Romania,* [2]*"Agrippa Ionescu" Emergency Military Hospital, Balotesti Cardiovascular Disease Center, Bucharest, Romania,* [3]*Epigenetics Center, Research Department, Bucharest, Romania,* [4]*The Association for Education in Nutrition, Bucharest, Romania,* [5]*Victor Babes" University of Medicine and Pharmacy, Deparment of Genetics, Timisoara, Romania,* [6]*"Carol Davila" University of Medicine and Pharmacy, Department of Genetics, Faculty of Dental Medicine, Bucharest, Romania,* [7]*Epigenetics Laboratory for Advanced Biomarkers - ELAB/ITA-BINNOTECH-NIBS, Bucharest, Romania.*

Introduction: The human population worldwide faces an alarming increase in the incidence of obesity in all races, sexes, social, cultural, religious or geographic environments.Purpose: Verifying the FTO rs9939609 and ADRB3 rs4994 genetic variants frequencies in our cohort and their association with obesity. Setting-up an early detection test for the predisposition for this disorder in our country would be an important step in stopping its development. Material. Methods: The selected cohort for genotyping consisted of 64 subjects, 44 obese and 20 controls (33 adults, 23 children, 8 Prader-Willi-syndrome patients*).* The results were tested in correlation with obesity parameters and associated disorders. Results: This is a first approach of genotyping in a Romanian cohort comprising adults and children for two genes related both to energy accumulation and expenditure. The FTO allele A was more associated with obesity in adults than in children (statistical for both). The FTO rs9939609 polymorphism is a common SNP in our study group, its mutant A allele showing higher frequencies than worldwide. The ADRB3 polymorphism is a rare variant: its C allele proved correlations, some statistical, with obesity susceptibility, although no homozygous mutant subjects were reported. The rs4994 frequency was higher in our groups than worldwide. ADRB3 indicated higher associations with obesity predisposition in children. Prader-Willi subjects showed high frequencies of both polymorphisms. Conclusions: The study revealed to be highly populational and not completely in concordence with reported literature. A greater number of subjects and more obesity associated polymorphisms are needed for determining a Romanian obesity gene map and genetic susceptibility test.

PS18.71

New methods for family based studies identify genetic regions underlying oral cleft risk

I. Ruczinski, *T. H. Beaty;*
Johns Hopkins University, Baltimore, MD, United States.

Oral clefts represent more than half of all craniofacial malformations, with an overall prevalence of about 1 per 600-700 live births worldwide. While there is substantial variation in birth prevalence across populations, oral clefts demonstrate strong familial aggregation and relatives of affected individuals are at significantly increased risk compared to the general population. Genome-wide association studies have shown numerous genes (including IRF6, ABCA4 and MAF) and even regions with few or no known genes (such as 8q24) play an important role in the etiology of oral clefts. However, much of the observed familial aggregation and heritability of oral clefts remains unexplained.

Large-scale sequencing in extended multiplex families can help to define the relationship between disease and genetic variants too rare in the population to be detected through tests of association in conventional study designs. Case-parent trio designs guard against confounding due to population stratification in tests for linkage and association with common markers, and also allow for the assessment of de-novo events and parent-of-origin effects. Both approaches can be readily adapted to test if structural variants also control risk to oral clefts.

We present the results from applying newly developed statistical methods and software for nucleotide and DNA copy number variants to data from family-based studies of oral clefts in subjects of Asian and European descent, identifying several novel genes and regions (including ADAMTS9, CDH1, and 7p14.1) as potential candidates underlying the etiology of oral clefts.

Association of the MMPs genes single nucleotide polymorphisms with gastric and duodenal ulcer in Volga-Ural region of Russia

E. Shaymardanova[1], *A. Nurgalieva*[1], *L. Gabbasova*[2], *O. Kuramshina*[2], *A. Krukova*[2], *R. Sagitov*[3], *U. Ismagilova*[3], *R. Sharafutdinov*[3], *R. Fayzullin*[3], *E. Khusnutdinova*[4,1];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Bashkir Medical State University, Ufa, Russian Federation,* [3]*Emergency Hospital, Ufa, Russian Federation,* [4]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation.*

Peptic ulcer disease (PUD) refers to painful sores or ulcers in the lining of the stomach (GU) or duodenum (DU). Recent studies have indicated that gastric ulceration is associated with cleaving and remodeling of the extracellular matrix (ECM) by matrix metalloproteinases (MMP). The aim of this study was to investigate the allele and genotype distribution of SNPs in the MMP1 (rs2276109, rs4994379), MMP2 (rs2285053), MMP3 (rs3025053), MMP9 (rs3918242, rs17576), MMP12 (rs2276109) and metalloproteinase

tissue inhibitors TIMP2 (rs8179090), TIMP3 (rs9619311) genes in patients with PUD and healthy donors from Volga-Ural region of Russia.
The patient group consisted of 353 individuals with PUD, the control group included 285 unrelated non-ulcer individuals with different ethnic origins (Russians, Tatars, Bashkirs). Genomic DNA was extracted from peripheral blood leucocytes by standard phenol/chloroform method. Genotyping was performed by PCR-RFLP analysis.
The analysis shows that genotypes rs494379*A/G, rs17576*A/G are associated with the risk of PUD in Tatars (P=0.001;OR=2.37 and P=0.003;OR=2.19, respectively). Genotypes rs494379*A/G, rs17576*A/G are also markers of the increased risk of PUD development in H.pylori-positive individuals (P=0.007;OR=2.29 and P=0.009;OR=2.23, respectively), whereas rs3025053*5A/6A was protective (P=0.03;OR=0.43).
Thus, we have determined statistically significant association between MMPs genes polymorphisms and peptic ulcer in Volga-Ural region of Russia.

PS18.73
Utilizing the Jaccard index to reveal population stratification in sequencing data: A simulation study and an application to the 1000 Genomes Project

D. Prokopenko[1,2], *J. Hecker*[1,2], *E. Silverman*[3], *M. Pagano*[4], *M. Noethen*[2], *C. Lange*[1,5,3], *H. Loehlein Fier*[1,2];
[1]Institute of Genomic Mathematics, University of Bonn, Bonn, Germany, [2]Institute of Human Genetics, University of Bonn, Bonn, Germany, [3]Channing Laboratory, Brigham and Women's Hospital, Boston, MA, United States, [4]Department of Biostatistics, Harvard School of Public Health, Boston, MA, United States, [5]Department of Biostatistics, Harvard School of Public Health, Boston, Germany.

Population stratification is one of the major sources of confounding in genetic association studies, potentially causing false-positive and false-negative results. Here, we present a novel approach for the identification of population substructure in high density genotyping data/next generation sequencing data. The approach exploits the co-appearances of rare genetic variants in individuals. The method can be applied to all available genetic loci, does not require linkage disequilibrium (LD) pruning, and is computationally fast. Using sequencing data from the 1000 Genomes Project (phase 3), the features of the approach are illustrated and compared to existing methodology (i.e. Eigenstrat). We find that our approach works particularly well for genetic loci with very small minor allele frequencies. The results suggest that the inclusion of rare-variant data/ sequencing data in our approach provides a much higher resolution picture of population substructure than it can be obtained with existing methodology. Furthermore, in simulation studies, the proposed methodology maintains the type 1 error accurately and shows higher power in some scenarios.

PM18.74
New putative regions of positive selection based on a sample of Mexican indigenous population

M. Contreras-Sieck[1,2], *M. Ortega-Sanchéz*[2], *M. Villalobos-Comparán*[1], *M. Menjivar*[3,1], *V. Acuña-Alonzo*[2], *S. Canizales-Quinteros*[3,1], *S. Romero-Hidalgo*[1];
[1]Instituto Nacional de Médicina Genomica, Distrito Federal, Mexico, [2]Escuela Nacional de Antropología e Historia, Distrito Federal, Mexico, [3]Facultad de Química, Universidad Nacional Autónoma de México (UNAM), Distrito Federal, Mexico.

The simultaneous genotyping of hundreds of thousands of SNPs in previously uncharacterized populations is of great importance given its potential to detect signals of recent positive selection as well as to depict insights of their genetic structure and their relationship to other human populations. To this end, we analyzed 442,450 SNPs in 469 individuals from four indigenous populations throughout Mexico (167 Nahuas, 103 Mayas, 98 Totonacs and 101 Zapotec). We calculated Fst, IHS an XP-EHH statistics to detect possible footprints of positive selection using two sets of data representing Asian and European population as outgroups, focusing on signals that relate to metabolic traits. Based on genetic differentiation, when Indigenous and European populations are considered, preliminary results clearly identified EDAR and SLC45A2 genes. In addition to this a 60 kb region was identified in chromosome 15 involving SLC28A2 gene. When comparing Indigenous and Asian population's three strong signals in chromosomes 14, 20 and 22 were found. Of particular interest is the result obtained in chromosome 14 where a 2 Mb region is detected including two long intergenic non-protein coding RNA and MDGA2, a gene previously associated to metabolic traits in GWAS. Further studies are being design to confirm these results to better understand their biological meaning.

PS18.75
Increased expression of proinflammatory signal transducer TLR4 receptor is associated with preterm birth

M. Pandey, *M. Chauhan, S. Awasthi;*
King George`s Medical University, Lucknow, India.

Introduction- Toll-like receptor-4 (TLR4) is the major endotoxin-signaling receptor and is crucial for the initiation of immune response. Inflammation within the uterus has been implicated in the pathogenesis of preterm birth. In the present study, we reveal the possible implication of TLR4 expression and function for immunologic immaturity and vulnerability of premature and even mature newborns. However, little is known about their expression and regulation in inflammatory pathway. Therefore, we aimed to assess the association of expression of TLR-4 in mothers with preterm birth.
Material and methods- A total of 135 mothers each who delivered preterm and term births were included. Total RNA was isolated from blood of all subjects and the quantification of TLR-4 expression was measured by real time PCR. The18SrRNA gene was used as an endogenous control (housekeeping gene).Results were evaluated using the delta-delta Ct method, where delta Ct was calculated as (TLR4 Ct) (18SrRNACt), and the relative quantity of TLR4 mRNA expression was calculated by the delta-delta Ct as 2-[case sample delta Ct)− (control sample delta Ct)].
Results-TLR4 mRNA expression was found to be 2.5 ±0.08 fold higher in cases (TLR4 mRNA levels of 0.72 ± 0.037) than in controls (TLR4 mRNA levels 0.498 ± 0.038, p=0.0002).
Conclusion-We concluded that the expression of TLR4 mRNA was elevated in mothers with preterm birth. It may be used as a biomarker associated with preterm labor.

PM18.76
Identification of rare disease codes in ICD-9-CM and exploration of Minimal Hospital Data

P. M. Urbina[1], *A. D'Havé*[2], *V. Van Casteren*[1], *I. Mertens*[2], *E. Swinnen*[1];
[1]Scientific Institute of Public Health , WIV-ISP, Elsene - Brussels, Belgium, [2]2. Federal Public Service of Health, Food Chain Safety and Environment, Brussels, Belgium.

For financial reimbursement, Belgian hospitals need to comply with compulsory registration of the Minimal Hospital Data (MHD). These comprise various data on all hospital admissions at patient level. Our ultimate goal is to query this comprehensive repository to answer various health care related questions in the area of rare diseases (80% of which are genetic diseases).
Unfortunately, such analyses are hampered by lack of a suitable codification/classification system in the hospital information systems. Although efforts are being made to introduce the ORPHA rare disease codes, diagnostic information in the MHD was coded with ICD-9-CM. Since January 2015, ICD-10-CM is in use .
In order to investigate the problem of rare disease coding more thoroughly and to enable the exploitation of historical data, we aimed to identify all codes of interest in the ICD-9-CM and ICD-10-CM. Mapping and linearization of the ORPHA codes to ICD-10-CM codes is done by Orphanet (INSERM) and available at orphadata.org. ICD-9-CM/ ICD-10-CM conversion tables were created by the FPS. By standardizing and combining these lists we distilled a final set of ICD9-CM codes for rare diseases of equivalent, broader as well as narrower terms.
We conclude that for rare diseases, the transition to ICD-10-CM was indispensable due to a higher degree of granularity. We will discuss the mapping methodology, its accuracy and results. In addition, we will illustrate the value of MHD analyses for identification of rare diseases by presenting information derived from MHD for a representative rare disease.

PS18.77
Rare variant association tests for longitudinal family studies

Y. Chiu[1], *L. Chien*[1], *F. Hsu*[2], *D. W. Bowden*[3];
[1]Division of Biostatistics and Bioinformatics, Institute of Population Health Sciences, National Health Research Institues, Zhunan, Taiwan, [2]Department of Biostatistical Sciences, Winston-Salem, NC, United States, [3]Center for Diabetes Research, Center for Genomics and Personalized Medicine Research, Department of Biochemistry, Winston-Salem, NC, United States.

Identification of rare variants has been shown to be critical in dissecting the disease etiology for they are often functional relevant. Family studies enriched with affected members are likely to aggregate functional variants, thus, increase statistical power for rare variant detection. Longitudinal family studies further provide additional information for identifying genetic and environmental factors associated with disease over time. However, rare variant analysis methods of longitudinal family data remain fairly li-

mited, which need to account for different sources of correlations as well as to handle large sequencing data efficiently. To identify rare variants in longitudinal family studies, we extend the powerful pedigree-based burden and kernel association tests for genetic longitudinal studies. The proposed methods model phenotypes following a distribution in the exponential family. Confounding factors as fixed effects can be adjusted for. These tests account for the complex correlations between repeated measures from the same phenotype (the serial correlation) and between individuals within the same family (the familial correlation). We use generalized estimating equation (GEE) approaches to generalize the pedigree-based burden and kernel tests to multiple correlated phenotypes under generalized linear model framework. Comprehensive simulation studies were conducted to compare the proposed tests with marginal models using GEE and mixed effects models under a variety of configurations. The proposed tests are applied to the Diabetes Heart Study (DHS). Significant exome variants of POMGNT1 and JAK1 genes associated with type 2 diabetes are identified.

PM18.78

Strategies to improve the performance of rare variant rare disease association studies by optimizing the selection of controls

N. Zhu[1], *V. Heinrich*[1], *T. Dickhaus*[2], *J. Hecht*[3], *P. Robinson*[1], *S. Mundlos*[1], *T. Kamphans*[4], *P. Krawitz*[1];
[1]*Institute of Medical Genetics and Human Genetics, Charité-Universitätsmedizin Berlin, Berlin, Germany,* [2]*Weierstrass Institute for Applied Analysis and Stochastics (WIAS), Berlin, Germany,* [3]*Berlin-Brandenburg Center for Regenerative Therapies (BCRT), Charité-Universitätsmedizin Berlin, Berlin, Germany,* [4]*Genetalk, Berlin, Germany.*

When analyzing a case groups of patients with ultra-rare disorders the ethnicities are often diverse and the data quality might vary. The population substructure in the case group as well as the heterogeneous data quality can cause substantial inflation of test statistics and result in spurious associations in case-control studies if not properly adjusted for. Existing techniques to correct for confounding effects were especially developed for common variants and are not applicable to rare variants. We therefore analyzed different strategies to select suitable controls for cases that originate from different populations and differ in data quality. We developed an approach to build up a control group that is most similar to the individuals in the case group with respect to ethnicity and data quality by means of a metric that puts more weight on rare variants. We simulated different disease entities on real exome data and show that a similarity-based selection schemes can help to reduce false-positive associations and to optimize the performance of the statistical tests. We reanalyzed collections of unrelated patients with Kabuki make-up syndrome, Hyperphosphatasia with Mental Retardation syndrome and Catel-Manzke syndrome for which the disease genes were recently described. We show that rare variant association tests are more sensitive and specific in identifying the disease gene than intersection filters and should thus be considered as an favorable approach in analyzing even small patient cohorts.

Genetic variations in Interleukin genes and recurrent spontaneous abortions

A. Sozou[1], *F. Malakasi*[1], *K. Pappa*[1], **K. Agiannitopoulos**[1], *S. Rapti*[1], *A. Hatzaki*[2], *K. Lamnissou*[1];
[1]*Department of Genetics & Biotechnology, Faculty of Biology, University of Athens, Athens, Greece,* [2]*Dept of Genetics and Molecular Biology, AlfaLAB "Leto", General Maternity and Pediatric Clinic, Athens, Greece.*

Indroduction: Inflammatory cytokine cascades have been implicated in the pathogenesis of pregnancy loss. Polymorphisms in cytokine genes may affect the risk of recurrent spontaneous abortions (RSA) but genetic association studies have often contradictory results among different populations. The purpose of this study was to investigate whether polymorphisms in the interleukin genes IL-6 and IL-1 are implicated in pregnancy outcome.
Methods: A total of 220 Greek women were examined for the IL-6 -174 T/C and IL-1 Ra polymorphisms. The patient group consisted of 120 women with at least three unexplained recurrent spontaneous abortions before 20 weeks of gestation while 100 women with at least two live births and without history of abortions served as controls. All individuals were genotyped by the PCR-RFLP method, for the first polymorphism, and by PCR method for the second polymorphism.
Results: The data between the two groups were analyzed by chi-square test or Fisher's exact test. Our results indicated that for both studied polymorphisms there are no significant differences in genotype or in allele frequencies between the patient and the control group.
Conclusion: Conversely to some other populations, in our Caucasian population the polymorphisms IL-6 -174 T/C and IL-1 Ra are not associated with the risk for RSA.

PM18.80

BMD loci underlie developmental determination of ethnic differences in skeletal fragility across populations due to selection pressures

C. Medina-Gomez[1], *A. Chesi*[2], *D. H. M. Heppe*[1], *B. S. Zemel*[2], *J. Yin*[1], *H. J. Kalkwarf*[3], *A. Hofman*[1], *J. M. Lappe*[4], *A. Kelly*[2], *M. Kayser*[5], *S. E. Oberfield*[6], *V. Bone mineral density (BMD) is a highly heritable trait used both for the diagnosis of osteoporosis in adults and to assess bone health in children. Ethnic differences in BMD have been documented, with markedly higher levels in individuals of African descent, which partially explain disparity in osteoporosis risk across populations. To date, 63 independent genetic variants have been associated with BMD in adults of Northern-European ancestry. Here, we demonstrate that 61 of these variants are predictive of BMD early in life by studying their compound effect within two multiethnic pediatric cohorts. Furthermore, we show that within these cohorts and across populations worldwide the frequency of those alleles associated with increased BMD is systematically elevated in individuals of Sub-Saharan African ancestry. The amount of differentiation in the BMD genetic scores among Sub-Saharan and non-Sub-Saharan populations and together with neutrality tests, suggest that these allelic differences are compatible with the hypothesis of selective pressures acting on the genetic determinants of BMD, providing a new example of polygenic adaptation in a human trait.

PS18.81

The regional analysis of Slovenian mitochondrial gene pool reveals sharp gradient of J1c haplogroup

A. Zupan, *N. Hauptman, D. Glavač;*
Faculty of Medicine, Ljubljana, Slovenia.

Introduction: The Slovenian territory, which is geographically positioned in central Europe between the Alps, the Adriatic Sea, Pannonian basin and Dinaric Mountains, has experienced turbulent historic events, which are reflected in different archaeological cultures found in the area. Turbulent historic events and diverse geography of the region have produced a diverse contemporary population whose genetic analysis could provide insight into past demographic events.
Materials and Methods: In order to characterise the Slovenian mitochondrial gene pool at the micro-geographic level and to compare it with surrounding populations we analyzed a total of 402 individuals from five Slovenian regions, by typing HVR I, HVR II and coding region polymorphisms of mtDNA.
Results: Analysis revealed 47 haplogroups and subhaplogroups, the most common of which were H*, H1, J1c, T2 and U5a. The intra-population comparison revealed a sharp gradient of J1c haplogroup between different Slovenian populations, with the peak frequency of 24.5 % in the population of Littoral Region. The high frequency of J1c haplogroup among the population of Littoral Region could represent the genetic trace of the early Neolithic expansion along the East Adriatic coastal region, which is in line with the archaeological horizon known as an Impressed Ware culture, whose findings are characteristic for Slovenian Littoral Region.
Conclusion: These results outline not only the impact of early Neolithic genetic input on a modern Slovenian genetic structure, but also an importance of regional sampling strategy for the understanding of historical demographic events which define the history of East Adriatic and Central European populations.

PM18.82

Folic acid supplementation influences the distribution of neural tube defect subtypes: a registry-based study

J. E. H. Bergman, *E. Otten, J. B. G. M. Verheij, H. E. K. de Walle;*
University Medical Center Groningen, Groningen, Netherlands.

Objective: To study the effect of folic acid supplementation on the distribution of neural tube defect (NTD) subtypes.
Design: Registry-based, case-only study.
Setting: Northern Netherlands, 1997-2012.

Population: Live births, stillbirths, miscarriages and terminated pregnancies due to fetal anomaly with an NTD registered by EUROCAT Northern Netherlands with birth years 1997-2012. After excluding cases with unspecified NTD location, unknown maternal folic acid supplementation status, or a probable syndromal or chromosomal cause for the NTD, we had 173 cases in our study population.
Methods: Chi-square testing was used to assess differences in NTD subtype distribution between two groups: correct folic acid supplementation and incorrect or no folic acid supplementation. We then assessed whether exposure to the main risk factors for NTD influenced the NTD subtype distribution.
Main Outcome Measures: The proportion of anencephaly, cervical/thoracic spina bifida, lumbar/sacral spina bifida, and encephalocele per folic acid group.
Results: Proportionally fewer cervical/thoracic cases and more lumbar/sacral spina bifida cases were present in the correct folic acid supplementation group than in the group with incorrect or no folic acid supplementation, and this was irrespective of the presence of the main NTD risk factors. The effect on NTD subtype distribution was only seen when folic acid supplementation was started before conception.
Conclusions: Folic acid not only prevents the occurrence of a significant proportion of NTDs, but might also decrease the severity of NTDs, as long as supplementation is started before conception.

PS18.83
Population-based detection of structural variants in normal and aberrant genomes

J. Monlong, *G. Bourque;*
McGill University, Montreal, QC, Canada.

Structural Variants(SVs) are key elements in evolution and complex diseases. Their detection from high-throughput sequencing(HTS) data has evolved substantially increasing its sensitivity to smaller events and breakpoints resolution. However the fraction of false positive predictions remains non-negligible and few efforts have been directed toward problematic regions such as low-mappability or repeat-enriched genomic regions, known to be rich in SVs but generally excluded from analyses. After revealing important complex technical bias in HTS, we propose to use a large set of experiments and a population-based approach to robustly identify of abnormal regions genome-wide.
Comparing read coverage across hundreds of samples requires an appropriate normalization step. We show that a general normalization is not sufficient to correct systematic sample-specific variation and develop a flexible and targeted approach. The statistical test for each bin uses a Z-test-like score adjusted by a robust multiple-testing correction. We test our approach on more than 100 normal and tumor whole-genome paired datasets from three different cancer resequencing projects. We show that more concordant germline events and tumor-specific ones are detected, compared to other approaches. Very few regions of the genome were excluded and a number of SVs were detected in low-mappability region. The comprehensiveness and extended genomic coverage of the approach will benefit the characterization of variation in low-mappability regions as well as cancer and disease related studies where complex SVs play an important role.

PM18.84
Infering variants contributing to synthetic association

A. Lacour;
German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany, Bonn, Germany.

It has been suggested that association of common variants with complex diseases can be created by multiple rarer variants. While the hypothetical properties of such synthetic associations have been elaborated, so far no method has been provided for the systematic retrieval of genetic variant sets that create a synthetic association. Variants giving rise to synthesis might be located several Mb away from the major association signal. Testing all possible combination of n nearby variants results in an exponential number of tests, 2^n-1. In view of this, the need for an efficient search strategy is obvious. In this work, we define filter criteria based on linkage disequilibrium measures and allele frequencies which reflect expected properties of synthesizing variant sets. From those we obtain potentially synthesizing sets and, by using the identified variants as covariate parameters in a regression model, subsequently evaluate whether they actually explain the main association signal. We apply our algorithm to confirmed consensus susceptibility loci of Alzheimer's disease which have been published recently in a large meta-analysis study.

PS18.85
Influence of Ethnicity in Association of CAPN10, PPARG and PGC-1α Genes with T2D from North-West Indian Population

R. Sharma;
Guru Nanak Dev University, Amritsar, India.

Type 2 diabetes (T2D) is a global public health crisis threatening all economies especially those of the developing countries. India exhibits different ethnic population structure comprising of various caste groups which practice strict endogamy. The present study investigated the association of CAPN10 (SNP-43, SNP-19, SNP-63), PPARG (Pro12Ala) and PGC-1α (Thr612Met, Thr528Thr, Gly482Ser, Asp475Asp, Thr394Thr, IVS2+C>A) polymorphisms in 1125 samples including 554 T2D cases and 571 controls from Bania, Brahmin and Jat-Sikh ethnic groups of North-West India. Minor allele of CAPN10 SNP-43, -19 polymorphisms provide risk towards T2D in Brahmin and Jat-Sikh groups; SNP-63 in Bania and Jat-Sikh groups. G-allele of PGC-1α Gly482Ser polymorphism was found to play protective role against T2D in Jat-Sikh group (p=0.002). Intriguingly, it provided 1.48 fold increased risk towards T2D predisposition in Bania group (p=0.009) suggesting population specific risk towards T2D. However, no association of PGC-1α (Asp475Asp) and PPARG (Pro12Ala) polymorphisms were seen in any group. In CAPN10 gene, the 212-haplotype in Bania group, 221-haplotype in Brahmin, 211 and 221-haplotypes in Jat-Sikh group conferred increased risk towards T2D susceptibility. PGC-1α haplotypes GGGGCA, GGGGTC in Brahmin; GAAGTC, GGGGTC in Jat-Sikh group provide 1.5-5 fold increased T2D risk. Differential pattern of genetic association and haplotypes of studied genes emphasized the role of ethnic-heterogeneity in T2D. The inconsistency of genetic effects of studied polymorphisms across populations from different ethnicities was investigated through meta-analysis indicating the role of population stratification. Thus, for risk calculation and proper medical intervention, knowledge of the ethnicity and nature of variation in risk factors needs serious attention.

PM18.86
Large scale meta-analysis of genome-wide data after 1000 genome imputation identifies multiple new loci associated with telomere length.

C. P. Nelson[1,2], *M. Mangino*[3], *N. J. Samani*[1,2], *V. Codd*[1,2], *on behalf of the ENGAGE Consortium Telomere Group;*
[1]*Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom,* [2]*National Institute for Health Research Leicester Cardiovascular Biomedical Research Unit, Glenfield Hospital, Leicester, United Kingdom,* [3]*Department of Twin Research and Genetic Epidemiology, King's College London, London, United Kingdom.*

Introduction: Mean leukocyte telomere length (LTL) exhibits considerable interindividual variability and has high heritability estimated at 0.70 (95% CI 0.64-0.76). Both shorter and longer LTL have been shown to associate with age-related diseases, including coronary artery disease (CAD) and some cancers. We previously reported seven loci associated with LTL. Using these in a genetic risk score analysis implies a causal link between shorter LTL and increased CAD risk. However, the extent to which the association of shorter LTL with other age-related disorders is causal in nature remains unclear. Identifying additional genetic variants that affect LTL and testing their association with disease through mendelian randomisation approaches could clarify any causal role.
Materials and methods: We report preliminary results from a genome-wide meta-analysis of LTL in up to 44,708 individuals, from 21 cohorts, after imputation using the 1000 genomes reference panel.
Results: We have redefined the lead signal for many of the known loci. Using an FDR of 1% in an additive model we identify ten novel loci affecting LTL. We also performed a recessive analysis which identified an additional 13 loci using an FDR of 5%. The novel loci includes both genes involved in telomere biology (ATM, DCAF4, POT1) as well as genes with no known involvement (MPHOSPH6, DCC).
Conclusions: Imputation to a large reference panel and assessing both additive and recessive modes of inheritance has brought the total number of loci associated with telomere length to 30.
Grants & fellowship: The ENGAGE Consortium was funded by the European Union.

PS18.87
Frequency of COL4A3/COL4A4 mutations amongst families segregating glomerular microscopic hematuria and evidence for activation of the unfolded protein response - Focal and segmental glomerulosclerosis is a frequent development during ageing.

L. Papazachariou, *P. Demosthenous, M. Pieri, G. Papagregoriou, I. Savva, A. Pierides, K. Voskarides, C. Deltas;*

University of Cyprus, Nicosia, Cyprus.

Familial glomerular hematuria(s) comprise a genetically heterogeneous group of conditions which include Alport Syndrome (AS) and thin basement membrane nephropathy (TBMN). Here we investigated 57 Greek-Cypriot families presenting glomerular microscopic hematuria (GMH), with or without proteinuria or chronic kidney function decline, but excluded classical AS. We specifically searched the COL4A3/A4 genes and identified 8 heterozygous mutations in 16 families (28,1%). Eight non-related families featured the founder mutation COL4A3-p.(G1334E). Renal biopsies from 8 patients showed TBMN and focal segmental glomerulosclerosis (FSGS). Ten patients (11.5%) reached end-stage kidney disease (ESKD) at ages ranging from 37-69-yo (mean 50,1-yo). Next generation sequencing of the patients who progressed to ESKD failed to reveal a second mutation in any of the COL4A3/A4/A5 genes, supporting that true heterozygosity for COL4A3/A4 mutations predisposes to CRF/ESKD. Although this could be viewed as a milder and late-onset form of autosomal dominant AS, we had no evidence of ultrastructural features or extrarenal manifestations that would justify this diagnosis. Functional studies in cultured podocytes transfected with wild type or mutant COL4A3 chains showed retention of mutant collagens and differential activation of the unfolded protein response (UPR) cascade. This signifies the potential role of the UPR cascade in modulating the final phenotype in patients with collagen IV nephropathies.

Recessive inheritance and inbreeding in Thyroid cancer

H. Thomsen[1], *B. Chen*[1], *G. Figlioli*[1,2], *R. Elisei*[3], *C. Romei*[3], *M. Cipollini*[2], *A. Cristaudo*[3], *F. Bambi*[4], *E. Paolicchi*[2], *P. Hoffmann*[5,6], *S. Herms*[5,6], *S. Landi*[2], *K. Hemminki*[1,7], *F. Gemignani*[2], *A. Försti*[1,7];

[1]*German Cancer Research Center (DKFZ), Molecular Genetic Epidemiology, Heidelberg, Germany,* [2]*Department of Biology, University of Pisa, Pisa, Italy,* [3]*Department of Endocrinology and Metabolism, University of Pisa, Pisa, Italy,* [4]*Blood Centre, Azienda Ospedaliero Universitaria A. Meyer,, Firenze, Italy,* [5]*Department of Genomics, Life and Brain Center, University of Bonn, Bonn, Germany,* [6]*Division of Medical Genetics, University Hospital Basel; Department of Biomedicine, University of Basel, Basel, Switzerland,* [7]*Center for Primary Health Care Research, Clinical Research Center, Lund University, Malmö, Sweden.*

Genome-wide association studies (GWASs) have identified several single-nucleotide polymorphisms (SNPs) influencing the risk of thyroid cancer (TC). Most cancer predisposition genes identified through GWASs function in a co-dominant manner, and studies have not found evidence for recessively functioning disease loci in TC. Our study examines whether homozygosity is associated with an increased risk of TC and searches for novel recessively acting disease loci. Data from a previously conducted GWAS were used for the estimation of heritability, the detection of runs of homozygosity (ROH) and the determination of inbreeding to unravel the influence on TC. Association on a SNP-by-SNP basis reached genome-wide significance at a level of P<10-8, with eight SNPs representing true differences in homozygosity between cases and controls. The rate of ROHs per person was significantly higher in cases than in controls. The average ROH size and length of ROHs per person was also higher for cases than controls. A total of 16 recurrent ROHs of rather short length were identified although their association was not significant at a genome-wide level. Several recurrent ROHs harbor genes associated with risk of TC. All of the ROHs showed significant evidence for natural selection (iHS, Fst, Fay-Wu's H). The higher inbreeding among cases support the existence of recessive alleles that cause TC. Although regions of homozygosity were rather small, it might be possible that variants within these ROHs affect susceptibility to TC and may function in a recessive manner.

PS18.89

METAINTER: meta-analysis tool for GWAS allowing for interaction

T. Vaitsiakhovich[1], *D. Drichel*[1], *C. Herold*[1], *A. Lacour*[1], *V. Schüller*[1], *T. Becker*[1,2];

[1]*German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany,* [2]*Institute for Medical Biometry, Informatics and Epidemiology, University of Bonn, Bonn, Germany.*

Introduction: Meta-analysis of summary statistics from Genome-wide association studies (GWAS) may lead to discovery of new susceptibility loci without exchange of genotype data. Well-known p-value combination methods can be applied to an arbitrary association test. However, these methods do not provide summary effects and are underpowered for high-dimensional models. Results of related genome-wide interaction analyses (GWIA) have rarely been meta-analyzed due to complexities underlying the process of their synthesis.

Materials and Methods: Summary statistics of single-SNP GWAS can be integrated in one-step meta-analysis. For two-SNPs GWIA, we suggest a two-stage procedure to guarantee computational feasibility. At stage I, complete GWIA is conducted in each study participating in meta-analysis using a fast pre-test. All studies retain top ranking results to merge them in a „joint" list of SNP pairs. At stage II, the joint list is analyzed in each study by an advanced (regression) test. The results of stage II can then be meta-analyzed using proper software. We introduce an efficient, powerful and freely available tool METAINTER, which implements recently developed method for the synthesis of multiple regression slopes and three further meta-analysis methods. METAINTER enables meta-analysis of interaction tests, single-marker tests with several degrees of freedom, global haplotype tests etc. We conducted a real data analysis of six GWAS of type 2 Diabetes (T2D). The results were meta-analyzed with METAINTER.

Results: We obtained evidence for interaction between SNPs in PPP2R2C, associated with T2D and close to LOC101928448, associated with body fat distribution.

Conclusions: We introduce an efficient and powerful pipeline for the meta-analysis of GWIA.

PM18.90

Sex specific GWAS reveals new loci associated to red and white wine liking.

N. Pirastu[1], *M. Kooyman*[2], *M. Traglia*[3], *A. Robino*[4], *S. M. Willems*[2], *G. Pistis*[5], *N. Amin*[2], *C. Sala*[5], *L. C. Karssen*[2], *C. Van Duijn*[2,6], *P. Gasparini*[1,4];

[1]*Università degli Studi di Trieste, Trieste, Italy,* [2]*Genetic Epidemiology Unit, Department of Epidemiology, Erasmus Medical Center, Rotterdam, Netherlands,* [3]*Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milano, Italy,* [4]*Institute for Maternal and Child Health - IRCCS "Burlo Garofolo", Trieste, Italy,* [5]*Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milan, Italy,* [6]*Centre for Medical Systems Biology, Leiden University Medical Center, Leiden, Netherlands.*

Recent studies in the genetics of wine liking have found a strong association between white wine liking and the HLA-DOA gene. However given the great differences shown in wine preference by man and women we have decided to conduct a sex specific GWAS on red wine and white wine liking using 5 isolated population coming from Italy (INGI-CARL , INGI-FVG , INGI-VB), Netherland (ERF) and Central Asia (SR) using a total of 1682 man and 2184 women. GWAS on man identified 4 genome wide significant loci (p<5x10-8). Best hits for each locus are: rs78560355 (p=7.5x10-10) close to the PLCL1 e rs112080424 (p=3.9x10-8) close to TNS3 for red wine and rs35662810 (p=1.2x10-8) close to LOC100288392 and rs72517376 (p=2.14x10-8) inside LGALS2 for white wine. PLCL1 in particular has been previously associated to the maximum number of alcoholic drinks consumed at one time. We decided to verify if the identified SNPs had an impact on alcohol consumption. We thus created a score based on the discovered SNPs. The value for each person was estimated as: wine_liking_score = genotypeSNP * betaSNP. The created score showed a significant and similar effect in the CARL and FVG populations (lbeta 0.13 and 0.11 respectively, combined p=0.003). The identified genes are one of the first examples of association between genetic variants and common foods. Further more we have shown that the identified genes have an effect on total alcohol consumption suggesting a causal relationship between wine liking and alcohol consumption.

PS18.91

Paternal genetic landscape of Croatian Eastern Adriatic islands in a wider European context

J. Šarac[1], *T. Šarić*[1], *D. Havaš Auguštin*[1], *S. Rootsi*[2], *S. Missoni*[1], *R. Villems*[2], *P. Rudan*[1,3];

[1]*Institute for Anthropological Research, Zagreb, Croatia,* [2]*Estonian Biocentre, Tartu, Estonia,* [3]*Anthropological Center of the Croatian Academy of Sciences and Arts, Zagreb, Croatia.*

Croatian Eastern Adriatic islands represent well-characterized genetic isolates, concerning their ethnohistory, biological traits, disease prevalence, migration patterns and environmental and sociocultural characteristics. Such small communities can reflect large demographic processes that happened in human prehistory and history and give us insight into the ancient migratory paths and forming of the Croatian and Southeast European gene pool. The aim of this study was to evaluate the level of isolation of insular populations based on the observed haplogroup distribution and frequencies of 720 samples from 12 Croatian subpopulations and to define the main processes that have shaped present Y chromosome variation of Eastern Adriatic islands and Croatia in general. A high level of haplogroup and haplotype diversity has been detected in the overall sample and the observed haplogroup frequency distributions correspond to an average European population, suggesting a dynamic gene flow in this region throughout history. The PCA plots show that the position of different Croatian subpopulations mostly corresponds to their actual geographic location. Also, it is noticeable that most of them are stretched along an axis, depending of the portion of I2a2-M423 and R1a-M458/M558 sublineages in their sample. Although the

studied insular populations show an expected (mostly Paleolithic) paternal genetic structure corresponding to their geographic location, genetic structure of some islands exhibits interesting results due to the significant effect of evolutionary forces and specific historic episodes (like Lastovo, Cres and Dugi otok).

PS18.93

Phylogeographic refinement of human Y chromosome haplogroup E provides new insights into the early dispersal of herders in sub-Saharan Africa

B. Trombetta[1], *E. D'Atanasio[1], A. Massaia[1,2], M. Ippoliti[1], A. Coppa[3], F. Candilio[3], G. Destro Bisol[3], G. Russo[4], J. Dugoujon[5], P. Moral[6], D. Sellitto[7], A. Novelletto[8], R. Scozzari[1], F. Cruciani[1,7];*

[1]Dipartimento di Biologia e Biotecnologie „Charles Darwin", Sapienza Università di Roma, Roma, Italy, [2]The Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [3]Dipartimento di Biologia Ambientale, Sapienza Università di Roma, Roma, Italy, [4]Dipartimento di Sanità Pubblica e Malattie Infettive, Sapienza Università di Roma, Roma, Italy, [5]Laboratoire D'Anthropologie Moléculaire et Imagerie de Synthése, Centre National de la Recherche Scientifique (CNRS), Université Toulouse-3 Paul-Sabatier, Toulouse, France, [6]Department of Animal Biology-Anthropology, University of Barcelona, Barcelona, Spain, [7]Istituto di Biologia e Patologia Molecolari, CNR, Roma, Italy, [8]Dipartimento di Biologia, Università di Roma „Tor Vergata", Roma, Italy.

Recently, a high number of Y chromosome SNPs has been discovered through next generation sequencing studies, but the geographic distribution for most of these variants remains largely unexplored.

Haplogroup E is the most common human Y chromosome clade within Africa and its internal branches have been linked to a wide range of human movements. To increase the level of resolution of haplogroup E, we disclosed the phylogenetic relationships among 729 mutations found in 33 haplogroup DE Y-chromosomes sequenced at high coverage in previous studies and further dissected the E-M35 subclade by genotyping 62 informative markers in about 5000 samples from 118 worldwide populations.

The phylogeny of haplogroup E showed novel features compared to the previous topology, including a new basal clade. Within haplogroup E-M35, we resolved basal polytomies and assigned all the E-M35* chromosomes to different new monophyletic clades. Through a Bayesian phylogeographic analysis, we associated each node of the tree to specific geographic areas. By this analysis, we identified a new E-M35 sub-Saharan clade, which originated about 11 kya in the northern part of the Horn of Africa. SNP-based dating, phylogenetic structuring and geographic distribution of this clade (and its sub-clades) are consistent with a multi-step dispersal of herders within eastern Africa and its subsequent diffusion to sub-equatorial areas.

Our results provide new insights into the evolutionary hypotheses about the spread of pastoralism in Africa and increase the discriminative power of the E-M35 haplogroup for use in forensic genetics through the identification of new ancestry informative markers.

PM18.94

Spatial variation of the Y-chromosome: The global patterns and correlations with other genetic systems, linguistic and geography

O. Balanovsky[1], *A. Pshenichnov[2], S. Koshel[3], R. Sychev[1], R. Villems[4], E. Balanovska[2];*

[1]Vavilov Institute of General Genetics, Russian Academy of Sciences, Moscow, Russian Federation, [2]Federal State Budgetary Institution „Research Centre for Medical Genetics", Moscow, Russian Federation, [3]Faculty of Geography, Lomonosov Moscow State University, Moscow, Russian Federation, [4]Estonian Biocentre, Tartu, Estonia.

We developed the "Y-base" database, which includes frequencies of 500 Y-chromosomal haplogroups in 4200 populations worldwide, with total sample size 142,000. 130,000 Y-chromosomes came from 300 published papers and remaining 12,000 are our unpublished data.

Using this dataset we created the world spatial distribution maps of 230 haplogroups. This World Atlas of Y-chromosomal variation was created by GeneGeo software, which we developed for digital map analysis in gene geography. The zones of sharp changes in frequencies were interpreted as genetic boundaries; the main boundary crosses Eurasia and includes not only mountain (Himalayas and Caucasus) but also steppe segments.

The question arises to which degree patterns of Y-chromosomal variation agree with data on other genetic systems. To answer, we characterized all extant ethnic groups speaking Balto-Slavic languages by mitochondrial DNA (N=6,876), Y-chromosome (N=6,079) and genome-wide SNPs (N=296). We found that genetic distances, based on autosomal and Y-chromosomal loci, show a high correlation (0.9) both with each other and with geography but slightly lower correlation (0.7) with the mitochondrial DNA and linguistic affiliation.

The high-throughput sequencing of the Y-chromosome reveals thousands phylogenetically informative SNPs. Population screening for these markers subdivides old haplogroups with subcontinental zones of spread into multiple young haplogroups with restricted areas - thus providing excellent tools for reconstructing population history. This approach allowed us successfully subdivide C2-M217, N1c-M178, and G1-M285 into 35 new subhaplogroups, to create their frequency distribution maps and estimate the SNP and STR mutation rate on the Y-chromosome.

PS18.95

Corsican genetic heritage: Y-chromosome story

J. Di Cristofaro, *S. Mazières, A. Tous, C Di Gaetano, A.A. Lin, A. Piazza, R. J. King, P.A. Underhill, J. Chiaroni;*

UMR7268 ADES, Marseille, France.

The scarcity of human remains in Corsica leads to uncertainties of its first peopling. First modern human might have arrived during Paleolithic, as great glaciations had form bridges between Toscana and Corso-Sardinian Island, allowing humans to cross at different time in Pleistocene.

Conflicting results have been published concerning the genetics of the Corsican populations and their relationship with Sardinian, French and Tuscans populations. It appears obvious that Corsican populations display high heterogeneity, exacerbated between North and South; this is confirmed by anthropological, archeological and linguistic data. Moreover, continental historical genetic input could be modest, despite many historical campaigns. Thus, the genetic characteristics of the Corsican population could be the result of Neolithic or Paleolithic migrations.

The objective of the present study is to get an insight of the Corsica peopling by the analysis of the Y-chromosome. This study comprises data from populations from the Mediterranean zone, totaling 890 individuals. Samples were collected from 18 populations from Corsica, 1 from Provence and 3 from Toscana.

All samples were type for the 19 main haplogroups and according to each sample genotype, further analyses were performed: 84 binary markers were genotyped and 53 were informative.

Haplogroups profile in Corsica showed some signature from both France and Toscana, but mostly display its own specificity. The strongest genetic structure was encountered when the populations were considered into four main geographical groups: northwest, south and east, northern peninsula, and western region. Because of the haplogroups described here and their diversity, these results support Neolithic and Paleolithic migrations rather than historical movements to Corsica.

Beta thalassemia is a monogenic disorder characterized by reduced or absent β-globin chain synthesis. More than 200 disease causing mutations have been identified in the beta globin gene; such mutations can seriously affect the production of β-globin chains and consequently cause β- thalassemia.

In some regions of Saudi Arabia such as AlHassa; β- thalassemia occurs at a frequency as high as 3.4% in premarital couples. Meanwhile, no comprehensive mutational screening for the β-globin gene has been carried out so far in Saudi Arabia. This study reports the complete molecular screening of the entire β- globin gene in 120 Saudi β- thalassemia patients. Sequencing of the entire open reading frame and LCR of the β-globin gene identified 7 homozygous disease causing point mutations and 9 compound heterozygous disease-causing mutations of these one is novel. MLPA analysis revealed a number of deletions in our patients. In addition haplotype analysis using 5 restriction enzymes identified 22 different haplotypes in our cohort of patients. Carrier status was also determined in enrolled family members. This study characterizes the common mutations and variants in the β-globin gene in Saudi Arabia and reports new variants and mutation.

This study was supported by grants from King Abdul-Aziz City for Science and Technology (KACST), King Faisal specialist Hospital and research center (KFSH&RC), and Kind Saud University (KSU).

PS19.01

An integrated approach to the introduction of Genomics into the NHS in England

S. L. Hill, *R. Cashman, S. Chapman, L. Quayle, J. Stewart;*
NHS England, London, United Kingdom.

As part of the NHS contribution to the 100,000 Genomes Project, NHS England committed to putting in place arrangements to enable the acquisition of samples and accompanying clinical data of sufficient quality to enable whole genome sequencing under the contractual arrangements between Genomics England (a company owned by the Department of Health set up to deliver the 100,000 Genomes Project) and Illumina (the company Genomics England procured to deliver the sequencing and support the analysis of the resulting genome).
Since July 2014, a transparent and rigorous procurement exercise has been conducted to commission and designate the first ever Genomic Medicine Centres (NHS GMCs). The service specification detailed every element of the sample and data pipeline in participants with rare disease and cancer (from acquisition to validation of whole genome sequence findings to feedback to clinical teams and participants) and provides not just the contractual basis for service delivery but a baseline for measuring improvement and the quality of outcomes. This will serve as a catalyst to a broader transformation programme to introduce genomic technologies into clinical care across the NHS in England in a systematic and sustainable way for public and patient benefit, to support scientific endeavour and diagnostic delivery and industry collaborations.
Already we have seen the NHS GMCs adopt innovative patient and public co-production to design their genomics service, the creation of genomics MDTs spanning a multitude of specialisms, creative workforce training and forward thinking approaches to informatics.

Perspectives of adolescents regarding their genetic counselling experience: a qualitative study

A. Pichini[1,2,3], *C. Shuman*[2,3], *M. Kaufman*[4], *K. Sappleton*[5], *D. Chitayat*[2,3,6], *R. Babul-Hirji*[2,3];
[1]*Clinical Genetics Department, Saint Michael's Hospital, Bristol, United Kingdom,* [2]*Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, ON, Canada,* [3]*Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada,* [4]*Division of Adolescent Medicine, The Hospital for Sick Children, Toronto, ON, Canada,* [5]*Centre for Innovation and Excellence in Child & Family Centred Care, The Hospital for Sick Children, Toronto, ON, Canada,* [6]*Prenatal Diagnosis and Medical Genetics Program, Mount Sinai Hospital, Toronto, ON, Canada.*

Introduction: Adolescence is an intense period of development that involves creating a sense of identity, autonomy, relationships and values. This can be complicated by having a genetic condition. Genetic counselling can play an important role in providing information and support to this patient population; however, resources and guidelines are currently limited. We sought to investigate the experiences and perspectives of adolescents with a genetic condition regarding their genetic counselling interactions.
Methods: This study utilized a qualitative exploratory approach, specifically the Interpretive Description methodology. Eleven semi-structured interviews were conducted with adolescents diagnosed with a genetic condition who received genetic counselling between the ages of 12 and 18 years at The Hospital for Sick Children. Transcripts were analysed thematically using qualitative content analysis.
Results: Three major interrelated themes emerged from analysis: (1) understanding the genetic counsellor's role; (2) increasing perceived personal control; and (3) adolescent-specific factors influencing adaptation to one's condition. Additionally, a list of suggested tools and strategies for genetic counselling practice were elucidated.
Conclusions: To our knowledge, this study is the first to explore the perspectives of adolescents with respect to their genetic counselling experience. Information gleaned from this study will contribute to the development of an adolescent-focused framework to enhance emerging genetic counseling approaches for this patient population, and will facilitate the transition process from pediatric to adult care within patient and family-centered contexts.
This study was funded by The Hospital for Sick Children Trainee Start-Up Fund.

PS19.03

Multidisciplinary counselling in genetic tests for Amyotrophic Lateral Sclerosis

S. Penco[1], *L. Mosca*[1], *C. Lunetta*[2], *A. Marconi*[2], *S. Pozzi*[2], *C. Tarlarini*[1], *E. Maestri*[2], *V. Sansone*[2], *G. Rossi*[2], *G. Gesu*[1];
[1]*Niguarda Ca' Granda Hospital, MIlano, Italy,* [2]*NeuroMuscular Omnicentre, Fondazione Serena Onlus, MIlano, Italy.*

Amyotrophic Lateral Sclerosis (ALS) is a devastating rare late onset neurodegenerative disease which affects motor neurons in the primary motor cortex, brainstem and spinal cord.
The etiopathogenesis of the disease is still known however several genetics factors have been identified and the hypothesis of multifactoriality is the more accreditated.
The discovery of genetic abnormalities causing familial (FALS) and sporadic (SALS) ALS allowed patients to access to genetic test; consequently, the elaboration of a clinical, genetic and psychological asset allowing to cope genetic issues is required. To date, no specific guidelines for neurological disorders genetically inherited exist, with the exception of Huntington's disease (HD).
In 2013 our team group introduce in the context of genetic counselling, a multidisciplinary approach characterized by the integrative participation of three different professionals, psychologist, geneticist, and neurologist in order to face all aspects related to the pathology and to understand and manage information in a personal and familial way.
We report here the clinical experience of a project dedicated to the development of a specific model of genetic counselling for ALS patients, based on suggestions on genetic counselling for this disease.

PM19.04

Reflections on the reactions of breast cancer patients who do not fulfill the criteria for BRCA1 and BRCA2 genetic testing

V. C. Anastasiadou[1,2], *G. Tanteles*[1], *E. Aristidou*[1], *A. Kotti*[2], *T. Delikurt*[1];
[1]*The Cyprus Institute of Neurology and Genetics; Clinical Genetics Clinic, Nicosia, Cyprus,* [2]*Makarios Medical Center; Clinical Genetics Clinic, Nicosia, Cyprus.*

Since 2004, cancer patients have been referred to the Cancer Genetics Clinic (CGC) for tailored hereditary risk assessment and genetic counselling based on the type of cancer, family history and age of diagnosis. For breast cancer patients, the CGC team has recently started to use the Manchester scoring system (MSS) in order to assess patients' hereditary risk and eligibility for BRCA1 and BRCA2 genetic testing. The MSS is a relatively new scoring system that is devised to estimate the possibility of identifying pathogenic mutations in the BRCA1 and BRCA2 genes, with a 10% cutoff level for testing eligibility. Patients who score less than 10% on the MSS following risk assessment are not eligible for genetic testing. These patients are offered a careful explanation of the eligibility criteria, risk assessment, psychosocial counselling and are advised on the importance of their continuation with cancer screening. They are also advised to contact the CGC in the event that they or a family member has a new cancer diagnosis so that an updated risk assessment is offered to them. In this poster, we will reflect on the impact of using MSS at CGC as well as comment on the various reactions of these patients who are not offered genetic testing because they scored below the cutoff level.

PS19.05

Personalized medicine in cancer prevention- BRCA screening in unaffected Ashkenazi Jewish women. Randomized controlled trial of different pre-test strategies

S. Lieberman[1,2], *A. Tomer*[1], *A. Ben-Chetrit*[3,4], *O. Olsha*[5], *R. Beeri*[1], *A. Raz*[6], *A. Lahad*[2,7], *E. Levy-Lahad*[1,2];
[1]*Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel,* [2]*Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel,* [3]*Department of Obstetrics and Gynecology, Shaare Zedek Medical Center, Jerusalem, Israel,* [4]*Women's Health Center, Ramat Eshkol, Clalit Health Services, Jerusalem, Israel,* [5]*Department of Surgery, Shaare Zedek Medical Center, Jerusalem, Israel,* [6]*Ben-Gurion University of the Negev, Be'er-Sheva, Israel,* [7]*Department of Family Medicine, Clalit Health Services, Jerusalem, Israel.*

BRCA1/2 carriers have high breast/ovarian cancer risks that can be diminished by risk-reduction surgeries. However, approximately half of carriers lack significant family history, and would only be identified through general testing. The Ashkenazi Jewish population is a model for such screening, given high prevalence (1/40) and testing sensitivity (>95%) of three common mutations. Large scale testing may require adjusting the counseling process. We are examining the impact of excluding pre-test face-to-face genetic counseling (GC) in the population screening setting.
Ashkenazi Jewish women age ≥ 25 years, were randomized to two pre-test arms: traditional GC vs. written information only (WI). Feelings, knowledge and attitudes toward testing were assessed using questionnaires one week (Q1) and 6 months (Q2, ongoing) post-testing.
Among the first 309 participants we identified six carriers (1.9%) Another 6 carriers were identified by cascade testing in 10 relatives of these carriers. At Q1, satisfaction was very high or high in both GC (62%, 33% respectively) and WI (54%, 41%), but higher in GC (p=.002). IES (impact of events)

scores were similar in both groups. At Q1, personal perceived control (PPC) scores and knowledge were higher in GC (p=.005; p=.0002), but absolute differences were small; PPC: 0.17 of 2 points, knowledge: 1.14 of 10 points. At Q2, only PPC scores remained higher in GC: 1.46 vs. 1.23 in WI (p=.008). These ongoing results suggest that in the screening setting, forgoing pretest GC may be a legitimate alternative. This option could be considered in cases of logistic or cost limitations.

PM19.06

Evaluation of an information day for individuals with BRCA1 and 2 gene mutations in the East Anglian region (UK): participant feedback and reflections

J. Hague, *L. Hughes, H. E. Shipman;*
East Anglian Medical Genetics Service, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom.

Background: Our aim was to address ongoing support and management needs of families with hereditary cancer syndromes. With ever increasing pressure on genetics services, a cost- and time- effective approach that has been widely adopted to address this is to organise Information Days. These provide families/individuals with up to date information about medical management and psychological implications. Following our recent information day, we present our participants' feedback and our reflections for future programme development.
Programme: All 561 individuals with a known pathogenic mutation in BRCA1/2 who underwent genetic counselling and testing through the East Anglian Medical Genetics Service were invited to attend the day, along with family/friends. 196 people attended the day. The programme included presentations about BRCA mutations, risk reducing surgery, the support group, FORCE, and research, as well as a 'Q&A' panel discussion. 59 feedback forms were completed, many of which reflected the views of the family rather than of individuals.
Feedback and Reflections: The feedback from participants was overwhelmingly positive, with many expressing how valuable they had found the day and requesting future events. In particular they commented on their increased knowledge and understanding, and the benefits of a forum to meet with other BRCA1/2 families. Several requested that future events better address the support needs of men and have a stronger focus on addressing psychosocial aspects. The feedback will direct how we propose to develop an ongoing programme in our catchment area.

PS19.07

Recommendations vs. Reality: Genetics referrals for all invasive serous ovarian cancers

R. Demsky, *J. M. McCuaig, A. Volenik, B. Rosen, R. Kim, S. Randall Armel;*
Princess Margaret Cancer Centre, Toronto, ON, Canada.

It is well recognized that having a diagnosis of invasive serous ovarian cancer (SOC) is associated with an increased risk of having a BRCA1 or BRCA2 mutation. Therefore, numerous guidelines recommend that women with this diagnosis are offered genetic testing irrespective of family history or age at diagnosis. Despite such guidelines, previous data from the Princess Margaret Cancer Center (PM) in Toronto, Canada demonstrate that only 23% of women diagnosed with SOC were seen for genetic counselling. To improve genetic counselling uptake, changes in pathology reporting, appointment scheduling, and referring physician education were implemented. Following these interventions, referral and genetic counselling uptake rates were examined for all SOC cases at PM between 2010 and 2013. Of 430 SOC cases, 59% (253/430) were referred for genetic counselling and 54% (233/430) attended an appointment. Of those who received genetic counseling, 94% (220/233) proceeded with genetic testing and 23% (50/220) harboured a BRCA1 or BRCA2 mutation. Notably, 34% (17/50) of women with a mutation had no family history of breast or ovarian cancer. Despite changes to increase uptake of genetic counselling, a significant number of eligible women are still not receiving genetic testing. Considering the high mutation rate in this population and the value of such results in determining treatment and identifying high-risk families, it is imperative that all women diagnosed with SOC are offered genetic testing, irrespective of family history or age at diagnosis.

PM19.08

How reassuring is a negative result? Rapid genetic testing of BRCA1 and BRCA2 during treatment for breast cancer.

P. Greene, *D. Stirling, S. Drummond;*
South East Scotland Clinical Genetics service, Edinburgh, United Kingdom.

Women diagnosed with breast cancer, who also have a BRCA1 or BRCA2 mutation have a high risk of a second primary breast cancer (1). Offering these patients the opportunity to find out their BRCA status between diagnosis and surgery could help inform their surgical treatment and also give them the opportunity to consider including a prophylactic element to their surgery.
From the beginning of 2014 breast surgeons in Edinburgh have been able to refer patients, who meet a certain threshold, for rapid testing of BRCA1 and BRCA2. The aim being to get results back to patients and their surgeons in time for them to be of use in making surgical decisions.
In this poster we will present the criteria that were used to target the testing, and how the referral process was managed. We will present the outcome of the testing in this small group of patients and also asses the influence the result had on surgical decisions by comparing the patients stated intentions about surgery prior to testing and their eventual surgical treatment.
We will conclude with some brief reflections on the counseling and ethical issues genetic testing during diagnosis raises.

Should women with breast cancer before 40 years be included in rutine genetic test in the Genetic Counseling Units? The Castilla y León experience

A. Pascual Rodríguez[1,2,3], *E. SánchezTapia*[1,2,3], *L. Robinson García*[1,2], *T. Martín Gómez*[3,4], *R. Vidal Tocino*[3,4], *J. Cruz Hernández*[2,3,4], *R. González Sarmiento*[1,2,3];
[1]*Molecular Medicine Unit. Department of Medicine. University of Salamanca., Salamanca, Spain,* [2]*Institute of Molecular and Cellular Biology of Cancer. Univeristy of Salamanca-CSIC, Salamanca, Spain,* [3]*Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain,* [4]*Department of Clinical Oncology University Hospital of Salamanca, Salamanca, Spain.*

Breast cancer (BC) is the most common invasive cancer worldwide in women and it is also the leading cause of death from cancer amongst women. BC in young women is rare and only 5-7% occurs in women under 40 years.
Nearly 5-10% of patients suffering from BC have genetic predisposition. Most of hereditary breast and ovarian cancer syndromes are caused by a germline mutation in the BRCA genes. Genetic counseling allows to find subjects with hereditary genetic predisposition to cancer, to implement preventive measures reducing the incidence of these tumors and early diagnosis to improve survival.
The aim of this study was to review the inclusion criteria of women with BC below 40. From the unit of genetic counseling of Castilla y Leon between 2003-2013, 206 women diagnosed with BC under 40 were included in this study. Genomic DNA was isolated from peripheral blood and BRCA1/2 coding regions and intron-exon boundaries were amplified by PCR and analyzed by Sanger sequencing.
The prevalence of a BRCA1/2 germline pathogenic mutation was 22 (10,7%). From these patients 18,1% did not have familial history of breast/ovarian cancer. 72% of these mutations were found in BRCA1 where 75% of these carriers have familial history of breast/ovarian cancer. In relation to 184 non-carriers patients, 81 women had positive familial history.
Our results suggest that women below 40 without familial history should not be included for BRCA1/2 genetic studies although it is necessary to perform an economical analysis before take the definitive decision.
Supported by PI13/01741 and Consejería de Sanidad de la Junta de Castilla y León

PM19.10

Difference and similitude regarding breast and ovarian screening program and prophylactic surgery guidelines in women carriers of a BRCA mutation: results of a European online survey

C. M. Maugard[1,2,3], *N. Taris*[4,1], *F. Gillmann*[1], *C. Mathelin*[1], *C. Cordier*[1,2,4];
[1]*Hôpitaux Universitaires de Strasbourg, Strasbourg, France,* [2]*Hôpital Pasteur, Colmar, France,* [3]*Université de Montréal, Montréal, QC, Canada,* [4]*Centre Paul Strauss, Strasbourg, France.*

Introduction: Female carriers of a *BRCA* mutation have a high risk of developping breast and/or ovarian cancer. In France, the National Institute of Cancer published in 2009 guidelines for breast and ovarian cancer early detection and prevention in female carriers. As a part of a reflexion dealing with these guidelines, we initiated a European study on breast screening program and gynaecological monitoring aimed at female carriers of a *BRCA* mutation.
Material and Methods: we collected information regarding these programs through an online survey. Health professionals (physicians, medical gene-

ticist, nurses, oncologists, gynecologist, psychologists, genetic counsellors) in charge of *BRCA* mutation carriers in the context of a genetic clinic were asked to participate to this survey through the ENGNC group electronic mailing list.
Questionnaire regarding *BRCA* mutation carriers took into account three different situations: 1) women non-affected with cancer, 2) women affected with breast cancer, 3) women diagnosed with ovarian cancer. For each of them, participants were asked about breast-awareness, clinical breast examination, breast and ovarian screening program, prophylactic surgery (mastectomy and/or salpingo-oophorectomy) and chemoprevention programs.
Results : We already obtained questionnaires replies from nine European countries: France, Netherlands, Ireland, England, Hungary, Germany, Italy, Sweden, Switzerland. A second round of letters was sent in order to encourage additional participants to complete the survey.
We will report about similitude and differences in screening and prophylactic surgery guidelines according to each group of patients, and their country or evenly provinces of residence.

PS19.11
Inherited childhood cancers: parents' perceptions of children's information needs

*K. J. Ahmed[1], **M. Ahmed**[2], S. Ahmed[3];*
[1]School of Medicine, University of Leeds, Leeds, United Kingdom, [2]Yorkshire Regional Genetics Service, Leeds, United Kingdom, [3]Leeds Institute of Health Sciences, University of Leeds, Leeds, United Kingdom.

Multiple Endocrine Neoplasia type 1 (MEN1) and type 2 (MEN2) are autosomal dominant cancer syndromes that are associated with significant morbidity and mortality. Early genetic testing and diagnosis of MEN1 and MEN2 can allow for medical care to improve cancer related outcomes. There is little research on communication with children about genetic testing for childhood cancers. This study explored parents' experiences and perceptions of children's information needs for genetic testing for MEN1 and MEN2. Semi-structured qualitative interviews were conducted with seventeen parents whose children had been tested for either of these cancer syndromes in the twelve months preceding the time of recruitment. The findings show that parents found it difficult to broach the subject of predictive genetic testing for cancer with their children, and many would have valued support to do so from healthcare professionals (HCPs). Parents also believed their child was over-burdened with information from the HCPs, and would have valued a pre-consultation meeting with the HCP only to ensure the information was tailored to the child's needs and temperament. Parents had differing views about the use of the word 'cancer' in consultations with their child. While some believed it should be avoided because of its perceived association with imminent death, others explained that the familial nature of the condition meant that their child could associate cancer with living a 'normal' life. These findings have implications for the way in which HCPs communicate with parents and children about genetic testing for MEN1 and MEN2 to improve efficacy of consultations.

PM19.12
Cancer genetics management for primary care providers

M. Dougherty[1,2], *E. Edelman[3], T. Nissen[3], K. Reed[3];*
[1]American Society of Human Genetics, Bethesda, MD, United States, [2]University of Colorado School of Medicine, Aurora, CO, United States, [3]The Jackson Laboratory, Bar Harbor, ME, United States.

The American Society of Human Genetics and The Jackson Laboratory have developed and implemented an interactive educational program to improve the clinical skills of primary care providers (PCPs) in assessing and managing genetic risk for cancer. This blended learning program consists of 6.5 hours of in-person content, monthly communications, and access to online resources. The program addresses learning objectives that help providers learn about and practice: collecting a targeted family history; identifying red flags and patterns of inheritance; assessing the clinical utility of testing; facilitating patient decision-making; communicating the benefits and limitations of testing; and using guidelines to manage care. The program was piloted with 21 PCPs in the U.S. in November 2014. Participants completed knowledge, attitudes, and confidence assessments pre and post, which were analyzed by paired t-tests. Participants demonstrated improved confidence in their ability to assess hereditary cancer risk, determine appropriate referrals, and discuss the benefits, risks, and limitations of genetic testing with patients (all $p<0.001$), increased agreement with attitudes related to genomic risk assessment ($p<0.05$), and improved knowledge related to risk assessment, genetic testing, and clinical management ($p = 0.01$). These early results suggest that this innovative program can build PCP skills in the assessment and management of hereditary cancer, supporting improved patient care. Based on this successful pilot, the program will be implemented more broadly and will serve as a framework for future programs and expanded audiences to improve clinical integration of genetics into practice.

PS19.13
Population genetic carrier screening for cystic fibrosis, fragile X syndrome and spinal muscular atrophy: Exploring experiences of carriers identified through the VCGS Reproductive Genetic Carrier Screening program

*C. Beard[1,2], **L. A. Di Pietro**[2,3], D. Amor[1,4], A. Archibald[1,2,4];*
[1]University of Melbourne, Parkville, Australia, [2]Murdoch Childrens Research Institute, Parkville, Australia, [3]Genetic Support Network of Victoria, Parkville, Australia, [4]Victorian Clinical Genetics Services, Parkville, Australia.

Due to advancing genetic technologies, population carrier screening for multiple inherited conditions can now be offered. This research aimed to explore how women experience undergoing carrier screening for three common inherited conditions; cystic fibrosis (CF), spinal muscular atrophy (SMA) and fragile X syndrome (FXS), through the Victorian Clinical Genetics Services (VCGS) Reproductive Genetic Carrier Screening (RGCS) program.
This study adopted a qualitative approach based on phenomenology. Ten female participants were recruited and in-depth semi-structured interviews undertaken. Two received a pre-mutation carrier result for FXS, three received a carrier result for CF and five for SMA. Coded transcripts were analysed using thematic analysis to identify emerging themes.
The majority of participants were pregnant during screening and described the decision to have the test as straight forward. Participants' experienced emotional responses (anxiety and stress) whilst waiting for their partner's test result and completed online research to discover more about the relevant condition during this time. Participants were in favour of population carrier screening, preferably offered prior to conception.
The findings of this study elucidated that genetic counsellors (GCs) play an essential role within this program, supporting couples after they receive a carrier result given the varying consent processes undertaken prior to screening. The implementation of Internet resources and GC facilitated guidance to access reliable online information is crucial to help empower couples and assist the coping process. Improving awareness of the availability of population carrier screening within the community will also help improve knowledge levels and facilitate preconception screening.

PM19.14
Barriers and facilitators of cascade screening for hereditary breast/ovarian cancer in a statewide randomly selected sample

M. C. Katapodi[1,2], *D. Duquette[3], K. Mendelsohn-Victor[2], B. Anderson[3], J. Yang[2], L. Northouse[2], K. Milliron[4], S. Duffy[5], D. Ronis[2], S. Merajver[6], N. Janz[7], S. Roberts[7];*
[1]University of Basel, Basel, Switzerland, [2]University of Michigan, School of Nursing, Ann Arbor, MI, United States, [3]Michigan Department of Community Health, Lansing, MI, United States, [4]University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, United States, [5]Ohio State University, School of Nursing, Columbus, OH, United States, [6]University of Michigan, School of Medicine, Ann Arbor, MI, United States, [7]University of Michigan, School of Public Health, Ann Arbor, MI, United States.

Genetic counseling is recommended for young women diagnosed with breast cancer and their close relatives. Cascade screening is a new public health intervention that promotes systematic familial testing among relatives of individuals with known mutations. In an effort to assess the feasibility of statewide cascade screening, we examined the willingness of young breast cancer survivors (YBCS) invite their high-risk relatives to participate in such a program.
A randomized trial aiming to increase awareness of cancer genetics, identified a random sample of 3000 YBCS, diagnosed 25-45 years old, and stratified by race (Black/Other), through the Michigan Cancer Surveillance Program. YBCS' responses helped identify high-risk, unaffected, female relatives. A linear regression analysis, guided by the Theory of Planned Behavior, examined demographic and clinical characteristics, access and attitudes towards healthcare services, family history, and family environment as predictors of the proportion of eligible relatives YBCS were willing to contact (number willing to contact/ number of all high-risk relatives).
Responses from 859 eligible YBCS (33%) helped identify 1842 high-risk relatives; YBCS were willing to contact 1271 (69%). Willingness to contact a greater number of relatives ($\beta=23.2$), positive family history of cancer ($\beta=1.0$), and higher cancer self-efficacy ($\beta=0.9$) were associated with contacting a greater proportion of relatives. Having a larger family ($\beta=-15.8$) and being Black ($\beta=-.9$) were negatively associated with the proportion of relatives contacted.
Most YBCS were willing to contact relatives for cascade screening, suppor-

ting the feasibility of this approach. Results suggest barriers and facilitators in disseminating information about hereditary breast/ovarian cancer among families.

PS19.15

consanguinity and recessive disorders in East Lancashire (UK)- A multi-disciplinary approach

N. Khan[1], *A. Allen*[2], *G. Kerr*[3], *W. Parvaiz*[2], *H. Kingston*[1];
[1]*Genomic Medicine ST Mary's Hospital Oxford Road Manchester, Manchester, United Kingdom,* [2]*Family Health and Wellbeing Consortium, Blackburn, United Kingdom,* [3]*East Lancashire Public Health, Blackburn, United Kingdom.*

Populations practicing consanguinity are at increased risk of having children with autosomal recessive genetic disorders. In Blackburn with Darwen (BwD), families of South East Asian heritage account for 25% of the population and the majority are married to a relative. The infant mortality rate in BwD is the highest in the UK (HSCIC 2014), with the increase largely attributed to autosomal recessive disorders.

An Enhanced Genetic Service was developed in BwD in 2012, to provide genetic services to affected ethnic minority families. Whilst contributing significantly to the genetic management of these families, lack of awareness of genetic issues in the community was apparent; amongst health care practitioners as well as the general public. It was clear that there were also barriers to accessing genetic services for families where culture, language and lack of information reduced opportunities for obtaining appropriate support.

The current, genetic counsellor led initiative embraces a multi-tiered approach, aiming to improve knowledge of genetic issues affecting the ethnic minority population in the community, to encourage engagement with genetic services and to co-ordinate a package of medical and social support.

The unique element of this innovation project has been the establishment of Genetic Outreach workers, linking in to the genetics service, and the strong working partnership that has been developed with community based health care services and voluntary sector agencies.

The development and outcomes of this project will be presented. These have implications for other areas within the UK and Europe that have similar population demographics.

PM19.16

Developing a Master of Science in genetic and genomic counselling in Scotland a collaboration between the West of Scotland Genetic Services and the University of Glasgow

C. M. Watt[1], *M. Jackson*[2], *L. Sharp*[2], *L. Marks*[2], *E. S. Tobias*[1], *West of Scotland Genetic Counselling Team;*
[1]*West of Scotland Genetic Services, Glasgow, United Kingdom,* [2]*University of Glasgow, Glasgow, United Kingdom.*

Members of the West of Scotland genetics service contribute to the University of Glasgow's Master of Science (MSc) in medical genetics. The course was established in 1984 and runs annually for 30 students. In 2014 it was awarded the United Kingdom (UK) Prospects Postgraduate Award for best Postgraduate Teaching Team.

Each year undergraduate and post graduate students ask about becoming genetic counsellors in Scotland. Currently in the UK there are two MSc courses in genetic counselling one based at Manchester University in England and the other at the University of Cardiff in Wales. Both these courses are accredited by the Genetic Counsellor Registration Board (GCRB) and the European Board of Medical Genetics (EBMG). For Scottish students wishing to become registered genetic counsellors in the UK this means applying to courses in Manchester and Cardiff.

Genetic counsellors in Scotland are now working with Glasgow University to develop a MSc in genetic and genomic counselling which will run alongside the medical genetics course. This new course will have to meet Masters level for university approval and it will have to meet the EBMG and GCRB criteria for accreditation. The team have sought opinions from experts in the fields of genetic counselling and education which have proved invaluable highlighting areas for improvement to ensure the MSc in genetic and genomic counselling course meets the required standards.

The course will be based at the university's new education centre at South Glasgow University Hospitals. The course is seeking accreditation prior to enrolling students.

PS19.17

Genetic counselling services in Germany: outcomes of the GenBIn-Study

I. Nippert;
Institut für Humangenetik - Universitätsklinikum Münster, Münster, Germany.

Until recently, nationwide empirical data on the structure and utilization of genetic counselling services were not available for Germany. This lack impacts an informed assessment of the development of services after the enactment of the German Genetic Diagnostics Act (GenDG). The GenDG regulates the use of genetic information and materials in the course of genetic testing. All genetic testing is subject to indication and prescription by a licensed physician, requesting binding qualified counselling and information of patients. A Gene Diagnostics Commission (GEKO) has been tasked to issue guidelines related to each individual paragraph of the act. Guidelines for the provision of genetic counselling services were issued in 2012. Objectives: to create a databank that allows for comparing the status quo ante in 2011 with developments of genetic counselling service structures and utilization after the implementation of the GEKO guidelines. Methods: A retrospective empirical study to describe genetic counselling services in 2011 (PartI), followed by a documentation of services in 2015-2016 (Part II). Results Part I: 33 university-based counselling centres and 78 private practice centres were asked to participate. 2092 counselling cases were obtained. Marked differences were found between university-based centres and private practice centres in regard to: referrers, indication for counselling; reported workload; waiting time and case management. The data will serve as a baseline for data to be obtained in 2015-2016 and will facilitate informed assessment of the impact of the GEKO guidelines. (German Federal Ministry of Health: IIa5-2513-FSB-203)

PM19.18

Challenges of genetic counselling, genetic testing and clinical management of asymptomatic children of parents with catecholaminergic polymorphic ventricular tachycardia (CPVT1)

N. Moreton[1], *G. Ciotti*[2], *C. J. Garratt*[3], *S. Henriques*[1], *K. Metcalfe*[1], *W. G. Newman*[1], *C. Noctor*[2], *L. Venetucci*[3];
[1]*Manchester Centre for Genomic Medicine, University of Manchester, Clinical Genetics Service, 6th Floor, St Mary's Hospital, Central Manchester University Hospitals NHS Foundation Trust, Oxford Road, Manchester, M13 9WL, Manchester, United Kingdom,* [2]*Paediatric Cardiology Department, Royal Manchester Children's Hospital, Central Manchester University Hospitals NHS Foundation Trust, Oxford Rd, Manchester M13 9WL, Manchester, United Kingdom,* [3]*Manchester Heart Centre, Manchester Royal Infirmary, Central Manchester University Hospitals NHS Foundation Trust, Oxford Road, Manchester, M13 9WL, Manchester, United Kingdom.*

Catecholaminergic polymorphic ventricular tachycardia (CPVT1) is a cardiac channelopathy inherited in an autosomal dominant pattern. Characteristically patients present with recurrent fainting, seizures or sudden death after physical activity or emotional incidents resulting from high adrenaline levels. On average symptoms present before the age of 10 years. Genetic testing of RYR2 associated with CPVT1 is readily available. If a parent has a clinical diagnosis of CPVT1 and carries an RYR2 mutation predictive genetic testing (cascade screening) is offered to first degree relatives including children. Genetic testing of an asymptomatic child for a familial RYR2 mutation is a complicated decision and can cause psychological stress for the family. Using case studies we present the genetic counselling issues needed to be explored in order for fully informed consent to be reached prior to predictive genetic testing for CPVT1. These include:

Variability of presentation and incomplete penetrance of CPVT1

Evidence of the pathogenicity of the RYR2 mutation

Difficulties in clinically diagnosing CPVT1 in young children

Exercise restriction (RYR2 mutation carriers to avoid highly competitive sports)

Consideration of prophylactic beta blockade or defibrillators in asymptomatic RYR2 mutation carriers

Emotional impact of testing on the family

Difficulties in quantifying individual sudden death risks associated with CPVT1

Given the nature of these discussions there is a need for close collaboration between clinical geneticists, genetic counsellors, laboratory staff, paediatric and adult cardiologists to enable consistent yet individualised care for the family.

PS19.19

Focus on the public health implications and predictors of carrier testing in cystic fibrosis families.

I. Duguépéroux[1,2], C. L'Hostis[1], M. P. Audrézet[1,2], G. Rault[3], P. Parent[4], M. Blayau[5], S. Schmitt[6], **C. Férec**[1,2]*, V. Scotet[1];*
[1]INSERM UMR 1078, Brest, France, [2]University Hospital - Lab of Molecular Genetics, Brest, France, [3]Reference Cystic Fibrosis Centre, Nantes-Roscoff, France, [4]University Hospital - Dep of Medical Genetics, Brest, France, [5]University Hospital - Lab of Molecular Genetics, Rennes, France, [6]University Hospital - Lab of Molecular Genetics, Nantes, France.

Objective: Carrier testing enables relatives of cystic fibrosis (CF) patients to know their status regarding the CFTR mutation that segregates within their family. This test allows prevention in families and thus detection of new 1/4 risk couples. This study assessed the impact of carrier testing and searched for the predictors of uptake to testing.
Methods: Forty patients born in Finistère (Brittany, France) between 1980 and 2004 were enrolled. Family trees were faced with the CFTR gene studies performed in the regional laboratories.
Results: Among the 462 non-parent relatives eligible for testing, 185 had testing, corresponding to an adjusted percentage of uptake of 40.4% (95% CI: [33.8%; 46.9%]). Carrier testing enables detection of 5 new 1/4 risk couples, leading to 8 prenatal diagnoses and 5 terminations. Testing also allows to reassure many relatives (as non-carrier by testing or deduction, n=247), plus 60 couples (in whom mates of carrier relatives were negative). Finally, logistic regression adjusted for clustering revealed that the main predictors of being tested were female gender (OR=1.6, p=0.007), having a high a priori risk (OR1/2 vs 1/4=3.5, p=0.006; OR2/3 vs 1/4=31.5, p<0.001) and being over 18 y. at time of diagnosis (OR=2.5, p=0.008). Over 1/3 of the tested relatives had parental project or ongoing pregnancy.
Conclusion: Our study assesses, for the first time in Europe, uptake of CF carrier testing, a critical tool to reassure non carriers and to detect new at-risk couples. It also highlights factors influencing the choice to be tested.

PM19.20

Meeting the needs of cystic fibrosis carrier parents

F. Beecroft[1]*, C. Sherlaw[2], I. Doull[3], S. Moat[3], A. Clarke[4];*
[1]West Midlands Regional Clinical Genetics Service, Birmingham, United Kingdom, [2]Queen Elizabeth Hospital, Birmingham, United Kingdom, [3]University Hospital of Wales, Cardiff, United Kingdom, [4]Cardiff University, Cardiff, United Kingdom.

Introduction: Cystic fibrosis (CF) screening for all newborns has been available in Wales since 1996. This identifies a few unaffected carriers in addition to affected children.
Methods: Notes from the newborn screening (NBS) laboratory and the medical genetics service were used to identify children with positive screening tests and those whose families had accessed the medical genetics service. Parents of children identified as CF carriers through NBS between 1996 and 2001 were invited to participate in this study if they had disclosed their child's carrier status. Six families were interviewed about their experiences of finding out their child was a CF carrier and communicating this to their child and wider family.
Results: Parents emphasised the need for a short period between positive screening result and the sweat test distinguishing those affected from carriers. Although some parents had worried about disclosing carrier status to their child, this caused no lasting distress. Parents would have liked to receive advice about discussing carrier status with their children but little was available. No family knew how to seek a genetics referral. Some parents were unclear about the risks of their other children being carriers. Uptake of genetic services by the parents' sibs was lower than in families with an affected child: their wider families often appeared uninterested when parents discussed carrier status.
Conclusion: Professional support for effective communication around the time of a positive screening test is important. Parents may also appreciate support in communicating the implications of carrier status to their children.

PS19.21

Equipping physicians for direct-to-consumer genetic test discussions: a pilot study.

L. M. Jackson, *L. Goldsmith, H. Skirton;*
Plymouth University, Plymouth, United Kingdom.

Direct-to-consumer (DTC) genetic tests are available online, however there is little practical guidance for healthcare professionals (HCPs) and consumers concerning their use. One US study concluded that HCPs should be given "the information and tools they need to help patients make informed decisions about DTC genetic testing". A decision support tool was developed to guide HCPs and patients through a pathway that includes relevant actions and information on the appropriateness of the test. This tool is freely accessible online (http://www.eurogentest.org/index.php?id=939&no_cache=1).
Before the dissemination of any clinical tool, it is essential to conduct an evaluation with a sample of the target population. This small pilot study was conducted to evaluate the decision support tool. Fourth and fifth year medical students were recruited at Plymouth University to take part in an extensive mock consultation with a patient regarding their possible use of a DTC genetic test. In this way we aimed to investigate how useful the tool was in a clinical situation. Participants completed a qualitative debrief immediately following the consultation and their responses were analysed for common themes. It was found that HCPs should be encouraged to familiarise themselves with the tool ahead of an appointment to avoid interrupting the flow of the consultation. The tool was reported to be a useful device for guiding decisions and providing information to patients. With the launch of 23andMe susceptibility testing in the European market, this tool is a timely addition to the primary physician's toolkit.

PM19.22

Down syndrome integrated screening: two-years experience of Public Heath Service in Navarra region of Spain

C. Catalli, *M. Martinez Jaurrieta, L. Morales Garófalo, A. Bengoa Alonso, P. Torrecillas Brun, M. Ramos Arroyo;*
U.O. Genética Médica - Complejo Hospitalario de Navarra, Pamplona, Spain.

Down syndrome (DS) is one of the most frequent causes of fetal pathology, accounting for 8% of all cases of congenital disorders. Its incidence correlates with maternal age and screening programs are recommended.
While not-invasive prenatal diagnosis is rapidly growing as accurate screening method, the costs, the need of confirmation through an invasive test and the lack of long-term experience do not still allow its integration in population-based screening from Public health services. Here we present the experience with DS integrated screening program in Navarra, Spain, provided by the "Servicio Navarro de Salud-Osasunbidea". In more than 10.000 consecutive pregnancies, corresponding to 90% of all pregnancies in the population of reference, which underwent DS screening program, the integration of biochemical markers (PAPP-A, total B-HCG and aFP), sonographic measure of nuchal translucence at week 12 and maternal age allowed a detection rate of Down Syndrome of 88% with a false-positive rate of 3% for a fixed risk of 1:360.
Comparing to previous years in which amniocentesis was offered to all women with positive results on second trimester biochemical studies or advanced maternal age (>35 yearsor more), this DS screening program reduced the number of unnecessary invasive tests by almost 75%, with a higher detection rate. We demonstrate that the integrated screening program for DS in our public health service is effective and a viable option for population-based Down screening programs.

PS19.23

Ethical and legal issue of early prenatal screening in Moscow region

V. L. Izhevskaya[1]*, L. A. Zhuchenko[2];*
[1]Research centre for medical genetics, Moscow, Russian Federation, [2]Moscow Regional Research Institute of Obstetrics and Gynecology, Moscow, Russian Federation.

Analysis of legal regulation and ethics in early prenatal screening in the Moscow region was made. Early prenatal screening program was carried out as part of the Russian national project „Health" and was regulated by the Federal and Regional Governments and the orders of the Ministry of Health. Early prenatal screening program in the Moscow region was started in 2011; more than 150 000 pregnant women (about 70% of all pregnant women living in the region) were examined in 2011-2013. 2380 pregnant women were included in the risk group of fetal chromosomal pathology, invasive diagnosis was carried out in 1668 of them (70%), 416 rejected it. These data may indicate that women used their right to refuse testing, but may be the result of low efficiency of genetic counseling, especially its information components. Analysis of the reasons for rejection of invasive diagnosis was carried out. Frequent reasons were fear of complications (35%), unwillingness to make a decision in early pregnancy (22%), the desire to have a child regardless of his health (19%), confidence that the baby will be healthy (13%). Respondents named medical and domestic reasons for rejection of invasive diagnosis rather than religious or moral principles. The high proportion of women who were afraid of complications and was not ready to make a decision may reflect defects in information and psychological components of genetic counseling for early prenatal screening. This work was supported by the Russian Foundation for Basic Research, project 13-06-00710a

PM19.24

Use of electronic databases and pedigrees in cancer genetic counselling - the counsellee's experience

V. Stefansdottir[1,2], *O. Johannsson*[3], *J. Jonsson*[1,2], *H. Skirton*[4];
[1]*Dept. of Genetics and Molecular Medicine, Landspitali – National University Hospital of Iceland, Reykjavik, Iceland,* [2]*Dept. of Biochemistry and Molecular Biology, Univ. of Iceland, Reykjavik, Iceland,* [3]*Dept. of Medical Oncology, Landspitali – National University Hospital of Iceland, Reykjavik, Iceland,* [4]*Faculty of Health and Human Sciences, Plymouth University, Plymouth, United Kingdom.*

Introduction: Individuals and families generally seek cancer genetic counselling because of strong family history of cancer. In Iceland, pedigrees are made using a large genealogy database dating back to at least 1840 and the electronic Cancer Registry holding accurate breast cancer information from 1911 and other cancers from 1954. The aim of this study was to ascertain the acceptability of using databases to make pedigrees and inform on genetic risk assessment.
Material and Methods: Using qualitative methods, counsellees from known BRCA families (n=225) were invited to participate in focus groups via an online bulletin board. A total of 19 participants were allocated randomly to four groups, three of women and one of men only. Data were analyzed using thematic analysis.
Emerging themes arising from the results were motivation for testing, requirements for testing, impact of testing, emotional response and electronic database issues. Participants did not oppose and most trusted the information from the electronic databases. Some addressed concern about data privacy Participants had no specific concerns over other family members' attitudes to use information from databases.
Conclusions: This study has shown that use of databases to confirm genetic information and obtain accurate genealogical information for risk assessment is acceptable to families in Iceland. However, Iceland has a stable population and a long history of using genealogical records and these results may not be transferable to other cultures. Further research is indicated to determine if other populations share similar trust in databases.

PS19.25

Attitudes toward genetic research on children in Japan

Z. Yamagata[1], *K. Muto*[2];
[1]*University of Yamanashi, Yamanashi, Japan,* [2]*University of Tokyo, Tokyo, Japan.*

[Aim] Many birth cohort studies have been conducted worldwide. The ethics of genomic research on healthy children is paid attention. The aim of this study is to determine the attitudes of the general Japanese public toward genetic research on children and to clarify factors related to such attitudes based on nationwide surveys conducted in 2013. [Methods] From the general Japanese population, 2,000 people were selected using a stratified two-phase sampling method. In a mail survey administered in 2013, the participants were surveyed regarding the following topics: (1) their attitudes toward genetic testing, the genetic testing of children, and obtaining blood donations from children for research; (2) their level of scientific literacy regarding genomics; and (3)their demographic information and socioeconomic status. [Results] The response rate was 57.7%(1,154/2,000). Conducting genetic testing on children for disease susceptibilities was favored by 58.4% of participants. Regarding obtaining blood donations from children, 46.7% approved, 21.6% disapproved, and 31.7% were undecided. The multiple logistic analysis odds ratio regarding genomic literacy was 1.28 (95% confidence interval = 1.05-1.50). Regarding whether seeking consent from children is appropriate, 45.4% of people answered that seeking consent from a child is acceptable if the child understands the details of the research and 39.2% answered that seeking consent from a child is acceptable if the child can judge the pros and cons of participating in the research. These responses were associated with the level of genomic literacy. [Discussion] The results of this study suggest that people's genomic literacy is essentially related to people's perspective on genomic research on children.

The Italian External Quality Assessment in classical cytogenetics, coordinated by the National Centre for Rare Diseases- Istituto Superiore di Sanità, is an institutional activity; it covers prenatal, postnatal and oncological diagnosis.
All schemes are retrospective; assessment takes into account technical performance, analysis, interpretation and reporting of two cases sent by participants according to SIGU "Guidelines for cytogenetic diagnosis 2013" and ECA "Guidelines and Quality assurance for acquired cytogenetics". In 2013 the category of poor performace was defined.
At the end of the round participants receive a report; until now ten EQA rounds have been completed.
The total number of participants in 2014 was 75; 52, 64 and 28 laboratories participated in the prenatal, postnatal and oncological scheme respectively.
A satisfactory performance was given to the 88% and 75% of participants in constitutional and oncological diagnosis respectively. In constitutional diagnosis eight laboratories were poor performers; one laboratory was poor performer in both prenatal and postnatal diagnosis.
Critical errors leading to poor performances were: a) misleading ISCN errors (four reports); b) misleading ISCN errors and incorrect description of the result or interpretation (two reports); c) incorrect karyotype reconstructions (one case); d) inadequate banding quality (two cases); e) incorrect cytogenetic diagnosis (one case).
In oncological diagnosis seven laboratories were poor performers for: a) incomplete or inadequate analysis (three cases); b) incorrect cytogenetic diagnosis (two cases); c) cytogenetic result description absent (two reports); d) incorrect interpretation (two reports).
We will show the EQA state of the art and the 10th round results.

PS19.27

Exploring health professionals' opinions of the All Wales Familial Hypercholesterolaemia Cascade Testing Service as a model for genetic service delivery

R. Heaton[1,2], *N. Taverner*[2], *J. Hill*[2];
[1]*Manchester Centre for Genomic Medicine, Manchester, United Kingdom,* [2]*Institute of Cancer & Genetics, Cardiff University School of Medicine, Cardiff, United Kingdom.*

Familial Hypercholesterolaemia (FH) is a relatively common disorder, with a high risk of mortality from coronary heart disease at a young age. FH can be diagnosed clinically and/or by identification of a pathogenic mutation. When FH is identified, early deaths can be prevented by administering serum cholesterol-lowering drugs.
The All Wales Cascade Testing Service, introduced in 2010, endeavours to systematically identify and treat affected individuals. Cascade testing is routine in genetic practice, but this service offers a novel way of delivering genetics services in collaboration with another medical specialty. Diagnostic genetic testing of individuals affected by FH is managed within the lipid clinics and cascade genetic testing of relatives is offered by the genetics service.
This study explored health professionals' opinions on the delivery of cascade genetic testing by a multidisciplinary service, and whether they consider this to be a good model for providing genetics input. Nine participants (three nurses, two genetic counsellors and four consultants) participated in semi-structured interviews. These were transcribed and thematically analysed.
Most (7/9) thought the FH Cascade Testing Service was an excellent model which worked well. However, many (5/9) felt that this level of service may not be necessary for a treatable condition and had reservations as to how well it would work if translated into other areas of the UK. It was suggested that it may be more appropriate for each specialty to include staff trained to manage inherited conditions, calling on the services of the regional genetics service if and when necessary.

PM19.28

How communication of genetic information within the family is addressed in genetic counselling: a systematic review of research evidence

Á. Mendes[1,2], *M. Paneque*[1,3], *L. Sousa*[2,4], *A. Clarke*[5], *J. Sequeiros*[1,3];
[1]*I3S – Instituto de Investigação e Inovação em Saúde, and IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal,* [2]*Dept. Health Sciences, Univ. Aveiro, Aveiro, Portugal,* [3]*ICBAS, Univ. Porto, Porto, Portugal,* [4]*Cintesis (Center for Health Technology and Services Research), Aveiro, Portugal,* [5]*Institute of Medical Genetics, School of Medicine, Cardiff Univ., Cardiff, United Kingdom.*

Supporting consultands to communicate risk information with their relatives is key to obtaining the full benefits of genetic healthcare. Guidelines

recommend that professionals should not directly contact family members and that they should actively encourage consultands to transmit relevant information to their relatives and support them throughout this communication process; however, there is lack of clarity on how this should be done. To understand how healthcare professionals address this issue in clinical practice and what interventions are used specifically to assist consultands in their communication of genetic information to appropriate relatives, we conducted a systematic review. Four electronic databases were searched for papers published, in English, January 1997 through May 2014. Hand-search in four subject-specific journals was also performed. Fourteen papers met the inclusion criteria defined.
Thematic data analysis has shown that dissemination of information within families is actively encouraged and supported by professionals. Three overarching themes emerged: (1) direct contact from genetic services: sending letters to relatives of mutation carriers; (2) professionals' encouragement of initially reluctant consultands to share relevant information with at-risk relatives; and (3) assisting consultands in communicating genetic information to their at-risk relatives, which included subthemes as (i) psychoeducational guidance and (ii) written information aids.
Findings suggest that professionals' practice and interventions are predicated on the need to proactively encourage family communication. We discuss this in the context of what guidance of consultands by professionals might be appropriate, as best practices to facilitate family communication, and of the limits to non-directiveness in genetic counselling.

PS19.29
How are genetic counsellors educated? A systematic review of the evidence.

C. Ingvoldstad[1], M. Seven[2], **C. Cordier**[3]*, N. Taris[4], M. Paneque[5], H. Skirton[6];*
[1]CLINTECH, Obstetrics and Gynaecolgy, Karolinska Institutet, Stockholm, Sweden, [2]Koç University School of Nursing, Istanbul, Turkey, [3]Department of oncology and Hematology, Strasbourg, France, [4]Centre Paul Strauss, Strasbourg, France, [5]Centre for Predictive and Preventive Genetics, IBMC, University of Porto, Porto, Portugal, [6]Plymouth University, Plymouth, United Kingdom.

The need for appropriately trained genetic counsellors to support genetic healthcare is now acknowledged. However, while programs for education of genetic counsellors exist in a number of countries, these do not conform to any specific international standards. This systematic review was conducted to evaluate the publications for research of evidence regarding components of educational programmes for genetic counsellors worldwide. Databases were searched for studies published in English from 2000-2014 related to the topic. We identified 406 potential papers, of these 11 studies met the inclusion criteria. The findings indicate that, in general, the theoretical components of genetic counsellor programs conform to the recommendations and requirements of relevant professional bodies. However, clinical preparation of genetic counsellors in real-life professional practice settings seems to be less well addressed as this is essential to ensure genetic counsellors are able to provide safe patient care after graduation. Further work to gain agreement internationally on genetic counsellor education is needed.

PM19.30
An exploration of families' beliefs about the causes of psychosis or schizophrenia and whether they feel they will benefit from psychiatric genetic counselling.

S. Balasingham[1]*, M. Arribas Ayllon[2], J. Walters[3];*
[1]University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [2]Cardiff University School of Social Sciences, Cardiff, United Kingdom, [3]Cardiff University School of Medicine, Cardiff, United Kingdom.

Introduction: Since the full spectrum of genetic variants that confer susceptibility for complex psychiatric conditions (CPCs) remains unknown, genetic testing and counselling presents challenges. The literature to date while incomplete has profound implications for our understanding of aetiology, family burden and disease-associated stigma, demonstrating the need for a psychiatric genetic counselling (PGC) intervention. Research into the experiences of affected families can help to surmount these barriers and improve patient experience, providing a foundation from which genetic counsellors can develop confidence in the value of their services, even in the face of uncertainty.
This paper explores family experiences and the potential for the development of a PGC service in the UK.
Methods: Using a qualitative approach; relatives of individuals with schizophrenia or a related diagnosis were asked a series of open-ended questions about their experiences, their beliefs about cause, and their views about genetic testing and PGC. The interviews were recorded, transcribed and thematic analysis was applied to the dataset.
Results: The majority of participants reported no interest in genetic testing but most of them thought that GC would be invaluable to understanding aetiology and the psychosocial aspects of CPCs. Overall, respondents believed that there is genetic vulnerability to developing CPCs and despite genetic testing being unavailable a PGC intervention may be of value to future generations.
Conclusion: Ultimately, these findings offer insight into the delivery of PGC, which could be applied to other areas of genetic counselling (GC) where uncertainty lies, with a downstream effect on future GC practice.

PS19.31
Talking about uncertainty - a communication skills training model for professional development.

K. Dunlop[1,2]*, M. Saleh[1], R. Fleischer[3], B. Hopper[4], R. Lim[5], S. Dunn[5,2];*
[1]Centre for Genetics Education NSW Health, Sydney, Australia, [2]Sydney Medical School - Northern, University of Sydney, Sydney, Australia, [3]Department of Medical Genomics, Royal Prince Alfred Hospital, Sydney, Australia, [4]Children, Young People and Families (CYP&F), Taree, Australia, [5]Pam McLean Centre, University of Sydney, Sydney, Australia.

Rapid development in genomic technologies has increased the potential for uncertainty in the interpretation of test results. Talking with patients about uncertainty is more complex and challenging than ever. For some time, Communication Skills Training (CST) for professional development of genetic counsellors in NSW, Australia, has been successfully based on an exploratory learning model of facilitated role plays utilizing actors in comprehensive scenarios. However, evaluation of a 2012 CST workshop requested by genetic counsellors on 'talking about results of uncertain significance' found that 'uncertainty' was lost in role-play. Some participants reported a need for something tangible and to hear 'how others talk about it'. In 2014, the Centre for Genetics Education, NSW Health with the Pam McLean Centre, Sydney University, redeveloped the one day workshop to explore the concept of 'uncertainty' and work with participants' counselling experience to build a toolkit for practice. Two role plays, targeting consultation around 'results of uncertain significance' followed. Genetic counsellors (16) and geneticists (2) attended. Learning needs were met (89% entirely, 11% partially) including the opportunity to observe, reflect upon and apply different approaches to talking about uncertainty, relevance to practice (90%) and confidence. All were likely to refer back to the tool kit (100%). Two senior counsellors reported they had not thought about their practice this way before. A targeted approach to CST around 'uncertainty' that provides participants with tools as well as retains the benefits of exploratory learning may assist professional development of health professionals in this important area.

PM19.32
Genetic counsellors in Sweden - Their role and value in the clinical setting

R. Pestoff[1], H. Skirton[2], **C. A. Ingvoldstad**[3]*;*
[1]Faculty of Health Sciences, Regional Genetics Clinic, University Hospital, Linköping, Sweden, [2]Applied Health Genetics, Plymouth, United Kingdom, [3]Karolinska Institute, Solna, Sweden.

Genetic testing is becoming more commonplace in general and specialist health care and should always be accompanied by genetic counselling, according to Swedish law. Genetic counsellors are members of the multi-disciplinary team providing genetic counselling. We examined the role and value of genetic counsellors in Sweden, using a cross-sectional on-line survey. The findings showed that one main difference between a genetic counsellor and medical geneticist was that the doctor had the main medical responsibility. The genetic counsellors added value in the clinical setting by acting as the "spider-in-the-web", having a holistic, ethical and psychological view, being able to offer continuous support and build a relationship with the patient, and being more accessible than medical geneticists. Genetic counsellors in Sweden contribute substantially to the care of patients in the clinical genetic setting.

PS19.33
Genetics education in primary care - preference for an informal learning model

J. J. MacKenzie[1]*, C. Webber[1], C. Armour[2], R. Birtwhistle[1], G. Brown[1], M. Flavin[1], S. Phillips[1], L. Ruhland[1], J. Carroll[3];*
[1]Queen's University, Kingston, ON, Canada, [2]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, [3]University of Toronto, Toronto, ON, Canada.

Objective: The objective of this study was to explore Primary Care Providers' (PCPs) perceptions of genetics in primary care practice and their genetics education and resource needs.
Method: This was an exploratory, qualitative study using 10 semi-structured

interviews and 3 focus groups with urban and rural participants. Key informants for the interviews included a purposefully selected sample of family physicians, nurse practitioners, and health administrators. Volunteer family physicians participated in focus groups. Thematic analysis was used; data was interpreted using constructivist grounded theory. Use of a distanced interviewer, standardized protocol, and member checking assured consistency and trustworthiness of the data
Results: PCPs recognized the value of genetics, but issues around the extent to which genetics should or could be incorporated into daily practice were expressed. PCPs, particularly in rural areas, described being judicious in referring patients for consults and stated their role included an assessment of which patients could be managed locally. To support their decision making, a need for resources was identified. Preferred approaches across all PCPs included informal learning opportunities such as "virtual" hallway consults, web-based cases and Telehealth consults. Participants became interested in supporting further genetics education opportunities locally.
Conclusion: PCPs see value in genetics but identify challenges integrating genetics into practice. Identifying opportunities for informal learning has the potential to improve primary care genetics CME and to optimize PCPs involvement in genetic risk assessment, diagnosis and management. Success in incorporating genetics into daily medical practice has the potential to reduce the interval from presentation to intervention, resulting in improved health outcomes.
Supported by CTAQ endowment fund

PM19.34
Genetic Tests, Genetic Diagnosis and Bioethical Issues: Evaluation of Medical Student's Opinion

N. Oliva-Teles[1], *C. Carmona*[1], *R. Nunes*[2], *A. Fortuna*[1];
[1]*Centro de Genética Médica Doutor Jacinto Magalhães/Centro Hospitalar do Porto, EPE/ Unidade Multidisciplinar de Investigação Biomédica, Porto, Portugal,* [2]*Departament of Social Sciences and Health, Faculty of Medicine of the University of Porto, Porto, Portugal.*

The increasingly wide range of available genetic tests (GTs), understood as the analysis of hereditary characteristics using the techniques of molecular biology, biochemistry or cytogenetics, is used for the diagnosis of many genetic pathologies. These techniques, of growing sophistication and detail, allow a more accurate clarification of unclear medical conditions, but frequently produce "unexpected results" (UR) or "variants of unknown clinical significance". The diverse ethical problems that relate to GTs, their results, and deciding who may/should be informed of findings constitute a serious challenge to health professionals.
Integrated MSc Medical Students (74) from the Faculty of Medicine, University of Porto, Portugal, volunteered to answer the 13 questions of a questionnaire about the above-mentioned problems. The statistical analysis of results was done using SPSS, version 20. The social characterization of samples revealed that mean age of students was 21,44, mostly females (70,3%). Main results showed: 1- genetic counselling before/after GT was considered very important (69%/73%.); main concern as "professional" dealing with UR is user's anxiety (82,4%); UR should importantly be transmitted in case of mendelian disease (36,5%) and affected carriers (35,1%); it was very important (18,9%)/important (45,9%) to further investigate UR; only sometimes (63,5%) a more precise genetic diagnosis may be beneficial, although it would help to understand the disease (74,3%); the user, if competent adult, should decide if/when do genetic tests (68,9%).
With this preliminary investigation, the authors highlight the importance of bioethics studies as useful tools for medical training.

Kyoto Model of developing a human genetics education program in Japan

N. Akiyama, *M. Torishima, T. Wada, S. Kosugi;*
Department of Medical Ethics and Medical Genetics, Kyoto University Graduate School Of Medicine, Kyoto, Japan.

[Introduction] Genetic tests are becoming common in Japan. The curriculum guidelines of primary, junior high, and high schools in Japan includes little information regarding human genetics. In order to improve genomic literacy in Japan, we are developing an educational program of human genetics.
[Methods and Results] (1)International comparison of human genetics education at school: We analyze the national curriculums of science in Japan and other countries, with particular attention to the genetics and human genetics in order to establish human genetics education program. (2) Exhibition of human genetics as a program of an entertainment for kids: More than 3000 kids and their families participated in the two-day event, and more than 500 come to our exhibition. Families studied DNA, gene and chromosome. (3) Lectures in a high school biology class: We conducted three 50-minute lectures on human genetics. We discussed several genetic subjects, including genetic tests and prenatal diagnosis. (4) Seminars on human genetics for primary schoolchildren: We hold eight seminars in a year for about 100 schoolchildren in total each time. Each four-hour seminar is composed of lectures, experiments and discussions.
[Conclusions] Our project is unique in that students in the postgraduate course of genetic counseling and certified genetic counsellors are leading this project. The main purpose of our project is to familiarize children and parents with human genetics. We have just started the program, and it will take time to evaluate our project. We are developing teaching materials. This work is supported by the Educational research fund of Kyoto University and Japan society for the promotion of science

PM19.36
Creating educational iPhone, Android and Windows smartphone multi-platform apps to facilitate understanding of clinical genomics and related terminology

A. P. Tobias[1], **E. S. Tobias**[2];
[1]*Hutchesons' Grammar School, Glasgow, United Kingdom,* [2]*University of Glasgow, Glasgow, United Kingdom.*

Introduction:
A high proportion of postgraduate students now use Apple (iOS), Android or Windows smartphones. Mobile internet access is, however, often intermittent or slow (eg on public transport). Moreover, online information is often unhelpful, particularly in relation to complex topics (such as clinical genomics terminology). Smartphone apps (applications) can provide user-friendly alternative information sources.
An app was created to provide easily accessible, comprehensible and illustrated explanations of commonly used (but often confusing) clinical genomics acronyms, terms and processes (eg "FASTQ", "BVCF", "GVCF", "IGV" and "Bowtie2"), for students and professionals. An interactive quiz app based on the same material was also created, permitting self-assessment.
Materials and Methods:
A cross-platform application programming language was used, with Apple iOS and Android software development kits (SDKs), to build device-specific apps. Creating iOS apps also required an Apple iOS Developer Program Licence and the latest Apple Xcode software.
Results:
An illustrated, indexed, searchable and advertisement-free, educational app plus an accompanying self-assessment quiz app were created and tested on Android, iOS and Windows. Using the same programs and licences, the authors recently also created several medical genetics self-assessment apps (that have already been used by 273 undergraduate medical students with 978 total downloads). Anonymous feedback collected from the students has been 100% positive.
Conclusions:
It is hoped that these clinical genomics apps will be found useful by genetics students (and perhaps even by professionals). Although their creation is complex, smartphone apps represent a convenient and quick means of obtaining information and of enhancing learning.

PS19.37
Workforce Transformation: Health Education England's Genomics Education Programme

A. Seller, *A. Kelly, T. Packwood, A. Wright, J. Dean, T. Clayton, S. Young, V. Davison, S. Hill;*
Health Education England, Birmingham, United Kingdom.

The UK aims to become the first country to introduce whole genome sequencing into its mainstream healthcare system to aid clinical decision making, and has launched the 100,000 Genomes Project (www.genomicsengland.co.uk) to pave the way in this area.
Health Education England (HEE) has responsibility for improving the quality of care of patients, through education, training and the personal development of all staff within the National Health Service (NHS) in England. We have therefore established an ambitious Genomics Education Programme (GEP) to support the 100,000 Genomes Project and prepare the NHS for a future in which genomic medicine is fundamental to the patient pathway (www.genomicseducation.hee.nhs.uk)
The programme is comprehensive in addressing the training and educational needs of the highly specialised, specialised and general workforces. As part of this, we are:
• devising e-learning and workshops to support each step of the 100,000 Genomes Project pipeline;
• providing a Master's in Genomic Medicine for up to 550 medical, scientific

and nursing staff, plus online CPPD modules for all staff;
• commissioning 28 higher specialist training (HSST) posts in Genetics and Molecular Pathology, with six more planned for Clinical Bioinformatics; and
• developing awareness-raising courses and videos suitable for all NHS staff.
Early evidence that our approach is effective is reflected in 600+ registrations for our first two online courses, with 200+ completions. The programme is also very active on social media, with 2,500 Twitter followers and a monthly retweet reach of 85,000.

PM19.38
RARE-BestPractices - supporting best quality care for rare diseases

K. A. Ritchie, *J. Harbour, T. Lorna;*
Healthcare Improvement Scotland, Glasgow, United Kingdom.

Over 30 million Europeans are rare disease (RD) patients. RD are defined as affecting no more than 5 per 10000 persons and there are approximately 6000 recognised rare conditions, many with a genetic basis. Diseases are often life threatening or chronically debilitating and present a significant burden to patients, carers and service providers. Access to best care across the European Union (EU) is inconsistent and limited by proximity to disease experts, insufficient evidence for decision making and clinician's lack of experience of low prevalence conditions.
RARE-Bestpractices is a four year project delivering an online platform to improve care management through the sharing, appraisal and development of RD best practice, knowledge and information. The project focus is to collect, evaluate and disseminate existing RD guidance, to cultivate a robust methodology and suite of tools appropriate to RD guideline development, and to facilitate collaboration, knowledge exchange and research in the area of RD.
Collection development is underway to populate new RD guidelines and research recommendation databases. The guideline database will facilitate appraisal of new and existing guidance using AGREE II methodology to support easy identification of best quality clinical guidance for clinicians, patients and their carers.
RDs affect a large number of the population. By bringing together stakeholders from across the EU the project will deliver a suite of RD management tools from a single access point to improve equity of care in this patient group.
The RARE-Bestpractices project is funded by the European Union's Seventh Framework Programme. Project Ref.: n° 305690.

Streamlining services to ensure equality of care for patients with or at risk of Haemoglobinopathies in Cardiff

C. Kirwan[1], *B. Player*[1], *P. Palmer*[2];
[1]*All Wales Medical Genetics Service, Cardiff, United Kingdom,* [2]*Sickle Cell and Thalassaemia Centre, Cardiff, United Kingdom.*

The All Wales Medical Genetic Service and Sickle Cell and Thalassaemia Service have been working together since 2013 to ensure equality of care for patients found to be carriers of or affected by Haemoglobinopathies. This has required multidisciplinary working between Genetics and Haematology and a comprehensive service is now being delivered to these patients. Pathways were devised for four areas; antenatal, non-urgent, possible Alpha Thalassaemia carriers and affected individuals.
Antenatal: Patients with abnormal/unusual haemoglobin screening results were referred to Medical Genetics via the antenatal clinic. Partner testing was arranged where requested and high risk couples offered prenatal diagnosis or neonatal testing.
Non-urgent: All carriers of clinically significant Haemoglobinopathies were seen routinely by Specialist Genetic Counsellors in the genetics clinic. Those who required further testing to confirm the carrier state were not seen until molecular testing had been carried out. This allowed the results to be explained in full without the need for further appointments.
Possible Alpha-Thalassaemia Carriers:
Due to the high carrier frequency of possible Alpha Thalassaemia, with up to around 17% of the world population being carriers, it is neither necessary nor possible to confirm all carriers. A standard letter was drawn up inviting those from areas with a high prevalence of Alpha Zero Thalassaemia, namely South East Asian or Mediterranean descent, to contact us. A patient information sheet was provided for all others.
Affected: It was agreed that affected individuals would be seen directly by the Consultant Haematologists and the Sickle Cell and Thalassaemia Nurse Specialist.

PS19.39
100 recorded interviews with human geneticists

P. S. Harper;
Institute of Medical Genetics, Cardiff, United Kingdom.

Between 2003 and 2014 the author has undertaken 100 recorded interviews with older human and medical geneticists from a wide range of countries, mainly European. Most of the interview transcripts are now available on the www.genmedhist.org website (also now accessible via the ESHG website), and they provide a wide-ranging insight into the origins and early development of the field that complements its written history.
Prominent themes include the early applications of human cytogenetics, the beginnings of human molecular genetics and the development of clinical and laboratory genetic services in different countries.
The interviews give a vivid picture of many of the founders of human and medical genetics, including much unpublished information on their early work and lives. Descriptions by those interviewed of their own teachers and mentors extends this information back in time to those already active before World War 2.
The challenge of extending this project and ensuring that it continues to cover younger generations of workers is now being taken up by ESHG and will hopefully provide a valuable resource for future historians and for all who wish to learn how human and medical genetics have developed worldwide, and especially across Europe, from their beginnings to the present time.

PS19.41
Family Communication in Inherited Cardiovascular Conditions in Ireland

S. B. Whyte[1], *H. Shipman*[2];
[1]*Institute of Medical Genetics, Cardiff, United Kingdom,* [2]*Cardiff University, Cardiff, United Kingdom.*

ABSTRACT: Over 100,000 individuals living in Ireland carry a mutated gene for an inherited cardiac condition (ICC), most of which demonstrate an autosomal dominant pattern of inheritance. First-degree relatives of individuals with these mutations are at a 50% risk of being a carrier, disclosing genetic information to family members can be complex. This study explored how families living in Ireland communicate genetic information about ICCs and looked at the challenges of communicating information, factors that may affect communication and what influence this had on family relationships.
Face to face interviews were conducted with nine participants using an approved topic guide and results analysed using Thematic Analyses. The participants disclosed that responsibility to future generations, gender, lack of contact and proximity, all played a role in family communication. The media was cited as sources of information and knowledge of genetic information tended to have a positive effect on families. Results from this study indicate that individuals are willing to inform family members, particularly when there are children and grandchildren at risk, and different strategies are utilised. Furthermore, people do not live in vacuums and their understanding of genetics is partially regulated, not only by their families but by the way society handles information. Therefore, genetic health professionals should take into account the familial influence on individuals and their decision to attend genetic services, and also that of the media.

PM19.42
Premarital genetic counseling for a familial mutation as a family initiative towards prevention of Lamellar Ichthyosis: a five year experience

K. S. Al-Kharusi, *Z. Bruwer;*
Sultan Qaboos University Hospital, Muscat, Oman.

Targeted testing for a known familial mutation can be a powerful tool in countries with limited options for recurrence risk reduction or prevention such as termination of affected fetus. Sultanate of Oman is one of the Islamic countries that follow regulations against termination of fetus unless for maternal indications. Preimplantation genetic diagnosis is allowed under regulations but not available within the country. Considering the fact that family intermarriage is favored, providing premarital genetic counseling and testing for individuals at risk of familial disease should aid risk reduction. A highly inbred family with autosomal recessive Lamellar Ichthyosis has had a known familial mutation in the TGM1 gene since 2008. Despite the availability of the test the number of individuals considering carrier status testing was unremarkable for four years. The main barrier of premarital testing is the geographic distance to the testing center, where the family have to travel thousands of miles for counseling and testing. Avoidance of social and cultural stigma had also discouraged the testing. In the last two years, three new births of affected children from distantly related parents facilitated the

family affinity towards testing; hence number of individuals attended the clinic for carrier status counseling and testing has dramatically increased. To date, 22 cases had attended for genetic counseling and testing in comparison to seven before the new births. There are still barriers to overcome so the family can access the service effectively; like distance travelling and cost. Training a genetic nurse or organizing mobile genetic counseling clinic might facilitate better premarital planning and avoidance of new cases.

PS19.43
Management of MCA/MR through a local service network in Languedoc-Roussillon region (France).

P. SARDA[1,2,3], *F. Margaill*[2], *L. Pinson*[1,3], *C. Coubes*[1,3], *P. Blanchet*[1,3], *M. Willems*[1,3], *M. Perez*[1,3], *E. Haquet*[1,3], *G. Lefort*[1], *J. Puechberty*[1,3], *D. Geneviève*[1,2,3];
[1]*Département de Génétique Médicale et Chromosomique, MONTPELLIER cedex 5, France,* [2]*Réseau Vivre avec une Anomalie du Développement en Languedoc-Roussillon, Montpellier, France,* [3]*Centre de Référence Anomalies du Développement et Syndromes Malformatifs, Montpellier, France.*

Multiple congenital anomalies/mental retardation (MCA/MR) involve the physical: malformations, growth disorders, sensory difficulties,⋯ and « cerebral »: neurological, cognitive difficulties, behavioral troubles development of an individual. They affect close to 3% of the population and account for over 3000 rare disorders. Management of patients is multidisciplinary and goes beyond the simply medical domain. In addition to doctors many other healthcare professionals are involved at an early stage : physiotherapists, medico-social and education personnels.
In 2009, to meet the needs of patients and their families with such rare diseases leading to MCA/MR, the VADLR (Live with a Developmental Anomaly in the Languedoc-Roussillon) health network was created to weave a web of practitioners and institutions tightly around patients. The mission of the network is to
-contribute to the development of an efficient and coordinated local structure to accompany patients with a developmental anomaly,
-increase the knowledge and training of professionals and patients,
-facilitate access to information,
-direct towards proper care and facilitate access to legal rights,
-contribute to coordinating the actions of all players involved in complex situations.
After 5 years, assessment is positive: for 2014 we recorded 3130 calls,15 963 internet connections (http://www.anomalies-developpement-lr.net), 138 families accompanied. Since the creation of the network, more than 1200 professionals have been trained.
The increasing solicitation of this regional local service network signifies its usefulness to patients and professionals.

„Mendel's city" Brno celebrate Mendel's legacy - 150 years of the genius of genetics

R. Gaillyová[1,2,3], *I. Valášková*[1,2], *P. Kuglík*[4,1], *O. Dostál*[5];
[1]*University Hospital, Dept. of Medical Genetics, Brno, Czech Republic,* [2]*Masaryk University, Faculty of Medicine, Dept. of Biology, Brno, Czech Republic,* [3]*Masaryk University, Faculty of Medicine, Department of Laboratory Methods, Brno, Czech Republic,* [4]*Masaryk University, Faculty of Science, Department of Experimental Biology, Brno, Czech Republic,* [5]*Mendel Museum Masaryk University, Brno, Czech Republic.*

In 2015 we are commemorating 150 years since Mendel's lectures in Brno. Gregor Johann Mendel presented on the 8th of February and 8th of March 1865, for the first time, the results of his research at a meeting of the Natural Science Society in Brno. His perceptive observational talent and use of mathematics stood behind the defining of three principles, often referred to as Mendel's principles of heredity.
Mendel Museum with the great support of many Czech and foreign partners celebrate this important anniversary with exhibitions and conferences.
In cooperation with The Czech Society of Medical Genetics, Department od Medical Genetics, University Hospital Brno, Medical Faculty and Faculty of Science Masaryk University Brno we organize „The week of human Genetics" with lectures for the public „Unveiling the secrets of the human geonome", The Student Scientific Conference on Biomedicine , The National Congress of the Society of Medical Genetics, Czech Republic, The 48th Annual Cytogenetic conference and the conference „Human Genetics from Mendel to the Present Day". Other conferences: Research in plant genetics (From Mendel's peas to the present), The Darwin Day 2015 and Mendel Lectures 2015 and exhibitions: Hugo Iltis - the first Mendel´s biographer, The Construction Set Of Life. For the 150th anniversary of Mendel's laws in State Darwin Museum in Moskow and „Unseen for many years" a unique exhibition of Mendel´s original documents prepared in cooperation with University of Illinois.
The Anniversary is held under the auspices of Prime Minister of Czech Republic, Rector of Masaryk University Brno and The Czech Committee of UNESCO.

Neonatal screening: a historical-comparative perspective

C. van El, G. Loeber, **M. Cornel**;
VU University Medical Center, Amsterdam, Netherlands.

After the first regional initiatives to screen newborns for PKU in the United Kingdom and United States in the 1960s, several European countries set up screening programmes. Though the number of disorders screened for gradually increased, European countries differed in their choices for specific screening strategies and the number of disorders screened for: from 1 to 29 (Loeber et al., 2012). For instance, in case of Congenital Hypthyroidism, the Netherlands followed Canada and several US states in the strategy used to detect both primary and central forms of CH, while most European countries concentrated on the primary forms. The Netherlands was one of the first countries to introduce screening for Congenital Adrenal Hyperplasia (in 2000). The reasons for this variety may range from health care priorities and budgets to practical considerations, organisational constraints or, perhaps, chance. Pollitt (2006) has suggested that the differences may be related to the professional background of individuals involved in policy-making. For the US the influence of patient organisations and commercial parties has been mentioned (Paul & Brosco, 2013) . For the Netherlands we did not find evidence that these latter forces have played a major role.
In our (poster) presentation we will highlight our research on the expansion of the Dutch programme after its beginning in 1974 (Loeber & Van El 2014). In addition we present an initiative to stimulate historical-comparative research on the rationale for the different choices that have been made regarding the expansion of neonatal screening in Europe.

PM19.46
Genetic counseling difficulties due to novel mutations in patients with Neurofibromatosis Type I.

M. Tsipi, *M. Tzetis, E. Fylaktou, K. Kosma, S. T. Kitsiou;*
Department of Medical Genetics, University of Athens, Athens, Greece.

Neurofibromatosis Type I is one of the most common autosomal dominant disorders. It is caused by mutations of the NF1 gene. Disease penetrance is about 100%, while patients present mutational, allelic or phenotypic heterogeneity. Clinical features include café-au-lait spots, skinfold freckling, cutaneous or plexiform neurofibromas, optic gliomas and Lisch nodules of the iris.
Molecular diagnosis includes multi-step PCR, sequencing of all exons of NF1 and multiplex ligation-dependent probe amplification. The protocol was validated in a cohort of 80 NF1 patients and their relatives, identifying the germline mutations in the most of the cases. The effects of these mutations were assessed in combination with the clinical phenotype and using in silico analysis.
Our results include 28 known and 23 novel variants in coding and non-coding regions. The majority of novel mutations included stop codon mutations and small insertions or deletions. We also found whole NF1 gene deletion at two unrelated patients with severe clinical manifestations. Novel variants were analyzed with bioinformatic tools; "PolyPhen2", "SIFT", "Pmut", "Mutation Taster", "Mutation Assessor", "Provean v.1.1" and "Human Splicing Finder", and family segregation analysis was assessed from available family members. Evaluation of novel and de novo missense mutations is more complicated. The factors taken into account are the type of amino acid change, the sequence conservation across species and the in silico output of at least three different prediction tools. More specific, our work underlines the high frequency of novel mutations and additionally confirms phenotypic heterogeneity even within the same family, which complicates genetic counselling especially in cases of an ongoing pregnancy.

PS19.47
Role of genetic nurses in the Sultanate of Oman: Achievements and challenges

I. Alhaddabi, *A. Al Saegh, A. AL Habsi;*
Sultan Qaboos University Hospital, Muscat, Oman.

In Oman, the Genetic and Developmental Medicine Clinic (GDM) was officially opened on December 6th 2011.The GDM is one of the specialty clinics in Sultan Qaboos University Hospital, which started with one geneticist physician and three staff nurses including one clinical nurse specialist. Clinical Genetics is a highly dynamic field with constant evolution and there was an

urgent need to involve the Omani nurses to contribute to the Omani healthcare. To meet with the growing demand and to provide quality care to the patients, the clinic expanded to involve four specialized physicians in clinical genetics, four clinical nurse specialist and genetic counselors. The genetic nurses adopted several tasks including the following: obtaining detailed family history and constructing a pedigree. Providing genetic information and psychosocial support to individuals and families for patient considering genetic testing, couples who have had multiple miscarriages and pre-marital genetic testing. The nurses were also involved in counseling families with known metabolic disorders, developmental disorders and hereditary cancer syndromes. Being a genetic nurse in Oman was associated with some challenges: the high rate of consanguinity and high numbers of patients with autosomal recessive disorders, low public awareness about genetic disorders, dealing with old cultural believes and denial and limited training in genetics at the nursing schools. Despite having all those challenges and the complexity of the tasks taken up by the genetic nurses, we have managed to help many families by learning from other staff members, attending courses and getting involved with the weekly multidisciplinary meetings.

PM19.48

An online tool to train non-geneticists how to consent cancer patients for BRCA testing

S. Talukdar[1], *D. Riddell*[2], *A. George*[2,3], *H. Hanson*[2,2], *N. Rahman*[2,2];
[1]*Institute of Cancer Research, London, Sutton, United Kingdom,* [2]*Division of Genetics & Epidemiology, Institute of Cancer Research, London, United Kingdom,* [3]*Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom.*

Genetic testing for BRCA1 and BRCA2 (termed 'BRCA') has increasing implications for the optimal management of cancer patients, impacting on treatment and ongoing cancer surveillance and providing useful information for the wider family. NGS has made BRCA testing faster and cheaper. However, the gene testing pathways in most countries have not adapted to serve the potential increased throughput and remain focussed on the needs of unaffected at-risk individuals rather than cancer patients. To address these issues we have developed an oncogenetic BRCA testing pathway whereby members of the cancer team consent eligible cancer patients for BRCA testing after completing 30 minutes online training.

The training resources are fast, flexible, robust and highly accessible. They include e-learning videos (on YouTube) and comprehensive supporting information, all delivered via a simple online system. The resources empower the cancer team to take ownership of their learning and provide support and guidance from the genetics team where required.

To date 57 clinicians in the Royal Marsden cancer units have completed training during a wider, successful implementation of the oncogenetic gene testing pathway. 93% rated the training as "Good" or "Excellent". Feedback from patients consented by cancer team members that had completed the training showed that >95% felt well informed.

The training resources are now freely available at www.mcgprogramme.com/brcatesting.

Furthermore, the principles can be readily adapted for other genes / diseases for which a mainstream model of gene testing is applicable. This work was undertaken by the MCG programme, funded by the Wellcome Trust Grant 098518/Z/12/Z.

PS19.49

The Benefit of hindsight - the views of early adopters regarding preparation for personal genome testing

K. K. Barlow-Stewart[1], *J. Fleming*[1], *B. Terrill*[2], *M. Dziadek*[2], *E. Kirk*[3], *A. Roscioli*[3,2];
[1]*University of Sydney, Sydney, Australia,* [2]*Garvan Institute of Medical Research, Sydney, Australia,* [3]*Sydney Children's Hospital, Sydney, Australia.*

Due to increasing availability of personal genome sequencing (PGS) there is a need to explore preparation of individuals pursuing testing. Potential participants were those who undertook PGS offered by Illumina Inc. through the first Australian Understand Your Genome Event in April 2014 and were recruited through their referring clinical geneticist. Seven, all professionals with genetics expertise, have been interviewed to date (RR 48%). Results included an autosomal dominant condition (NF1) not previously clinically identified; carrier status for recessive condition(s); a number of variants identified as likely pathogenic and many of uncertain significance; and pharmacogenetically relevant mutations. Themes identified included: 1). Rationale for being an early adopter. Most were motivated by objective professional interest and curiosity, without anticipating personal or family impact. 2.) Barriers. These included skepticism of colleagues, family members and privacy concerns. 3.) Pre-testing information and consent. Positive counselling experiences were reported with clinical geneticists. 4.) Impact of test result over time. Despite an initial objective motivation for testing, all expressed surprise at subjective impacts of the results. Several who initially perceived their results as "boring", later recognized their relevance, as health problems developed or family history was interrogated more closely. One participant with a known deletion causing carrier status, not identified by PGS, was concerned that a lay person may misinterpret the result. Disclosure of results has been limited. 5.) Reflection. All had no regrets about having PGS. However, in hindsight, participants felt certain issues needed greater emphasis at the pre-test session: expectations; residual risk; changes in interpretation with developing phenotypes; and personal and family impact and communication.

PM19.50

Encounters with prenatal and pre-implantation genetic diagnosis: Are we really offering a holistic clinical genetic service in Oman?

Z. Bruwer, *K. Al Kharusi, A. Al Foori, M. Al Hinai;*
Sultan Qaboos University Hospital, Muscat, Oman.

The incidence of congenital anomalies and/or genetic disorders in the Omani population has reached figures greater than double the global statistics. Prenatal diagnosis (PND) and pre-implantation genetic diagnosis (PGD), contributing elements to a holistic clinical genetic service, provide at-risk parents with options to prevent the birth of an affected child. PND can be utilized by Omani couples, as long as the termination of pregnancy (TOP) is for a severely affected fetus, and occurs prior to the first 120 days. However, the practice of this procedure is impeded by the lack of services able to offer TOP, while PGD services are only accessible by travelling to international centers.

The increase in the number of requests for PND and PGD calls for an open ethical and legal discussion around this topic. We therefore elected to gather descriptive data from patients requesting PND/PGD over a two year period (2013-2014) to portray and examine the current situation faced by Omani couples. Twenty-three cases were identified and included in the study. The service user's perspective on PND and PGD, test results and patient driven outcomes together with the identified benefits and limitations of each are compared and contrasted. Interviews additionally provide data on the impact of the decision for the couple and their family and the effect of undertaking the procedure, on future pregnancy-related decisions.

A multitude of logistical, religious and psychosocial challenges are faced by patients. Awareness of the current situation will be extremely valuable in improving the service according to the patient's needs

PS19.51

Improving access to psychological services: Evaluation of a pilot project in Manchester Centre for Genomic Medicine

R. M. MacLeod[1], *C. Moss*[2], *C. Stopford*[1], *D. Rogers*[1], *P. McEvoy*[2], *C. Baguley*[3];
[1]*Manchester Centre for Genomic Medicine, Institute of Human Development, University of Manchester and Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [2]*Six Degrees Social Enterprise, The Angel Centre, Salford, United Kingdom,* [3]*Psychological Professions Network, NHS Health Education North West, Manchester, United Kingdom.*

The Improving Access to Psychological Therapies (IAPT) initiative in England aims to support the implementation of NICE guidelines for people suffering from depression and anxiety disorders. Psychological Wellbeing Practitioners (PWPs) have been located in primary care and NHS clinics such as Diabetes and Respiratory Medicine to provide low intensity psychological interventions based on a collaborative care model. We report an evaluation of a pilot project, supported by NW Health Education England, to look at the acceptability of an IAPT practitioner offering a weekly clinic within a Regional Genetic Centre.

24/40 patients referred to the IAPT practitioner by genetic counsellors between January and May 2014, took up the offer of psychological support. Of these 24 individuals; 8 received between 2-6 counselling sessions and reached recovery, 9 were signposted to local psychological services, 7 opted for telephone contact and 2 dropped out. The PWP contributed to teaching sessions within the department and helped with triaging and signposting of those patients requiring additional psychological support. Qualitative interviews with 8 genetic counsellors revealed that the most effective element of the project was the part it played in facilitating referral pathways that improved the access to local psychological services. The genetic counsellors were all very positive about the benefits of having access to specialist mental health advice from the PWP, who was able to see a small caseload of patients and advise on availability of community and online counselling services to the genomic medicine team.

PM19.52

A multiple case study approach to patients and caregivers as sources of innovative ideas and solutions

P. Oliveira[1], L. Zejnilovic[1], **S. A. Oliveira**[2,3]*;*
[1]Católica-Lisbon School of Business and Economics, Lisboa, Portugal, [2]Instituto de Medicina Molecular, Lisboa, Portugal, [3]Instituto Gulbenkian de Ciência, Oeiras, Portugal.

Introduction: Recent academic literature shows that patients and caregivers are a significant source of innovative solutions related to their medical condition. To date, little is known about the process by which these innovations emerge, how they diffuse, and how they impact the lives of patients and caregivers.
Objectives: We followed a multiple-case study approach to map a set of patient innovations and adoptions of patient innovation cases, and systematically explore how and how far patients and caregivers innovate in the health care field. In addition, we propose some explanations for why patients and caregivers stop at a certain stage of progression of the innovation process.
Material and Methods: We conducted 15 extensive semi-structured interviews with patients and caregivers of the following group of diseases: spinal cord injuries, Angelman syndrome, epidermolysis bullosa, cerebral palsy, and hemiparesis. These individuals shared their disease experiences and their efforts, or the lack of them, to overcome specific health problems. This includes 4 "holistic" case studies and 26 "embedded" case studies. We analyzed patient innovation paths and present them in the fall-offs conceptual framework.
Results: Through a cross-case analysis, we find that duration of the disease, complexity and pressure of a certain situation, belonging to a group or a community, and perceived value of a solution are among the most important reasons that impact how far patients and caregivers take their innovations.
Conclusion: As a result of our multiple-case analysis we present a set of propositions from which future research in the field is warranted.

PS19.53

Rare diseases - Romania progresses in the last years

M. Gafencu[1]*, G. Doros[1], M. Papa[1], D. Dan[2], O. Adam[1], Z. Andrei[1], M. Puiu[1];*
[1]University of Medicine &Pharmacy Victor Babes, Timisoara, Romania, [2]National Alliance for Rare Diseases Romania, Zalau, Romania.

Introduction. Rare diseases began to be a priority for patients and subsequently for patient support groups in our country after 2005. Doctors were called to join them and mixed organizations have delayed occur. ANBRaRo Alliance was the first NGO to bring real changes in terms of attitude and then bringing a change in Ministry of Health approach.
Method. We used data provided by the 6 existing clinical genetics centers placed in university cities from our country, with doctors working in this field and with NGOs established in support of different groups of patients with rare diseases.
Results. The last decade has been one that has completely changed the dates of this issue in Romania. These diseases have actual opportunity to be treated in small numbers but the way was opened and National Health Insurance House are dedicated annually to these patients. The actions were guided by the rules of the EURORDIS and interdisciplinary was a vital principle. The only major deficient is the diagnosis system.
Several actions sensitizing the public about the area were used - The Romanian Rare Disease Day campaign, conferences for patients, courses for Journalists, media materials.
Conclusions. The road will include other collective efforts and current patients are still deprived of all complex diagnostic and therapeutic approach required by this area, but coming years must bring the same rate change for this class of diseases. The role of patient organizations as the engine of initiatives in this area was decisive.

PM19.54

Patient innovation under rare diseases and chronic needs

P. Oliveira[1], L. Zejnilovic[1,2], H. Canhao[3], E. von Hippel[4], **P. Abrantes**[3]*;*
[1]Católica-Lisbon School of Business and Economics, Lisbon, Portugal, [2]Carnegie Mellon University, Pittsburgh, PA, United States, [3]Institute of Molecular Medicine, Lisbon, Portugal, [4]MIT Sloan School of Management, Cambridge, MA, United States.

Introduction: Patients afflicted by rare diseases (RR) often need to develop innovative solutions to cope with the disease. The impact of this innovative capacity and the driving factors for innovation in patients with RR are not clearly understood. The objectives of this work were to measure frequency of RR patient innovation; to measure efforts by patients to share their solutions; to explore which factors drive patients to come-up with solutions and share them with others.
Material and Methods: A questionnaire grounded in user innovation theory was adjusted to RR context and 500 patients were surveyed. Two medical professionals validated solutions reported by patients and multivariate regression models were developed to test relationships between our key variables and patient innovation and solution sharing.
Results: 263 of respondents reported having a solution; 46 reported solutions that they personally find valuable, and that are also evaluated as novel by expert medical evaluators. The likelihood that patients innovate increased with education level and with increase in perception of limitations imposed by the disease. 84 individuals shared their solutions, and the most common mode of sharing was patient-to-patient (74 individuals). There was a positive relationship between the impact of a solution on the respondents' overall quality of life and likelihood of patients sharing their solutions, and an inverted relationship between age and the solution sharing.
Conclusion: The innovation and solution sharing characteristics observed in our study may be a tremendous potential resource of information to improve management and care for many who are similarly afflicted.

Referral pathways to the Department of clinical genetics within a Czech Republic teaching hospital.

V. Curtisova[1,2]*, K. Adamová[1,2], P. Čapková[1,2];*
[1]Department of Medical Genetics, Fakultní nemocnice Olomouc, Olomouc, Czech Republic, [2]Universita Palackého, Olomouc, Czech Republic.

Timely referral to a clinical geneticist depends on the knowledge of referring clinicians of the scope of clinical genetics services. We set out to map who are our referring clinicians based on the structure of our consultations.
The Department of Clinical Genetics of the Teaching Hospital Olomouc serves a population of about 920,000 inhabitants and is staffed by 3.1 clinical geneticists. The hospital is one of eleven teaching hospitals in the Czech Republic and the sixth largest. It has 1200 beds and 50 departments.
In total 1584 genetic consultations were performed by the Department in 2014 (510 consultations per clinical geneticist). We divided them according to the prevailing diagnosis into paediatric (305, 19%), related to infertility (225, 16%), related to ongoing pregnancy (417, 26%), oncologic (327, 21%), neurologic (327, 21%) and others (191, 12%).
A large proportion of consultations were requested by the doctors from within the hospital. This may reflect the specialist care the hospital provides and the structure of the health care in the Czech Republic, where primary care physicians usually refer the patients with more complicated problems to a specialist, who then deals with their further care. It may also reflect on the limited knowledge of the possibilities of genetic testing by primary care physicians including the referral pathways, indications for and the benefits of genetic testing.
This finding has implications on targeting continuous postgraduate medical education of clinical genetics in the Czech Republic.

PM19.56

Evaluation of reimbursement systems of genetic tests in the NGS era and health care costs planning of NHS: urgent need in 2015

D. A. Coviello[1]*, A. Seri[1], M. I. Parodi[1], M. Balducci[1], C. Lanza[1], S. Casati[2];*
[1]Laboratory of Human Genetics, E.O. Ospedali Galliera, Genoa, Italy, [2]UNIAMO, Italian Patient Federation on Rare Diseases, Venice, Italy.

Next Generation Sequencing has improved genetic testing but also analysis of molecular biomarkers in medicine and in particular in oncology.
To update the reimbursement system for laboratory tests is an urgent need both in US and Europe. US Medicare health insurance announced that "laboratories performing test panels (i.e., tests for multiple biomarkers ordered together and completed on a single sample) must begin to register each panel under the MolDx Program". This means that "laboratories must obtain a unique MolDx identifier for each panel and bill such panels with a single CPT code. Currently, many laboratories submit these multiple biomarker "panels" as individual tests, providing a CPT code for each biomarker included in the panel".
In Italy the NHS is updating the reimbursement system and it is going to charge panels of tests that will be useful to answer a diagnostic question and not any more the single gene test.
We have performed a systematic analysis of activities and costs needed to perform genetics tests and we have identified a number of indicators to assess the workload. All these parameters have been incorporated into software to compare the performance activity and to evaluate performance within the same laboratory or to perform a benchmarking with other laboratory in the country. Activity-Based Costing is the methodology used to assigns the cost of each activity. The evaluation of costs and performance could be a way to establish a correct public health policy and to evaluate clinical utility and costs/benefits.

PS19.57

Different ways of multi-disciplinary working. The results of a prospective observational cohort study of referrals to a UK regional genetics service.

C. M. Benjamin[1,2], *C. Houghton*[2], *C. Foo*[2], *C. Edgar*[2], *G. Mannion*[2], *J. Birch*[2], *I. Ellis*[2], *A. Weber*[2];

[1]*Health Research Methodology and Implementation Hub (HeRMI), School of Health, University of Central Lancashire, Preston, United Kingdom,* [2]*Merseyside and Cheshire Clinical Genetics Service, Liverpool Women's NHS Foundation Hospital Trust, Liverpool, United Kingdom.*

Differing genetic service delivery models exist across Europe with clinicians developing innovative ways of working to meet demand.

This paper presents the first empirical prospective observational cohort study of UK multi-disciplinary genetic service delivery. It describes and explores collaborative working practices including the utilisation and role of clinical geneticists and non-medical genetic counsellors. Six hundred and fifty new patients referred to a regional genetics service were tracked through 850 clinical contacts until discharge. Referral decisions regarding allocation of lead health professional assigned to the case were monitored, including the use of initial clinical contact guidelines. Significant differences were found in the cases led by genetic counsellors and those led by clinical geneticists. Around a sixth, 16.8% (109/650) of referrals were dealt with by a letter back to the referrer or re-directed to another service provider and 14.8% (80/541) of the remaining patients chose not to schedule an appointment. Of the remaining 461 patients, genetic counsellors were allocated as lead health professional for 46.2% (213/461). A further 61 patients did not attend. Of those who did, 86.3% (345/400) were discharged after one or two appointments. Genetic counsellors contributed to 95% (784/825) of total patient contacts. They provided 93.7% (395/432) of initial contacts and 26.8% (106/395) of patients were discharged at that point. The information from this study informed a planned service re-design. More research is needed to assess the effectiveness and efficiency of different models of collaborative multi-disciplinary working within genetics services.

Grant support: Liverpool Women's NHS Foundation Hospital Trust Charitable Grant.

Communicating genomic research results to patients: our experience from the Developmental Genome Anatomy Project (DGAP)

T. Kammin[1], *Z. Ordulu*[1,2], *J. F. Gusella*[3,2,4], *E. C. Liao*[3,5], *M. E. Talkowski*[3,2,4], *C. C. Morton*[1,4,2];

[1]*Brigham and Women's Hospital, Boston, MA, United States,* [2]*Harvard Medical School, Boston, MA, United States,* [3]*Massachusetts General Hospital, Boston, MA, United States,* [4]*Broad Institute of Harvard & MIT, Cambridge, MA, United States,* [5]*Harvard Stem Cell Institute, Boston, MA, United States.*

DGAP is a collaborative research study that serves to annotate the human genome. Participants are recruited with apparently balanced chromosome rearrangements and abnormal phenotypes and Whole Genome Sequencing (WGS) using our jumping library approach is employed to determine chromosomal breakpoint regions. We validate pathogenicity of disrupted and/or dysregulated genes using cellular or animal models.

Interpreting diagnostic significance of identified genomic regions sometimes generates information of clinical relevance for participants. However, little consensus exists as to what research studies do with their findings, particularly if results are of uncertain clinical significance, and an historical approach has been not to return any information. Here we use DGAP cases to discuss the potential benefits or harms to participants if such research results are communicated.

First, we describe a case where we delayed reporting research results for several years whilst we sought validation of our findings. The family independently pursued their own investigations through online searches, eventually leading to suspicion of the same candidate gene. We discuss the impact of our delay in sharing our research results with the family and the value in directing the validation testing.

We also present two prenatal cases where the fetus was found to have a *de novo* balanced rearrangement early in pregnancy. We used our WGS approach to report results to the parents within two weeks of referral. We discuss the impact our research results had on their decisions concerning their pregnancies, describing the ethical dilemmas that arose from both research and clinical perspectives.

YouTube, animation and genetic education

S. Lynch[1], *J. A. Turner*[2], *J. P. Casey*[3];

[1]*National Centre for Medical Genetics,Temple street Children's Hospital,, Dublin 1, Ireland,* [2]*National Centre for Medical Genetics, Dublin 12, Ireland,* [3]*Temple street Children's Hospital,, Dublin 1, Ireland.*

We have developed a number of short videos, some animated, to help develop integrated online genetic education. Our vision is to develop core videos on topics such as pedigree drawing, genetic cascade and predictive testing, exome/genome sequencing, incidental findings and ethics, relevant to practises in Ireland. Outside of the core, we have specialist topic videos relevant to genetics, created by colleagues from diverse disciplines. Our target audience are health care professionals from all aspects of mainstream medicine.

Much of our content, such as our six animated videos, are freely available on YouTube. These videos already have ~20,000 views. Families can view them prior to an appointment.

We found that short videos (~5 minutes) are more popular; the viewer stays with the video through its entirety in contrast to long videos. As viewers post thumbs up and thumbs down as well as comments, this is a useful way of gaining prompt feedback. Our two recent chromosome translocation videos have already had 6,000 views and are being linked in with Unique, the rare chromosome support group. We are translating these videos into ten languages to increase applicability. http://bit.ly/RecipTranslocation & http://bit.ly/RobsTranslocation

Feedback includes:"Wow this video was more helpful than any other genetic video on Youtube" & "Now I understand it thanks".

Whilst YouTube is used by the public to access genetic information, much of the educational content is aimed as researchers. There is a market for simple genetic information to be developed for the public.

PS20.01

Ethical, legal and societal implications of biobanking at European level: a Common Service of the European biobank and biomolecular research infrastructure

A. Cambon-Thomsen[1,2], *J. Bovenberg*[3], *M. G. Hansson*[4], *M. Lavitrano*[5], *M. T. Mayrhofer*[2], **H. Howard**[6];

[1]*Inserm-Université Toulouse III, Toulouse, France,* [2]*BBMRI-ERIC, Graz, Austria,* [3]*Legal Pathways, Aerdenhout, Netherlands,* [4]*University of Uppsala, Uppsala, Norway,* [5]*University of Milano-Bicocca, Milano, Italy,* [6]*University of Uppsala, Uppsala, Sweden.*

BBMRI-ERIC - Biobanking and BioMolecular resources Research Infrastructure - European Research Infrastructure Consortium is a unique infrastructure where >16 member states have joined forces to setup a Pan-European distributed research infrastructure in order to facilitate the access to biological resources and facilities and to support high quality biomolecular and biomedical research. Common Services (CS) form a key element of the infrastructure. The proper consideration of ethical, legal and social issues (ELSI) is key to any biobanking activity. The CS ELSI aims to facilitate and support cross- border exchanges of human biological resources and data attached for research uses, collaborations and sharing of knowledge, experiences and best practices. This is particularly relevant for human genetic research where biobanking is a vital element.

Methods and Materials

Following a preparatory meeting and a call for tender in 2014, a Common Service ELSI was established starting in February 2015.

Results

The missions of this CS are, in the domain covered by BBMRI-ERIC:

Ethics check of research proposals submitted to BBMRI-ERIC ;

Monitoring of ELSI issues;

Policy: follow up relevant evolution in legislations/regulations and public consultations at European level;

Advising and Help-desk: provide updated background information and guidance regarding ELSI, towards harmonisation;

Dissemination: of results of relevant surveys and studies ;

Tools development: organize tools and services to address ELSI ;

Experience sharing regarding ELSI, notably data protection ;

Education: specific training.

Conclusion

The CS ELSI is addressing many of the ELSI preoccupations of geneticists and collaboration with ESHG may be of interest.

PM20.02

Identification of men with a genetic predisposition to prostate cancer: targeted screening of BRCA1/2 mutation carriers and controls. The IMPACT study Quality of Life Study

The IMPACT study is recruiting male BRCA1/2 mutation carriers and controls (tested negative for a mutation), to undergo annual PSA screening +/- prostate biopsy. In addition to the screening protocol 15 centres are running a quality of life (QoL) study which aims to: (1) evaluate the psychosocial impact of screening for prostate cancer (PrCa) in terms of (a)cancer worry, (b)distress of screening and (c)health related QoL; (2) identify factors associated with negative psychosocial outcomes; (3) determine compliance with screening over time.
Methods: Men completed a questionnaire prior to each annual screening visit. The questionnaires included sociodemographic data and the following measures: HADS, IES, SF36, MAX-PC, Cancer Worry Scale, self reported risk perception and a knowledge questionnaire (understanding of BRCA1/2 and PrCa). The results of the baseline questionnaires are presented.
Results: In total 484 men enrolled in the QoL study and uptake was 82-100% at participating sites. Mean scores for HADS and SF36 were within reported population norms and mean IES scores were within normal range. No statistically significant differences were observed between groups. Average knowledge score was 77%, demonstrating a good understanding. Mean MAX-PC scores were low suggesting a low level of prostate-cancer specific worry. Cancer worry levels were low and BRCA2 carriers in particular perceived their risk of PrCa to be higher than average.
Conclusions: Uptake of the QoL study is high in participating centres. Baseline psychosocial measures suggest a low prevalence of distress and participants demonstrate a good level of knowledge about PrCa and the BRCA1/2 genes.
Grant support: Cancer Research UK, McAulay Foundation, NIHR Biomedical Research Centre

PS20.03
Managing genetic testing in childhood

C. King, **R. A. Newbury-Ecob***;*
University Hospitals, Bristol, United Kingdom.

Traditionally geneticists have urged caution in genetic testing in childhood in order to preserve autonomy. Advances in medicine mean that a greater number of tests are being carried out that have a predictive component. With greater awareness of genetic status from screening programmes and genomic testing we can no longer advocate that genetic testing should only be undertaken in exceptional circumstances.
The lack of a robust evidence base for the long term psychosocial outcomes leaves the decision to test at the discretion of the geneticist. The concept of best interest is unclear and there may be a conflict of interest between parents and child. When should testing be carried out at the request of the parents, how and when should testing be discussed with a child and how and when should results be communicated subsequently.
We have reviewed all cases in our department where predictive or pre-symptomatic genetic testing has been carried out in childhood and examined the factors influencing the decision to test.
For predictive testing in all cases the parent requesting was the mother even when the affected parent was the father. Testing was more likely to be requested and undertaken where there were traumatic family circumstances and often in an attempt to end the impact of the condition on the family. Testing was often carried out ultimately because of fear of harm to the patient-professional relationship.
We present details of the cases learned and discuss the ethical framework and legal landscape.

PM20.04
Public attitude towards self-government of consumer targeted genetic testing in Japan

K. Muto[1], *A. Nagai*[1], *Z. Yamagata*[2];
[1]The University of Tokyo, Tokyo, Japan, [2]Yamanashi University, Chuo, Japan.

Background: Japanese ministries are considering regulations governing DTC genetic testing. The METI has endeavored to set recommendations to quality control, scientific evidence, and informed consent, which allow self-governance. On the other hands, the MHLW thoroughly review the definitions of "diagnosis" to regulate DTC genetic testing. Our aim was to clarify public attitudes toward scientific evidence and self-government of DTC testing.
Methods: In March 2014, an anonymous online survey was administered to 24,718 men and women aged 20-69 years in Japan. The questionnaire included questions concerning genetic knowledge, attitudes toward genetic testing and the regulations governing DTC genetic testing.
Results: 7,540 individuals completed surveys. The mean age of the respondents was 45.7 ± 14.0 years. With respect to questions regarding willingness to undergo 6 types of genetic testing by scientific evidence, around 50% of respondents reported that they could not decide whether to undergo any type of genetic testing. 56.5% of them require ban on acquisition of unneeded personal information and only 39.7% of them are interested in ban on scientifically groundless tests.
Discussions: Our results suggest that members of the Japanese public have positive attitudes toward genetic testing, which provides useful information concerning the prevention and treatment of disease, and may attach less importance to scientific evidence supporting genetic testing than academic societies and the METI do.

PM20.06
Storage and future use of consumers' samples and data in direct-to-consumer genetic testing companies offering whole genome sequencing

E. Niemiec[1,2], *H. C. Howard*[3];
[1]Department of Law, University of Turin, Turin, Italy, [2]Centre for Ethics and Law in the Life Sciences, Leibniz University Hannover, Hannover, Germany, [3]Centre for Research Ethics and Bioethics, Uppsala University, Uppsala, Sweden.

Whole genome sequencing (WGS) creates an unprecedented amount of data providing a powerful tool for clinical care and research. Recently, WGS has also been offered by commercial direct-to-consumer genetic testing (DTC GT) companies. The DTC offer of genetic tests has already brought attention to potentially problematic issues such as storage and future use of consumers' data and samples and informed consent. The aim of this study is to analyse the policies of DTC companies offering WGS with regard to the storage and future use of data and samples and how these issues are included in informed consent. The findings will be discussed in the context of relevant policy documents. Preliminary analysis of websites of two DTC GT companies, Illumina and GeneYouIn, reveals that they may, in fact, use consumers' samples and sequencing data for unspecified research. The companies specify that the genetic data of their consumers will be anonymized and that consumers have the possibility of opting out of research. Furthermore, the information about use of data and samples for research purposes is included in the consent forms, which consumers are asked to agree to or sign before undertaking the test. This study will contribute to the discussion on the ethical offer of DTC GT companies involving research activities. Part of this work is supported by an Erasmus Mundus Joint International Doctoral in Law, Science and Technology Fellowship, the Swedish Foundation for Humanities and Social Sciences and the CHIP ME COST Action IS1303.

PS20.07
Stigma: an ongoing challenge for families of individuals with Down syndrome

M. Van Riper[1], *H. Choi*[2], *S. Phetrasuwan*[3];
[1]University of North Carolina Chapel Hill, Chapel Hill, NC, United States, [2]Kyunpook National University, Daegu, Korea, Republic of, [3]Mahidol University, Bangkok, Thailand.

Introduction: Current estimates suggest that over 6 million people in the world have Down syndrome (DS). Most individuals with DS spend the majority of their lives living with their family. Existing findings suggest that while some families have difficulty adapting to the ongoing challenges associated with raising an individual with DS, others adapt successfully and some even thrive. Stigma experiences may play a critical role in how well a family adapts. Therefore, the purpose of this study was to explore experiences with stigma among families of individuals with DS living in Ireland, Korea, Portugal, Thailand, United Kingdom, and USA.
Method: Over 1200 parents of individuals with DS completed an online survey which included a variety of self-report measures plus open-ended questions concerning how parents were informed of the DS diagnosis. A sub-set of parents were also interviewed.
Results: Many parents reported experiencing stigma when they were first informed of the diagnosis of DS. Stigma experiences also occurred when the individual with DS: 1) had serious health issues, 2) needed additional ser-

vices or resources, and 3) participated in activities outside the family home. Many parents felt professionals involved in health care and educational services often perpetuate the stigmas surrounding DS. Other factors thought to perpetuate stigmas were societal attitudes towards people with disabilities and national policies.

Conclusion: More research is needed to examine the link between stigma and adaptation in families of individuals with DS. Ideally this research should be cross-culture to capture variations both within and between different cultures.

PM20.08

Is there an ethical and/or legal obligation for healthcare providers to re-contact former patients in light of new genetic findings?

D. Carrieri[1], *S. Dheensa*[2], *A. M. Lucassen*[2], *P. D. Turnpenny*[3], *A. J. Clarke*[4], *S. E. Kelly*[1];
[1]*University of Exeter, Exeter, United Kingdom,* [2]*University of Southampton, Southampton, United Kingdom,* [3]*Royal Devon and Exeter Hospital, Exeter, United Kingdom,* [4]*University of Cardiff, Cardiff, United Kingdom.*

Advances in genetics and genomics have the potential to allow more accurate diagnoses, improve knowledge of disease aetiology and risk, and inform therapeutic decisions.

For health benefits of genomics to be achieved, a number of issues in clinical implementation need to be addressed, including ethical and practice issues that have yet to be examined empirically and conceptually in any depth. Key among these is the clarification of professional responsibilities and obligations, as well as patient expectations, for re-contacting patients in light of new genetic findings and the re-interpretations of earlier findings. These issues are becoming more urgent with the arrival of Genomics England and related endeavors.

Our current three-year (2014-2017) ESRC funded project 'Mainstreaming Genetics: Re-contacting patients in a dynamic healthcare environment' http://ex.ac.uk/mgc addresses these questions. In particular it aims to:

1. Survey current clinical practices regarding re-contacting in the NHS and other European healthcare systems
2. Analyse the ethical and legal issues surrounding a potential responsibility or obligation to re-contact patients
3. Investigate patient and healthcare professional perspectives concerning re-contacting in different medical specialties using semi-structured interviews, vignettes, and questionnaires
4. Engage with stakeholders to integrate the above findings and analyses in the drafting of professional guidance or to develop a professional framework for making decisions about re-contacting patients

We will present and discuss the framing and initial findings of this project.

PS20.09

Quality of life of patients with the classic type of Ehlers-Danlos syndrome

A. Junkiert-Czarnecka[1], *D. Czarnecki*[2], *M. Ziolkowski*[2], *O. Haus*[1];
[1]*Department of Clinical Genetics Collegium Medicum in Bydgoszcz, Bydgoszcz, Poland,* [2]*Departrment of Psychiatry Nursing, Faculty of Health Sciences, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Toruń,, Bydgoszcz, Poland.*

The Ehlers-Danlos syndrome (classic type, cEDS) is a non-inflammatory, heritable connective tissue disorder, caused by incorrect synthesis and structure of collagen. Patients with EDS present large spectrum of phenotypes, they may have cutaneous, musculoskeletal, cardiovascular anomalies and additionally non-localized pain of the whole body. Clinical symptoms of classic type of EDS have great impact on patients physical and mental health.

The purpose of the study was evaluation of the quality of life of patients with cEDS using Polish version of SF-36 questionnaire.

41 patients (37 women and 4 men) were enrolled in the investigated group. The SF-36 is organized into areas: physical health (PH), physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), mental health (MH), vitality (VT), social functioning (SF), role-emotional (RE), general physical health (PCS) and mental health (MCS). All areas were evaluated. Additionally in investigation socio-demographic data (education), pedigree and clinical data (cEDS-positive relative in the family and strength of pain) were taken into account. Data analysis was carried out using the Statistical Package for the Social Sciences 21.0 (SPSS) (p-value≤0.05).

According to SF-36 test patients with cEDS have much worse than the average quality of life in areas: BP, GH and VT (physical functioning) and much better than the average quality of life in areas: SF, RE and MH (mental functioning).

Having at least one cEDS-positive relative decreased quality of life in SF, MH and MCS fields. Pain experienced by patients was the strongest factor decreasing physical and mental health quality of life.

PM20.10

Expanded carrier screening: are we ready? Results of an interview study with European geneticists

S. Janssens[1], *D. Chokoshvili*[2,1], *D. Vears*[3], *A. De Paepe*[1], *P. Borry*[2];
[1]*University of Ghent, Ghent, Belgium,* [2]*University of Leuven, Leuven, Belgium,* [3]*University of Melbourne, Melbourne, Australia.*

Preconception carrier screening aims to identify couples in which both partners are unaffected carriers of the same recessive disorder and have a 25% risk of conceiving an affected child. Although carrier screening has traditionally been performed for a small number of common disorders, recent advances in genetics led to the emergence of expanded carrier screening (ECS) panels, which screen for an increasing number of recessive disorders at little or no additional cost. However, expansion of screening panels adds a new layer of complexity to carrier screening, making large-scale implementation of ECS controversial.

In-depth interviews were conducted with 16 geneticists from 8 EEA countries in order to explore participants' views on ECS. While they acknowledge the important potential benefits of ECS, most participants were reluctant to start actively offering screening to the general population. They raised concerns regarding limited understanding of genetics among laypersons, which may result in misinterpretation or confusion over complex issues of ECS and preclude informed reproductive decision-making. Furthermore, the absence of suitable infrastructure, limited public resources, and lack of expertise in genetic testing among healthcare providers were all identified as important challenges to ECS in the general population. However, most participants believed ECS should be made available to the couples who request it. In addition, some geneticists favored routinely offering ECS to patients undergoing artificial reproduction (AR). It was argued that providers of AR have an obligation to utilize state of the art technologies such as ECS to avoid conception of a fetus with a severe disorder.

PS20.11

Disclosing genetic information to kin: a quantitative survey to analyze ethical and practical issues

D. d'Audiffret[1], *S. de Montgolfier*[2];
[1]*« Laboratoire Interdisciplinaire d'étude du Politique Hannah Arendt - Paris-Est » (LIPHA-PE) Université Paris Est Marne-la-Vallée (UPEM), Marne-La-Vallée Cedex 2, France,* [2]*IRIS (Institut de Recherche Interdisciplinaire sur les enjeux Sociaux. Ehess/ INSERM/CNRS), Paris, France.*

When a person is diagnosed with a serious genetic anomaly, the disclosure of this information can be relevant for other family members when prevention measures or treatment exist that can improve prognosis and_in some cases_even prevent a death. Research on this question has rarely been explored from the standpoint of healthcare professionals. We work on an interdisciplinary research study dealing with healthcare professionals' practices and related ethical issues in France, where the legislative framework has recently evolved.

Thus, we initiated an online quantitative research survey to get a clearer picture of the challenges arising from this issue, its real-world consequences in terms of medical care-service practices, and the stances that frontline professionals have taken in response to this new legal framework. 204 responses were obtained. The findings highlight very different patterns of practices depending on the genetic diseases concerned, and on the professionals' competencies in genetics. 26% of respondents declare having no competency in genetics.

It is equally crucial to sharpen a number of points, such as the nature of genetic testing, their possible prescription by non-geneticist clinicians, the scope of genetic counselling and its role in the disclosure process, the nature of information to deliver to patients and their relatives. Are all the genetic diseases concerned by the disclosure of information to kin? What changes in medical practices does genetics imply? Does genetics require a change of responsibilities?

*This abstract is supported by the INCa project "Family disclosure in human genetics: Implications and implementation in case of familial genetic disorders" (subvention 2013-130) and the Canceropole Ile-de- France.

PM20.12

How far do we need to go in transmitting genetic information to "family" members?

C. Farnos, *E. Rial-Sebbag;*
Inserm UMR 1027, Toulouse, France.

Because of it hereditary nature, genetic information has a personal and family dimension. The diagnosis of a serious genetic anomaly in a patient can be clinically relevant for other family members when prevention measures or treatment exist. According to the French law there is a legal obligation for

patients to inform their relatives about this diagnosis if this information is relevant for their health. This information can be delivered directly by the patient, or indirectly through the specific genetic information procedure to family members. Thus, all relatives potentially concerned can access the genetic information if they want to.
In 2011, le legislator went further by allowing the communication of relevant genetic information to children born after a gamete or embryo donation. In this case, the prescribing doctor and the Center for Medically Assisted Procreation (CMAP) must be involved in this transmission if the donor allows it. The adjunction of this provision gives raise to the so-called "biological family" while ignoring the current French legislation on the secret of origins, on the governance issues devoted to the CMAP and on the consequences on the donor and on the child. We will present the ethical and legal issues (privacy, responsibility) rose by this procedure essentially based on "the right to know".

Oncogenetic and disclosure of information to kin ? Which ethical questions and practical issues ?

S. de Montgolfier[1], *D. d'Audiffret*[2], *B. Derbez*[1];
[1]*IRIS (Ehess/Inserm), Paris, France,* [2]*LIPHA-PE) Université Paris Est Marne-la-Vallée (UPEM), Marne-La-Vallée Cedex 2, France.*

In the context of disclosure genetic information to kin, the breast and ovarian cancer are largely present in the available littérature but from the standpoint of patients and relatives (Chivers-Seymour et al. , 2010 et Bradbury et al., 2012), and rarely, if ever, from the standpoint of healthcare professionals. In our view, it is necessary to explore also the interactions between healthcare professionals and patients during the actual genetic counselling process. So the contexte of oncogenetic in France, where a new legislation frame this subject, we propose to present some results issue from two distinct methodologies. The first are a quantitative research survey via a online questionnaire which was set up to get a clearer picture of the practice, to let emerge the bioethics topics and the difficulty in the practice of genetic counselling. We will present the results of questionnaire filled by professional working in oncogenetic field. The second is an ethnographic approach i.e. fieldwork with observation combined with interviews to be able to describe "ethics as a practice" (Fassin, 2008)). We therefore consider that the ethnographic approach is a complementary way to address the implementation of this new legislative provisions bound to be subject to interpretation by actors.
We propose to share our hypothesis that oncogenetic is a model for the application of disclosing information to kin and try to show the difference of approach in other genetic fields.
*This abstract is supported by the INCa project "Family disclosure in human genetics: Implications and implementation in case of familial genetic disorders" (subvention 2013-130) and the Canceropole Ile-de- France.

Straight from the lab to the market: General public engagement with Direct-to-consumer genetic testing

J. Charbonneau;
Faculty of Law, University of Tasmania, Hobart, Australia.

With direct-to-consumer genetic testing (DTC), private companies provide tests and results directly to consumers in commercial transactions typically conducted online. DTC activities bypass traditional healthcare gatekeepers, representing a paradigm shift from medical to consumer and a transition from old to new economy regulatory and governance models. As consumer demand increases, concern has been raised about the potential for consumer detriment, especially psychological detriment, resulting from premature translation of genetic discoveries into for-profit tests.
When assessing the ethical, legal and social issues inherent in DTC, much of the focus has been on the interaction between individual consumers and DTC testing companies. The same holds true for assessing potential consumer detriment that drives consumer protection policy development and enforcement.
Modeling of the DTC space however has revealed morphing industry structures, increasing monetisation of DTC research databases and an expanding range of voluntary modes of consumer-to-consumer online engagement, illustrating the potential for consumer detriment extending far beyond an individual DTC transaction.
Fifteen hundred members of the Australian and American general public were surveyed to determine their ability to interpret and contextualize sample DTC genetic test results and the impact of individual risk interpretations on post-results psychological outcomes and behavioural intentions. Data was also collected on engagement with online sources of genetic information, online sharing of genetic information, interaction with healthcare professionals, and participation in DTC research. Results illustrate commonalities and differences by level of risk, disease, country and respondent demographic characteristics, providing insight to regulators and those developing governance frameworks.

PS20.15
Minors and their genetic identity

R. E. Van Hellemondt[1], *M. J. Vonk*[2];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Leiden University Law School, Leiden, Netherlands.*

The right to respect for privacy and family life encompasses both the right to have access to information regarding one's genetic origins as well as the right to have access to health information, including information about (the risk of) hereditary diseases. Regarding genetic testing, there is a universal consensus that minors have 'a right not to know'. This means that restraint must be exercised on genetic testing in order to safeguard a minor' right to an 'open future'. The right to respect for privacy and family life also requires that every child should be able to establish details of his biological origins, i.e. the 'right to know' who his genetic parents are.
Both situations - information regarding (the risk of) genetic diseases as well as knowledge about one's biological origins - concern a right to have access to information concerning one's genetic identity. However, the two basic principles applicable here are fundamentally different. The question is whether this different approach to the right to information about biological origins on the one hand and to genetic information about (the risk of) diseases on the other hand is justifiable?
In this study, we will examine the scope of the 'right to know' and the 'right not to know' in the light of the EVRM and the International Convention on the Rights of the Child. This study contains an overview of international literature and case law review regarding both rights in relation to genetic testing for health purposes and on personal origins.

PM20.16
What do patients think about the use of genome sequencing in the NHS?

A. E. Hazelton, *L. K. Petchey;*
Genetic Alliance UK, London, United Kingdom.

Abstract body: Genome sequencing is beginning to make its way into mainstream clinical practice in the UK, offering great potential for the effective diagnosis and future treatment of many conditions. As those most likely to benefit from the earliest uses of genome sequencing technologies, the views of patients and families affected by diagnosed and undiagnosed genetic conditions will be crucial in making decisions around its use in the context of clinical diagnosis and care. Through an online engagement project, comprised of videos, podcasts, questions and free text, we sought the views of these patients and families on the use of genome sequencing in the National Health Service (NHS) from the comfort of their own homes at a time convenient for them. Our results showed overwhelming enthusiasm from patients and families for genome sequencing to become a part of their routine care on the NHS and for sharing their genomic data for research. The findings also highlighted the value patients and families ascribe to the support offered by genetic counsellors. They cautioned though that at present they felt the NHS needed to do more to prepare for the integration of genome sequencing into clinical practice.

Sciences, M.K. Ammosov North-Eastern Federal University, Yakutsk, Russian Federation, [7]Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation, [8]Novosibirsk State University, Novosibirsk, Russian Federation, [9]Laboratory of Human Molecular Genetics, Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation, [10]Department of Genetics and Fundamental Medicine, Bashkir State University, Ufa, Russian Federation, [11]Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

Introduction of a sign language in special schools for deaf people led to growth of assortative marriages between them and contributed to increase of genetic fitness of deaf people. Combined effect of assortative mating and relaxed selection probably has doubled the GJB2 gene associated deafness in the US over the past 200 years (Nance et al., 2004; Arnos et al., 2008). High prevalence of the GJB2-deafness and relatively recent (~ 60 years ago) introduction of sign language among deaf people were recorded in Yakutia (Eastern Siberia). We performed study of the marital structure of deaf people in Yakutia as the first stage for following prediction of prevalence of the GJB2 gene associated deafness in Eastern Siberia. Data on marital status and family size of 121 hearing impaired individuals aged 25 to 67 years (mean 44.8 ± 9.3) from Yakutia was collected by special questionnaires. It was found that 114 of 121 respondents (94.2%) were married and/or had children, and 107 among married deaf individuals had a deaf marriage partner. Thus, the assortative mating rate among deaf people in Yakutia is 93.9%, that is one of the highest rates compared to other regions of the world (79.0% in the US; 46.8% in Turkey; 37.5% in Mongolia; 10.0-30.0% in Tunisia, and 10.0% in Varmland region of Sweden). The study was supported by the RFBR grants #15-04-04860_a, #14-04-01741_a, #15-44-05106-r_vostok_a, the State project #6.656.2014/K, and the Integration project of Siberian Branch of RAS №92.

PM20.18

Implementing a guideline to standardize the Citation Of BioResources in journal Articles (CoBRA) : a call to the scientific community.

A. Cambon-Thomsen[1], A. Calzolari[2], P. De Castro[2], L. Mabile[1], F. Napolitani[2], A. Rossi[2], E. Bravo[2], **E. Rial-Sebbag**[3]*;*
[1]Inserm-Université Toulouse III, Toulouse, France, [2]Istituto Superiore di Sanità, Rome, Italy, [3]Inserm-Univeristé Toulouse III, Toulouse, France.

Background
Recently for the first time, a guideline called CoBRA -Citation of BioResources in journal Articles was proposed for reporting bioresource (biological samples, data and databases) use in research articles.
Methods
A standardized citation scheme for bioresources was developed as part of the 'Journal editors working subgroup' of the BRIF (Bioresource Research Impact Factor) initiative, in collaboration with scientists and science editors. Dissemination phase is supported by The EQUATOR (Enhancing the QUAlity and Transparency Of health Research) network.
Results
The proposed citation guideline was published (BMC Medicine, February 2015) with the following main features: each individual bioresource that is used to perform a study must be mentioned in the Method section and should be cited as an individual "reference [BIORESOURCE]" according to a delineated format using a unique identifier when possible. One way to acquire such an identifier is through the description of the resource in a meta-journal such as OJB (http://openbioresources.metajnl.com/).
Conclusions
Adopting the CoBRA scheme described here will improve the quality of bioresource reporting and will allow their visibility and traceability in scientific publications, thus increasing the recognition of bioresources' value and relevance to genetic research. The ESHG as well as other scientific and professional societies are being solicited to encourage their community to use this guideline.

PS20.19

A new regulation for a new era of genetic testing - revision of the Swiss Federal Act on Human Genetic Testing (HGTA)

N. Keller, *R. Schaub, A. Raps, T. Binz;*
Federal Office of Public Health, Public Health Directorate, Berne, Switzerland.

As genomic science advances, genetic testing is becoming more common, especially outside its usual application in the clinical context. New commercially available tests can provide hints on athletic talents, the appropriate individual diet or one's ethnical origins. The Swiss Federal Act on Human Genetic Testing (HGTA) does only regulate the clinical application of genetic testing. However, the new fields of application for genetic tests are at present not regulated. With the aim of preventing the misuse of genetic tests and therefore protecting human dignity and personality, especially of children, the HGTA is currently revised and the scope is broadened to all kind of genetic tests.
The preliminary draft of the HGTA envisages expanding its scope to genetic testing outside the medical context: Tests potentially harming persons in their dignity and personality must not be offered as direct to consumer tests (e.g. testing of children's athletic talents). Biological samples for genetic tests have to be collected by certified specialists (e.g. pharmacists). Only if there is no potential for misuse, tests may be offered directly to consumers. Testing on children outside a medical context is generally not allowed. The catalogue of criminal provisions is expanded to the misuse of genetic tests through private persons which should provide additional protection. Furthermore, it is planned to inform the public about genetic testing and its regulation.
The preliminary draft of the HGTA was on public consultation from February until May 2015. The revised HGTA is scheduled to enter into force at the earliest in 2018.

PM20.20

No more frontiers between research and care? Legal analysis of genome sequencing clinical implementation in France.

A. Pigeon, *A. Cambon-Thomsen;*
Inserm-Université Toulouse III, Toulouse, France.

Genetic information is specific. Unlike other kind of medical information, it is all at once personal, familial, predictive and potentially identifying. Due to these characteristics, the French legislator established a particular legal framework for this information either in the clinical setting or in research. The translation of new sequencing technologies in the clinical setting however questions the relevance of the different laws in force and gives rise to ethical and legal issues. The aim of this research is to address, in the light of the new dispositions adopted by the French law in 2011, the relevance of the legal framework related to genetic information in both research and clinic vis-à-vis the implementation of new sequencing technologies.
These technologies allow a large or the whole exploration of the genome. Thus massive information is produced and its interpretation may exceed the scope of the initial diagnosis. The possibility of incidental findings challenges the relevance of information and consent, the communication of results and the medical practitioner responsibility.
New technologies also blur the boundaries between research and care. The production of sequencing data in a clinical setting generates useful data for research. Conversely, relevant information for the patient may be produced in the course of genetic research. In this context, databases may be constructed and fed by both parties. The inputs of the various parties at stake are particularly relevant in the context of these new realities. Supported by FP7 3Gb-TEST GA 602269 and ESGI GA 262055.

PS20.21

Realising genomics in clinical practice: ethical policy making in action

A. Hall[1], *C. Alberg[1], N. Hallowell[1,2], T. Finnegan[1], M. Kroese[1], H. Burton[1];*
[1]PHG Foundation, Cambridge, United Kingdom, [2]Institute of Public Health, Cambridge, United Kingdom.

The translational gap between research and clinical applications is a significant deterrent to biomedical innovation and adverse regulation is sometimes cited as a disincentive for translating novel technologies. In this presentation, we report the findings of an 18 month PHG Foundation project which evaluated the ethical, legal and social implications of implementing next generation sequencing (NGS) (including NGS panel tests, whole exome and whole genome sequencing) into clinical care in the UK NHS. Our rationale was that the translation of these technologies into practice could be facilitated by addressing these ethical, legal and social challenges prospectively rather than on an ad-hoc basis as they arise. Five iterative stakeholder workshops were held on the following topics: the experiences of empirical researchers as NGS technologies are implemented in clinical settings; the impact of these technologies on the interface between research and clinical care in genomics; the influence of these technologies on the clinical patient pathway; using targeted approaches based on gene lists as a precursor to opening the genome and effect on consent, technical aspects, reanalysis and recontact; and finally the infrastructural prerequisites of evidence base development and mandated data sharing. Focusing on ethical challenges - obtaining a valid and informed consent, ensuring effective data sharing, developing managed systems for gene list construction, proportionate systems for reporting incidental findings, and the potential for reanalysis and recontact within a publicly funded but resource limited health system - has fostered a comprehensive framework for action, that has been welcomed by stakeholders and will build public trust.

PM20.22

Beyond personal: Deliberating the social, ethical and legal issues of personalised medicine in expert and citizen dialogues

C. G. Schwarz, *B. Gschmeidler, A. Petschnig;*
Open Science - Lebenswissenschaften im Dialog, Vienna, Austria.

Today, the term personalised medicine is associated with different visions in biomedicine. Although it most often refers to biomarker-based strategies of patient stratification, it may also encompass proactive, predictive, and post-treatment approaches to healthcare. Personalised medicine thus is still a term subject to negotiation among stakeholders, including the general public. Additionally, technical, cost and data protection issues are up for debate. Since patients and citizens in general are called upon to make their biological tissue and genetic data available for personalised medicine-related research purposes, public participation is considered necessary to realise the vision of personalised medicine in socially robust ways on the EU and national level.

The paper presents the results of a deliberative project with experts and citizens on personalised medicine in the Austrian context throughout the year 2014. It analyses how experts from a variety of backgrounds (molecular biology, medicine, industry, ethics, and regulation) discussed the current framework conditions, expectations and challenges for personalised medicine in three stakeholder workshops, and compares these results with how members of the general public debated the term personalised medicine, prevention, cost, and data contribution issues in four citizen dialogue events. The paper focuses specifically on the central social, ethical and legal issues that were raised in these dialogue processes and reflects on the implications of these findings for communication activities directed towards the general public.

The project is funded by the Austrian Federal Ministry of Science, Research and Economy.

PS20.23

Are PGD users more liberal than policy makers? Attitudes of Israeli PGD consumers regarding justified uses for PGD compared with regulations

S. Zuckerman[1], *S. Gooldin*[2], *G. Altarescu*[1];
[1]*Hebrew University; Shaare Zedek Medical Center, Jerusalem, Israel,* [2]*Hebrew University, Jerusalem, Israel.*

PGD technology can increasingly detect genetic disorders and traits. Ethic committees are involved in understanding which usage for PGD is ethically justified. There has been considerable debate about the different uses of PGD and especially about the regulation of selecting embryos with non lethal, treatable or late onset conditions. Almost all guidelines worldwide ban PGD to less severe conditions or highly regulate it.

Exploring attitudes toward ethical and sociological aspects of PGD among 35 Israeli PGD users (carriers of autosomal recessive, dominant and X-linked disorders; HLA-matching) reveal totally different notions rather than these strict guidelines. High overall approval of PGD to any medical condition including non-lethal conditions, treatable conditions (e.g. deafness) and late-onset conditions (e.g. cancer predisposition) was mentioned and the onset age of condition did not play a role in the arguments for preventing any kind of abnormality. As to the controversial issue of social sex selection, the majority of surveyed subjects thought it would be appropriate to allow it for purposes of family balancing or cultural preferences. Yet, most of those in favor of this use thought performing PGD for this use only is an extreme step. In conclusion, our sample of Israeli subjects shows permissive attitudes to different application of PGD. These liberal attitudes of PGD users are not reflected in the guidelines made by the many ethic committees discussed these issues.

The isolation between medical-bioethics experts' decisions and PGD consumers' perspectives should not be ignored in the professional discussion and the design of policy making.

PM20.24

Ethical issues regarding presymptomatic and predictive genetic testing in Romania

R. Dumache[1,2], *M. Puiu*[1,3], *S. Popovici*[4], *V. Ciocan*[1,2], *C. Muresan*[1,2], *A. Enache*[1,2];
[1]*"Victor Babes ,'University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Institute of Forensic Medicine, Timisoara, Romania,* [3]*Children's Emergency Hospital, Timisoara, Romania,* [4]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.*

Genetic testing allow the identification of individuals who are carriers of some mutations in their genes, these mutations being the cause of some genetic disorders. Presently, three types of genetic testing are known: diagnostic, carrier and predictable. Predictive tests identify whether an individual is carrier of a genetic mutation and if there is the possibility to develop genetic disorders at a late on set. It is known that the first autosomal dominant genetic disease for which a predictive test was developed is Huntington's disease.

Unfortunately, if in the diagnostic and carrier tests we have the technical possibilities and they are correlated with the norms of the Romanian Medical System, when we talk about the predictive genetic tests, the situation is different because this type of diagnostic test isn't implemented yet in Romania. In Romania, we have some limitations regarding this type of predictive tests, because we don't have interdisciplinary teams in the hospitals to coordinate the management of these cases. Another limitation regards the ethical problems of information and patient consent. The lack of policy decisions, education campaigns, misinformation and lack of understanding regarding genetic diseases, leads to discriminatory practices.

All these problems need to be urgently solved and implemented in Romania, due to the special aspects belonging to them, especially in patients with Huntington disease.

PS20.25

Psychological Impact of Tumor Screening in *SDHX* Mutation Carriers Recruited in a 3 Year National Protocol

K. LAHLOU-LAFORET[1], *S. M. CONSOLI*[1], *A. CAUMONT-PRIM*[2], *V. ROHMER*[3], *A. GIMENEZ-ROQUEPLO*[4], *on behalf of the PGL.EVA investigators;*
[1]*U.F. de Psychologie et Psychiatrie de Liaison et d'Urgences - Université Paris Descartes, Assistance Publique – Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France,* [2]*Unité d'Épidémiologie et de Recherche Clinique - Assistance Publique – Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France,* [3]*INSERM, Centre d'investigation Épidémiologique , Service d'Endocrinologie, Centre Hospitalo-Universitaire, Angers, France,* [4]*Service de Génétique – Université Paris Descartes, Assistance Publique – Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France.*

Background: Tumor screening in hereditary paraganglioma allows early surgery. PGL-EVA is a 3 year French national protocol of tumor screening in SDHx mutation carriers.**Methods**: Depression (BDI-13), state and trait anxiety (STAI) and stress due to genetic test result (IES-R) were assessed at baseline in 197 subjects. Depression and state-anxiety were assessed again after tumor screening and then once a year.**Results**: At baseline, depression and stress were higher in index cases (p=0.023) than in relatives (p=0.013). After tumor screening, depression (p=0.003) and anxiety decreased (p=0.006). Final score of depression at 36 months (73 patients) was significantly associated with baseline score (p<0.001), without any significant change. Higher depression scores were observed in index cases vs relatives and in women vs men. Final anxiety scores were significantly associated with baseline scores (p<0.001), without any significant change.

In women, anxiety scores decreased between baseline and 36 months (p=0.03). The evolution of depression and anxiety scores was neither associated with the screening of new tumors, nor with the status of index cases vs relatives.

Anxiety score evolution was negatively associated with baseline trait-anxiety and stress.**Conclusions**: Tumor screening in genetically predisposed subjects does not lead to worsening emotional disturbances after three years of follow-up. A decrease of anxiety is observed in the more sensitive group of subjects at baseline.

PS20.27

Correlation between the levels of the awareness and the anxiety as factors, determining the quality of genetic counselling

E. Zayakova[1], *S. Shopova*[1], *A. Savov*[2];
[1]*Department of Neuropsychology, Universiry Hospital „Sv. Naum", Sofia, Bulgaria,* [2]*National Genetic Laboratory, Sofia, Bulgaria.*

Introduction: This research is part of a longitudinal study of the factors that influence the GC process. We analyse how awareness and the basic attitudes toward GC can affect the ST. We have explored the effect of the diagnostic procedures, the maternity in advanced age, the family reproductive history and the impact of the ST.

Materials and Methods: We analyse the influence of the information about GC to the ST levels. The ST levels are explored with STAY. The awareness toward the GC is tested with authors' questionnaire. We tested women, pointed for GC after biochemical screening, amniocentesis and risk pregnancy. We assume that a higher level of awareness, in combination with the age as a risk factor, leads to increasing ST.

Results: The women with higher levels of awareness show higher ST. These levels show a direct relation with the awareness levels, in combination with the age as a risk factor and with the pathological reproductive history. The women with minimum knowledge about GC perceive it as serial procedure. They do not accept it as a risk. The ST levels of these women are lower and

no significant difference is mentioned toward their TA.
Conclusions: The awareness about GC, in combination with advanced age maternity, leads to an increase of the ST levels. Analysing this factor can help better understanding the GC process and suggests creating an algorithm for psychological support.

PM20.28
What IF? A European perspective on the use of WGS in the clinic

S. Leonard[1,2], *S. Julia*[1,2,3], *A. Cambon-Thomsen*[1,2];
[1]UMR U 1027, Inserm, Toulouse, France, [2]Université de Toulouse, Université Paul Sabatier Toulouse 3, UMR 1027, Toulouse, France, [3]CHU Toulouse, Hôpital Purpan, Service de Génétique Médicale, Toulouse, France.

The different perspectives in North America and Europe regarding the clinical use of whole genome sequencing (WGS) have been the subject of much debate. A number of areas of divergence, both across and within Europe and North America have been identified. Surveys of genetics professionals and other stakeholders seeking their perspectives on the issues raised have been carried out in North America and Canada but there is little data regarding the views of those with an interest in clinical genetics in Europe. In the context of 3Gb-TEST, a European coordination action, we have carried out a Europe-wide web based questionnaire of 147 individuals from 25 countries with a professional interest in whole genome sequencing to elicit their views on a range of ethical issues including opportunistic screening, consent, incidental findings (IF) and re-contact. There was large convergence for a longer consent procedure and returning clinically actionable IF, whereas other issues elicited divergent positions. The findings of this survey will be discussed along with the output of a European workshop to be held in May 2015 aimed at progressing the debate around these issues. Based on this, suggestions for further and more precise guideline formation for the transfer of WGS to the clinic will be outlined. Supported by FP7 GA 602269.

PUBLISHED ABSTRACTS

J01.01
MMP genes polymorphism and pregnancy loss

E. Mashkina, *K. Saraev, R. Tsurikov, T. Marakhovskaya, E. Butenko;*
Southern Federal University, Rostov-on-Don, Russian Federation.

Physiological pregnancy causes tissue reconstruction in maternal organism. Structural changes in developing embryo and forming placenta are even more complex and include not only cell division and connected tissue forming processes, but also cell migration, extra-embryonic tissue invasion into maternal tissues. All these processes demand intercellular space and tissue structure reconstruction, that depends on metalloproteinases and it's inhibitors system functioning. The data on a value of metalloproteinases genes allele variants in early embryogenesis disturbances are poor and controversial. The purpose of current study was to investigate the association between *MMP* genes polymorphism and pregnancy loss.
DNA samples were isolated from blood leukocytes of 134 women with early pregnancy loss and 144 women with normal pregnancy. -1607insG MMP-1 gene, A-8202G MMP-9 gene and C536T TIMP-1 gene polymorphisms were analyzed with allele-specific PCR. The distribution of genotype and allele frequencies of 1697insG MMP-1 gene polymorphism in women with early pregnancy loss was equal to control group. While percentage of homozygous genotypes of A-8202 allele of MMP-9 gene was increased compared to control group. Women with certain genotype had 2.6 fold spontaneous pregnancy loss relative risk increase. The distribution of genotypes of A-8202G MMP-9 gene polymorphism in women with early pregnancy loss differed from control group ($p<0.01$). There was no difference in genotype and allele frequencies of C536T TIMP-1 gene polymorphism between studied groups of women. Thus, the allele variants of MMP-9 gene are associated with pregnancy loss risk. This study was supported by the federal assignment № 6.98.2014/K from Russian Minist<ry of Science and Education.

J01.02
Three cases of rare *SRY*-negative 46,XX males with complete masculinization and a review of the literature

B. LEE[1], *S. KIM*[1], *J. KIM*[1], *H. RYU*[1,2], *J. LEE*[3], *S. PARK*[1], *J. SEO*[3];
[1]Laboratory of Medical Genetics, Cheil General Hospital and Women's Healthcare Center, Seoul, Korea, Republic of, [2]Department of Obstetrics and Gynecology, Cheil General Hospital and Women's Healthcare Center, Seoul, Korea, Republic of, [3]Department of Urology, Cheil General Hospital and Women's Healthcare Center, Seoul, Korea, Republic of.

Introduction: *SRY* (sex-determining region Y) gene located in Yp11.3 has been thought to trigger gonads to differentiate to testes and play a critical role in the sex determination process. To identify the clinical characteristics of *SRY*-negative male patients and detect candidate gene(s) in male sex reversal, we performed a retrospective study for cases of 46,XX males with a review of the literature.
Materials and Methods: *SRY*-negative 46,XX males who referred for cytogenetic analysis from 1983 to 2013 were studied for clinical findings, seminal analysis, basal hormone profiles, conventional cytogenetic analysis and polymerase chain reaction.
Results: Chromosome analysis for cultured peripheral blood cells of 8,386 individuals revealed 46,XX males in 19 cases (2.27%). Of these, three cases (0.04 %) were confirmed for the absence of the *SRY* gene.
Conclusions: We report three cases of rarely detected *SRY*-negative 46,XX males with data that will help to assess the incidence of sex reversal in Korea. Through a literature review of 102 cases, candidate gene(s) for sex determination were identified and include genes on autosomes or the X chromosome that may function to induce sex reversal under the absence of *SRY* with gene dosage variation.

J01.03
First results of fetal chromosome aneuploidy testing using cell-free DNA in Lithuania

D. Serapinas[1,2,3];
[1]Alfa Clinic, Vilnius, Lithuania, [2]Lithuanian university of health sciences, Kaunas, Lithuania, [3]Mykolas Romeris university, Vilnius, Lithuania.

Backround. Circulating free DNA (fDNA) in blood of pregnant women is a mixture of genomic DNA of maternal and fetal origin. When applying the right method its analysis helps to detect fetal chromosomal aneuploydies with high sensivity and low fals positive rates.
Methods. Retrospective study of 80 singleton pregnancies between 9 and 20 weeks. Maternal blood was collected at Alfa Clinic (Vilnius) and send to Natera (San Carlos CA USA). cfDNA was isolated from maternal plasma, and targeted multiplex PCR amplification followed by sequencing of 19 488 po-

lymorphic loci covering chromosomes 13, 18, 21, X, and Y was performed. Sequencing data were analyzed using the NATUS algorithm that determines the copy number for each of the five chromosomes tested.
Results. Results were provided for 79 (98.8%) of the 80 cases. Most cases were in high risk pregnancy group (advanced maternal age and abnormal serum screening). Three cases were correctly identified as aneuploid, including trisomy 21 , trisomy 18 and rare case of mosaic case of X monosomy, with no false positive results. Test specificity showed 99% (CI 98-99.9 %) efficancy because all cases were confirmed by amniocentesis. One case was with low fetal fraction (2.3 %), however because of abnormal serum screening (very low PAPP-A and free beta-hCG) ammniocentesis and cyrtogenetic analysis was performed that revealed triploidy 69 XXY.
Conclusions. cfDNA testing in maternal blood using targeted sequencing of polymorphic loci at chromosomes 21, 18 and X showed accurate detection of fetal autosomal aneuploidies including chromosomal mosaicism. It helped to reduce the need of unnecessary invasive procuderes (CVS and amniocentesis).

J01.04
Assessment of possible correlation between sperm parameters and the incidence of aneuploidy in sperm of infertile males

S. Farcas[1], *M. Cosma*[1], *M. Stoian*[2], *D. Amzar*[1], *N. Andreescu*[1], *M. Puiu*[1];
[1]University of Medicine &Pharmacy Victor Babes, Timisoara, Romania, [2]University of Medicine &Pharmacy Carol Davila, Bucuresti, Romania.

Introduction The causes of infertility are very complex, cytogenetic anomalies being one of the possible causes. In the last years was taken in consideration the hypothesis that not only somatic chromosomal anomalies but also germ cells chromosomal aberrations could lead to reproductive failure. The difficulties related to chromosomal evaluation in germ cells were overcome by the development of molecular cytogenetic techniques use.
Aim. We have study the hypothesis of a possible correlation between sperm parameters and the incidence of aneuploidy.
Materials and method In this study we used multicolor FISH probes for chromosome 13, 18, 21, X and Y and strict scoring criteria, in order to evaluate 35 patients with oligoasthenoteratozoospermia (OAT) and 20 individual with normal fertility.
Results The overall incidence of disomy in the OAT group showed a weak to moderate correlation with the semen parameters. In this study we found a moderate negative correlation between the disomy incidence and the sperm concentration (r=-0.49). By comparing the disomy incidence and the progressive motility and the normal morphology we found a weak negative correlation, the correlation coefficients were r=-0.39 and r=-0.36 respectively. Previous studies have reported negative correlation between the rate of chromosome aneuploidy and semen parameters.
Conclusions The molecular cytogenetic analysis allows the identification of patients with an increased risk for reproduction failure and facilitate an appropriate counseling in order to inform the patients about their reproductive options, the genetic preimplantation testing and the prenatal genetic tests that are available.

J01.05
Citogenetic and molecular genetic analysis of mirror duplication of chromosome 21

B. O. Petrovic[1], *M. Komnenic-Radovanovic*[1], *O. Stojkovic*[2], *J. Stamenkovic*[2], *N. Dragicevic*[3];
[1]Institute for gynecology and obstetrics, Clinical center of Serbia, Belgrade, Serbia, [2]Faculty of medicine, Belgrade University, Belgrade, Serbia, [3]Institute for endocrinology, Clinical center of Serbia, Belgrade, Serbia.

INTRODUCTION: We present a new case of mirror duplication of chromosome discovered by cytogenetic analyses, and further studied with molecular markers. CASE RAPORT: Female newborn had all characteristics typical for Down syndrome: facial dysmorphia, muscle hypotonia, a single flexion furrow of the fifth finger on the right hand, short fingers and a heart anomaly. Derivative chromosome 21, was detected in all 30 studied metaphase cells. G banding technique showed translocation between two chromosomes 21, joined with terminal ends of the long arm. C banding technique showed a single centromere. QF – PCR analysis of newborn's DNA, showed six markers on the chromosome 21 with trisomic dialelic patterns (D21S1442, D21S1414, D21S1435, D21S1446, D21S1809, D21S1412), one marker with trialelic trisomic (D21S1437) and one normal heterozygous marker (D21S1411). Parents had normal karyotypes. After QF – PCR analysis from parents' DNA, normal markers ratios were found in father's DNA, but one marker (D21S1437) in mother's was in trialelic state . Mother had muscle hypotonia, a flat nasal bridge and a single flexion furrow of the fifth finger on the left hand, but she was a person of average intelligence and without other specific clinical characteristics. CONCLUSION: Literature data imply that region 21q22.3 is critical region for phenotype of Down syndrome, but this case also implies the role of region 21q21 (to wich marker D21S1437 maps) in some clinical features of Down syndrome.

Association of folate, methionine cycle genes and the second phase of xenobiotic's detoxification genes in moldovian women with pregnancy losses

V. Hlistun[1], *N. Usurelu*[1], *V. Egorov*[1], *K. Boiciuc*[1], *A. Parii*[2], *A. Muntean*[2], *V. Sacara*[1];
[1]Institute of Mother and Child, Chisinau, Moldova, Republic of, [2]Centre of Reproductive Health and Medical Genetics, Chisinau, Moldova, Republic of.

Introduction: Pregnancy loss (PL) is a devastating reproductive problem affecting approximately 5% of women trying to conceive. The aim of this study is to provide a relatively comprehensive account of the association between mutations in GSTM1, GSTT1, GSTP1, MTHFR, MTR and MTRR and PL.
Materials and Methods: The prevalence of these polymorphisms was compared in 164 women with two or more pregnancy losses in the first and second trimester, and 64 women without history of miscarriages, with 2 healthy births. We used PCR and PCR-RFLP methods.
Results. The results of this study showed that women with PL have a higher proportion of the MTHFR 677TT (OR=3.35), MTHFR 677CT (OR=1.16), MTR 2756AG (OR=1.21) and GSTT1 null genotype (OR=1.09) compared with the control group, however, the difference was not statistically significant. The prevalence of GSTT1 null+MTHFR 677CT and compound 677CT/1298AC were higher in the study group than in the control group (14% versus 8% and 27% versus 23%, respectively). The gene polymorphisms MTHFR 677TT, MTR 2756GG were significantly more frequent in the patients with second trimester PL (P<0.05) and the prevalence of GSTM1 null, GSTP1 105 Val/Val, MTRR 66AA were more higher in the patients with first trimester losses, but there was not statistically significant.
Conclusion: The risk of PL is higher for women carrying MTHFR 677TT, MTHFR 677CT, MTR 2756AG and GSTT1 null. MTHFR 677TT and MTR 2756GG genotypes were significantly more frequent in the patients with second trimester PL (P=0.006. OR=0.16 and P=0.002. OR=0.06).

J01.07
Genetic causes of male infertility in patients with azoospermia from Serbia - eight years experience

B. Dobric, *D. Radivojevic, T. Lalic, M. Miskovic, S. Cirkovic, J. Vukajlovic, M. Djurisic;
Mother and Child Health Care Institute of Serbia, Belgrade, Serbia.*

Introduction: According to the World Health Organization, infertility affects 10-15% of couples and male factor represents 30-50% of cases. Genetic factors were found to have important roles in the etiology of idiopathic azoospermia and severe oligospermia patients, affecting sperm production or sperm transport.
Materials and Methods: Since 2006, samples of 62 azoospermia patients were analyzed using cytogenetic, molecular cytogenetic and molecular genetic methods. Cytogenetic analysis were performed on cultured PHA-stimulated blood lymphocites using GTG banding. Fluorescence in situ hybridization (FISH) was performed using a Y chromosome specific DYZ3 locus. Presence of microdeletions in AZF region on Y chromosome was analyzed using multiplex PCR reactions for amplification of ZFX/ZFY, SRY, AZFa, AZFb and AZFc regions.
Results: Cytogenetic analysis showed presence of aberrant karyotype in 9 patients. Structural chromosomal aberrations were detected in four patients (one with dicentric Y chromosome, two with deletion of long arm of Y chromosome, delYq11.22 and one patient with balanced translocation). Numerical chromosomal aberrations were detected in five patients (four of them with 47,XXY karyotype and one patient with two Y chromosomes-47-,XYY). Results of molecular genetic testing showed that five patiens had AZF deletions (two with AZFc deletion and three with AZFbc deletion). All patients were offered genetic counseling service in our hospital.
Conclusion: The results of this study have determinated the cause of azoospermia in 19.35% of all analysed patients. Given that our results showed high prevalence of genetic aberrations in infertile men, application of genetic testing in such cases is fully justified.

J01.08
GSTM1 and GSTT1 null genotypes and the risk of non-obstructive azoospermia: a case-control study in an Iranian population

E. Abbasifarid[1], *R. Mirfakhraie*[2], *G. Javadi*[1];
[1]Islamic Azad University, Science and Research Branch, Tehran, Iran, Islamic Republic of, [2]Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Approximately 15-20% couples are suffered from infertility and about half of these cases are due to male infertility. Spermatogenesis impairment is the most common cause of male infertility. Reactive oxygen species (ROS), such as the superoxide anion and hydroxyl radical, can be produced by human spermatozoa. There is growing evidence that oxidative damage to the human spermatozoa membrane is an important pathophysiological mechanism in human male infertility. The aim of the present study was to investigate whether there is a genetic association between the glutathione-S-transferase (GST) enzyme and idiopathic male fertility. We examined GSTT1 and GSTM1 polymorphisms in 100 infertile men with non-obstructive azoospermia and 100 fertile men as the control group using multiplex PCR. The GSTM1 null genotype was present at frequencies of 0.57 in infertile cases and 0.42 in controls (OR=1.83, 95%CI=1.04-3.20; P=0.034).These frequencies were 0.15 and 0.15 for GSTT1 null genotype respectively (OR=1, 95% CI=0.46-2.17; P>0.05).The frequency for the null genotypes of both GSTM1 and GSTT1 in patients was 72% versus 57% in controls (OR=1.93, 95%CI=1.07-3.49; P=0.027). Our results suggest an association between GSTM1 null genotype and idiopathic azoospermia.

J01.09
A double translocation found in prenatal diagnosis

M. Souto, P. Botelho, R. Arantes, C. Carnide, M. Martins, O. Moutinho, **R. Pinto Leite***; Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal.*

Translocations are the most frequent structural chromosomal abnormalities and may pass undetected through generations. Miscarriages, infertility or the birth of a child with an unbalanced form of translocation usually reveals the existence of a familial chromosomal translocation. The development of new techniques, such as array Comparative Genomic Hybridization (aCGH), has increased the resolution of novel or rare microdeletions/microduplications, but chromosome analysis remains the gold standard to delineate chromosomal structural rearrangements.
The authors present a case of a 45-year-old pregnant woman referred for the first time to our prenatal center. She had a previous history of ten miscarriages, not investigated, and five healthy children. Amniotic fluid (two cultures) and parent's blood cultures were performed according to the protocols established in the laboratory. Oligonucleotide aCGH was applied.
Cytogenetic analysis of amniotic fluid revealed a double translocation: t(1;2)(p34.1;p23)mat and t(1;5)(q10;q10), a *de novo* situation. aCGH analysis didn´t detected any gain or loss involving the translocated segments and the ultrasound parameters were normal. The couple decided to continue the pregnancy.
Cases of unrelated double translocations are extremely rare, there are only seven cases described and six of them were *de novo*. The presence of an inherited and a new translocation detected in a prenatal diagnosis implies a more careful approach in the pregnancy follow up. Currently prenatal diagnosis can benefit from the advances of the molecular techniques that are very useful for the precise characterization of chromosomal anomalies.
The authors will present a review of the previous described cases and compared with this case.

J01.10
The most frequent mutation in the CFTR gene among CF children and adult CF patients

A. A. Stepanova[1]*, S. A. Krasovsky*[2]*, E. L. Amelina*[2]*, N. V. Petrova*[1]*, A. V. Polyakov*[1]*;* [1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Pumonology Research Institute Federal Medical and Biological Agency of Russia, Moscow, Russian Federation.*

Cystic fibrosis is an autosomal disorder with high clinical variability that is associated with CFTR mutations.
In this work we analyzed DNA CF children and CF adult patients from different regions of Russia to compare the distribution of the 19 mutations (CFTRdele2,3, F508del, I507del, 1677delTA, 2143delT, 2184insA, 394delTT, 3821delT, L138ins, 604insA, 3944delTG, G542X, W1282X, N1303K, R334W, 3849+10kbC>T, S1196X, 621+1g>t, E92K), that are the most frequent mutations in Russian Federation.
We analyzed 296 CF children and 501 adults CF patients. The middle age of adult patients is 27 years old and the middle age of children is 7 years old.
The most frequent mutations (F508del and CFTRdele 2.3) were found among children F508del - 53.2% and among adult patients 50.6%, CFTRdele2.3- 6.7% among children and 6.5% among adults and didn't discover the significant distinctions between groups. Mutations I507del, 2143delT, 2184insA, 394delTT, 3821delT, L138ins, 604insA, 3944delTG, G542X, N1303K, S1196X, 621+1g>t, E92K were met from 0 to 5.4% and also didn't find the significant distinction between groups. For mutations W1282X, 1677delTA, 3849+10kbC>T, R334W was found differences among groups ($p < 0.05$). Mutations W1282X and 1677delTA are associated with heavy clinical phenotype and in adult CF patients was found less often than among CF children. Mutations 3849+10kbC>T and R334W belong to IV class of mutations in CFTR gene and as result is a mild form of CF. In adult CF patients was found more often than among CF children.
Thus in our work we can see that "mild" mutations are found more often among adult CF patients and "severe" mutations are among children.

J01.11
Restrictions of the QF-PCR method in detecting fetal aneuploidies

N. Teran, *H. Jaklič, B. Peterlin, M. Volk; UMC Ljubljana, Ljubljana, Slovenia.*

Quantitavive fluorescent polymerase chain reaction (QF-PCR) has proved to be an accurate, robust and efficient method for detecting the most common aneuploidies.
We reported some restrictions in testing of prenatal samples using commercial QF-PCR assay.
At 33 weeks of pregnancy, amniocentesis and QF-PCR was performed because of ultrasound abnormalities. In the absence of the bloodstaining the allele ratios were inconclusive showing two different profiles. After QF-PCR of mother blood sample was performed, we found out that this result was consistent with mother's profile.
In our second case, a 38-year old female underwent chorionic villus sampling due to advanced maternal age. Conventional chromosomal analysis showed 47,XXY[6]/47,[6]/47,XY,+8[19]/47,XY,+18[35]. A subsequent QF-PCR after amniocentesis revealed a normal 13,18,21 chromosomes pattern and the abnormal sex chromosome profile which could be compatible with a XY/XXY mosaicism. Cells with trisomy 18 were probably confined to the placenta or presented in less than 10% of amniocytes.
In another case, a CVS was obtained from pregnant woman with fetal ultrasound abnormalities. The QF-PCR of multiple X/Y specific markers showed abnormal sex chromosome pattern. AMXY marker showed a skewed 1.7:1 ratio, Yq marker did not amplify. After karyotyping, FISH and chromosome Y microdeletion analysis, the results showed 46,X,del(Y)(q12).ish der(Y)(wcpY+,DXYS153+,SRY+,DYZ3+,DXYS153+). In cases of abnormal markers for sex chromosomes further testing is recommended.
The presented cases demonstrate that caution should be taken when conflicting results are observed or abnormal X/Y pattern is present in prenatal sample. Analysis of prenatal samples might be complicated by variable sample quality, mosaicism or maternal cell contamination.

J01.12
Prenatal finding of pericentromeric inversion of chromosome 3

P. Tesner, *J. Drabova, M. Stolfa, D. Novotna, E. Kocarek; Department of Biology and Medical Genetics, Charles University - 2nd Faculty of Medicine and Univers, Prague, Czech Republic.*

Every prenatal finding of not clearly pathogenic chromosomal abnormality is a very difficult situation in genetic counselling. Even postnatally, it is frequently impossible to certainly correlate the cytogenetic finding and particular phenotypic abnormality.
We present a case of Czech patient with prenatal finding of de novo pericentric inversion 46,XX,inv(3)(p11.2q21) in the amniotic cells obtained by an amniocentesis performed for the advance maternal age, there were no other risk indicators.
In literature, there is only one similar case in Spedicato FS et al.: Pericentric inversion inv(3)(p11q21). [J Med Genet. 1984 Oct;21(5):396.] The inversion was detected in a newborn with a prominent forehead and receding chin, a left preauricular tag, a long philtrum, and pendulous cheeks. Its familial occurrence in other normal relatives (father, brother, paternal aunt and her daughter) emerged afterwards. Today in our case we had the result of array-CGH in addition - no deletion was detected in the breakpoint or anywhere else.
With this knowledge parents in decided not to terminate their pregnancy (with acceptable residual risk which is always inevitable). The rest of pregnancy proceeds without any complication so far - the estimated date of delivery is in the middle of February. After the delivery, the child will be examined and the prenatal cytogenetic finding will be confirmed (and extended) by the analysis of the peripheral blood sample. All of these results will be presented on the meeting.
Our work is supported by Grant Agency of Charles University (no. 264811) and Technology Agency of the Czech Republic (no. TA01010931).

J01.13

Analyzing The FSHR Polymorphisms in İnfertile Turkish Woman

*S. Yılmaz[1], **S. Aydos**[2], A. Karadağ[2], M. Taşpınar[3], Ö. Gün Yılmaz[4], A. Sunguroğlu[2];*
[1]Cukurova University, Faculty of Medicine, Department of Medical Biology, Adana, Turkey, [2]Ankara University, Faculty of Medicine, Department of Medical Biology, Ankara, Turkey, [3]Yüzüncüyıl University, Faculty of Medicine, Department of Medical Biology, Van, Turkey, [4]Zekai Tahir Burak Women's education and research hospital, Ankara, Turkey.

Follicle-stimulating hormone (FSH) by binding to a specific receptor play a major role in the development of follicles and regulation of steroidogenesis in the ovary, and spermatogenesis in the testis. There were studies analyzing the effects of the SNP in exon 10 (codon 307 and 680) and in the core promoter region (at position -29) of the FSHR gene on spermatogenesis, but for our knowledge there were no studies analyzing the effects of these 3 SNPs' combinations on female fertility.

In this study, the allelic, genotype, and haplotype frequency distributions of these 3 SNPs in the FSHR gene were analysed 102 infertile women, 99 unrelated healthy control individuals. The distribution of the polymorphisms was confirmed by Hardy-Weinberg equilibrium test. In infertile patients, linkage disequilibrium between the -29, Ala307Thr and Asn680Ser of FSHR polymorphisms was indicating same linkage disequilibrium. However, there were no statistical differences ($p>0.05$) in the allele, genotype and haplotype frequencies of the polymorphisms between the infertile patients and the controls. Also there was no differences between FSH, LH and E2 levels and genotypes in -29, 680 SNPs ($p>0.05$). It was found only significant relation between 307 SNP GG genotype and FSH level ≤10 and GA genotype and FSH level >10 ($P=0.016$).

The present study was the first to determine the polymorphism of the FSHR core promoter at position -29 alone and in combination with the two common SNPs in exon 10 in Turkish infertile women population. These findings indicate the significance of Ala307Thr GA genotype may be a predictive marker for poor ovarian reserve.

J01.14

Maternal plasma expression of fetal hsa-miR-99a in pregnancies with congenital heart defects

L. Kehler, *O. Biró, L. Lázár, J. Rigó, B. Nagy;*
1st Dept. of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary.

Introduction: Only one out of eight congenital heart defects (CHD) is associated with chromosomal disorders, yet non-invasive prenatal diagnostics focuses majorly on screening for trisomies instead of cardiac malformations. Assumed to modify up to 60 percent of human protein-encoding genes, microRNAs play an important role in cardiogenesis and present an intriguing marker for standalone CHD-screening. The aim of this study was to investigate the role and the maternal plasma expression of fetal hsa-miR-99a in pregnancies affected by CHD.

Materials and methods: Peripheral blood samples were collected from 39 pregnant women: 22 pregnancies were affected by CHD and 17 pregnancies were CHD-free controls. MiRNA was isolated from maternal serum and quantitative real-time PCR was carried out to determine the expression of total-miRNA, u6-snRNA and hsa-miR-99a.

Results: While there was no significant difference between the miRNA concentrations among CHD-affected and control group (5.54 ng/µl vs. 6.40 ng/µl), we found significantly up-regulated hsa-miR-99a levels in the CHD-affected group (1.78×10^{-2} ng/µl ± 3.53×10^{-2} vs. 1.09×10^{-2} ± 3.55×10^{-3} ng/µl, $p = 0.038$).

Conclusions: According to our study, hsa-miR-99a is overexpressed in pregnancies affected by a variety of CHD, could be used to monitor fetal cardiogenesis during early pregnancy and to non-invasively screen for CHD independent of chromosomal disorders.

Study of the FMR1 gene structure among women with ovarian dysfunction from the Basque Country

*M. Barasoain[1], G. Barrenetxea[2,3], I. Huerta[1,4], M. Télez[1,4], E. Ortiz-Lastra[2], J. González[2], B. Criado[5], **M. Arrieta**[1];*
[1]Department of Genetics, Physical Anthropology and Animal Physiology. Faculty of Science and Technology. University of the Basque Country, Leioa, Spain, [2]Department of Medical-Surgical Specialities. Faculty of Medicine. University of the Basque Country, Leioa, Spain, [3]Center for Ginecology and Reproduction. Praxis Bilbao Clinic, Bilbao, Spain, [4]Virgen de Begoña Clinical Analysis Laboratory (Medikosta), Erandio, Spain, [5]Cooperativa de Ensino Superior Politecnico e Universitario (CESPU), Porto, Portugal.

Primary ovarian insufficiency (POI) is defined as irregular menses and elevated gonadotrophin levels before or at the age of 40 years. The FMR1 intermediate (35-54 CGGs) and premutation (55-200 CGGs) alleles have been related with the development of this condition. A group of 68 women with ovarian dysfunction of unknown aetiology and 47 control women from the Basque Country was analyzed. The length of the repeat and the AGG interspersion pattern were evaluated. In relation to the number of CGG repeats, the frequency of alleles with 35-200 CGG repeats was statistically higher in the patient group (12.50% vs. 0%). This group was divided into three categories: group 1, irregular cycles, reduced fecundity and FSH levels <10 IU/l; group 2, irregular cycles reduced fecundity and FSH levels ≥10 IU/l and group 3, amenorrhea for at least 4 consecutive months and FSH levels ≥10 IU/l. In the three subgroups the frequency of alleles with 35-200 CGG was statistically higher than in controls. Regarding the AGG interspersion pattern, many of the intermediate and premutation alleles among patients appeared to have two interruptions (70%), the first AGG located in the 10th position (75%) and more than 15 CGG at the 3' end (83.3%). Interestingly, among these alleles the predominant structure was 9+9+n, indicating a loss of AGG interruptions at the 3' end. Therefore, the data showed that among patients the alleles were more unstable and that this instability influencing the FMR1 expansion might be related with the development of an ovarian dysfunction.

J01.16

The improvement of prenatal screening of aneuploidies and preeclampsia in Ist to IIIrd trimester by 1T QUAD test

M. Macek sr., *M. Pešková, R. Vlk, M. Turnovec, M. Vlčková, P. Tesner, A. Štambergová, M. Macek jr.;*
University Hospital Motol, Prague, Czech Republic.

The aim of the study was to verify the screening success of 1T QUAD test (PAPPP-A, fbhCG, AFP, PlGF) and examination of decerased PlGF levels within IInd-IIIrd trimester.

Biomarker levels were examined on Delfia Xpress and LifeCycle 3 and Preeclampsia Predictor software were used (Perkin Elmer). MAP, arteria uterina pulsatility index and extended genetic risks questionnaire were collected.

Efficiency of PAPP-A, fbhCG and 1T QUAD was compared in 400 pregnancies, retrospective evaluation of PlGF and PAPP-A in 35 pregnancies with PE.

The 1T QUAD has significantly higher success than PAPP-A and fbhCG only as reliability for aneuploidy and PE risk calculation. Trisomy 21 risk 1:50000-1:100000 was in 56% in 1T QUAD compared to "dual" strategy with 2.1%. It provides optimal NIPT indication according selected risk criteria. Same PE screening success is guaranteed by decreased PlGF levels in IInd trimester as in Ist one, in intermediate and late PE detection even in negative Ist trimester PlGF screening. PlGF 5th percentile levels were created for 9-38th week for improvement of all PE types prediction. PlGF levels higher than 270 pg/ml in IInd and IIIrd trimester eliminate in 100% PE risk.

The 1T QUAD strategy significantly improves aneuploidy and PE detection in Ist trimester. Decreased PlGF levels in IInd trimester within 14-20th and 20-29th weeks significantly improve detection of not only aneuploidy and all types of PE but also severe disorders of prenatal development.

Supported by FN Motol (00064203, Modern Therapy), IGA NT13770 and OPPK CZ.2.16/3.1.00/24022.

The Role of ADAMTS5 Proteases In Male Infertility

Y. YUKSELTEN[1], *O. S. AYDOS[1], A. SUNGUROGLU[1], K. DEMIRCAN[2], K. AYDOS[3];*
[1]Ankara University, School of Medicine, Department of Medical Biology, Ankara, Turkey, [2]Turgut Ozal University, School of Medicine,Department of Medical Biology, Ankara, Turkey, [3]Ankara University, School of Medicine, Department of Urology, Ankara, Turkey.

Introduction: The defect of matrix remodeling and the imbalance of ECM's construction and destruction are important in male infertility. It is not enough to explain idiopatic cases because there are lots of unknown subjects in studyings which make clear spermatogenesis process.

The development of molecular methods is needed because it lets us to understand the fertilization steps and will be used in these patients. Lately there are lots of studies in literature about metalloproteinases which have different physiological functions in human metabolism and play a crucial role in construction and destruction of ECM. But there are very few studies about male infertility

İn this study, our aim is to investigate the role of ADAMTS5 proteases which is responsible for degrafdation of ECM in spermatogenesis.

Material method: In this study, we divided infertile mens into four groups. We isolated protein from semen samples taken from 10 control, 10 oligospermia, 10 idiopatic infertile and 5 azoospermia groups. We analysed protein levels with western blot.

Results : According to results, we determined that the protein levels of ADAMTS5 decreased 2,68 and 1,66 fold in azospermia and oligospermia groups respectively than control groups. And we didn't find any differences between control groups and idiopatic infertile groups.

Conclusion: It is very important to understand molecular function and organization of ADAMTSs which will be significant in enlightining the process of spermatogenesis in male infertility. Therefore we need to determine more biomarker related to male infertility.

Arrixaca, IMIB-Arrixaca, Murcia, Spain, [3]Clinical Genetics - INGEMM, Instituto de Genética Médica y Molecular, IdiPAZ- Instituto de Investigación Sanitaria del Hospital Universitario La Paz-Universidad Autónoma de Madrid, Madrid, Spain, [4]Obstetrics and Gynecology, H. Clinic Universitary V. Arrixaca, IMIB-Arrixaca, Murcia, Spain, [5]Medical Genetic Seccion, H. Clinic Universitary V. Arrixaca, IMIB-Arrixaca, Dep. Med Genetics. UCAM-Univ Católica, Murcia, Spain.

Introduction
More than 4 million infants have been born after assisted reproductive techniques (ART) around the world. There are contradictories data about neonatal outcomes and risk of major congenital malformations (MCM) in this population. Objective: to describe the prevalence of neonatal complications and MCM at the age of one year in a cohort of children born after ART compared to spontaneous births, and to determine associated factors.
Material and methods
Prospective cohort study of children born from women undergoing IVF/ICSI treatment between may 2012-february 2013, in Assisted Reproduction Service of Spanish tertiary Hospital. Cause of infertility, embryo transfer (ET) day (D), maternal age, neonatal outcome and presence of MCM were analysed.
Results
107/121 live births were assessed (participation 88%). Mean maternal age: 32 years. 26% were multiple gestations (MG). Prematurity in 22/107 (20%) associated to MG (19/22). Mean birth weight: 2900 g (p40). 19/107 needed hospitalisation. At the age of one, 11 presented MCM (10%) according to ICD-10 classification: congenital malformation of cardiac septa (6), aortic valve (1), nervous system (2) and congenital hydronephrosis (1). It was associated significantly ($p<0.05$) to ET D5/D6 and feminine infertility was a protective factor. No association with maternal age or MG.
Conclusions
Neonatal hospitalisation and prematurity were higher than in spontaneous births, but it seems to be associated to MG. Prevalence of MCM was higher than expected and congenital heart disease was the most frequent. The association with late ET suggests that the culture might be a predisposing factor. Further studies will be necessary to assess these results.

The Association Between Inherited Thrombophilia and Spontaneous Abortion: A Comparative Study

S. Yalcintepe[1], *O. Ozdemir*[2], *S. O. Hacivelioglu*[3], *C. Akurut*[2], *E. Koc*[3], *A. Uludag*[2], *E. Cosar*[3], *F. Silan*[2];
[1]Department of Medical Genetics, Numune Training and Research Hospital, Adana, Turkey, [2]Department of Medical Genetics, Canakkale Onsekiz Mart University, Canakkale, Turkey, [3]Department of Gynecology and Obstetrics, School of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey.

Purpose
To evaluate the association of trombophilic factors and spontaneous abortion we studied the genotypes of Factor V Leiden (FVL), Protrombin G20210A, MTHFR C677T, PAI-1 4G/5G, ACE I/D, eNOS E298D, Apo E E2/E3/E4 for spontaneously aborted fetal materials, their mothers and fertile women as control group.
Methods
Target SNPs for each gene were analysed by real time PCR technique after genomic DNA isolation from maternal blood-EDTA, control group blood-EDTA and spontaneously aborted fetal tissues. Statistical analysis was done with medcalc statistical programme. Twenty-three spontaneously aborted materials, twenty-two mothers who had these abortions and twenty-two fertile women were included in this study.
Results
PAI-1 4G/5G+4G/4G ($p=0.0017$), 4G/4G ($p=0.0253$), eNOS 894GT+894TT ($p=0.0011$) genotypes and T allele ($p=0.0185$), Apo E E3/E4+E3/E2+E2/E4 ($p<0.0001$) genotypes, E2 ($p<0.0001$) and E4 ($p<0.0001$) alleles were higher in spontaneously aborted fetal materials comparing with their mothers and control group. Factor V Leiden, Prothrombin G20210A, MTHFR C677T, ACE I/D polymorphisms were not different in aborted materials and both mothers and control group ($p>0.05$).
Conclusion
PAI-1 4G/5G, eNOS E298D and Apo E E2/E3/E4 polymorphisms were associated with increased risk of spontaneous abortion comparing the abortion materials with their mothers and control group.

The analysis of polymorphism of genes cyitokines at women with chronic salpingoophoritis

G. M. Iskhakova, *A. U. Khamadyanova, U. R. Khamadyanov, T. V. Viktorova;
Bashkir State Medical University, Ufa, Russian Federation.*

The chronic salpingoophoritis(CSO) - a widespread infectious inflammatory disease of appendages of a uterus with a relapsing course. Search of associations of polymorphic loci of genes of TNFA, IL1B and IL1RN with development of CSO was a research objective. Comparison of distribution of frequencies of genotypes and alleles of a polymorphic locus 3539C>T gene IL1B between groups of patients and control revealed authentically significant prevalence of a genotype of IL1B*-3539C/C in group of control (P=0,0045). This genotype can be a marker of the lowered risk of development of a chronic salpingoophoritis for which odds ratio of chances made 0,14. As a result of the carried-out analysis of a polymorphic locus 3539C>Tgene of IL1B was revealed association allele by IL1B*3539T with the increased risk of development of a disease in the studied group (OR=3,03).

J01.21

Hereditary thrombophilia as one of the causes of pregnancy losses in Moldavian women

D. Badicean[1], *K. Boiciuc*[1], *N. Usurelu*[1], *A. Parii*[1], *A. Muntean*[1], *E. Plingau*[2], *V. Sacara*[1];
[1]Centre of Reproductive Health and Medical Genetics, Chisinau, Moldova, Republic of, [2]University of Academy of Science of Republic of Moldova, Chisinau, Moldova, Republic of.

Introduction: Recurrent pregnancy losses (RPL) are affecting approximately 3% of women and are a significant clinical problem, in many cases associated with thrombophilia. An increased risk of thrombophilic complications occurs during pregnancy, owing to reorganization of the coagulation/anti-coagulation and phibrinolitic organisms systems that are thought to be an evolution adaptation to reduce blood losses during delivery.
The aim of this study was to screen the incidence of five thrombophilic mutations and to determine if their presence is associated with RPL.
Materials and Methods: using RFLP/PCR were screened the FII(G20210A), FV(G1691A), VKORC1(C1173T and G1639A) and PAI1(4G/5G) mutations in case/control groups. Case group contained 274 women with 2 or more abortions and control group - 68 women with at least 2 normal pregnancies and no abortion. For data analysis was used Chi-square test and Odds ratio (OR) calculations.
Results: the incidence of homozygous and heterozygous mutations in FII (OR 2.18, 95% CI 0.26, 18.13, $p>0.05$), FV (OR 6.86, 95% CI 0.90, 52.48, $p<0.05$) genes was associated with RPL in the case group and represent a risk factors. The same is true for homozygous mutation (T1173T) in the VKORC1 gene (OR 3.26, 95% CI 1.07, 9.91, $p>0.05$). No associations with RPL were obtained for mutations in PAI1 gene.
Conclusions: obtained data demonstrates that mutations in FII, FV and VKORC1 genes may play a crucial role in case of RPL. Is necessary to perform the screening for genes mutations causing hereditary thrombophilia in women with RPL and apply/adjust the anti-coagulation treatment.

Preimplantation genetic diagnosis (PGD) for carriers of balanced translocations

J. Gontar, *N. Buderatskaya, I. Iljin;
Medical center IGR, Kiev, Ukraine.*

With the help of modern in vitro fertilization technologies (IVF) it is possible to identify and transfer to uterus only genetically normal embryos from couples where one of the partners is a carrier of chromosomal anomaly. Such patients have high risk of producing genetically compromised embryos[1].
Of 236 IVF+PGD cycles, 30 (335 embryos) were held for rearrangement carriers to identify embryos with balanced karyotype by FISH. The investigation was made on single blastomere, which was biopsied on the cleavage stage.
Among 335 embryos analyzed, 25,97% were balanced but only 14,03% had euploid set of chromosomes. Analysis of embryo karyotype according to the translocation type revealed that balanced euploid specimen occur in 2 times

more often in case of Robertsonian translocation than for reciprocal ones (namely 2,3 and 1,2 embryos per cycle, respectively). Nevertheless, total proportion of balanced samples for 2 types of structural rearrangement was approximately equal. Results of the diagnostics according to the sex of translocation carrier showed that when woman had the balanced rearrangement 29,41% of embryos were balanced while in case of paternal carriership the corresponding percentage was slightly lower (24,07%). Obtained data is consistent with the results of other researchers [2,3].
Modern genetic technologies give a chance for patients with structural rearrangements to avoid gamete donation and have healthy genetically related progeny.

Association between Folate Pathway Genes and Cleft Lip With or Without Cleft Palate in a Chinese Population

Y. Hu[1], *L. Jin*[1], *E. Chen*[2];
[1]*School of Stomatology, Capital Medical University, Beijing, China,* [2]*Beijing Tongren Hospital, Capital Medical University, Beijing, China.*

Objective Non-syndromic cleft lip with or without cleft palate (NSCL/P) is a common congenital defect and gene-environmental factors involve in this disorder. Periconceptional intake of folate may reduce the risk of NSCL/P. The present study was designed to investigate if genetic variations in three folate pathway genes, including transcobalamin II (TCN2), methionine synthase (MTR) and betaine-homocysteine methyltransferase (BHMT), contribute to NSCL/P aetiology.
Methods DNA was obtained from 481 individuals with NSCL/P and 558 healthy subjects. Three known single nucleotide polymorphisms (SNPs) (rs1801198, rs955516 and rs3733890) present in the TCN2, MTR, and BHMT genes were genotyped by Matrix-Assisted Laser Desorption/ Ionization Time of Flight Mass Spectrometry (MALDI-TOF MS) approach.
Results SNP rs955516 showed allelic association with NSCL/P, higher frequencies of A allele in NSCL/P patients compared with those healthy individuals (X2=11.200, P=0.0008). Higher proportion of NSCL/P patients carry rs955516 AA and rs3733890 AA genotypes (OR=1.84, 95%CI=1.29-2.63; OR=1.65, 95%CI=1.08-2.53). The gene-gene interaction test show evidence of trans-phase interaction for MTR and BHMT combinations (X2=20.320, df=6, P=0.0024).
Conclusion Our study suggests that gene-gene interaction of MTR and BHMT genes play a vital role in the pathogenesis of NSCL/P in Chinese population.

Prenatal diagnosis of cryptic translocation t(5p;17q) detected with fluorescent in situ hybridisation

E. Sukarova-Angelovska[1], *M. Kocova*[1], *G. Ilieva*[1], *E. Sukarova-Stefanovska*[2], *T. Hristova-Dimkovska*[3];
[1]*Pediatric Clinic, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Research center for genetic engineering and biotechnology, MASA, Skopje, Macedonia, The Former Yugoslav Republic of,* [3]*Gynecology Clinic, Skopje, Macedonia, The Former Yugoslav Republic of.*

Reciprocal chromosomal rearrangements, de novo or inherited, often raise a concern about the fetal health and outcome in the affected pregnancies. The size and origin of the translocated chromosomes could be variable. Cryptic translocations often remain undetected and misdiagnosed. Several studies confirmed that there could be a loss of a certain amount of genomic material within breakpoints, which lead to uncertainties in predicting the pregnancy outcome.
A 38 year pregnant woman approached our clinic for a genetic counseling. This was her first pregnancy, ultrasound follow up showed normal fetal growth; the amniocentesis was done due to the advanced maternal age. Conventional cytogenetic report showed putative deletion of short arm of chromosome 5. Additional cordocentesis has been done at 18 week of pregnancy. MLPA analysis showed that 5p critical region was present. FISH has been done, using 5p/q probe (Cytocell aquarius, Cat No LPU 013), which showed cryptic de novo translocation 46,XX, ish t(5p;17q). Reduced fetal growth was recorded after 20th week, and together with cytogetetic finding were decisive for the parents to terminate the pregnancy. Examination at autopsy showed dismorphism consistent with cri du chat syndrome-micrognathia, hypertelorism, SGA, as well as underdeveloped brain for gestational period. Novel technologies in molecular cytogenetics and array techniques could help in detecting minor imbalances and decrease the risk of the birth of malformed fetus. Combination of several prenatal methods (ultrasound and genetic techniques) can help in decision making concerning prenatal diagnosis.

The correlation between sperm DNA fragmentation and IVF outcome in Iranian population

s. samadpoor[1], *D. Ali*[2], *E. Mahmoodi*[1], *M. Noruzinia*[3];
[1]*Sarem Cell Research Center- SCRC, Sarem Women's Hospital, Tehran, Iran, Tehran, Iran, Islamic Republic of,* [2]*Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [3]*Tarbiat Modares University of Medical Sciences, Tehran, Iran, Islamic Republic of.*

Background: as previous studies have mentioned that sperm chromatin integrity is vital for successful pregnancy and implantation. This study was designed to examine the relationship between the results of sperm chromatin structure assay (SCSA) and the outcome of IVF.
Method: After collection of semen samples from men of proven fertility (n = 47) and patients from an infertile population (n = 66), semen specimen were frozen at 80°Cfor later SCSA analysis. On the day of analysis, the samples were quickly thawed and analysed immediately. Spermatozoa are treated with a low pH buffer that denatures DNA at sites of DNA strand breaks. The sample is then stained with fluorescent intercalating dye, Acridine orange. Flowcytometry analysis was used to separate ssDNA as fragmented DNA from dsDNA as integrated DNA reported as DFI (DNA Fragmentation Index). Current references indicate that DFI more than 27% correlates with IVF failure.
Results: In this study significant relationship between DFI over 27% of couples with IVF failure (43.3%) compared to normal group (13.3%) was observed ($p<0.05$).
Discussion:The above analyses show that the SCSA infertility test is significantly predictive
for reduced pregnancy success using in vivo, IVF. These data clearly indicate that the SCSA is an important component of the infertility workup and suggest that if a man has a DFI of >30% that IVF should probably not be considered.

J01.26
Ring chromosome 22 in azoospermic patient: case report

V. B. Chernykh[1,2], *L. F. Kurilo*[1], *Y. O. Kozlova*[1], *N. V. Shilova*[1], *A. V. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

We report on a patient with rare genetic abnormality, ring chromosome 22. The patient is 30-years-old infertile man who presented proportional normal stature (tall 178 cm, weight 90 kg), normal masculinization and no sign of congenital abnormalities, chronicle diseases and mental retardation. The proband had fertile 28-years-old sister, which had healthy daughter. Non-obstructive azoospermia was diagnosed by repeated sperm examination in patient, but detailed analysis of ejaculate sediment allowed to find single abnormal morphology spermatozoa and ~200 immature germ cells.
Chromosome analysis was performed on cultivated peripheral blood lymphocytes using GTG- and C- staining techniques. FISH analysis with subtelomeric chromosome 22 probe (Tel Vysion 22q, Abbott Molecular) was done on metaphase chromosomes and interphase nuclei of peripheral lymphocytes. Y chromosome microdeletions were analyzed by multiplex PCR for SRY, ZFX/ZFY and 20 Yq specific STS loci from AZF a,b,c regions.
Chromosome analysis showed 46,XY,r(22)(p11q13) karyotype. FISH analysis confirmed a presence of non-mosaic ring chromosome 22, at that the breakpoints were localized in telomeric 22q region. Since no chromosomal material was loss, revealed chromosome abnormality is balanced. No Y chromosome microdeletion was detected by PCR analysis. Karyological analysis of immature germ cells from ejaculate sediment showed incomplete spermatogenesis arrest at prepachytene and pachytene stages of prophase I of meiosis. Evidently, it was resulted from a presence of ring chromosome in the karyotype.

J01.27
MED12 gene mutations and leiomyoma: A report from Iran

M. Khorrami[1], *R. Mirfakhraie*[2], *M. Amin-Beidokhti*[2], *S. Irani*[1];
[1]*Islamic Azad University, Science and Research Branch, Tehran, Iran, Islamic Republic of,* [2]*Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of.*

Background: Uterine leiomyomas are the most common benign tumor arise from smooth muscle tissue in reproductive-age women which cause reduced fertility rates. These tumors are the most common cause of hysterectomy and surgery and seriously affect women community's health. Recent identification of MED12 (the mediator complex subunit 12 gene) mutations in most uterine leiomyomas provides a new and promising candidate gene for understanding the cause and tumorigenesis of leiomyomas. The aim of this study was to investigate the frequency of MED12 intron 1 and exon 2 mutations in uterine leiomyomas of Iranian patients.
Material and methods: We screened a total of 36 uterine leiomyomas from 20 patients for MED12 intron 1 and exon 2 mutations using single-strand conformation polymorphism (SSCP) method.
Results: 7 (19.44%) leiomyoma harbored a mutation in MED12 exon 2. Four fibroids (57.1%) displayed a missense mutation in codon 44 including G44R, G44S, and G44D mutations. We also observed three (42.9%) deletions including p.L36_K42del, p.V41_S52del and p.D34_ N40del. All three mutations are predicted to result in an in-frame transcript. None of the tumors displayed somatic mutations in the intron 1.
Conclusion: All mutations are predicted to be damaging at the protein level .This study confirms a major role of MED12 in the genesis of leiomyomas.

J01.28
Investigation of Diagnostic Value of Chromosome Analysis and BAC based Array CGH in Prenatal Diagnosis

H. Savli, *Seda Eren Keskin, Naci Cine, D. Sunnetci Akkoyunlu;*
KOCAELİ UNIVERSITY, KOCAELİ, Turkey.

Introduction:This study aims to investigate the diagnostic value of BAC-based Array CGH and chromosome analysis in prenatal diagnosis.
Material and Methods
This study included the chromosome analysis and BAC-based Array CGH analysis of 140 amniocentesis samples with prenatal diagnosis indications.
Results
Karyotype analysis showed trisomy 21 in four patients, trisomy 18 in five patients, monosomy X in one patient, and other anomalies in three patients. The BAC-based Array CGH analysis showed four patients with trisomy 21, four patients with trisomy 18, one patient with monosomy X as numerical chromosome anomaly, and partial duplication was observed in chromosome 14 in one case as a structural anomaly.
Conclusion
The Array CGH is the most effective method to be able to complement the cases where chromosome analysis, a gold standard in prenatal diagnosis, proves to be insufficient.
Considering the inherent limitations of both methods, complementary features should be introduced in order to be able to give most accurate data at the right time

J01.29
A case of mosaic 45,X/46,XY infertile man with AZF deletion

P. TASDEMIR[1], *M. BALASAR*[1], *A. ACAR*[2];
[1]*NECMETTIN ERBAKAN UNIVERSITY SCHOOL OF MEDICINE DEPARTMENT OF MEDICAL GENETICS, KONYA, Turkey,* [2]*ISTANBUL BILIM UNIVERSITY DEPARTMENT OF MOLECULAR BIOLOGY AND GENETICS, ISTANBUL, Turkey.*

Introduction:Frequency of chromosomal abnormalities is approximately %15 in azoospermic men.45,X/46,XY mosaicism or mixed gonadal dysgenesis is associated with phenotypes ranging from normal male development to clinical signs of Turner syndrome.Y chromosome with structural chromosomal abnormalities is unstable and can be lost during mitosis.Therefore structural chromosomal abnormalities of Y chromosome can be observed in individuals with 45,X/46,XY mosaic karyotype.We report here a mosaic 45,X/46,XY infertile man withAZF deletion and normal male phenotype.
Methods:Karyotype analysis of peripheral blood was performed for the patient.We detected 45,X/46,XY mosaicism. FISH analysis was performed including X and Y centromere probes.Y chromosome microdeletions were investigated by polymerase chain reaction(PCR) assays.Also we investigated the AZF and SRY regions microdeletions of patient's father.
Results:Our patient was a 31-year-old male,has been married for 7 months and they were distant relatives.The patient was referred to Medical Genetics department from Urology with azospermia and infertility diagnosis.The physical examination was normal except sparse eyebrows.Karyotype analysis was 45,X[20]/46,XY[39].After applying XY centromeric FISH analysis we detected %63 XY and %37 X interphase cells.Molecular analysis revealed that AZFa and SRY regions were present but AZFb, AZFc and AZFd regions were deleted.The father's results were normal.
Conclusion:45,X/46,XY mosaic karyotype and AZF deletion were not hereditary.Genetic counselling was given to the family. We concluded that wide AZF region deletions was caused 45,X/46,XY mosaic karyotype status in our patient to reveal unstable Y chromosome during mitosis.Our aim is to emphasize that Y chromosome microdeletions should be analysed in 45,X/46,XY mosaic karyotype was detected in infertile men with normal phenotype.

J01.30
The impact of prenatal invasive genetic testing on chromosome abnormalities incidence and sex balance at birth

O. Miljanovic[1], *S. Teofilova*[1], *D. Likic*[2];
[1]*Centre for medical genetic and immunology, Clinical centre of Montenegro, Podgorica, Montenegro,* [2]*Institute for Public Health of Montenefro, Podgorica, Montenegro.*

One of the key roles of invasive prenatal genetic testing is to reduce the incidence of chromosomal abnormalities (ChA) among newborns. The aim of this study was to estimate the influence of invasive prenatal genetic testing on the frequency of ChA in newborns and the sex ratio at birth.
The data from central register for cytogenetic prenatal and postnatal testing were analyzed retrospectively within period 2000 - 2014. Sex ratio at birth was estimated using the data of the Statistical Office of Montenegro.
Chromosomal abnormalities were found in 100 (2.45%) out of 4072 prenatal cytogenetic analysis. Aneuploidies were the most common ChA (2.1%), and strongly correlate with the most frequent indication - advanced maternal age (61%). The most common ChA was pure trisomy 21, detected in 47 fetuses (1.1%). Unbalanced structural rearrangements were found in 13 (0.3%).
The frequency of ChA (primarily aneuploidies) among newborn infants was significantly reduced within examined period. The frequency of trisomy 21 dropped from 1 per 633 in the period 2000-2003, to 1 per 1407 newborn infants in the period 2011-2014 Constant trend of significant male predominance at birth was found within estimated period: ranging 107, 5 - 113, 4 male per 100 female newborns, and it cannot be explained as "natural appearance".
Based on a 15 years data on cytogenetic analyzes, our results contribute to the establishment of baseline data on the occurrence of ChA in newborn population. Consecutive trend of male predominance at birth may refer on possible misuse of prenatal diagnosis for the purpose of prenatal sex selection.

J01.31
Structural chromosomal abnormalities (CA) in couples with reproductive disorders: examination of the phenomenon of female predominance among carriers of reciprocal translocations

N. V. Kovaleva;
The Turner's Scientific and Research Orthopaedic Institute for Children, St. Petersburg, Russian Federation.

Female predominance among carriers of reciprocal translocations (rec) has been commonly explained by male sterility, though appropriate comparative studies had not been carried out. The objectives of this study were comparative analysis of rates of balanced CA carriers among patients with infertility and among patients with recurrent miscarriages and comparative analysis of male-to-female ratio (sex ratio, SR) in the carriers. Method: Meta-analysis of data from 25 publications on prevalence of CA in couples with reproduction failures. Results: Among couples with infertility, rec carriers were found in 0.46% of males (63/13,573) and in 0.38% of females (51/13,595), SR=1.2, not different from population value of 1.06. Robertsonian translocation (rob) carriers were found in 0.52% of females and in 0.16% of males, SR=3.2, different from 1.06, $p<0.001$. Carriers of inversion (inv) were less frequent among males (0.15% vs 0.26%). Among couples with recurrent miscarriages, rec carriers were more frequent compared to those among infertile couples: 0.86% of males (113/13,192) and 1.54% of females (203/13,192), SR=0.56, $p<0.001$. Robs were found in 0.41% of males and in 0.74% of females, SR=0.55, $p<0.001$. Rate of inv was 0.14% in both males and females. Conclusion: The data obtained corroborate with the conception of female predominance among fertile carriers of rob due to male sterility. However female predominance among fertile carriers of rec can not be explained by the same reason. Firstly, there is no significant male prevalence among infertile carriers, secondly, the rate of rec carriers among infertile males is lower compared to that among fertile patients.

J01.32
Generation of divalent DNA vaccine based on p39 gene of Brucella melitensis and shiga-like toxin 2 (stx2) gene of Escherichia coli

A. Doosti[1], *P. Ghasemi-Dehkordi*[2], *M. Kargar*[3];
[1]*Biotechnology Research Center, Islamic Azad University, Shahrekord Branch, Shahrekord, Iran, Islamic Republic of,* [2]*Cellular and Molecular Research Center,*

Shahrekord University of Medical Sciences, Shahrekord, Iran, Islamic Republic of, [3]Department of Microbiology, Islamic Azad University, Jahrom Branch, Jahrom, Iran, Islamic Republic of.

The virulence factors such as shiga-like toxin (Stx) and immunogenic P39 protein in Escherichia coli and Brucella melitensis, respectively are related to disease of digestive system in human worldwide. In present study the stx2 and p39 genes were cloned into expression plasmid pEEF1D-FLAG (pcDNA 3.1+) as a divalent DNA vaccine candidate. The Enterohemorrhagic E. coli ATCC 3081 and smooth virulent B. melitensis strain M5 were obtained and cultured on specific media. Bacterial DNA was extracted from colonies and used for p39 and stx2 genes amplification by PCR. The amplified products on 2% agarose gel electrophoresis revealed 285 and 1220 bp fragments for stx2 and p39 genes, respectively. Each amplified genes were T/A cloned into pGEM-T easy vector and pGEM-T-stx2 and pGEM-T-p39 were produced. The stx2 and p39 genes were sub-cloned in linearized expression vector (pcDNA 3.1+) using HindIII, XhoI and XbaI restriction enzymes and pCDNA3-stx2-p39 was generated. This final construct was confirmed by PCR and enzymes digestion. The results were showed stx2 and p39 genes were sub-cloned into pcDNA 3.1+ to generate pcDNA 3.1+-stx2-p39 recombinant vector, successfully. According to these findings novel recombinant pcDNA 3.1+-stx2-p39 construct was produced in this study could be useful as DNA vaccine candidate in animal models against shiga-like toxin producing E. coli and virulence B. melitensis strains in future studies.

J01.33
Prenatal case of 17q12 deletion detected by SNP array

V. Krutilkova, *V. Becvarova, M. Trkova, E. Kulovany, D. Stejskal;*
Centre for Medical Genetics and Reproductive Medicine GENNET, Praque, Czech Republic.

The 17q12 microdeletion syndrome is among the 10 most common microdeletions in children with unexplained neurodevelopmental delay. These microdeletions are associated with a wide range of phenotypes, including renal cyst, diabetes syndrome, genital tract abnormalities, developmental delay and learning difficulties, and more recently autism spectrum disorders and schizophrenia.
We report prenatal case of 17q12 microdeletion detected by Illumina SNP array using HumanCytoSNP-12v2.1. Generated data were analysed by Illumina KaryoStudio 1.4 and GenomeStudio V2011.1.
In the foetus with ultrasound detected unilateral multicystic dysplastic kidney de novo 17q12 microdeletion was found. A 1,4 Mb deletion of 17q12 region contained two OMIM genes ACACA (OMIM 200350) and HNF1B (also known as TCF2, OMIM 189907). The parents decided to terminate the pregnancy. The autopsy confirmed unilateral multicystic dysplastic kidney and described contralateral kidney with abnormal nephrogenesis, bicornuate uterus, vaginal atresia and mild hepatic fibrosis. The described features are consistent with Renal cysts and diabetes syndrome (RCAD, OMIM 137920). The SNP array is very useful in identifying of the small structural abnormalities of foetal chromosomes. This is important to specify prognosis of an affected foetus.

J01.34
Evaluation of genetic variations in exon4 and exon5 of RABL2B gene in infertile men with immotile short tail sperm defect.

H. Hosseini[1,2], *M. Sabbaghian[1], A. Mohseni Meybodi[1], T. Modarresi[1], M. Sadighi Gilani[1];*
[1]Royan Institute for Reproductive Biomedicine, Tehran, Iran, Islamic Republic of,
[2]University of Science and culture, Tehran, Iran, Islamic Republic of.

The immotile short tail sperm (ISTS) defect, is a syndrome which causes male infertility. Patients with ISTS disorder have immotile short-tailed sperms which can not fertilize oocyte. Numerous proteins are involved in sperm structure. One of these proteins is RAB Like 2B (RABL2B), which recently its essential role in sperm tail assembly and fertility in male mouse has been demonstrated. So its gene, which called RAB Like 2B (RABL2B), is an appropriate candidate gene in human studies. RABL2B protein has 4 GTP binding domains. Exons 4 and 5 of this gene code two of these essential domains. The purpose of this study was to evaluate the genetic variations of exons 4 and 5 of RABL2B gene in infertile men with ISTS defect and controls. In this study, 30 infertile men with ISTS defect and 30 normozospermic men as controls were recruited. Remarkably, because of the rarity of this disorder, it took 2 years to collect patients samples. To study the genetic variations, DNA was extracted from peripheral blood, then PCR sequencing was done. Sequence analysis results did not identify any mutations or single-nucleotide polymorphisms (SNPs) in exons 4 and 5 of RABL2B gene in patients and controls. Considering the fact that RABL2B is evolutionarily so conserved and exons 4 and 5 have a very important role, therefore the absence of variations is fully justified. On the other hand, as RABL2B has a high expression in testis, evaluation of other parts of this gene is recommended.

Screening of Fetal Chromosome Aneuploidies in the First and Second Trimester of 125170 Iranian Pregnant Women

D. D. Farhud[1], *E. Seyyed Kavoosi[2], S. Younessi[3], M. Zarif Yeganeh[4];*
[1]School of Public Health, Tehran University of Medical sciences,, Tehran, Iran, Islamic Republic of, [2]Tehran Genetic Clinic, 22Keshavaraz BLvd., Tehran, Iran, Tehran, Iran, Islamic Republic of, [3]Valiasr Street, Niloo Laboratory, Tehran, Iran, Tehran, Iran, Islamic Republic of, [4]Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical sciences,, Tehran, Iran, Islamic Republic of.

Background: Aneuploidy is one of the main causes of congenital anomalies, mental and physical problems in newborns. The aim of this study was to determine the various chromosomal aneuploidy in first and second trimester screening of pregnant women in Iran.
Methods: We conducted a descriptive retrospective study on 125170 pregnant women who were referred to a major referral medical laboratory for prenatal diagnosis (2007-2010). Patients were divided into 3groups: first trimester screening (FTS), second trimester screening (STS), and combined screening groups. In each group a questionnaire was filled out, and amniocentesis and cytogenetic analysis were carried out.
Results: Total prevalence of aneuploidy in 125170 pregnant women was one in 491, (DetectionRate=%82.7 for Down syndrome). The DR for DS in three groups were as follow: %87.5 for FTS (25783women), %80.9 for STS (91345women), and %94.7 for combined tests (8042women). Total number of cases with Edward's were 18, Patau's six, Klinefelter six, triploidy three, and Cri-du-chat syndrome one cases.
Conclusion: The present study shows the frequency of aneuploidy in first and second trimester screenings in a major medical laboratory in Tehran. The prevalence of aneuploidies grows with increased maternal age. The rate of aneuploidy in first trimester is higher than second.

J01.36
Genetic variants of KITLG, SPRY4 and BAK1 genes determining increased risk of testicular germ cell tumors in fertile man and patients with infertility

E. Ivkin[1], *M. Nemtsova[1], V. Rudenko[2], D. Mikhaylenko[2], V. Chernykh[2];*
[1]Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation,
[2]Research Centre of Medical Genetics Russian Federation, Moscow, Russian Federation.

Introduction: More recently, genome-wide association studies (GWAS) have reported association of testicular germ cell tumors (TGCTs) with KITLG, SPRY4, BAK1 genes.
Materials and Methods: The aim of this study was to determine alleles and genotypes of high risk for patients with infertility for the identification of the TGCT risk group for clinical monitoring. Five SNPs mapping to SPRY4 (rs4624820, rs6897876), KITLG (rs995030, rs1508595) and BAK1 (rs210138) were genotyped in 77 fertile men and 71 unfertile patients with AZF deletion on the Y chromosome.

genes	Allele	Risk allele	Controls	Cases	Per allele OR (95% CI)	Heterozygote	Homozygote	p trend
SPRY4								
rs4624820	A/G	A	24/38/15	19/38/14	0.91(0.58-1.44)	1.07(0.46-2.52)	0.85(0.33-2.18)	0.68
rs6897876	C/T	C	28/33/16	21/32/18	0.79(0.50 -1.26)	0.86(0.38-1.98)	0.67(0.28-1.61)	0.35
KITLG								
rs995030	G/A	G	45/30/0	46/25/0	1.17(0.65-2.11)	0.82(0.42-1.60)	1.23(0.63-2.40)	0.55
rs1508595	G/A	G	43/29/4	35/30/6	1.31(0.78-2.19)	1.45(0.37 -5.67)	1.84(0.48 -7.05)	0.31
BAK1								
rs210138	G/A	G	0/24/53	0/30/41	1.45(0.80-2.63)	1.45(0.80-2.63)	1.29(0.03-6.35)	0.16

Results: The combination of high risk genotypes for all three genes (ACGGG) was detected in 4/77 normal fertile men and 10/71 patients with infertility and AZF deletion. We were unable to identify the significant increase in the frequency of high risk genotypes combinations among the patients with infertility compared to normal fertile men.
Conclusions: We identified infertile patients with a combination of high risk genotypes for all genes, KITLG, SPRY4 and BAK1. These patients may have an increased risk of developing TGCTs, which should be considered for further consultation and monitoring. Genotyping of patients in clinical high-risk groups (infertility, cryptorchidism and microlitiasis) might be an additional factor for an individual prognosis.

J01.37
Mutation in SYCP3 gene in a woman with recurrent miscarriage

V. Radoi, *R. Bohiltea, L. Bohiltea, C. Paraschiv;*
UMF Carol Davila, Bucharest, Romania.

Introduction
Aneuploidy, a chromosomal numerical abnormality in the conceptus or fetus, occurs in at least 5% of all pregnancies and is the leading cause of early pregnancy loss in humans.
SYCP3 gene encodes an essential structural component of the synaptonemal complex. This complex is involved in synapsis, recombination and segregation of meiotic chromosomes.
Mutation of the SYCP3 gene have been shown to generate an aberrant synaptonemal complex and might be lead to recurrent pregnancy loss.
Material and Methods
We report a 33 years old woman with 2 miscarriages with aneuploid fetus. All known causes, such as hormonal, structural, immunological and coagulation disorders were excluded. Karyotypes (patient and husband) were normal.
The SYCP3 657T>C mutation was examined using PCR performed under standard condition.
Results
Mutation 657T>C was identified in SYCP3 gene.
Conclusion
Mutation in SCYP3 gene may be associated with recurrent miscarriage caused by fetal aneuploidy. Further studies are needed in women with recurrent pregnancy loss to confirm our conclusion.

J01.38
MTHFR gene A222V mutation as marker of risk of pathology of the embryonal development

L. F. Mitrohina, *A. B. Maslennikov, A. R. Shorina, E. V. Maslova, Y. I. Bravve;*
State Novosibirsk Regional Clinical Diagnostic Center, Novosibirsk, Russian Federation.

Genotyping of a mutation of A222V (677C/T) of a MTHFR gene which according to the available data is an objective marker of the complicated course of pregnancy and violation of an embryonal development is carried out. For research samples of genomic DNA of 127 women (from 18 to 50 years) the residents of Novosibirsk selected by the epidemiological principles and 102 women (from 20 to 44 years) with the stood pregnancy or not incubation of pregnancy are used.
In control group of women there were tipirovana all three possible a genotype of the analyzed MTHFR gene locus: CC (53,54%), CT (39,38%) and TT (7,08%) which distribution corresponded to Hardy-Weinberg expected at balance. Frequency allele 677C made 0,732, and allele 677T - 0,268. In group of women at whom pregnancy ended with an abortion or the stood pregnancy, there were genotipirovana three possible genotypes which frequencies however had reliable differences from the first group of the surveyed: CC (37,25%), CT (47,06%) and TT (15,69%) with a frequency allele 677C - 0,608, and allele 677T - 0,392. The comparative analysis of the surveyed groups showed higher frequency of prevalence of a mutation of A222V (as in a heterozygotic, and homozygous form) among women with reproduction pathology. On the one hand it confirms the predictive importance of this genetic marker (especially MTHFR TT genotype), and on the other hand testifies to an imperative need to pay the closest attention to a hypergomocysteinemiya problem among women with pathology of a reproduction and pregnant women.

J01.39
PLACENTAL GROWTH FACTOR AS A PROGNOSTIC MARKER FOR PREECLAMPSIA AND GENETIC VARIANTS LEVEL OF PIGF IN PREGNANT WOMEN WITH PREECLAMPSIA

A. Nagimtayeva, *Borovikova A., Abildinova G.;*
National Research Center for Maternal and Childhood, Astana, Kazakhstan.

Placental growth factor (PlGF) is one of the most important regulators of the formation of the placenta and its vascularization villi.
The study included 70 pregnant women with preeclampsia mild to severe and 50 healthy pregnant women for all patients was carried out molecular genetic testing of susceptibility genes to preeclampsia. Low levels of PlGF (below 100 pg / ml) in the serum of pregnant women testified about the high risk of developing preeclampsia, which is confirmed by correlation between the levels of PlGF and the severity of preeclampsia (r = 0,43). The association of molecular genetic markers of genes folate cycle, clotting factors, vascular endothelium, vascular gene to the level of placental growth factor in pregnant women with preeclampsia. Found that pregnant women with the presence of the mutant allele of the MTHFR gene 677T genotype and AGT 521T, as well as having homozygous (TT) eNOS3 gene, marked the lowest concentration of PIGF 76,3 pg / ml and 87.3 pg / ml. and 43.2 pg / ml., respectively. The proportion of placental growth factor was the highest in women with mutations in the genes: F5 1691A (254,3 pg / ml) and F2 20210A (217,6 pg / ml). Also in the group of pregnant women with preeclampsia with genotypes - MTHFR A1298S and AGT T704S, the level of PIGF remains within the norm (128.7 pg / ml and 143.5 pg / mL, respectively).

The role of miRNA polymorphisms in recurrent pregnancy loss: a case control study

M. Amin-Beidokhti[1], **R. Mirfakhraie**[1], *S. Zare-Karizi[2], F. Karamaldin[3], N. Salsabili[4], M. D. Omrani[1];*
[1]Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [2]Islamic Azad University Varamin Pishva Branch, Varamin, Iran, Islamic Republic of, [3]Shafa hospital, Semnan, Iran, Islamic Republic of, [4]Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.

Recurrent pregnancy loss (RPL) has been traditionally defined as two or more clinical aberrations pregnancies lost before the 20th week of pregnancy in humans that occurs in 1 in 100 pregnancies around the world. Several data suggest that miRNAs may be essential for the normal function of the reproductive system. Polymorphisms in the pre-miRNAs may have negative effects on mature miRNA processing and expression. The purpose of the present study was to investigate the association of miR-196a2T>C (rs11614913) and miR-499A>G (rs3746444) polymorphisms with RPL in Iranian women. We used PCR-RFLP and Tetra ARMS PCR for genotyping of miR 499aT>C and miR 196a2C>T in 83 women with RPL and 100 fertile women with no history of miscarriages respectively. There was no association between miR-499A>G polymorphism and RPL (OR=1.43, 95% CI=0.36-5.67; P=0.61). However, significant difference in distribution of miR-196a2 rs11614913 ge¬notypes was found in RPL patients in comparison to controls (OR=2.69, 95% CI=1.03-7.03; P=0.04). The present study shows an association between miR 196a2C>T polymorphism and RPL in Iranian women with RPL.

J01.41
The study of AZFa microdeletions in Iranian patients with non-obstructive azoospermia

M. Jandaghi[1], *R. Mirfakhraie[2], M. Amin-Beidokhti[2], S. Irani[3], A. Dusti[1];*
[1]Islamic Azad University of Shahrekord, Shahrekord, Iran, Islamic Republic of, [2]Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [3]Islamic Azad University, Science and Research Branch, Tehran, Iran, Islamic Republic of.

Infertility is defined as the inability to fertile after 12 months of sexual intercourse without using any contraceptive method. Y-chromosome microdeletions are among the most important genetic factors causing male infertility with different frequencies in azoospermic men. According to the European Academy of Andrology (EAA) and the European Molecular Genetics Quality Network (EMQN) guidelines molecular analysis of the AZFa region involves the use of the two STS markers sY84 and sY86. In the present study 50 azoosperm patients who had no deletions in the AZFb and AZFc region were studied for deletions in the AZFa region. 50 men who had at least one child were considered as the control group. Microdeletion frequencies were calculated using the Multiplex PCR for SY81, SY746, SY742, USP9Y, DDX3Y, SY86, SY84 STS markers. The results indicated the deletion of USP9Y, SY81, DDX3Y markers with the frequency of 4% for each one. However, no deletion was observed for sY84 and sY86 markers. There was no deletion in the control group. Based on the present results, it seems that the type of Y chromosome microdeletion in the AZFa region may be different based on racial differences in different populations. Therefore, the effective AZFa markers for the diagnosis of male infertility may be different at least in Iranian infertile men.

J01.42
EFFICIENCY OF PRENATAL DIAGNOSIS OF DUCHENNE MUSCULAR DYSTROPHY AND SPINAL MUSCULAR ATROPHY FOR LAST 5 YEARS IN MOLDOVA

I. Grosu[1], *V. Sacara[1], R. Stratila[2];*
[1]Laboratory of Human Molecular Genetics , Institute of Mother and Child,, Chisinau, Moldova, Republic of, [2]Center for Reproductive Health and Medical Genetics, Institute of Mother and Child,, Chisinau, Moldova, Republic of.

Introduction. The monitoring and prevention of hereditary diseases are the current tasks of medical genetics and health. Prenatal diagnosis (PD) is one of the methods proposed. Muscular dystrophy Duchenne/Becker (DMD/B) and spinal muscular atrophy (SMA) are neuromuscular hereditary disorders that are frequently encountered in Moldova and can be detected through prenatal diagnosis (PD).
Methods. After medico-genetic consultation pregnant women with high risk of hereditary disease DMD/B and SMA undergo PD, which Moldova is achie-

ved by methods such as amniocentesis and then multiplex PCR, PCR/RFLP, the primer sets specific and polymorphic sites.
Results. We present a retrospective study for five years of PD of neuromuscular disorders with high frequency in Moldova. In total were performed 15 prenatal diagnoses: 9 - DMD/B and 6- SMA during 2010-2014. Based on the results the indirect diagnosis is more useful in Moldova. Thus were detected 4 affected fetuses, 3 of them were with DMD/B and 1 with SMA. Have been analyzed the strategies for prenatal diagnosis of these diseases in different countries.
Conclusion. Prenatal diagnosis is an effective way to prevent the birth of children with hereditary diseases. In the last 5 years thanks to efforts to raise public awareness is notice an increase of the number of appeals for prenatal diagnosis The methods of modern (MLPA etc.)molecular genetics of PD raise the efficiency and precision to 98%. Efficiency of prenatal diagnosis in Moldova is 71,4%. Analyzing different diagnostic methods used in the world was proposed the method which will be better implemented in Moldova.

DETERMINATION OF HUMAN SPERM DNA FRAGMENTATION WITH AN IMPROVED SPERM CHROMATIN DISPERSION (SCD)TEST

N. Thi Trang, *Nguyen Hoai Bac, Luu Thi Lan Huong, Nguyen Minh Tuan Anh, Le Hong Hoa;*
Hanoi Medical Univercity, Ha Noi, Viet Nam.

Objectives: To improve SCD protocol and develop it as a simple kit for the determination of sperm DNA fragmentation.
Study subjects: 50 human semen samples with concentration more than 5 million per ml, at the Department of Biomedical - Genetics, Hanoi Medical University.
Methods: Using sperm chromatin dispersion technique to assess human sperm DNA fragmentation as protocol discribed by Fernandez (2003).
Results: We determined the range of chemical concentrations in the lysis solution and the sperm DNA fragmentation of 50 human semen sample by using the improved SCD kit, and the sensitivity and specificity of the improved SCD (>95%).
Conclusion: We improved suscessfully a SCD protocol in the lysis solution components and developed it as a simple kit with specificity and sensitivity comparable to Halosperm commercial kit for assessing human sperm DNA fragmentation.

Aloe vera-induced modulation of nitric oxide signaling pathway and androgenesis in the testis rat leydig cells

S. Asgharzadeh[1,2], *M. Rafieian-kopaei*[3], *A. Mirzaeian*[3];
[1]*Ph.D Student Department of Molecular Medicine School of advanced Medical Technologies Tehran Univers, Tehran, Iran, Islamic Republic of,* [2]*Medicinal Plant Research Center, Shahrekord University of Medical Sciences,, Shahrekord, Iran, Islamic Republic of,* [3]*Medicinal Plant Research Center, Shahrekord University of Medical Sciences, Shahrekord, Iran, Islamic Republic of.*

Background: Inducible nitric oxide synthase (iNOS) through its product, nitric oxide (NO), contributes to the induction of germ cell apoptosis. This study was designed to investigat the effects of Aloe vera gel on male rat reproductive organs and its relation with serum NO and expression of iNOS gene in testis cells.
Methods: 36 adult male Wistar rats were designed into 3 equal groups. The rats received normal saline (control) or Aloe vera gel at doses of 150 and 300 mg/kg, orally for 60 days. Then they were mated with untreated female rats. Then reproductive organs of rat weights, semen quality, serum testosterone concentrations in male rats and the rate of fertility in female rats were assessed. At the same time, the in vivo capacity to produced NO, was measured by Griess method and gene expression for iNOS was also studied by Real Time-PCR.
Results: A PCR product of the expected size amplified iNOS mRNA gene was expressed in testis cells and increased the serum NO level after 60 days in the treatment groups, in compared to control. Furthermore, the weights of the testes, seminal vesicle and the sperm count of male rats and serum testosterone concentrations as well as the pregnancy rate were reduced in experimental groups compared to control.
Conclusion: These results may suggest that AVG has adverse effects on the reproductive system of adult male rat through NO signaling pathway. Therefore, it is recommend to be avoided in male subjects in whom the reduction in reproductive capacity is important.

J01.45
The importance of MTHFR gene mutation test in patient with recurrent miscarriages and normal homocystein level

K. Daugelaite, **E. Puisyte**, *D. Serapinas;*
Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania.

Homocysteine is an enzyme encoded by MTHFR (methylenetetrahydrofolate reductase) gene located on chromosome 1. Mutations in MTHFR gene may result in the afflicted metabolism of homocysteine and thus might increase the risk of recurrent miscarriages. In some cases, recurrent pregnancy loss could be prevented by prescribing folic acid and B group vitamin supplements. The demand of MTHFR gene sequencing for variations is commonly overlooked by doctors or genetic counsellors. To highlight this problem we present a case study of recurrent miscarriages in a patient with a homozygous c. 655C>T variation in MTHFR gene with clinically normal homocysteine level (11.2 mmol/l). There is the need of molecular genetic testing for MTHFR gene variations in patients with recurrent miscarriages because treatment of hyperhomocysteinemia exist.

J01.46
Prenatal and postnatal correlations in velo-cardio-facial syndrome

F. M. NEDELEA[1,2], *A. Vayna*[1], *A. Veduta*[1], *M. Bari*[1], *D. Stambouli*[2], *G. Peltecu*[1];
[1]*Clinical Hospital Filantropia, Bucharest, Romania,* [2]*Cytogenomic Medical Laboratory, Bucharest, Romania.*

DiGeorge syndrome (velo-cardio-facial) is the most common microdeletion syndrome(22q11.2) in humans, having the incidence about 1/4000 newborns. It is diagnosed in about 1/68 cases of heart malformations(Wilson et al.,1994). It is characterised by a broad phenotypic variability, having important variability even among the same family affected members and between identical tweens.Frequent could be associated heart,kidney malformations, palatal anomalies, immune deficits. Comportamental problems and mental retardation are resent in about 46% of cases, with different severity , including delay of motor and verbal aquisition, autistic features , psichiatric disorers as depresion, bipolar affection and schisofrenia.
In our prenatal cases diagnostic suspicion was ultrasound diagnosis of heart malformations as truncus arteriosus and tetralogy of Fallot. In a newborn case, medical history of polyhydramnios, typical facies and heart malformation, in this case interrupted Aortic arch, rised suspicion of this syndrome. All cases were confirmed using arrayCGH and FISH technique.
In conclusion, presence of heart malformations in prenatal diagnosis it"s an important marker of a possible genetic syndrome. Additional, using of microarray analysis would allow as an increased number of microdeletion or microduplication syndromes to be diagnosed. Apart from prognosis of the heart malformation, clinical variability and variable association of intellectual disability, represents a challenging step in prenatal counselling of families.

J01.47
Prenatally Diagnosed Double Aneuploidy: 48, XYY+21

A. Khorrami[1], *M. Ziadi*[2], *A. kalantar Zonuzi*[3], *S. Sharif*[2], *R. Hossein Zade*[1], **S. Mohaddes Ardebili**[2];
[1]*Tabriz university, Tabriz, Iran, Islamic Republic of,* [2]*Tabriz university of Medical Science, Tabriz, Iran, Islamic Republic of,* [3]*Azad University, Tabriz, Iran, Islamic Republic of.*

The incidence of trisomy 21 is significantly correlated with maternal age and the presence of an extra Y chromosome in males is common occurrence,however the co-existence of both aneuploidies in patient is a rare phenomenon.We report prenatal diagnosis of 48,XXY,+21 karyotype on a fteus demonstrating increased nuchal translucensy measurement with ultrasoud scanning using amniocyte culture.The double aneuploidy was subsequently confirmed by FISH and QF-PCR.An amniotic fluid sample prepared from a 41year old woman with Azeri Turk ethnicity was received for cytogenetic analysis.The amniocyte culture and chromosomal analysis was performed using standard cytogenetic techniques.Uncultured amniocyte cells prepared from patients amniotic fluid sample on microscope slides by dual and three colore interphase FISH. Confirmation of the detected aneuploidy carried out by QF-PCR.Chromosome analysis of cultured amniocytes demonstrated 48,XYY,+21 in all G-banded cells. Analysis of hybridized cells with specific probes for the 5 clinicaly improtant chromosomes showed a single green signal for chromosme X,two red signal for chromosome Y.On the other hybridisation area three red signals specific for chromosomes 21.QF-PCR results confirmed 48,XYY+21, with extra 21 originating of second meiotic failure.Aneuploidies are due to non-disjunction at meiosis or post zygotic mitosis.The XYY occurs when sperms containing 2 copies of chromosome Y fertilize an ovum containing 2 copies of chromsome 21 instead of one. Non-disjunction leading to formation of 24,YY occure at paternal meiosis II

or mitosis, where Non-disjunction during maternal meiosis I is the common cause of trisomy 21.Complete disomy of chromosome Y and full trisomy of chromosome 21 detected in patient appears to be the result of meiotic non-disjunction occured during gametogenesis

J01.48
Comparison of orthodontic disorders is mono- and dizygotic twins

R. Gyergyay, *C. Bica, S. Pop, K. Mártha;*
UMF Tirgu-Mures, Tirgu-Mures, Romania.

Introduction:
Twin studies are one of the most effective methods of evaluating the interaction of genetic and environmental influences on a particular phenotype also in orthodontics. This study aims to compare the differences in dental and skeletal morphology in mono- and dizygotic twins.
Materials and methods:
10 sets of monozygotic (5 girls and 5 boys, mean age: 18.5 years) and 10 sets of dizygotic twins (same gender, 3 girls and 7 boys, mean age: 19.7 years) were assessed. Cast analysis, orthopantomographic and lateral cephalometric radiographs were evaluated for each subject.
Results:
Dimension and shape of the upper anterior teeth were the same in 99.69% of the monozygotic and 93.91% of the dizygotic twins. Monozygotic twins presented differences in the upper transversal width both in the molar and canine region. Whereas, dizygotic sets had different statical occlusions in the transversal and saggital planes, too. In 50% of the monozygotic and dizygotic sets, symmetrical dental position, while in 50% "mirror image" could be observed. Cephalometric analysis revealed slight differences in interincisal and lower central incisor inclination in both mono- and dizygotic sets.
Conclusions:
The results of this study explain the genetically inherited patterns of dental and skeletal disorders.

J01.49
Preimplantation Genetic Diagnosis (PGD) for monogenic disorders and chromosome rearrangements: an innovative approach for increased diagnostic efficiency and patient benefit.

C. Mackie Ogilvie[1], *P. Renwick*[1], *M. Khalil*[2], *Y. Khalaf*[2], *A. Lashwood*[1], *T. El-Toukhy*[2];
[1]*Genetics Centre, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom,* [2]*Assisted Conception Unit, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom.*

Introduction: PGD is traditionally performed by biopsy of cleavage-stage (Day 3) embryos, genetic testing of the biopsied material, and fresh embryo transfer. This approach provides limited time for analysis and interpretation of genetic testing, and for discussion of results with the couple; clinically there is also a risk of ovarian hyperstimulation syndrome (OHSS) and high multiple pregnancy rate.
Materials and Methods: 161 couples who were carriers of either monogenic diseases (n=127) or chromosomal rearrangements (n=34) underwent oocyte retrieval after controlled ovarian stimulation using a protocol optimised for reduction of OHSS. Trophectoderm biopsy of day 5 or 6 blastocysts was followed by vitrification. DNA analysis of biopsies was by whole genome amplification and Preimplantation Genetic Haplotyping for monogenic diseases or array CGH for chromosome rearrangements. Following diagnosis and patient counselling, single embryos were warmed and transferred.
Results: 85 pregnancies were achieved (53% per couple) with no cases of mild or severe OHSS (0%), one monozygotic multiple pregnancy (1.1% per pregnancy, similar to the natural incidence of multiple pregnancy) and high patient satisfaction. These results compare favourably with those in the prior 12 months, when 11 patients (4%) developed OHSS (P<0.001) and the multiple pregnancy rate was 13% (P<0.001). Testing throughput has increased from five to nine couples per week, delivering an 80% increase in productivity with no increase in staff numbers.
Conclusion: This novel strategy delivers efficiencies and patient benefit; embryo warming and transfer can be scheduled to allow time for robust diagnosis and patient results counselling.

J01.50
Large nuclear vacuoles as a possible marker of sperm DNA fragmentation

M. Mazilina[1], *E. Shilnikova*[2], *I. Fedorova*[2], *A. Gzgzyan*[2];
[1]*St. Petersburg State University, Saint Petersburg, Russian Federation,* [2]*Ott's Institution of Obstetrics, Gynecology and Reproduction, Saint Petersburg, Russian Federation.*

ICSI as a part of assisted reproductive technologies allows infertile men to father a child bypassing natural selection barriers. Sperm selection mainly relies on its morphological characteristics. Sure, the spermatozoa with normal morphology or with light pathology would be selected for fertilization. But in case of severe teratozoospermia one should choose the most appropriate sperm from those with abnormal morphology. So, to know if the sperm morphology reflects its DNA fragmentation was the aim of this study since the sperm DNA fragmentation is associated with reduced embryo quality, implantation and live birth rates.
Sperm samples from two men with normal somatic karyotypes and teratozoospermia were collected by masturbation. Shortly after ejaculate liquefaction under the high magnification the spermatozoa with large nuclear vacuoles were selected. As a control the spermatozoa with normal morphology were used. To analyze sperm DNA fragmentation TUNEL assay was used. Among sperm with large nuclear vacuoles DNA fragmentation rate was extremely higher compare to the control - 14,29% vs. 1,12% (p = 0,0008).
So, large nuclear vacuoles in sperm head may be a morphological marker of its DNA fragmentation. Understanding such a relationships helps to select spermatozoa with intact genome to improve fertilization efficiency and embryo quality.

Prenatal Diagnosis of Partial Monosomy 13q and Partial Trisomy 10q: A Case Report

E. Baranova[1], *N. Karetnikova*[1], *A. Ekimov*[1], *V. Bakharev*[1], *A. Gus*[1], *D. Trofimov*[1], **E. Shubina**[2];
[1]*Federal State Budget Institution „Research Center for Obstetrics, Gynecology and Perinatology" Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation,* [2]*Russian Medical Academy of Postgraduated Education (RMAPE), Moscow, Russian Federation.*

We report a prenatal case the combination of partial monosomy 13q and partial trisomy 10q which were detected by oligonucleotide array comparative genomic hybridization (aCGH). Chorionic villus sampling was done on 34-year-old woman at 13 weeks of gestation due to abnormal maternal serum screening and increase in nuchal translucency. The parents had a healthy daughter and there was no family history of miscarriage and neonatal deaths. The fetal karyotyping on chorion villus showed normal female karyotype 46,XX. The DNA was extracted and directed to Biobank. It was decided to continue the pregnancy. However, ultrasound examination at 21 weeks of gestation showed holoprosencephaly, microcephaly, soft tissue swelling of the head and trunk of the fetus. By means of oligonucleotide aCGH analysis (SurePrint G3 Human CGH Microarray Kit, 4x180K, Agilent) we identified a 15 Mbp duplication 10q26.11q26.3(120678170-135404523) and a 22 Mbp deletion 13q31.3q34(93390362-115059020) which were previously described as associated with these malformations in the fetus. After genetic counseling parents decided to terminate the pregnancy. Cytogenetic analysis revealed that the father was a carrier of the balanced translocation 46, XY,t (10;13)(q26.1;q31.3). Actually, aCGH analyses may be useful for detected unbalanced karyotype in fetuses with increased risk for chromosomal abnormalities at prenatal genetic counseling. In our case, this led to the identification of an unexpected parental translocation.

J01.52
Cytogenetic study of miscarriages after IVF and natural conception in women aged under and over 35 years

A. A. Pendina[1,2], *O. A. Efimova*[1,2], *O. G. Chiryaeva*[1], *A. V. Tikhonov*[1,2], *L. I. Petrova*[1], *V. S. Dudkina*[1], *N. A. Sadik*[1], *T. V. Kuznetzova*[1,2], *V. S. Baranov*[1,2];
[1]*D.O.Ott Research Institute of Obstetrics, Gynecology and Reproductology, St.Petersburg, Russian Federation,* [2]*St.Petersburg State University, St.Petersburg, Russian Federation.*

We compared the frequency and the spectrum of karyotype abnormality in the first trimester miscarriages in women, who conceived naturally (NC) and who conceived through in vitro fertilization (IVF). Patients were subcategorized by their age: <35 years (NC, n=173; IVF, n=108) and ≥35 years (NC, n=107; IVF, n=111). A total of 499 miscarriage karyotypes was analyzed. The spectrum and the relative proportions of different cytogenetic categories in karyotypically abnormal miscarriages differed neither between the NC and IVF patients aged <35 years, nor between the NC and IVF patients aged ≥35 years. In the patients aged <35 years, the incidence of abnormal miscarriage karyotype was lower in the IVF group (37.04% vs 62.43%). In the patients aged ≥35 years, the incidence of miscarriages with cytogenetic pathology did not differ between the NC and the IVF group (75.70% vs 58.56%). The lowest frequency of karyotypically abnormal miscarriages (29.82%) was detected in the young IVF-treated patients at <7 weeks of gestation.
Thus, IVF does not increase the risk of a pregnancy loss because of abnormal embryonic karyotype, nor does it increase the preponderance for any specific type of cytogenetic abnormality in both patients aged under and over 35 years. In young IVF-treated women early pregnancy loss is generally

caused by non-cytogenetic factors. Identification of a cytogenetically normal spontaneous abortion is clinically significant and reinforces the importance of developing an appropriate diagnosis and treatment strategies for IVF patients in order to reduce the risk of euploid pregnancy loss.

Ambiguous findings in prenatal aneuploidy screening by commonly used QF-PCR assays: a 2 year long Czech prospective study and need for compilation of marker abnormal patterns.

M. Libik, *L. Dvorakova, J. Chrudimska, J. Paderova, N. Ptakova, A. Holubova, D. Novotna, M. Macek jr., M. Macek sr.;*
University Hospital Motol, Prague, Czech Republic.

The Devyser Resolution v.2 QF-PCR assay (Devyser, Sweden) occasionally detects submicroscopic duplications which may suggest a "trisomic pattern" for a single marker, while the remainder indicates a normal chromosome complement. The CMGS/ACC Best Practice Guidelines (v2.01) state that abnormal marker patterns, flanked by normal results, may reflect presence of CNVs. We carried out a prospective study on amniotic fluids referred for QF-PCR testing for common aneuploidies, in parallel with karyotyping. Of the 271 prenatal samples received from 1/2014 to 1/2015, 6.3 % were aneuploid by QF-PCR testing and validated by karyotyping. In 9 female fetuses (46,XX) ZFY was found, which is normally present on the Y chromosome. This phenomenon will be further examined upon receiving parental DNA. In addition, we revealed a signal for marker "D18S386" located at locus 18q22.1. Parental DNA analysis was normal in all tested cases and proved that the extra peak in "D18S386" represents the missing paternal allele of marker "D13S305" (13q13.3). Aforementioned, markers have not been previously reported as representing inherited CNVs identified by markers from the QF-PCR assay under study. In this regard it is important to develop databases compiling such CNVs in order to assess their pathogenic impact in commonly used QF-PCR assays, and this information could reduce the need for follow up resampling of parents. Finally, trisomic markers not flanked by "normal" markers could indeed represent a clinically significant duplication which needs to be followed and reported to respective international databases. Supported by: FNM00064203, CZ.2.16/3.1.00/24022, NF-CZ11-PDP-3-003-2014, IGA NT13770.

Morphological markers of sperm DNA fragmentation

E. Shilnikova[1], *M. Mazilina*[2], *I. Fedorova*[1], *A. Gzgzyan*[1];
[1]*Ott's Institution of Obstetrics, Gynecology and Reproduction, Saint-Petersburg, Russian Federation,* [2]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation.*

Semen analysis is widely used to assess male fertility but it tells nothing about sperm DNA quality. Spermatozoa with fragmented DNA as believed are able to efficiently fertilize an egg reducing embryo quality and implantation rates. Searching some morphological markers of sperm DNA fragmentation allows IMSI to be recommended to exclude gametes with damaged DNA from fertilization.
As for this we analyzed sperm DNA fragmentation rate among patients with different predominant sperm head shapes.
Semen samples were collected from 80 subfertile males. Sperm head morphology was evaluated according to Kruger's strict criteria. The following head forms were identified: big, small, round, bulb, amorphous, elongated, double, spot, with abnormal acrosome, vacuolated, with a light pathology, normal. Sperm DNA fragmentation rate were analysed TUNEL assay. 2000 spermatozoa per sample were evaluated.
The highest sperm DNA fragmentation rate was observed for those who had spermatozoa with large nuclear vacuoles as a predominant sperm head shape (p≤0,0001). And the correlation was established between these two parameters (r=0,33, p≤0,05).
So large nuclear vacuoles may be a possible marker of sperm DNA damage and for those patients who had such shape as a predominant IMSI should be recommended.

The role of single nucleotide polymorphisms in developmental genes in the etiology of anorectal malformations

R. van de Putte[1], *C. H. W. Wijers*[1], *I. de Blaauw*[1,2], *C. L. M. Marcelis*[1], *C. E. J. Sloots*[2], *P. M. A. Broens*[3], *N. Roeleveld*[1], *L. F. M. van der Zanden*[1], *I. A. L. M. van Rooij*[1];
[1]*Radboud university medical center, Nijmegen, Netherlands,* [2]*Erasmus Medical Center, Rotterdam, Netherlands,* [3]*University Medical Center Groningen, Groningen, Netherlands.*

Introduction: Anorectal malformations (ARM) are one of the most frequently occurring birth defects of the gastrointestinal tract. In the majority of patients, multiple congenital malformations are present. The etiology remains unknown, but is likely to be heterogeneous with both environmental and genetic factors playing a role. The aim of this study was to test the association of ARM with two known polymorphisms in the developmental genes *BMP4* and *GLI2* in a large group of Caucasian patients, as well as the gene-gene interaction.
Material and methods: A case-control study was performed in a Caucasian population of 431 nonsyndromic ARM patients and 661 population-based controls. Patients and controls were derived from the AGORA (Aetiologic research on Genetic and Occupational/environmental Risk factors for Anomalies in children) data- and biobank of the Radboudumc Nijmegen, The Netherlands. Genotyping was performed using Kompetitive Alleles Specific PCR assays.
Results: The non-synonymous SNP rs17563 in *BMP4* was not associated with ARM, but we did find associations between ARM and the non-synonymous SNP rs3738880 in *GLI2*, especially in ARM patients with multiple congenital malformations (homozygous GG genotype: OR=2.1; 95%CI: 1.2-3.7). A 4-fold increased risk was shown when homozygous variant genotypes of both genes were present (OR=4.1; 95%CI: 1.0-17.8).
Conclusions: We showed independent associations between the variant in *GLI2* and ARM in patients with multiple congenital malformations. In addition, a gene-gene interaction was demonstrated between *BMP4* and *GLI2*, both downstream genes in the Sonic Hedgehog (SHH) pathway, which is involved in several important developmental processes.

Background
Hypospadias is a common congenital malformation of the penis with a dislocation of the urethral opening. It has a multifactorial etiology. Folate is important during embryogenesis. Folate levels are reduced by the C677T polymorphism in the methylenetetrahydrofolate reductase (*MTHFR*) gene, which is involved in the etiology of several birth defects, but was never studied for hypospadias. Maternal periconceptional use of folic acid supplements may compensate for reduced folate levels and play a role in the prevention of birth defects. Although this was confirmed for some congenital malformations, results for hypospadias are inconsistent. Therefore, we investigated independent associations and interactions of maternal folic acid use and maternal and infant *MTHFR* C677T polymorphisms with risk of hypospadias.
Methods
We conducted a case-control study among 697 nonsyndromic hypospadias cases and 711 controls from the AGORA data- and biobank. Information about folic acid use was derived from maternal questionnaires and DNA samples from mother and child were used to genotype the *MTHFR* C677T polymorphism. In the analyses, we assumed a dominant effect of the polymorphism.
Results
Preliminary univariable analysis showed a small protective effect of maternal periconceptional use of folic acid supplements on hypospadias risk (odds ratio (OR)=0.8, p=0.05). No associations were found for the infant or maternal *MTHFR* C677T polymorphism. However, lack of folic acid supplement use in combination with carrying the *MTHFR* C677T polymorphism increased hypospadias risk (infant or maternal polymorphism: OR=1.6, p=0.01).
Conclusion
This study showed an increased risk of hypospadias when no folic acid supplements were used and mother or child carried the *MTHFR* C677T polymorphism.

J01.57
Prenatal SNP-array trio analysis; overview of the past two years

D. Svaneby, *J. Graakjaer;*
Department of Clinical Genetics, Vejle Hospital, Vejle, Denmark.

Danish pregnant women are offered a risk assessment at gestational week 11. The risk assessment is based on ultrasound, blood sample and an individual clinical assessment.Danish fetal obstetricians have in collaboration with Danish Society of Medical Genetics agreed on three general criteria for at risk pregnancies (nuchal translucency> 3.4, any malformation, and small for gestational age). The past two years we have offered prenatal SNP-array analysis to pregnancies with increased risk. During this period our department was the only in Denmark offering prenatal trio SNP-array analysis.
This analysis is performed as a trio analysis where we analyze CVS or AF, and both parents at the same time. The result from the analysis was reported within a week.
Results:
In 2013 we analyzed 40 samples and in 2014 89 samples. Of these 129 samples, 21 abnormal samples were detected, of which 10 would not have been detected by traditional karyotyping.
Conclusion:
SNP-array is a fast and excellent method for prenatal analysis.
The advantages of SNP array trio analysis are quick results, exclusion of maternal contamination, detection of uniparental disomi, and correct identification of the sample.
Our results describe that SNP-array detects 8% more clinically significant results than traditional karyotyping.

J01.58
CHROMOSOME ABERRATIONS IN FETAL SAMPLES: AN INDIAN SCENARIO

B. B. Ganguly[1], *K. Ramachandran*[2], *B. G. Boricha*[2], *A. Srivastav*[2], *S. Kulkarni*[2], *B. K. Mitra*[3], *N. N. Kadam*[2];

Chromosome analysis is carried out in fetus for prenatal diagnosis and in recurrent miscarriages. Genomic analysis by employing conventional G-banding enables numerical and structural analysis on all chromosomes. FISH is considered as an adjunct for rapid detection of aneuploidies and also in a situation of unsuccessful outcome of tissue culture. In the present study, G-banding and FISH analysis were carried out on equal number of prenatal and abortus samples. The result was categorized in three age groups (maternal) as presented in the table below. FISH-detected abnormalities were significantly lower in both prenatal and abortus samples, most likely due to its limitation on structural changes. Fetuses of mothers below 25 years showed maximum aberrations followed by the elderly mothers above 35 years of age. Early marriage and multiple conceptions at early age could be the underlying factor. In abortuses, similar trend was observed though frequency was high in all age groups. G-banding analysis has detected significantly higher number of aberrations, which has been favored by detection of structural rearrangements. The report strongly advocates employment of conventional analysis in prenatal diagnosis and also recurrent miscarriages.

Genomic imbalances leading to disruption in spermatogenesis in patients with idiopathic male infertility

V. I. Damyanova, *D. K. Dimitrova, S. Hadjidekova, I. Dimova, A. Savov, B. Rukova, D. Nesheva, I. Vatev, D. Toncheva;*
Medical Faculty, Sofia, Bulgaria.

Introduction: The infertility affects 10-15% of all couples. In about 40% of the cases the male factor is reported to be the main reason for unsuccessful fertilization and 30% of the male infertility is idiopathic. In the current investigation we report microarray analysis data of the infertile males with azoospermia and oligoasthenoteratozoospermia.
Materials and methods: We tested 24 patients with idiopathic infertility by array CGH.
Results: We found deletions in 4 autosomal loci. The deleted region in 8p23.1 includes SPAG11B and SPAG11A-genes, associated with spermatozoa maturation and fertilization.
Deletion in 14q11.2 (EDDM3A and EDDM3B) could affect the synthesis and secretion of epididymides-specific proteins in nonobstructive azoospermic men.
The loss in 17q21.31, observed in two patients, encompasses TTLL6 - gene, important for sexual differentiation, spermatogenesis, and male fertility.
The deletion in 8p11.22, detected in two patients, affects two genes ADAM5 and ADAM32. The ADAM32 gene is expressed predominantly in the testis, suggesting a potential role for ADAM32 in sperm development or fertilization.
Conclusion: By aCGH are revealed specific microstructural aberrations in 8th and 14th chromosomes, with possible association with infertility. We suggest 7 potential candidate genes with presumed important biological significance in spermatogenesis, sperm capacitation and fertilization. This could contribute to more accurate diagnosis of infertility and personalized approach to infertile males.
Acknowledgments: Research was funded by Medical University of Sofia, Grant № 36/ 2011; №1/2013.

Study of demographic features and VSX1 mutations(1 and 5 exons) in patients with keratoconus in Chaharmahal va Bakhtiari province using PCR-SSCP and DNA Sequencing

s. parchami barjui, *A. Davoudian Dehkordi, S. Memarzadeh, M. Hashemzadeh Chaleshtori;*
cellular and mulecular research center, Shahrekord, Iran, Islamic Republic of.

Objective: Keratoconus (KC) is a disorder in which the cornea is swollen and thined and deformed. Many genes involved in the disease, but as evidence of the role of genes in the etiology of KC VSX1 is more sicnificant. Also in

some studies mutation in this gene have not been associated with disease. This study aimed to survey demographic features and determine the frequency of mutations in exons 1 and 5 of VSX1 in Chaharmahal va Bakhtiari province.
Materials and Methods: In this study mutations in two exons mutations 1 and 5 genes of VSX1 in 100 patients with keratoconus reviewed. DNA was extracted using standard phenol-chloroform method and PCR-SSCP screening for mutations in these genes had been confirmed. Also demographic features such as sex,age and place,…had been colleted by Questionnaire and analyzed by SPSS.
Results:In this study the prevalence of KC was about similar in men and women.(51% and 49%).many of them lived in urban area(75%). In the case of patients were no mutation in exon1 but we found a novel polymorphisms in 9 patients with c.1001A>G in exon 5.
Conclusion: Our investigation showed that the gene mutations associated with keratoconus disease, VSX1 mutation in very small samples of the disease in patients with keratoconus in Chaharmahal va Bakhtiari and clinical importance in this area is unconsiderable. also we found that changes in this gene are vary to different areas. Further investigation of these genes and his relationship with keratoconus will determine the necessary information for the prevention and management of these genes provides visual disturbances

J02.02
Association between MIF gene variation and response to glucocorticoid treatment in sudden sensorineural hearing loss

M. M. Amoli[1], *N. Yazdani*[2], *A. Kakavand Hamidi*[1], *H. Ghazavi*[2];
[1]*Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Research Institute, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [2]*Otorhinolaryngology Research Center, Amir-Alam Hospital, Department of Otolaryngology–Head and Neck Surgery, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.*

Subject: Several lines of evidence suggest the role of immune system in pathogenesis of sudden sensorineural hearing loss (SSNHL). Macrophage migration inhibitory factor (MIF) mediates its role in various immune and inflammatory conditions by regulation of immune reactions. Several studies have confirmed an association between MIF gene polymorphisms and susceptibility to various inflammatory and autoimmune disorders. The aim of this study was to explore the association between MIF (-173 G/C) polymorphism (rs755622) and SSNHL in an Iranian population.
Methods: In this case-control association study, SSNHL cases (N=77) were included. Normal healthy subjects (N=100) were also recruited from the same region. Genotyping for MIF (-173 G/C) polymorphism was carried out using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique.
Results: The association between MIF gene polymorphism in relation to hearing recovery after treatment with GC was investigated in patients with no improvement (N=38) in hearing loss compared with the group showing response to GC treatment (N=39). The frequency of the MIF -173 C allele carriers (GC+CC genotype) was significantly elevated in SSNHL patients who responded to glucocorticoid treatment compared to the patients with no response to treatment. (GC+CC vs GG) (p=0.02, OR=3.06, 95%CI;1.04-9.2).
Conclusion: These results suggest that MIF gene polymorphism is associated with response to glucocorticoid treatment in patients with SSNHL. This might indicate the involvement of various autoimmune and non-autoimmune mechanisms in the pathogenesis of the disease and the role of MIF gene in patients with autoimmune SSNHL with better response to glucocorticoid treatment which requires further investigation.

J02.03
Association between genetic polymorphisms of NQO1 C609T with risk of Cataract

n. zarei, *l. Saadat;*
Department of biology-shiraz university, shiraz, Iran, Islamic Republic of.

Introduction: Cataract is multifactorial eye disease that identified with disturbance of transparent ocular lens. There is significant evidence that oxidative damage acts as a major factor in the initiation and progression of numerous diseases, such as Cataract. NQO1 is antioxidant enzyme that prevent cells from oxidative stress. The aim of the present study is to investigate the association between *NQO1 C609T* polymorphism with susceptibility to Cataract.
Material and Method: We here carried out a case-control study that included 190 cataract cases and 190 healthy subjects. We examined the genotype distribution of *NQO1 C609T* (Pro189Ser) polymorphism, using the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) approach, to investigate the possible role of this SNP as a risk factor in Cataract development.
Result: We found that the variant CT heterozygous and CT/TT genotypes of the *NQO1 C609T* polymorphism were associated with increased risk of Cataract (CT vs. CC: OR = 1.61, 95% CI = 1.02-2.52, p value= 0.038), (CT/TT vs. CC: OR = 1.56, 95%CI =1.02-2.4, p value= 0.04).
conclusion: Current study showed that there is significant relationship between Cataract and *NQO1 C609T* polymorphism. With respect that NQO1 enzyme has a role in detoxification so decreasing its function by changing Pro189 to Ser increase the risk of Cataract.

J02.04
Molecular diagnostics of Pendred syndrome and Enlarged Vestibular Aqueduct in Russian patients.

O. L. Mironovich[1], *E. A. Bliznetz*[1], *T. G. Markova*[2], *A. V. Polyakov*[1];
[1]*Research Centre of Medical Genetics of the Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*National Research Centre for Audiology and Hearing Rehabilitation, Moscow, Russian Federation.*

Pendred syndrome is autosomal recessive inherited disorder characterized by a combination of sensorineural hearing impairment and euthyroid goiter, it accounts for 7.5% of all deafness. Hearing impairment is usually accompanied by abnormal development of the bony labyrinth (Enlarged vestibular aqueduct - EVA and / or Mondini dysplasia). Mutations in the *SLC26A4* gene, which codes for the pendrin protein, are responsible for both of Pendred syndrome and EVA, or Mondini dysplasia.
Prevalence and etiology of Pendred syndrome and / or EVA in Russian patients have not been studied. In the course of this work was studied a DNA samples of 10 patients with Pendred syndrome and / or EVA by using Sanger sequencing of entire coding *SLC26A4* gene sequence. The analysis of two patients with Pendred syndrome and one patient with EVA detected biallelic mutations in *SLC26A4* gene, in other patients mutations were not found. It was found, that no frequent specific *SLC26A4* pathogenic variants are present in the samples, one revealed mutation c.222G>T (p.Trp74Cys) is not published earlier. In connection with the results obtained, we started to research mutations in the *SLC26A4* gene in patients with Mondini dysplasia.

J02.05
Tumor Necrosis Factor promoter polymorphisms in Romanian patients with Age-related Macular Degeneration. Results from a pilot-study

R. Sfrent-Cornateanu[1], *R. Simionescu*[2], *R. Caisan*[3], *A. Popa-Cherecheanu*[1], *L. Voinea*[1];
[1]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania,* [2]*Oculus Ophthalmology Clinic, Bucharest, Bucharest, Romania,* [3]*National Hematology Institute Prof. C.T. Nicolau, Bucharest, Romania.*

Age-related Macular Degeneration (AMD) is condition that usually affects older adults, finally leading to blindness. The risk factors for AMD include genetic background. TNF-alpha polymorphisms were studied mostly in Asian populations regarding their influence on susceptibility of AMD (1).
We aimed to investigate two single nucleotide polymorphisms (SNP) of TNF-α in AMD patients from Romania regarding their possible influence on their clinical characteristics. We assessed 275 subjects (67 AMD patients versus 208 healthy controls) for -308 G/A (rs1800629) and -857C/T (rs1799724) TNF-alpha polymorphisms. These SPSs were genotyped using Real Time PCR technique (Taqman SNP Genotyping Assays C_2215707_10 and C_7514879_10 respectively, Applied Biosystems, USA). Statistical analyses, including Hardy-Weinberg equilibrium (HWE), were performed by using the SNPStats web tool for the analysis of association studies; values ≤0.05 were considered significant.
The distribution of both TNF-α polymorphisms were in HWE in all studied groups. The frequencies of minor alleles -308A and -857T and were similar in AMD patients and controls (0.07/0.12 and 0.25/0.20, respectively). The investigated SNPs show no significant difference regarding the allele carriage or genotype frequency between AMD and control subjects. Three main haplotypes were constructed (-308G/-857C, -308G/- 857T and -308A/-857C). There was found no significant association between any of these haplotype and AMD (global interaction p-value = 0.22).
Conclusion: TNF-alpha polymorphisms (-857 C/T and -308 G/A) seems to not influence susceptibility of AMD. These results should be confirmed on larger patients' cohort.

Mutation analysis of the PAX6 gene in congenital isolated aniridia patients from Russia

T. A. Vasilyeva[1], *R. A. Zinchenko*[1,2], *O. V. Khlebnikova*[1], *N. A. Pozdeeva*[3], *A. A. Voskresenskaya*[3], *N. V. Petrova N.V.*[1], *E. K. Ginter*[1];
[1]*Federal State Budgetary Institution „Research Centre for Medical Genetics", Moscow, Russian Federation,* [2]*Pirogov National Russian Research Medical University, Moscow, Russian Federation,* [3]*Federal State Institution IRTC "Eye Microsurgery" named after academician S.N. Fyodorov (Cheboksary branch), Cheboksary, Russian Federation.*

Aniridia (OMIM 106210) is a rare congenital ocular developmental abnormality resulting in incomplete formation of iris as the most manifest disease feature. Aniridia is caused by mutations in paired box gene 6 (PAX6; OMIM *607108; 11p13).
Aim: mutation analysis of thirty patients with congenital isolated aniridia from Russia.
Methods: thirty patients from twenty five unrelated families undergo ophthalmic examination and DNA-testing, which includes initial direct sequencing of PAX6 gene fourteen exons and after MLPA analysis (MRC Holland SALSA MLPA probmix P219-B2 PAX6, Amsterdam, the Netherlands). Subsequent linkage analysis validates revealed large deletions.
Results: There are nine patients with family history and twenty one sporadic cases.
Missense, nonsense, splice change, deletion/insertion mutations, small insertions and deletions were identified by sequencing in nineteen out of twenty nine cases. Revealed six novel point mutations are p.Asn164ThrfsTer174, p.Ser349ArgfsTer39, p.Ser294Val fsTer71, p.Ala99Leu fsTer54, p.Glu7Arg, p.Gln171Ter; seven known mutations are c.1032+6T>G, c. -128-2delA, p.Gln47Arg, p.Arg103Ter, p.Arg203Ter, p.Arg240Ter, p.Arg261Ter. Large deletions are determined in ten cases (a third of all identified changes, and a half of de novo).
Three unrelated families have nonsense mutation p.Arg203Ter, that is one of the known and commonly defined mutations in diverse populations. Likewise in three unrelated cases we identified a frequent known large deletion chr11:31307603_31650221del. Thus we have determined twenty one different mutations. In one case we fail to reveal either PAX6 mutation or lack of adjacent chromosome11region.
Five novel truncating mutations and a high rate of de novo defects including large rearrangements make up the peculiarity of mutations spectrum in patients from Russia.
Supported by RFBR grants 14-04-00525, 15-04-01859.

Analysis of associated with hearing loss GJB2 and GJB6 mutations in Cherkessk urban population of the Republic of Karachay-Cherkessia (Russia)

N. E. Petrina[1], *T. A. Vasilyeva*[1], *N. V. Petrova*[1], *A. N. Petrin*[2], *R. A. Zinchenko*[1,3];
[1]*Federal State Budgetary Institution „Research Centre for Medical Genetics", Moscow, Russian Federation,* [2]*Scientific and Practical Centre of medical care for children, Moscow, Russian Federation,* [3]*Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

Medical and population genetic study of nonsyndromic hearing loss (NSHL) is done in Cherkessk, an urban settlement in the Republic of Karachay-Cherkessia (Russia) (RKC). Connexins genes GJB2 and GJB6 are the most relevant in NSHL etiology. Up to date more than 200 pathogenic mutations associated with NSHL and numerous polymorphisms with unclear clinical consequences are detected in the GJB2 gene. In this study 87 RKC patients with NSHL have been examined for GJB2 coding region mutations and two GJB6 gene large deletions: DEL (GJB6-D13S1830) and DEL (GJB6- D13S1854).
24 RKC patients are homozygous and 7 - heterozygous for 35delG mutation in the GJB2 gene. The frequency of the 35delG mutation in total patients sample is 31.61%. The mutation 313del14 is revealed in NSHL patients from RKC (1.19%; n=2). Four sequencing variants noted as neutral polymorphisms are detected: c.79G>A (n=2), c.341G>A (n=1), c.186C > T (n=1) and c.457G>A (n=1). Pathogenic significance of the change c.457G>A is ambiguous (Matos T.D., 2011). In one case the polymorphic variants c.341G>A and c.79G>A compose a known haplotype. Neither but the 35delG mutation in the GJB2 gene, nor two large deletions in the GJB6 gene are detected. 16 out of 87 NSHL patients are Karachays. Only one Karachay patient has the mutation 35delG in homozygousity (6.25%). Screening of 136 healthy Karachays from the urban settlement Cherkessk (272 chromosomes) reveals one heterozygous carrier of the 35delG mutation in the GJB2 gene. Low population frequency of this mutation (0,368%) correspondes to low frequency among Karachay NSHL patients.

Long-term observation of patients with hereditary eye pathology

O. K. Janvareva[1], *M. O. Mkheidze*[2];
[1]*Medical Centre of St. Petersburg State University, St.Petersburg, Russian Federation,* [2]*Postgraduate teacher education academy, St.Petersburg, Russian Federation.*

Objective. Many systemic genetic diseases and syndromes e.g. Marfan syndrome, MPS disorders, chromosomal abnormality syndromes have significant ocular pathology. Whilst rare individually, together these disorders are a significant cause of blindness and visual impairment.
Sometimes ocular sings are the first manifestation of the hereditary diseases. Here we report on long-term observation of the patients with eye pathology.
Material and methods. There were 25,814 patients aged from 1mn to 30 yr under our observation from 1985 till 2015. Routine basic ophthalmic observation was performed for all patients. Genetic tests were used for patients suffering from hereditary diseases and their relatives.
Results. 405 patients (1.57%) were found to suffer from hereditary diseases with ocular symptoms. There were monogenic AD diseases: Best disease (n-30), Marfan syndrome (5), Waardenburg syndrome (n-12), Goldenhar syndrome (n-6), Crouzon syndrome (n-2), Pringle-Bourneville disease (n-1), Rieger syndrome (n-1), Sturge-Weber-Krabbe syndrome (n-3); AR diseases: albinism (59.3%), Usher syndrome (n-24), Ehlers-Danlos disease type VI (n-1), Goldmann-Favre syndrome (n-3), Stargardt syndrome (n-10); Bloch-Sulzberger syndrome, XD (n-5); lysosomal storage diseases: GM2 gangliosidosis Tay-Sachs (AR, n-3) and Sandhoff (AR, n-2), MPS1(AR, n-1), MPSIV (AR, n-1), neuronal ceroid lipofuscinoses Jansky-Bielschowsky (AR, n-1), Batten-Spielmeyer-Vogt (AR, n-1). 15 patients suffed from retinitis pigmentosa Leber. 37 patients were diagnosed with Down disease. Embryopathy was represented Gregg syndrome (n-1). Using genealogical analysis some relatives of the probands were found to have precursory or latent symptoms of eye disturbances
Conclusions. Early ophthalmic and genetic examination, specific treatment were the necessary condition for function optimization and social adaptation.

The analysis of the CRYAA gene in patients with hereditary congenital cataract from Bashkortostan Republic (Russia)

I. I. Khidiyatova[1], *I. M. Khidiyatova*[1], *L. U. Dzhemileva*[1], *S. R. Avkhadeeva*[2], *M. T. Aznabaev*[2], *E. K. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

Introduction: Cataracts are one of the leading causes of blindness in humans. To date, there are 22 genes, mutations in which are responsible for congenital cataract development. Mutations in the αA-crystallin (CRYAA) gene are one of the most frequent causes of congenital cataract. Different mutations in these gene lead to the development of distinct cataract phenotypes. The aim of the study was to analyze the CRYAA gene in patients from Bashkortostan Republic affected with congenital cataract.
Objective: DNA samples of 40 unrelated patients with isolated form of hereditary congenital cataract from Bashkortostan Republic were analyzed.
Methodology: The analysis was performed by direct sequencing of coding regions of the CRYAA gene.
Results: In three unrelated families we identified two new mutations which hadn't been described previously - c.253C>T (p.Leu85Phe) and c.291C>G (p.His97Gln). In a family with p.Leu85Phe mutation we found autosomal dominant congenital nuclear cataract associated with microphthalmia and microcornea, as well as strabismus and nystagmus developed later. Patients from two families with p.His97Gln mutation demonstrated isolated form of autosomal dominant congenital nuclear cataract. The total contribution of CRYAA gene mutations to the development of congenital hereditary cataract in the investigated region was 7.5 %.
Conclusion: Thus, two previously undescribed structural changes in the gene CRYAA were detected in hereditary congenital cataract patients from Bashkortostan Republic. To determine their functional significance further investigations are required. The study was supported by RFBR grant (14-04-97007_r_povolgie_a).

RP1 gene polymorphisms in a Retinitis pigmentosa patient affected by Congenital adrenal hyperplasia: a genotype - phenotype correlation

L. Donato, C. Rinaldi, A. Ruggeri, **E. Velardi**, *C. Scimone, R. D'Angelo, A. Sidoti;*
Department of Biomedical Sciences and Morphofunctional Images, Division of Biology and Genetics. University of Messina, Messina, Italy.

Introduction: Retinitis pigmentosa (RP) **(OMIM #268000)** is a genetic di-

sease involving the retina, the eye back portion, photosensitive and appointed to focus light signals towards the optical nerve and brain, after phototransduction. It is an uncommon condition affecting about 1/4,000 people in the USA and 1-5/10,000 in Italy. The term "pigmentosa" deals with the characteristic appearance of abnormal areas of pigment into the retina. Degeneration induces a slow and progressive death in photoreceptors and retinal pigment epithelium, losing ability to transmit brain the visual informations. Today about 50 RP causative genes are known[1]. We focused our attention on RP1, encoding a microtubule associated protein (MAP) needed for molecule trafficking between inner and outer segment of rods. We chose this gene due to its pathways correlations with congenital adrenal hyperplasia (CAH) ones, pathology that affects the proband of a Sicilian RP affected family (9 members).
We carried out a case-control study regarding this family vs a control group of 200 healthy sicilian donors.
The association of 5 single nucleotide polymorphisms (SNPs) of RP1 exon 4 and its 3' UTR with RP family phenotype was investigated .
Material and Methods: Genotyping was performed by PCR-RFLP (Polymerase-Chain-Reaction- Restriction-Fragment-Length-Polymorphism) and direct sequencing.
Results and Conclusions: Data obtained highlight the fundamental role of a haplotype, inferred by all analyzed RP1 polymorphisms suggesting a possible genotype-phenotype correlation between these SNPs coexistence and query disease.

GJB2 and GJB6 gene testing and genetic counseling in Romanian persons with non-syndromic hearing loss

C. Dragomir[1], *A. Ionescu*[1], *E. Severin*[2], *L. Savu*[1];
[1]*Genetic Lab, Bucharest, Romania,* [2]*Carol Davila, University of Medicine and Pharmacy, Bucharest, Romania.*

Hearing loss is one of the most common deficiencies at birth and is the most common disorder worldwide. One in about 500 newborns has permanent bilateral deafness. Epidemiological studies have shown that 50-60% of deafness cases have genetically causes and the mutations at the DFNB1 locus containing two genes - GJB2 and GJB6 - account for over half of non-syndromic hearing loss cases. Thus, our aim is to provide an updated spectrum of the GJB2 and GJB6 genes mutations in Romanian population in order to ensure an adequate approach.
Our studies (350 normal hearing persons and 125 children with non-syndromic hearing loss) based on molecular techniques (ARMS-PCR, PCR multiplex and DNA sequencing) found a carrier rate of 3.14 in Romanian population for 35delG GJB2 gene mutation. Analysis of the GJB2 gene revealed that about 50% of hearing impaired children presented 35delG mutation. The second mutant allele in the GJB2 gene was c.71G>A found in homo- or heterozygous forms as well, followed by c.-23+1G>A and c.380G>A mutations with lower frequencies. Also we found that the mutations in the GJB6 gene are not significant for Romanian population.
Considering all these aspects, genetic counseling should be offered in case of marriages between individuals with GJB2 mutations in their families. The genetic testing has also biomedical implications and defines new guidelines for clinical practice. Neonatal screening could provide an early diagnosis allowing appropriate intervention and increasing the chances of recovery of hearing in children.
This work received financial support through the project „CERO - Career profile: Romanian Researcher", grant POSDRU/159/1.5/S/135760.

Mutation detection of *PDS* gene in Iranian patients with hearing loss

N. Yazdanpanahi[1], *M. Tabatabaiefar*[2], *E. Farrokhi*[3], *M. Hashemzadeh Chaleshtori*[3];
[1]*Department of Biochemistry, Falavarjan Branch, Isfahan, Iran, Islamic Republic of,* [2]*Department of Genetics and Molecular Biology, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran, Islamic Republic of,* [3]*Cellular and Molecular Research Center, School of Medicine, Shahrekord University of Medical Sciences, Shahrekord, Iran, Islamic Republic of.*

Introduction: ***PDS*** (*SLC26A4*) has been mapped on 7q22-31.1 and is the second most common gene accounting for hereditary hearing loss (HL), after *GJB2*. The product of *PDS* is pendrin, a transmembrane anion transporter. Mutations of *PDS* are associated with recessive non-syndromic HL (DFNB4) and Pendred syndrome (PS). To date only a little is known about *PDS* mutations in Iran. In the present study mutations of this gene were investigated in Iranian subjects with HL to identify prevalence and types of *PDS* mutations in these patients.
Methods: Thirty unrelated Iranian families with hereditary hearing loss and without *GJB2* mutations were investigated for linkage to DFNB4 using 4 short tandem repeat (STR) markers. Following that, DNA sequencing of all 21 exons, their adjacent intronic sequences and promoter of *PDS* was carried out for mutation detection in families showed linkage. Clinical phenotype of patients with mutation was studied with temporal bone CT- scan, thyroid ultrasonography and thyroid hormone assays.
Results: Three families were linked to DFNB4 locus. Sequencing was clarified 4 *PDS* mutations (c.65-66insT, c.2106delG, c.863-864insT, c.881-882delAC) in exons 2, 19 and 7. Clinical phenotype investigations showed PS in these three families.
Conclusion: This study reveals the importance and specificity of *PDS* mutations in Iranian patients with hearing loss. So screening of this gene is important in hearing loss molecular diagnostics. Morever PS is probably a common syndrome among Iranian deaf patients.

J02.13
Panel base on next-generation sequencing for mutation detection in hearing impairment

L. J. Song[1,2], *Y. T. Yi*[1,2], *S. A*[1,2];
[1]*Binhai Genomics Institute, Tianjin, China,* [2]*Tianjin Translational Genomics Center, Tianjin, China.*

Hearing loss is the most common sensory impairment of human. At least 50% to 60% of childhood hearing loss was inherited. Identifying the genetic basis of deafness is a critical procedure for the clinical evaluation of deaf persons and their families. To date, 136 deafness loci have been identified, and about 90 genes have been cloned. However, the mutation frequency of many genes for HL is not clear, and the causes for majority deafness patients remained unknown. It is critical to develop an effective, comprehensive genetic testing platform for hearing loss.
We designed a panel including 307 deafness genes and the chondriogene, 76 samples with identified deafness gene mutations and YH genome DNA sample were used for the validation. And then screenings were carried out for a total of 147 patients with hearing loss, by target-capture and NGS.
For the 77 validation samples, the average depth of the targeted regions was more than 250 fold. The sensitivity and specificity for the mutation detection was 100%.
For patients with non-syndromic hearing loss, the positive rates were 56.6% (56/99) for early-onset hearing loss and 39.5% (17/43) for late-onset deafness, and candidate mutations were identified in 2 out of 5 patients with syndromic hearing loss.
The results show that our platform is sufficient accurate and effective for molecular diagnosis of hearing impairment.

J02.14
Is the KDR gene associated with Central serous chorioretinopathy

M. Akyol[1], *G. Erdogan*[1], *M. Erol*[2], *E. Turkoglu*[1];
[1]*Akdeniz University, Antalya, Turkey,* [2]*Antalya Training and Reseach Hospital, Antalya, Turkey.*

Central serous chorioretinopathy is an idiopathic ocular defect occurs in serous tissue of the macular region. Studies, showed that intraocular hemorrhage and fluid accumulation lead to reduced vision. Vascular endothelial growth factors (VEGFs) causes to many retinal diseases via inducing angiogenesis and leads to macular edema by increasing vascular permeabilities. TheKDR gene, is a VEGF receptor gene. Given that the VEGF gene family structure and cellular mechanisms, KDR gene mutations have been associated with central serous chorioretinopathy detachment.There has not been any genetic studies about KDR gene related with CSCR. Previousstudies indicates that VEGF-A plays a crucial role in physiopathology of CSCR disease.Therefore we have identified KDR gene sequence as candidate gene and region to explain potential effects of genetic factors on CSCR.
The aim of our project is to investigate the mutation spectrum in the KDR gene in patients with central serous chorioretinopathy and to determine the genotypephenotype relationship. Exonic regions of the KDR gene were sequenced with Sanger method to 32 cases with CSCR and 32 control groups. Consequently known rs140825421 (p>0.05) and rs2305948 (p=0,3) missense mutations, rs35961234 (p>0.05) and rs77722107 (p>0.05) synonymous, rs2219471 (p=0,59) and rs2305949 (p=0,86) intronic, rs4421048 UTR mutation and one novel hetdel_TAA deletion (p>0,05) were found.
Our results, were the first genetic study of KDR gene mutations causing CSCR. Emphasizes the requirement for complete screening of the mRNA sequence of KDR and VEGF-A genes for molecular diagnosis. The identification of mutations in genes of interest would also have importance in diagnosis and genetic counseling in our population

J02.15

Molecular genetic analysis of family with autosomal dominant deafness from Tatarstan revealed a novel mutation in MYO7A

A. V. Marakhonov[1], *F. A. Konovalov[1], N. V. Zernov[2], M. Y. Skoblov[2,3,4], R. A. Zinchenko[2,4];*
[1]Regenerative and Genetic Medical Center of the Human Stem Cells Institute, Moscow, Russian Federation, [2]Research Centre for Medical Genetics, Moscow, Russian Federation, [3]The Moscow Institute of Physics and Technology, Dolgoprudny, Russian Federation, [4]Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Introduction: Genetic epidemiological examination of isolated populations can often reveal relative abundance of hereditary conditions, which are rare in other populations. Rural regions of Tatarstan (Russia) are characterized by high occurrence of isolated hereditary hearing loss. Here we describe a family with recurrent postlingual hearing loss: the proband (woman) and one of her four sisters have hearing loss that manifested postlingually. Affected sister of proband has two children; one of them also developed progressive deafness. Molecular diagnosis in the family was determined with the aid of whole exome sequencing (WES) in conjunction with clinical observations.
Materials and Methods: During the field expeditions in Tatarstan, medical genetic examination and peripheral blood collection of familial cases of hearing loss was performed. Isolated DNA was routinely screened for frequent pathogenic mutations in *GJB2* gene. WES was performed on Illumina HiSeq 2000 at 85× depth. Verification of mutations identified by WES was done by Sanger sequencing.
Results: Screening for frequent mutations failed to identify common cause of observed condition. Among 60 genes associated with hearing loss, WES revealed an undescribed heterozygous mutation p.R848Q in *MYO7A* gene, located at a highly conserved position. The known clinical presentations and mode of inheritance described for *MYO7A*-related hearing loss corresponded well to our case.
Conclusions: Combination of WES with detailed analysis of clinical data enabled to identify causative mutation in a family with autosomal dominant hearing loss. This approach can enhance the current diagnostic pipeline for this condition.
This work was partially funded by RFBR grant 14-04-00525.

Targeted next generation sequencing successfully diagnoses 'rare' metabolic disorders for which childhood cataract is an early indication

R. L. Gillespie[1], *S. Waller[2], T. Fletcher[2], S. C. Ramsden[1], J. Clayton-Smith[1], I. C. Lloyd[3], G. C. Black[1];*
[1]Manchester Centre for Genomic Medicine, University of Manchester, Manchester, United Kingdom, [2]Genomic Diagnostics Laboratory, Manchester Centre for Genomic Medicine, Manchester, United Kingdom, [3]Manchester Academic Health Sciences Centre, Manchester Royal Eye Hospital, Manchester, United Kingdom.

Introduction
Childhood cataract (CC) is the leading global cause of lifelong visual loss. Around 50% of cases have a genetic aetiology. Inborn errors of metabolism represent a subset of causes, a number of which are treatable, making early identification crucial. Extreme genetic and phenotypic heterogeneity impedes the traditionally complex clinical/genetic/biochemical diagnostic pathway. Next generation sequencing (NGS) technologies have transformed the diagnostic approach.
Methods
We have successfully implemented an NGS target enrichment to screen 115 CC-associated genes. A close collaborative effort has enabled the development of an efficient diagnostic pipeline linking detailed clinical phenotyping, high through-put sequencing, data storage, bioinformatics and scientific interpretation to create a linear care pathway from patient to report.
Results
Cataract-targeted NGS has enabled a diagnosis rate of 75% in CC patients; 18% of cases are attributable to metabolic disease, indicating a higher prevalence than the literature suggests. Six different inborn errors of metabolism were identified, including apparently rare conditions such as stomatin-deficient cryohydrocytosis, lathosterolosis and cerebrotendinous xanthomatosis.
Discussion
Cataract-targeted NGS streamlines the care pathway of CC patients, reducing the requirement for a battery of diagnostic tests habitual to the pre-genomic era. Precise diagnosis of metabolic conditions for which CC is a primary indication, permits i) initiation of early therapeutic intervention to prevent disease progression ii) delineation of rare/complex phenotypes and iii) greatly improves diagnostic outcomes attributable to the implementation of stratified genomic medicine.

RGS6: A novel gene associated with congenital cataract, intellectual disability, and microcephaly in a Tunisian family

M. CHOGRANI[1], *F. S. Alkuraya[2], M. Kharrat[1], R. M'Rad[3,1], H. Bouhamed Chaabouni[1,3];*
[1]Faculty of Medicine of Tunis, Tunis, Tunisia, [2]King Faisal Specialist Hospital and Research Center, Riyad, Saudi Arabia, [3]Department of Congenital and Hereditary Disorders, Charles Nicolle Hospital, Tunis, Tunisia.

Introduction: Congenital cataracts show considerable clinical and locus heterogeneity. About 39 loci are involved in isolated or primary cataracts. Congenital cataract can occur in association with a large number of different metabolic diseases or genetic anomalies including intellectual disability and microcephaly. Here is the first report of gene identification in inherited congenital cataracts associated only with intellectual disability and microcephaly.
Materials and Methods: Five members (3 normal, 2 affected) of a 4-generation consanguineous Tunisian family with autosomal recessive congenital cataract associated with intellectual disability and microcephaly were screened. A whole-genome scan was performed with polymorphic microsatellites and homozygous regions were analyzed with integrated Systems Tool for Eye gene Discovery (iSyTE). Selected genes were analyzed by direct sequencing.
Results: Using whole-genome scanning, we identified six runs of homozygosity shared among affected members. Analysis of these regions by iSyTE allowed us to select 3 genes (*RGS6*, *PCNX*, and *P4HA1*) according to their expression in 3 critical stages of lens development. Upon screening for mutations by sequencing analysis, we found a novel mutation in RGS6, the splice-acceptor variant c.1369-1G>C that was not previously reported in congenital cataract phenotypes. Bioinformatics analysis suggested a deleterious effect of this mutation on protein structure and function.
Conclusion: This is the first report of a splice-site mutation of a novel lens specific gene *RGS6* in a phenotype associating AR congenital cataract, intellectual disability and microcephaly. This study highlighted the genetic heterogeneity of congenital cataract.

Prenatal diagnosis in families with autosomal recessive polycystic kidney disease - case reports

L. Obeidova[1], *V. Elisakova[1], M. Senkerikova[2], I. Grochova[3], Z. Kalina[4], J. Reiterova[5], J. Stekrova[1];*
[1]Institute of Biology and Medical Genetics of the First Faculty of Medicine, Charles University in Prague and General University Hospital, Prague, Czech Republic, [2]Department of Medical Genetics, Hradec Kralove University Hospital, Hradec Kralove, Czech Republic, [3]Prenatal Diagnostic Center, Brno, Czech Republic, [4]Department of Medical Genetics, Brno University Hospital, Brno, Czech Republic, [5]Department of Nephrology, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic.

Autosomal recessive polycystic kidney disease (ARPKD) is a severe form of polycystic kidney disease characterized by fusiform dilatations of renal collecting ducts and ductal plate malformation causing biliary ectasia and hepatic fibrosis. The most severely affected fetuses display enlarged echogenic kidneys, oligohydramnios and pulmonary hypoplasia. Arterial hypertension affects up to 80% of children with ARPKD and usually develops within the first months of life. ARPKD is caused by mutations in the PKHD1 gene located on chromosome 6p12 and extending over 470 kb of genomic sequence. The severity and early manifestation of ARPKD make parents of affected child seek reliable prenatal diagnosis to guide future family planning. Even though the standard second-trimester US imaging is still state-of-the-art method of ARPKD diagnosis, it is often not early enough for pregnancy termination. For that reason early prenatal diagnosis is feasible only by molecular genetic analysis. Here we present 2 Czech families with severe form of ARPKD causing perinatal death of index patient. In these families amplicon-based next-generation sequencing and MLPA (multiplex ligation-dependent probe amplification) analyses of the PKHD1 gene in fatally affected child were performed and so facilitated quick prenatal genetic diagnosis in next pregnancy when only positive amplicons with found mutation were analyzed, and therefore helped the diagnosis of ARPKD based most importantly on ultrasound screening. In both families only one mutation was confirmed in fetus and healthy baby was born.

The prevalence of iceA Helicobacter pylori gene in Eastern Siberia (Sakha Republic)

N. N. Gotovtsev[1], *N. A. Barashkov[1,2], K. E. Savvinova[3], V. G. Pshennikova[1], M. V. Pak[4], A. M. Rafailov[3], S. N. Lekhanova[5], S. A. Fedorova[1,2];*

[1]Laboratory of Molecular Biology, Institute of Natural Sciences, „M.K. Ammosov North-Eastern Federal University", Yakutsk, Russian Federation, [2]Laboratory of Molecular Genetics, „Yakut Scientific Center of Complex Medical Problems", Siberian Branch of the Russian Academy of Medical Sciences, Yakutsk, Russian Federation, [3]Department of Biology, Institute of Natural Sciences, „M.K. Ammosov North-Eastern Federal University", Yakutsk, Russian Federation, [4]Department of Endoscopy, Republic hospital №1 – National Center of Medicine, Yakutsk, Russian Federation, [5]Department of normal and pathological anatomy, operative surgery with topographic anatomy and forensic medicine „MK Ammosov North-Eastern Federal University", Yakutsk, Russian Federation.

Helicobacter pylori (Hp) is associated with gastrointestinal diseases [Suerbaum et al., 2002]. The iceA gene is the main virulence factor [Atherton et al., 1995] which most associated with peptic ulcer and chronic gastritis (CG). Recently, study was undertaken on a meta-analysis of clinical outcomes in carriers of different variants of iceA, which has been studied more than 5,000 people and showed that the majority of patients iceA1 allele is associated with peptic ulcer [Shiota et al., 2012]. Similar researches have not been conducted in Eastern Siberia (Yakutia). The aim of this study is to examine the prevalence of iceA Hp in Yakutia. The studied group consisted DNA samples, which were isolated from biopsies of 42 Yakut patients with confirmed diagnosis of CG by histological and cytological study. Among the investigated 42 clinical isolates iceA1 and iceA2 were detected in 33 and 9 patients, respectively. The prevalence of iceA1 in Yakutia was 78.5% (CI=0.64-0.88), which was significantly higher than in Europe - 29.5% (CI=0.34-0.44) and America - 46.5% (CI=0.31-0.41), but not differed from Asia - 58.9% (CI=0.58-0.64). The prevalence of iceA2 in Yakutia was 20.9% (CI=0.11-0.36), lower than in America - 55.4% (CI=0.50-0.60) and in Europe - 38.8% (CI=0.38-0.48), but not different from Asia - 26.3% (CI=0.22-0.28). Thus, the prevalence of iceA1/A2 in our study significantly differed from the prevalence in Europe and America ($p<0.05$), but was close to the values in Asian populations ($p>0.05$).

Biochemical And Genetic Markers Of Autoimmunity Of Hashimoto's Thyroiditis

E. Biktagirova[1], *O. Kravtsova[1], L. Sattarova[1], G. Vagapova[2], Z. Abramova[1];*
[1]Kazan Federal University, Kazan, Russian Federation, [2]The department of Endocrinology, Kazan State Medical Academy, Kazan, Russian Federation.

Hashimoto's thyroiditis (HT) is one of the most widely-spread diseases of the thyroid gland. AITDs are highly prevalent, affecting 1% to 5% of the population worldwide. One of the proposed mechanisms of the HT formation bases on genetic defect of specific CD8+ T-Lymphocytes infiltration of thyroid tissues and progressive thyroid cells damage. Genome-wide association syudies have revealed about 15 genes associated with HT such as MHC (HLA II region), CTLA-4, PTPN22, some proinflammatory cytokines (IL-1B, IL-4 and IL-6), TNF-a and TNFRSF1A, TNFRSF1B.

Subjects. The study included 137 unrelated healthy women who had no family history of chronic autoimmune, cardiovascular and inflammatory diseases, and 161 women with HT with normal and decreased thyroid function (eu- and hypothyroid respectively).Immunophenotyping of lymphocytes performed by flow cytometry «FACSCalibur». Determining the level of annexin V, TNF-a, TRAIL, and the serum was performed by ELISA using commercially available kits according to the manufacturer's instructions («Bender MedSystem», Vienna. Austria).

Genotyping of rs231775, rs5742909, rs4553808 gene CTLA- 4, rs2476601 gene PTPN22, rsl143634 gene IL 1B rs2243250 IL-4 gene, rsl800795 gene IL-6, rs1800629 gene TNF-a, rs4149570 and rs800692 TNFRSF1A gene,rs1061622 and del 15 bp gene TNFRSF1B was performed by CFX-96 real-time amplification system (BioRad, USA).

Results:

1. Hashimoto's thyroiditis characterized by TRAIL- induced apoptosis.
2. The genetic markers of HT are polymorphic loci rs4553808 and of rs231775 gene CTLA-4; rs1800629 gene TNF-a, rs800692 gene TNFRS1A; rs1143634 gene IL-1B.

X-linked Alport syndrome: cardiovascular symptoms and affected females.

O. Groznova, *D. Shentseva, L. Shagam, V. Sukhorukov, V. Dlin;*
Research and Clinical Institute for Pediatrics at Pirogov Russian National Research Medical Universi, Moscow, Russian Federation.

Background: Alport syndrome (AS) is an inherited disease. It is expected, that X-linked AS affected only males. In patients with autosomal dominant and autosomal recessive AS both sex affected.

Methods: coding exons and splice sites of the abovementioned genes were sequenced in on Ion Torrent platform.

Results: in Russian family were revealed 1 affected male and 4 affected females with a dominant missense mutation c.G3098A, p.1033 G>D in the collagen type IV alpha-5 gene causes X-linked AS. New phenotype findings were: cardiovascular abnormalities (asymptomatic aortic root enlargement, aortic and mitral valves insufficiency in affected male; ascending aorta enlargement, aortic and mitral valves insufficiency in 63 years old female; mitral valve insufficiency in 5 years old girl; early onset of systemic hypertension in 1 male and 3 females; early onset (before 3 years of age) and progression of proteinuria up to 2,0 g/l in affected females; absents of any ocular abnormalities. Glomerular filtration rate was low in affected male - 50 ml/min and slightly abnormal in all but one affected female: in 63 years old woman - 78 ml/min, in 29 years old woman - 82 ml/min, in 5 years old girl - 88 ml/min.

Conclusion: Affected females with X-linked AS demonstrate clinical symptoms of kidney disease and cardiovascular abnormalities. Cardiology examination may be necessary in all affected subjects.

Correlation of SNP polymorphisms in modifier genes with phenotype of Slovak cystic fibrosis (CF) patients

E. Tothova Tarova[1], *A. Soltysova[1,2], A. Ficek[1], L. Kadasi[1,2];*
[1]Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, [2]Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia.

Cystic fibrosis (CF) is the common lethal autosomal recessive disorder in whites. Classically, individuals with CF develop a disease characterized by progressive bronchiectatic lung disease with bacterial infections, pancreatic insufficiency, meconium ileus, chronic sinusitis and male infertility.

Even in patients with CF with identical CFTR genotypes, there is a wide range in the severity of lung disease. Environment and polymorphism in other genes play a particularly important role that modify the phenotypic presentation of a disease. So far, more than 80 modifying genes have been described in CF from those we have selected 11 that may influence the phenotype of patients with CF, specifically to lung disease, immunity, nutrition and liver cirrhosis. Among the selected genes include MBL2 (rs5030737, rs1800451, rs1800450 and in promoter -220), SERPINA1 (rs28929474, rs17580), ACE (rs4646994), TGFβ1 (rs1800470, rs1800471), TNFα (rs1799724, rs1800629, rs361525) GSTP (rs947894), GSTM (in-del), GSTT (in-del), HFE (rs1799945, rs1800562, rs1800730), NOS1 („AAT" repetition in intron13 and 20) and ADRβ2 (rs1042713, rs1042714, rs1042717). DNA polymorphisms were typed by PCR reaction, directed sequencing, single base primer extension assay (SNaPshot) and fragment analysis in 196 patients and 96 controls. Also spirometric, microbiological and other clinical data were collected from medical records.

The main aim of the study was the description the correlation of gained genotypes in modifying genes to the phenotype (clinical symptoms) of CF patients.

The role of the cytokine genes polymorphisms in peptic ulcer disease predisposition in Volga-Ural region of Russian Federation

A. Nurgalieva[1], *E. Shaymardanova[1], D. Nadyrshina[1], Y. Valova[1], A. Gizatullina[1], L. Gabbasova[2], O. Kuramshina[2], A. Krukova[2], I. Khidiyatova[1,3], E. Khusnutdinova[1,4];*
[1]Bashkir State University, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation, [3]Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation, [4]Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Russia, Ufa, Russian Federation.

Peptic ulcer (PUD) - a chronic disease based on recurrent gastric or duodenal ulcer (DU). One of the probable causes of the PUD development is infection by the bacterium Helicobacter pylori, but ulceration depends on a large number of endogenous and exogenous risk factors. The aim of this study was to analysis the association of cytokine genes polymorphisms

IL1B (rs1143634, rs16944), IL1RA (rs71941886), IL6 (rs1800796), IL8 (rs4073, rs2227307), IL10 (rs1800872) and TNFA (rs1800629). This study enrolled 353 patients with gastric and duodenal ulcers, 114 of them were infected by H.Pylori, the control group included 285 unrelated individuals without gastro-duodenal pathology with different ethnic origins (Russians, Tatars, Bashkirs). Genotyping was performed by TagMan real-time PCR. The analysis has revealed a strong association of rs1143634*C allele and rs1143634*C/C genotype of IL1B gene with the risk of PUD in Bashkirs (p = 0.006; OR = 2.87 and p = 0.002; OR = 4.49, respectively), with the risk of duodenal ulcer (p = 0.01; OR = 1.46 and p = 0.009; OR = 1.64, respectively). We have also detected that frequency of A/A genotype of the rs4073 of the IL8 gene are significant more prevalent in healthy donors than in H.Pylori-positive individuals (p = 0.02; OR = 0.46). The study shows that the polymorphisms s of IL1B, IL8 genes may contribute to the structure of the genetic predisposition of PUD in Volga-Ural region of Russian Federation.

Importance of HLA typing in diagnosing celiac disease in men and women

J. Poráčová[1], *L. Urbanová*[2], *M. Mydlárová Blaščáková*[1], *T. Kužma*[2], *M. Konečná*[1], *V. Sedlák*[1], *J. Vašková*[3], *L. Vaško*[3];
[1]*Presov University in Presov, Faculty of Humanities and Natural Sciences, Department of Biology, Presov, Slovakia,* [2]*AdLa s.r.o., Holleho 14, Presov, Slovakia,* [3]*University of Pavol Josef Safarik, Faculty of Medicine, Department of Medical and Clinical Biochemistry, Kosice, Slovakia.*

Introduction: Chronic gluten intolerance (celiac disease) occurs in genetically predisposed individuals. It is a multifactorial disease, which is affected by several environmental, immunological and genetic factors. The main factor affecting the genetic predisposition for celiac disease is HLA II. class DQ2 and DQ8.
Materials and Methods: In the group of patients, there were 200 women and 80 men (average = 38,5 years), who were examined for the HLA system II. class, heterodimers HLA DQ2 and HLA DQ8. To identify major haplotypes in the context of celiac disease, we used the method of Reverse Dot Blot with the aid of a commercial kit CeliacStrip (Opegen).
Results: The frequency of the haplotype HLA-DQ2 cis in women was 20.30% and 12.14% in men in any given group of patients. Women with DQ2 trans Hp2 were 12.38% and 7.6% men. In the statistical evaluation of the patients we did not find statistically significant differences in relation to gender, among tested men and women.
Conclusion: In comparison to the risk of haplotypes in women and men in this group of patients, it was found that women have a slightly higher prevalence for the risk of haplotype HLA DQ2.5, HLA DQ2.2 also combinations of HLA DQ2.5 and HLA DQ8 compared to men. Men have a higher frequency of risk due to the presence of haplotype HLA DQ8.
Acknowledgment: The work was supported by the Agency of Ministry of Education, Science, Research and Sport of the Slovak Republic, the project ITMS: 26110230100.

Melatonin Receptor 1b Polymorphisms In Bulgarian Patients With Policystic Ovary Syndrome.

S. Andonova[1], *R. Robeva*[2], *A. Tomova*[2], *A. Savov*[1], *P. Kumanov*[2];
[1]*National Genetic Laboratory, Medical University-Sofia, Sofia, Bulgaria,* [2]*Clinical Center of Endocrinology and Gerontology, Medical University– Sofia, Sofia, Bulgaria.*

Background: Polycystic ovarian syndrome (PCOS) is a complex endocrine disorder with a pronounced genetic predisposition. Pineal hormone melatonin could modulate reproduction pattern in several animal species, and disturbed melatonin secretion has been described in women with hyperandrogenic states. Nevertheless, the role of melatonin receptor polymorphisms for the development of PCOS is poorly investigated. Therefore, the present study aimed to investigate the relationships between melatonin receptor 1B (MTNR1B) polymorphisms rs10830962 and rs10830963 and clinical features of the syndrome.
Materials and methods: Genotyping for MTNR1B rs10830962 and rs10830963 was performed in 59 patients with PCOS by PCR-RFLP analysis.
Results: MTNR1B rs10830963 G allele was related to elevated levels of DHEAS in the investigated patients (p=0.007), while no significant associations with testosterone levels, presence of hirsutism or obesity were found (p>0.05). MTNR1B rs10830963 G allele was associated with a significantly lower LH to FSH ratio in obese PCOS patients (p=0.026). No significant associations between MTNR1B rs10830962 and PCOS clinical or hormonal features were established (p>0.05).
Conclusions:The present results suggest that MTNR1B rs10830963 but not rs10830962 polymorphism could influence the clinical expression of PCOS in women.
The present study was financially supported by the Medical University - Sofia.

Silencing of Important Molecules Having Roles in Pathogenesis of Idiopathic Pulmonary Fibrosis via RNA interference and Development of New Therapeutic Modalities

E. Uctepe[1], *M. Gündüz*[1], **H. Öksüz**[1], *F. Yılmaz*[2], *D. Aydın*[3], *E. Gündüz*[1];
[1]*Turgut Özal University Faculty of Medicine, Department of Medical Genetic, Ankara/Yenimahalle, Turkey,* [2]*Turgut Özal University Faculty of Medicine, Ankara/Yenimahalle, Turkey,* [3]*Turgut Özal University Faculty of Medicine, Department of Physiology, Department of Physiology, Ankara/Yenimahalle, Turkey.*

Idiopathic Pulmonary Fibrosis (IPF) is a disease that is characterized by the deposition of an excessive degree of myofibroblast cells and extracellular matrix components in the lower respiratory tract and lung interstitium. Median survival is 3 years after initial diagnosis. Prevalence rate varies from 14 to 43 per 100 000 people. Today, it is thought that recurrent epithelial damage and aberrant wound healing are the basis of IPF pathogenesis, resulting in the accumulation of fibroblasts in the lung. In addition, coagulation, apoptosis, angiogenesis pathway disorders, oxidative damage, and most recently epithelial–mesenchymal transition (EMT) are implicated in the pathogenesis of this disease. Major aim of our study is to show the fundamental role of osteopontin, Twist and Wnt-5a genes in IPF pathogenesis which these genes have been implicated by several studies in EMT and to show whether the suppression of these genes could be effective for IPF treatment examined. First of all, we treated A549 cell line with different dose of TGF-β to create EMT. We showed that after TGF-β treatment, E-cadherin expression is markedly decreased, on the contrary, Vimentin expression increased showing EMT. Then, Changes in the expression of genes responsible for EMT formation and fibrosis examined at the level of mRNA and protein performing siRNA knockdown for Osteopontin, Twist and Wnt-5a gene transcripts in lung alveolar cell lines.

Socs3 Polymorphisms in childhood obesity: Is the cytokine system in operation?

K. Ulucan[1], **M. Boyraz**[2], *E. Yesilkaya*[3], *F. Ezgü*[4], *A. Bideci*[4], *P. Cinaz*[4];
[1]*Marmara University, Faculty of Dentistry, Department of Medical Biology and Genetics, Istanbul, Turkey,* [2]*Gazi University, Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Turkey,* [3]*Gülhane Military Medical Academy, Department of Pediatric Endocrinology, Ankara, Turkey,* [4]*Gazi University, Faculty of Medicine, Department of Pediatric Endocrinology, Ankara, Turkey.*

Objective: Although polymorphisms in suppressor of cytokine signaling 3 (SOCS3) was reported to be related to obesity, metabolic syndrome and type 2 diabetes in various adult studies, there is a lack of data in children. In this study, we examined eight reported polymorphisms of SOCS3 in obese Turkish children with and without metabolic syndrome and compared the results with that of controls.
Methods: 148 obese and 63 age and sex matched control children were enrolled in the study. Genotyping procedure was carried out by PCR- sequencing protocole.
Results: The frequency of rs2280148 polymorphism was significantly higher in obese children with metabolic syndrome than that of the control group, whereas the frequency of rs8064821 polymorphism was significantly higher in obese children with metabolic syndrome than that of obese children without metabolic syndrome.
Conclusion: The significant association of certain SOCS3 polymorphisms with obesity parameters in both metabolic syndrome and metabolic syndrome related insulin resistance, hypertension, and fatty liver suggest that polymorphisms in this gene may play a role in the pathogenesis of metabolic syndrome and also that they can be potentially used as a marker for attenuated or agressive disease.

Molecular diagnosis of family with two sisters with clinical manifestation of simple virilizing form of congenital adrenal hyperplasia

M. Kocova[1], *V. Anastasovska*[1], *I. Bitoska*[2];
[1]*University Children's Clinic, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*University Clinic for Endocrinology, Diabetes and Metabolic Disorders, Skopje, Macedonia, The Former Yugoslav Republic of.*

Background: Congenital adrenal hyperplasia is an autosomal recessive dis-

order caused by steroid 21-hydroxylase deficiency in 90-95% of cases. Its classical simple virilizing (SV) form leads to virilization of external genitalia in newborn females and pseudoprecocious puberty in both sexes, due to reactive androgen overproduction. SV CAH is usually associated with I172N missense mutation at the CYP21A2 gene.
Method: Two sisters were diagnosed as classical SV CAH at the age 7 and 9 years respectively by standard clinical and biochemical procedures. They had virilization, and high 17OHP (>75 nmol/L) on ACTH stimulation test. Molecular detection of nine most common point CYP21A2 mutations in the patients and family members, using the PCR/ACRS method was performed. They received hydrocortisone for several years. At 35 and 37 years they were referred to the gynecologist due to oligomenorrhea, hirsutism, and infertility. After hormonal preparation IVF was performed in the older sister with no success.
Results: P30L/II72N genotype was observed in both SV patients. The I172N mutation in the heterozygote state was observed in their other two sisters, 43 and 28 years old, without clinical manifestation of CAH. Father was heterozygote for P30L mutation. The deceased mother has not been analyzed. She was probably a carrier of I172N.
Conclusion: Simple virilizing CAH appears with virilization causing oligomenorrhoea and infertility later in life. Molecular diagnosis is essential to provide the correct diagnosis and allows appropriate clinical and genetic counseling. Our findings suggesting that P30L as well as I172N caused SV CAH in these patients.

J03.12
The incidence dynamics of congenital hypothyroidism in the Northern Russian territories during eight-year period

L. Kolbasin, *S. Ovsyannikova, M. Khmelnitskaya, M. Novikova, E. Popova, A. Volykova, N. Kuntsevich, O. Kartseva, M. Donnikov, S. Zubaidullina, I. Urvantseva;*
Medical Genetics Counseling Department of Budgetary institution of Khanty-Mansiysk Autonomous Region – Ugra Regional Cardiology Clinics „Center for Diagnosis and Cardiovascular Surgery", Surgut, Russian Federation.

Objective: To investigate the incidence of the primary congenital hypothyroidism (CH) in the Khanty-Mansiysk Autonomous Region (KHMAO) according to newborn screening (NBS) data during last eight years.
Materials and methods: Retrospective evaluation of CH incidence dynamics in newborns based on the results of NBS in 2006-2013 years was performed. TSH levels in DBS were measured using "DELFIA Neonatal hTSH" kit following evaluation with locally established cut-offs. Threshold TSH values for CH detection were >9mU/L for newborns of 4-5 days of life and >5mU/L for newborns after 14 days of life. Samples with exceeded threshold were assayed again. TSH levels 5mU/L indicated newborns at risk of CH. These children were sent to pediatric endocrinologist consultation with follow-up diagnostics and treatment. Confirmatory diagnostics was performed by serum TSH, free T4 detection. Statistical validity was assessed by Student t-test, $p<0.01$.
Results: Eight years-long NBS coverage for KHMAO region was 98.9% with TSH level evaluated in 190 589 newborns. Confirmatory diagnostics was performed in risk group of 3 563 children. 76 children were diagnosed with CH with appointed replacement therapy. Thus, CH incidence within studied territory was 1:2 508 births with statistically significant incidence increase of 4.1 times between the minimum (1:5,292 live births in 2007) and the maximum (1:1,298 live births in 2010, $p<0.001$).
Conclusions: CH incidence in KHMAO region according to NBS for the 8-year period was 1:2,508 with 98.8% coverage. Its dynamics has a statistically significant increase of 4.1 times.

Gene - environment interactions analysis in occupational chronic bronchitis

L. Akhmadishina[1], *G. Korytina*[1], *O. Kochetova*[1], *M. Shaymukhametova*[2], *T. Viktorova*[1,3];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation,* [3]*Bashkir State Medical University, Ufa, Russian Federation.*

Occupational chronic bronchitis is one of the common disease and both genetic and environmental risk factors contribute to its etiology. A case-control study was conducted using 122 patients with occupational chronic bronchitis and 166 healthy workers to investigate the association of CYP1A2 (rs762551, rs35694136), CYP2F1 (rs11399890), NQO1 (rs1131341, rs1051740), UGT2B7 (rs7439366), CAT (rs1001179, rs769217), GSTP1 (rs1695, rs1138272) polymorphisms with the disease developing risk Analysis was performed to test for GxE interactions with exposures (smoking, PY, occupational experience) using logistic regression models.
It was shown CYP1A2 rs35694136 (P=0.02, in over-dominant model), UGT2B7 rs7439366 (P=0.002 in recessive model), CAT rs1001179 (P=0.02, in dominant model) were significantly associated with high risk of occupational chronic bronchitis development. When ethnicity, smoking, PY, occupational experience were included in the logistic regression model, it was shown association with risk of disease development for rs1131341 NQO1 (Padj=0.0004, ORadj=3.57), rs7439366 UGT2B7 (Padj=0.0024, ORadj=2.31), rs35694136 CYP1A2 (Padj=0.0041, ORadj=2.17). Statistically significant interaction with smoking status was defined for rs7439366 UGT2B7 (Pinteract=0.015, in over-dominant model) with PY-for rs11399890 CYP2F1 (Pinteract=0.05 in additive model).
Identifying GxE interaction will lead to better understanding of the development of occupational chronic bronchitis and potential biological mechanisms, and, in future, effective prevention strategies.
The investigation was partially supported by RFBR 14-04-97006 r_povolzye_a, 14-06-97003 r_povolzye_a, 13-04-00287 A; RFH 13-06-00101.

J03.14
Molecular analysis of CYP21A2 gene in patients with congenital adrenal hyperplasia (CAH) by sequencing

k. forouzanfar;
Tabriz University of Medical Sciences, tabriz, Iran, Islamic Republic of.

Congenital adrenal hyperplasia (CAH) is a hereditary metabolic disorder which is caused by the defects in the steroid 21-Hydroxylase CYP21A2 gene in an autosomal recessive manner. The most common form of this disease which is seen in more than 90% of patient is 21-Hydroxylase deficiency and 11-β- Hydroxylase placed on second stage. Identify of mutation at early stages is crucial.
AIMS:
Mutation identification in CYP21A2 gene at early stages.
Materials and Methods:
According descriptive epidemiological study patients with CAH were recruited from the Genetic Research Centre Of Tabriz in 2012 and 2013. Sampling and DNA extraction was followed by PCR on exons to find out mutation on CYP21A2 gene.Then sequencing has been done.
SPSS(version 22) was used for data analysing and descriptive statistics and the results were compared with the reference gene by blast, Generunner and MEGA-5 softwares. Obtained changes were compared with NCBI databases and also SIFT.
Polyphene and BDGP softwares was used to predict the performance of obtained changes.
Results:
prevalence of CAH in patients is in classic form (salt wasting & simple virilizing).
Analysing of the sequencing shows mutations located in Exons 6,7,8 and 10.
Study shows Q318S (g.1994 952 C>T) and V 237E (g.1383 710 T>A) were the most and E351K (g.2093 1051G>A) and V281L (g.1683 841 G>T) were the least frequent mutations. Also the level of mutation frequency in men was higher than women.
Conclusion:
Due to Observed mutations frequency in this study (was much higher than reported frequency in previous studies) Follow-up screening programs and using sequencing method for identification of mutations seems obligatory.

J03.15
A novel mutation of JAG1 causes Alagille syndrome

I. Micule[1], *I. Pukite*[1], *D. Sviridova*[1], *K. Rutka*[2], *B. Lace*[2];
[1]*Clinical University Hospital for Children, Riga, Latvia,* [2]*Biomedical Study and Research Centre, Riga, Latvia.*

Alagille syndrome (AS) is a complex multisystem disorder with manifestations primarily in liver, heart, eyes and skeleton and has also characteristic facial features. AS is caused by mutations in two genes - JAG1 (95%) and NOTCH2 (1-2%) and inherited in AD manner.
A one-month-old boy was referred to genetic counselling because of suspected Alagille syndrome. The child had cholestatic icterus and pulmonary stenosis on EchoCG. Liver biopsy was performed and it confirmed the paucity of bile ducts. The child has also other features of AS such as retinal hypopigmentation, renal dysplasia with small non-functioning right kidney and megaureter on the left side, he has malabsorption and growth failure. The family history is negative.
A mutation analysis of JAG1 gene was requested. The results revealed a previously unpublished sequence variant - an in-frame deletion c.53_73del (p.Leu18_Leu24del) in a heterozygous state. In silico analysis (HumanSplicingFinder) predicts this mutation as potentially deleterious. Sequencing of

1st exon of JAG1 gene of both parents was performed, but the deletion was not found, confirming a de novo event.
Two previously described in-frame deletions of the region which overlaps the region deleted in our patient have been reported as causative for Alagille syndrome. These are c.48_68del and c.63_74del (N.B.Spinner et al., 2000 and 2006). The sequence which is deleted in both previously reported cases and also in our case is six nucleotides long: CTGCTC and codes for one leucine and one cysteine residue. We propose that this cysteine residue plays crucial role in jagged1 protein folding, and the deletion of it affects function of the protein.

J03.16

Genotype and phenotype characteristics of patients with congenital adrenal hyperplasia due to 21-hydroxylase deficiency. The first intervention study in Armenia.

R. Markosyan, *T. Sargsyan, H. Hayrapetyan;*
Yerevan State Medical University, Yerevan, Armenia.

Congenital adrenal hyperplasia (CAH) is inherited autosomal recessive due to different kind of mutations in the CYP21.
Objective and hypotheses: The aim of this study was to evaluate clinical and molecular characteristics of the patients with CAH.
Metod: 20 patients diagnosed as CAH according to their clinical, hormonal and molecular finding, were in included. We thoroughly examined 20 patients with CAH and 2 asymptomatic individuals with a history of affected siblings. The mutations associated with CAH were identified by polymerase chain reaction and reverse-hybridization. The assay covers 11 mutations in the CYP21A2 gene: P30L, I2 splice (I2 G), Del 8 bp E3 (G110del8nt), I172N, Cluster E6 (I236N, V237E, M239K), V281L, L307 frameshift (F306+T), Q318X, R356W, P453S, R483P.
Result: Nine patients had classic CAH and presented with ambiguous genitalia and/or salt losing crisis. Eleven patients had the non-classic form of CAH and presented with precocious puberty. The remaining 2 subjects were asymptomatic. Screening the CYP21A2 gene, we detected Q318X heterozygous mutation in 9 patients, P30L/I2splice/del8bpE3/V281L compaund geterozygous mutation in another 2 patients, I2splice/I172N compaund heterozygous mutation in 4 patients,
Q318/R483P compaund heterozygous in 1 patient ,V281L/heterozygous mutation in 4 patients and P30L/Del8bp compaund heterozygous/I2splice hemizygous in 2 patients.
Conclusion: Larger studies are necessary: the genotype-phenotype discordance of these patients requires further explanation.

The influence of HLA class II genes in autoimmune liver and thyroid diseases association with celiac disease in children

O. N. Belei[1], *M. Pop*[2], *L. Olariu*[1], *T. Marcovici*[1], *I. Simedrea*[1], *O. Marginean*[1];
[1]*First Pediatric Clinic, University of Medicine and Pharmacy "Victor Babes" Timisoara, Romania, Timisoara, Romania,* [2]*Third Pediatric Clinic, University of Medicine and Pharmacy "Victor Babes" Timisoara, Romania, Timisoara, Romania.*

Background:Recent researches proved that classical definition of celiac disease(CD) comprises only 30% of cases with genetic predisposition, the majority of patients being pauci-symptomatic.Active-case finding in groups at risk for CD is considered cost/effective.Objectives:To determine the prevalence of CD in a pediatric population with autoimmune hepatitis(AIH) and autoimmune thyroid disorders(AITD) and in control lot and to assess the clinical forms of presentation and the HLA polymorphism in all cases. Methods:We screened for CD 74 children with AITD(lot 1), 62 children with AIH(lot 2) and 60 healthy children.In patients with at least one positive autoantibody for CD, intestinal biopsy was performed.All children underwent HLA typing for DQ2/DQ8.Results:CD prevalence was 7%(5 patients) in lot 1, 6%(4 patients) in lot 2 and 0 in control lot.There weren't significant differences between the frecquency of CD cases among children with AITD and AIH(p>0,05).Most of the cases presented as silent CD(78%).All children diagnosed with CD presented DQ2/DQ8 haplotype.20% of the control subjects associated heterozygous DQ2 alleles.From 69 children with AITD/without CD, only 3 patients(4%) presented heterozygous DQ2.From 58 children with AIH and negative results for CD, 37 patients(64%) associated homo or heterozygous DQ2/DQ8 alleles.Conclusions:Recommending AITD and AIH as selection parameters for CD screening in asymptomatic children is justified by the high frequency of gluten enteropaty obtained in this study(7% and 6% respectively).CD and AIH share selected combinations of genes coding for class II HLA, which could explain their coexistence.Besides immunosuppressives, early detection and dietetic treatment of CD in AIH children may prevent progression to end-stage liver failure.

Genealogy analysis of bronchial asthma

A. I. Bezrodnaya[1], *E. M. Khodosh*[2], *Y. E. Khodosh*[3];
[1]*Kharkiv National Medical University, Kharkiv, Ukraine,* [2]*Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine,* [3]*Kharkiv EC №45 «Academic Gymnasium", Kharkiv, Ukraine.*

Genealogical research allows to the practicing doctors to increase the effectiveness of medical and genetic counseling for secondary and tertiary prevention of the formation of groups at risk for asthma and improve mechanisms for identifying factors of manifestation.
The purpose and objectives. Purpose - genealogical analysis of susceptibility to disease relatives with varying degrees of relationship with a patient with asthma among populations of Kharkiv. Objectives: 1. Sets the coefficient of correlation between the age of manifestation of asthma in parents and children. 2. Investigate the predisposition to illness of relatives with varying degrees of relationship with a patient with asthma 3. Compare the features of sexual predisposition to asthma.
Results. Between the ages manifestation of asthma in parents and children is a direct connection. The value of the correlation coefficient for parent- children pairs is 0.54 (p <0.001). There is a variation of correlation coefficients depending on the sex of patients. Maximum correlative relationship was found in pairs „mother-descendant" (r = 0,73). In pairs „father-descendant" this index half as much. (r = 0,36). When comparing male and female predisposition to transfer asthma found that significantly more women than men who have relatives with asthma (φ♀ = 1,861, φ♂ = 1,281, Ffakt.> Ftabl.). Thus amount of sick relatives among the polled women-patients twice as much amount of sick relatives of patients-men as the first so second degree of cognation.
Conclusion: The maximum risk of asthma are relatives of the first degree relatives, particularly if the mother is sick.

Genes involved in fibrogenesis in predisposition to type 1 diabetes and diabetic nephropathy

N. V. Tarasenko[1], *I. A. Goncharova*[1,2], *A. V. Markov*[1], *E. I. Kondratieva*[3], *V. P. Puzyrev*[1];
[1]*State Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation,* [3]*Siberian State Medical University, Tomsk, Russian Federation.*

Vascular complications of diabetes are the leading cause of preventable morbidity and mortality of patients with diabetes. Case-control study included 585 people Russian living in Siberia (Tomsk, Kemerovo) - 285 patients with type 1 diabetes (T1D), among which 123 had diabetic nephropathy (DN) and 300 population-based controls. We studied 58 SNPs of 48 genes that are involved in the process of fibrogenesis, responsible for the functioning of the endothelium, associated with diabetes and diseases of the cardiovascular continuum. Specimens were evaluated using the Sequenom MassARRAY (USA). Association with the disease was obtained for the following markers: MMP3 rs679620 (p=0.004), ITGB5 rs1007856 (p=0.039), ITGA4 rs1143674 (p=0.002), LIG1 rs20579 (p=0.003), ADAMDEC1 rs3765124 (p=0.014), IFNL2 rs12980602 (p=0.029), PARP4 rs4986819 (p=0.043). Association with DN were obtained for SNPs: MMP3 rs679620 (p=0.002), ITGB5 rs1007856 (p=0.039), ITGA4 rs1143674 (p=0.028), COL1A1 rs2075555 (p=0.046), ADAMDEC1 rs3765124 (p=0.002), CD247 rs6668182 (p=0.049), PARP4 rs4986819 (p=0.014). Polymorphic variants MMP3 rs679620, ITGB5 rs1007856, ITGA4 rs1143674, ADAMDEC1 rs3765124, PARP4 rs4986819 showed association with both T1D and with DN. Specific for T1D are SNPs of genes LIG1 rs20579, IFNL2 rs12980602, and for DN COL1A1 rs2075555 and CD247rs6668182. Genes MMP3, ITGB5, ITGA4, ADAMDEC1 and COL1A1 involved in the formation of extracellular matrix, collagen metabolism that may lead to fibrotic changes in the renal tubules and interstitium, the progression of DN and the deterioration of the disease. Thus, genes involved into fibrogenesis labeled T1D complication associated with the development of fibrotic processes in the kidney - diabetic nephropathy.

Overlapping phenotypes to the Ryanodine Receptor 2 (RyR2) gene

C. Manzalini[1], *V. Caporale*[2], *M. Cannone*[3], *P. A. Merlini*[4], *D. Ardissino*[2], *N. Marziliano*[2];
[1]*University of Bologna, BOLOGNA, Italy,* [2]*Azienda Ospedaliero Universitaria di Parma, PARMA, Italy,* [3]*ASL Foggia, Foggia, Italy,* [4]*Azienda Ospedaliera Ospedale Niguarda Cà Granda, MILANO, Italy.*

Type two ryanodine receptor (RyR2) is a Ca2+ release channel on the endoplasmic reticulum (ER) of many type of cells including cardiac and pancreatic b-bells. However the functional role of RyR2 in insulin secretion remains controversial. To determine whether RyR2 channels are involved in glucose homeostasis we took advantage of rare RyR2 mutations that render the

channel "leaky" in patients with a form of exercise-induced sudden cardiac death known as cathecolaminergic polymorphic ventricular tachycardia (CPVT). Here we show that CPVT patients have previously unrecognised profound glucose intolerance. To determine whether leaky RyR2 channels in these patients cause glucose intolerance, we generated mice harbouring CPVT-linked RyR2 mutations. Pancreatic islets from these mice exhibited intracellular Ca2+ leak, activated ER stress response, mitochondrial dysfunction, decreased insulin secretion from pancreatic b-cells and glucose intolerance. Chronic pharmacologic inhibition of intracellular Ca2+ leak improved mitochondrial function and normalised insulin release and glucose intolerance. Thus the RyR2 channels play a heretofore unappreciated role in the regulation of insulin secretion and glucose tolerance.

The association of B4GALT1 and IGFBP3 genes polymorphisms with asthma in the Volga-Ural region of Russia.

A. S. Karunas, *B. B. Yunusbayev, Y. Y. Fedorova, G. F. Gimalova, E. K. Khusnutdinova; Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation.*

Asthma is a heterogeneous disease, usually characterized by chronic airway inflammation. The genetic basis for developing asthma has been extensively investigated. To date, more than thirty GWAS of asthma have been performed and significant associations have been published for nearly 100 asthma genes. The aim of our investigation was to identify asthma susceptibility genes in the Volga-Ural region of Russia. The study included 358 unrelated asthma patients and 369 control subjects of different ethnic origin (Russians, Tatars and Bashkirs). The genotyping was carried out using the Illumina Human610 quad array at the CNG (France) as a part of GABRIEL project. Five markers on chromosome 17q12-21 showed statistically significant association with asthma (p<4,79x10-7). Moreover, we revealed additional two regions of putative association with asthma. The first region was observed at chromosome 9p13 with rs12342831 in B4GALT1 (beta 1,4-galactosyltransferase, polypeptide 1) gene (p=4,232x 10-6); the second region - at chromosome 7p14 with SNP rs1496499 near to IGFBP3 (insulin-like growth factor binding protein 3) gene (p=4,77x10-6). To confirm these associations, we carried out association analysis two SNPs (rs12342831, rs1496499) in independent case-control group (310 asthma patients and 314 control individuals). We detected significant association between two SNPs and asthma in independent group. In summary, this study has revealed and replicated the association between asthma and rs12342831 (9p13), rs1496499 (7p14). Supported by a contract from the European Commission (018996) and the Russian Foundation for Basic Research (13-04-01397).

Pseudo-Bartter syndrome: the key to identifying an unknown allele in an infant with cystic fibrosis

C. Pienar[1,2], *I. Ciuca*[1,2], *L. Tamas*[3], *Z. Popa*[4], *L. Pop*[1,2];
[1]*Pediatrics Department, „Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [2]*2nd Pediatrics Clinic, Emergency County Hospital, Timisoara, Romania,* [3]*Biochemistry Department, „Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [4]*Cystic Fibrosis National Center, Timisoara, Romania.*

Introduction: Pseudo-Bartter syndrome (PBS) describes a complication of cystic fibrosis (CF) leading to hypochloraemic, hypokalaemic metabolic alkalosis. Aim: To present the case of a seven months baby girl diagnosed with CF at 3 months of age, who presented at 5 months with PBS. Case report: A history of repeated pneumonia, diarrhea and failure to thrive lead to performing a sweat test, which was positive (NaCl 110mM/l - Nanoduct system). We also performed a molecular genetic analysis of the CFTR gene for 29 mutations (kit Elucigene CF 29). It revealed a heterozygous state for F508del-CFTR. The other allele remained unknown. Nutritional therapy and pulmonary therapy was started. The infant was put on an enzyme replacement therapy. Despite the treatment and the family's compliance, her failure to thrive continued. At 5 months she presented with PBS. After the acute phase was resolved, we started supplementing with an oral NaCl solution and the result was an improved growth. The sweat test remained positive after her growth normalised (85mM/l). The kit we used identifies the most common mutations for the Central and Eastern European area. Thus, we performed a wider molecular genetic analysis and the results are pending. Conclusions: The sweat test remains pathognomonic for diagnosing CF. PBS delays the improvement of the nutritional status. Regarding the future pregnancies of the couple, the identification of the second allele is of most importance for offering a proper genetic counseling.

J03.23

Ulcerative colitis is under dual (mitochondrial and nuclear) genetic control

A. Rosa[1,2], *P. Abrantes*[2,3], *I. Sousa*[2,3], *V. Francisco*[2,3], *P. Santos*[2,3], *D. Francisco*[2,3], *J. M. Xavier*[4], *S. A. Oliveira*[2,3];
[1]*Unidade de Ciências Médicas, Centro de Competências das Ciências da Vida, Universidade da Madeira, Funchal, Portugal,* [2]*Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal,* [3]*Instituto Gulbenkian de Ciência, Oeiras, Portugal,* [4]*Universidade do Algarve, Faro, Portugal.*

Introduction: Cellular oxidative stress and genetic susceptibility have been implicated in the multifactorial aetiology of ulcerative colitis (UC). Even though the nuclear genome association with UC has been intensely investigated, the role of the second genome, the mitochondrial DNA (mtDNA), has received far less attention.
Objective: To perform a comprehensive analysis of the mtDNA contribution to UC susceptibility.
Materials and Methods: The association of mitochondrial single nucleotide polymorphisms (mtSNPs) and haplogroups with UC was tested in 488 cases and 833 controls of European ancestry from the NIDDK IBD Genetics Consortium Ulcerative Colitis Genome-Wide Association Study available through dbGaP (study accession number phs000345.v1.p1) and from studies 64 and 65 deposited in the Illumina Genotype Control Database.
Results: No evidence of population stratification could be detected using 218 AIMs for European Americans. 8 mtSNPs were significantly associated with UC but only A10550G in MT-ND4L would survive Bonferroni correction (Punadj=1.40E-07, ORG[95%CI]=4.52[2.46-8.30], 10550G allele: 8.1% of patients and 1.9% of controls). A10550G was equally associated in pairwise conditional analyses with the top GWAS SNPs (7.55E-07<Pcond,unadj<4.42E-06), suggesting that it constitutes an independent risk factor from nuclear-encoded susceptibility loci. Haplogroup K (Punadj=2.76E-02, OR[95%CI]=1.56[1.05-2.32]) and its K1 subcluster (Punadj=2.10E-02, OR[95%CI]=1.65[1.07-2.55]) increase risk for UC while the U5b lineage confers protection against UC (Punadj=2.41E-02, OR[95%CI]=0.40[0.17-0.91]), in accordance to its defining A7768G mtSNP (Punadj=1.50E-02, ORG[95%CI]=0.35[0.14-0.84]).
Conclusion: These results suggest that UC has a dual genetic control (mitochondrial and nuclear) that warrants further replication in independent datasets and reinforces its ethiopathogenic complexity.

Utilization of the diagnostic assay Multiplicom CFTR MASTR™ for cystic fibrosis genotyping.

L. Dvorakova, *N. Ptakova, M. Libik, A. Holubova, M. Macek jr., M. Macek sr.; Department of Biology and Medical Genetics, 2nd Faculty of Medicine of Charles University and University Hospital Motol, Prague, Czech Republic.*

Cystic fibrosis (CF) screening for population specific panels and large gene rearrangements has improved identification of majority of CF alleles. However, unsolved cases remain making genetic counselling difficult, particularly when the diagnosis is uncertain. Our diagnostic laboratory, involved in cystic fibrosis testing, is currently implementing NGS strategy as method of choice for fast screening of known mutations as well as resequencing of the CFTR gene. The aim of this study was to compare a NGS workflow and Sanger sequencing for specific resequencing of the coding and flanking intron regions of CFTR. We describe a pilot study comprising 8 samples being pre-characterized by Sanger than resequenced using a Multiplicom multiplexing assay for the CFTR gene, and subsequent NGS with MiSeq (Illumina). Data averages in 98% aligned reads, with all exons (except 3 and16) were covered with the mean read depth 1000x. Alternative allele variant frequency was on average 50% and we didn´t detect any mosaic forms of mutations. Within the regions covered by MiSeq-reads, all anticipated variants were detected. In exon 24 we found novel mutation c.4272C>A which has not been detected by Sanger DNA sequencing. Variant calling was performed applying Illumina Variant Studio. Resequencing of the entire coding sequence with NGS platform MiSeq/Illumina increases the sensitivity of mutation detection and is cost effective, especially when samples are multiplexed. Our experience indicates that NGS could be used in routine diagnostics of CF negative for commonly utilised assays.

Different types of mutations are responsible for expression of CAKUT phenotype in Bulgarian population

V. M. Penchev[1], *A. Boueva*[2], *G. Zlatanova*[2], *T. Gencheva*[1], *V. Mitev*[1], *R. Kaneva*[1], *O. Beltcheva*[1];

[1]Molecular Medicine Center, Medical University of Sofia, Sofia, Bulgaria, [2]Universital Pediatrics Hospital, Pediatric Nephrology and Hemodialysis Clinics, Sofia, Bulgaria.

Congenital anomalies of kidney and urinary tract (CAKUT) are the leading cause of end stage renal disease in children. They affect 1 in 500 live births and range from renal agenesis, to hypodysplasia, multicystic kidneys, duplex renal collecting system, megaureter, vesicoureteral reflux (VUR), etc. CAKUT may occur in isolation or as a part of syndrome accompanied by non-renal manifestations.

In the present study we performed the largest investigation for molecular pathologies identification in Bulgarian families with CAKUT. A total of 62 patients from 57 families were subjected to genetic testing. In the non-syndromic cases, TCF2, PAX2, SALL1, EYA1 and SIX1 genes were screened for mutations by Sanger sequencing and MLPA. In the CAKUT cases with complex pathological phenotype an array Comparative Genomic Hybridization (aCGH) was applied for detection of different chromosomal defects.

Various novel and known pathogenic mutations were found in a number of families such as missense variants and insertions in TCF2 and SALL1, partial or whole gene deletions affecting TCF2 and LPP, as well as chromosomal aberrations involving the 6p25 locus, the CFHR gene cluster and the entire chromosome 8. These defects explain the pathology in 11.5% of the families. Additional analysis are required for elucidating the genetic cause of CAKUT in the remaining cases.

The present study was funded under grants: DUNK01/2/2009; DMU 03/73/2011; MU 57/2014 and MU 18D/2014.

FBN1 gene analysis in suspected Marfan syndrome patients using a combined molecular genetic workflow

I. Balogh[1], *V. Majoros[1], L. Madar[1], E. Olah[2], K. Szakszon[2], G. P. Szabo[2], G. Pfliegler[3], K. Koczok[1];*

[1]University of Debrecen, Faculty of Medicine, Department of Laboratory Medicine, Division of Clinical Genetics, Debrecen, Hungary, [2]University of Debrecen, Faculty of Medicine, Department of Pediatrics, Debrecen, Hungary, [3]University of Debrecen, Faculty of Medicine, Department of Internal Medicine, Debrecen, Hungary.

Marfan syndrome is an autosomal dominant connective tissue disorder. Early establishment of the diagnosis is important because of severe cardiovascular complications of the disease. Sequencing of the fibrillin-1 (FBN1) gene has a 70-90% clinical sensitivity in patients with Marfan syndrome. We developed a rapid and reliable diagnostic workflow for FBN1 gene analysis by combining Sanger and next generation sequencing (NGS) methods.

Exons and flanking regions of the FBN1 gene were amplified in 65 amplicons. Homopolymer-containing exons (n=16) were sequenced using Sanger technology while all other amplicons were sequenced using NGS (Roche GS Junior), where coverage criteria was above 40x. Pathogenic mutations detected by NGS method were confirmed by Sanger sequencing.

Twenty-three families were tested. Marfan syndrome was confirmed in 10/23 unrelated patients. Eight missense and two small scale deletion/duplication mutations were detected among which six were novel alterations (c.5196delC, c.2585G>A, c.6032G>C, c.3038G>T, c.2288G>A and c.2272_2275dupTCAA). Combining NGS and Sanger sequencing methods we could establish reliable FBN1 gene analysis for Marfan syndrome diagnostics.

This study was supported by the Hungarian Research Fund (K109076, I.B.).

Worldwide recurrent missense mutation of the PTPN11 gene in a Hungarian patient with LEOPARD syndrome

K. Farkas[1], *N. Nagy[2,1,3], E. Nemes[4], F. Lakatos[4], M. Széll[5,1];*

[1]MTA SZTE Dermatological Research Group, University of Szeged, Szeged, Hungary, [2]University of Szeged, Dept of Medical Genetics, Szeged, Hungary, [3]Department of Dermatology and Allergology, University of Szeged, Szeged, Hungary, [4]Hospital of Orosháza, Orosháza, Hungary, [5]Department of Medical Genetics, University of Szeged, Szeged, Hungary.

LEOPARD syndrome (LS, OMIM 151100) is a rare monogenic disease. Its name is an acronym for the major features of this disease including multiple lentigenes, electrocardiographic conduction defects, ocular hypertelorism, pulmonary stenosis, genital abnormalities, growth retardation and sensorineural deafness. LS develops due to mutations in the protein-tyrosine phosphatase nonreceptor-type 11 (PTPN11) gene. Recently, we have identified a 51-year-old Hungarian man with LS. Direct sequencing of the PTPN11 gene revealed a worldwide recurrent missense mutation (c.836A/G; p.Tyr279Cys) in the PTPN11 gene. The detailed description of the Hungarian patient and the review of the previous studies reporting the same mutation are presented in this study. Elucidation of the genotype-phenotype correlations may promote the understanding of the mechanism and may contribute to the development of future therapeutic modalities.

J04.03

Novel mutations in two Hungarian sisters with oculocutaneous albinism type IV and reviewing the literature

N. Nagy[1,2,3], *K. Farkas[3], L. Tóth[1], B. Fabos[4], M. Széll[1,3];*

[1]University of Szeged, Dept of Medical Genetics, Szeged, Hungary, [2]University of Szeged, Dept of Dermatology and Allergology, Szeged, Hungary, [3]MTA SZTE Dermatological Research Group, University of Szeged, Szeged, Hungary, [4]Mór Kaposi Teaching Hospital, Kaposvár, Hungary.

Oculocutaneous albinism is a group of rare monogenic diseases characterized by decreased or absent pigmentation in the hair, skin and eyes. Due to the abnormalities of the pigmentation, the affected patient may suffer from photosensitivity and develop cancers of the skin. In addition to the variety clinical symptoms, the genetic background of this group of diseases is also heterogenic. In this study, two Hungarian sisters affected by oculocutaneous albinism were investigated. The clinical symptoms of the patients suggested the presence of the OCA type 2 or type 4 variant, therefore direct sequencing of the P and SLC45A2 genes were performed. Our results revealed two novel heterozygous mutations in the SLC45A2 gene: a missense mutation in exon 6 (c.1226G/A, p.Gly411Asp) and a nonsense mutation in exon 7 (c.1459C/T, p.Gln437X). Both patients are in compound heterozygous state and carry both mutations. The detailed description of the Hungarian patients and the review of the previously published mutations are presented in this study. Elucidation of the genotype-phenotype correlations may promote the understanding of the mechanism and may contribute to the development of future therapeutic modalities.

Study of FBLN5 and LOXL1 genetic variations in association with pelvic organ prolapse taking into account levator trauma and parity

M. B. Khadzhieva[1], *S. V. Kamoeva[2], S. K. Abilev[1], L. E. Salnikova[1];*

[1]N.I. Vavilov Institute of General Genetics, Russian Academy of Sciences, Moscow, Russian Federation, [2]Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Pelvic organ prolapse (POP) is a common urogynecological disease with a strong hereditary component. Traumatic and multiple childbirths may cause damage of pelvic ligaments and overdistention of the vagina and thereby increase the risk of POP developing. The proteins fibulin-5 (FBLN5) and lysyloxidase 1 (LOXL1) involved in elastic fiber synthesis and connection play an important role in POP development.

We analyzed the association of polymorphic variants in the genes of *FBLN5* and *LOXL1* with POP taking into consideration traumatic childbirths and parity. Groups under study included 210 females with POP and 291 matched controls. HaploView resource was used to select a set of "tag" SNPs. Nine *FBLN5* SNPs and three *LOXL1* SNPs were genotyped using the PCR reaction with confronting two-pair primers. After the stratification of the sample, we found the association of some alleles of *FBLN5* and *LOXL1* genes with POP in the groups with perineal trauma and ≥ 2 childbirths (Table 1). These data may be used to identify risk groups for POP development.

This work was supported by RFBR (grant 15-04-02378).

A search for genetic susceptibility marker to osteoarthritis in women with connective tissue dysplasia

A. Tyurin[1], *R. Khusainova[2], R. Davletshin[1], E. Khusnutdinova[2];*

[1]Bashkir state medical Univercity, Ufa, Russian Federation, [2]Institute of Biochemistry and Genetics, Ufa, Russian Federation.

The study of polymorphisms rs2228570 (s.2T/A/C/G, Met1Lys/Arg/Thr; FokI, rs10735810), rs1544410 (c.1024+283G>A; BsmI), rs7975232 (c.1025-49G>T, ApaI), rs731236 (c.1056T>C, TaqI) receptor gene of vitamin

D (VDR), was held in women suffering from osteoarthritis (OA) and showing signs of connective tissue dysplasia (CTD). The material for the study were DNA samples of 255 women aged from 23 to 61 years, mean age 51,4 ± 2,2 years. OA was diagnosed according to the criteria of the American Association of Rheumatology (1995). Availability CTD evaluated clinically using phenotypic table by TI Kadurina.
Significant influence of polymorphisms rs1544410 (c.1024+283G>A; BsmI) and rs7975232 (c.1025-49G>T, ApaI) VDR gene in the development of both OA and DST alone or with a combination of these pathological conditions was found. The largest contribution to the increase in the risk of developing OA and DST makes allele *G and genotype *G*G of BsmI locus. Genotype *A*A BsmI locus is a marker of reduced risk of CTD. Genotype *G*T ApaI locus increases risk of OA with CTD. Genotype *T*T locus ApaI is a marker of reduced risk of CTD as a whole, as well as the development of comorbidity. *CGG haplotype BsmI, ApaI, TaqI loci associated with an increased risk of connective tissue dysplasia, haplotype *CTA reduces the risk of comorbidity.

J04.06
Novel RUNX2 splicing mutation in a patient with cleidocranial dysplasia

F. Liska, *B. Chylikova, P. Martasek, A. Baxova;*
Charles University in Prague, Praha, Czech Republic.

Introduction: Cleidocranial dysplasia (CCD) is a rare autosomal dominant disorder caused by haploinsufficiency of Runt-related transcription factor RUNX2, which affects osteoblast function during endesmal osssification (and other processes), leading to clavicle hypo(a)plasia, persistent skull sutures, dental anomalies and other problems. In a patient with clinical diagnosis of CCD, we searched for the causal mutation in RUNX2.
Materials and Methods: All 9 exons of RUNX2 (longest isoform, NM_001024630.3) were amplified by PCR from genomic DNA isolated from peripheral blood and subjected to Sanger sequencing. For splicing detection, peripheral blood RNA was reversely transcribed and amplified with primers spanning exons 4-6.
Results: Patient is a 42 year old female diagnosed during childhood with CCD for bilateral aplasia of clavicles, impaired skull ossification, persistence of deciduous teeth, flatfoot and hip dysplasia. Sequencing of genomic DNA revealed G->A substitution at postition +5 in intron 5, not listed in dbSNP. Splicing prediction by three different tools showed modest drop in score, so we tested actual splicing by RT-PCR. Exon 5 was skipped in about 30% of transcripts, regarded to be enough to cause pathology. Interestingly, skipping exon 5 (105bp) does not lead to a frameshift. The resulting protein lacking part of the Runt domain and a nuclear localization signal may be therefore translated and may potentially represent a dominant negative.
Conclusion: In a patient with typical cleidocranial syndrome manifestation, a novel splicing variant was found in intron 5 donor splice site.
Supported by Charles University in Prague, Czech Republic (PRVOUK P24/LF1/3).

Rare case of skeletal dysplasia - multicentric carpotarsal osteolysis (MCTO) caused by MAFB gene mutation.

R. Smigiel[1], *M. Bloch*[2], *A. Prusek-Dutkiewicz*[3], *M. M. Sasiadek*[1];
[1]*Genetic Department Wroclaw Medical University, Poland, Wroclaw, Poland,*
[2]*Department of Social Pediatrics Wroclaw Medical University, Poland, Wroclaw, Poland,*
[3]*Regional Specialized Hospital, Wroclaw, Poland.*

Multicentric Carpotarsal Osteolysis (MCTO) is a rare type of skeletal dysplasia characterized by progressive osteolysis, affecting the carpal and tarsal bones and is frequently associated with renal failure (OMIM 166300). MCTO is monogenetic autosomal dominant disease caused by MAFB gene mutation.
We report 10-years old boy with MCTO diagnosed by sequencing of MAFB gene. Patient was born in the proper delivery time in a good condition, no developmental abnormality was noticed. When the boy was 2 years old he started to limp. When he was 4 he suffered while walking, his ankles and wrists were swollen. Juvenile rheumatoid arthritis was suspected. After some time, he could walk only on his heels. Besides the chronic renal failure was diagnosed. Moreover, intellectual disability type border-line is observed. In the tests of bones symptoms of osteoporosis and osteopenia and destruction of metaphyses structure was diagnosed. Dysmorphic facial features such as: small face, a slim nose, long eyelashes, maxillary hypoplasia, small mouth and thorax dysmorphism (slopping shoulders, narrow and carinatum thorax) and muscle weakness and atrophy of upper and lower extremities were also observed.
After clinical diagnosis of MCTO, MAFB gene mutation screening was performed by direct sequencing. Pathogenic de novo mutation (Pro59Leu) was revealed.
MCTO is progressive disease affecting skeletal system and kidneys. MCTO is usually presenting in early childhood with a clinical picture mimicking juvenile rheumatoid arthritis. Differential diagnosis of patients with coexistence of joints and renal problems should include MCTO as one of possible cause.

J04.08
Ectrodactyly and Ectodermal Dysplasia without cleft lip/plate: a case report

M. R. Pizzino[1], *I. Loddo*[1], *C. Liuzzo*[1], *M. Priolo*[2], *E. Gitto*[3], *E. Cusumano*[3], *L. Marseglia*[3], *M. C. Cutrupi*[1], *M. I. S. Crapanzano*[1], *S. Briuglia*[1];
[1]*UOC Genetics and Pediatric Immunology, University of Messina, Messina, Italy,* [2]*UOC Medical Genetics, AO Bianchi-Melacrino-Morelli, Reggio Calabria, Italy,* [3]*UOC Neonatal Intensive Care, University of Messina, Messina, Italy.*

Ectrodactyly or Split hand/foot malformation (SHFM), may occur either as an isolated malformation or coexists with other congenital anomalies (cleft lip/palate, ectodermal dysplasia or developmental delay/mental retardation). There are several relatively frequent syndromes in which ectrodactyly occurs as one of the multiple congenital anomalies. The most common involve EEC syndrome (Ectrodactyly, Ectodermal dysplasia, Cleft lip/palate syndrome) and EEC syndrome without cleft lip/palate.
We describe this rare disorder in a boy, who had ectrodactyly and ectodermal dysplasia, without cleft lips/palate. He is the only child of healthy nonconsanguineous parents. Pregnancy was complicated by threatened miscarriage and oligohydramnios and he was born full term. Birth weight was 2.300 kg. At birth he showed multiple morphologic abnormalities: ectrodactyly with agenesis of the third and forth ray and metacarpus in the right hand, agenesis of the third ray in the left hand, soft tissue syndactyly and median cleft in both hands, nail alterations to the toes, right preauricular appendix, sparse and thin hairs and eyebrows, xerosis with diffuse lamellar desquamation at the back, perineal hyperemia with disepithelization areas, agenesis of left kidney, cryptorchidism, micropenis, ostium secundum atrial septal defect. At 7 months of age his weight was 5.850 kg (<5°P), length 61.5 cm (<5°P) and presented psychomotor delay. Hair analysis showed: "Trichorrhexis nodosa, Pili trianguli et canaliculi, Trichoschisis". Karyotype analysis, Array-CGH and molecular analysis of TP63 gene were normal. We planned to perform molecular analysis of other genes involved, such as WNT10B and DLX5, to identify the molecular basis of this form of SHFM.

Molecular characterization of the natural occurring SERPINH1 Dachshund model of Osteogenesis imperfecta

U. Lindert[1], *M. Weiss*[2], *D. Eyre*[2], *F. Seeliger*[3], *I. Hausser*[4], *T. Leeb*[5], *M. Rohrbach*[1], *C. Giunta*[1];
[1]*Division of Metabolism, Connective Tissue Unit, University Children's Hospital, Zurich, Switzerland,* [2]*Department of Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, United States,* [3]*AstraZeneca R&D, Södertälje, Sweden,* [4]*4Electron Microscopic Laboratory, Dermatological Department and EM Core Facility, University of Heidelberg, Heidelberg, Germany,* [5]*Institute of Genetics, University of Bern, Bern, Switzerland.*

Osteogenesis imperfecta (OI) is a heritable connective tissue disease characterized by increased bone fragility, fractures and deformities of the skeleton. Mutations in at least sixteen genes have been associated with dominant and recessive forms of OI. SERPINH1 encoding the ER collagen chaperone HSP47 was identified to cause a severe form of OI in Dachshunds (Leu326Pro) and in one human patient.
To elucidate the disease mechanism underlying OI in the dog model, we applied a range of biochemical assays to mutant and control skin fibroblasts as well as on bone samples.
Type I collagen synthesized by mutant cells had decreased electrophoretic mobility. Procollagen was retained intracellularly with concomitant dilation of ER cisternae and activation of the ER stress response marker GRP78. In line with the migration shift detected on SDS-PAGE of cell culture collagen, extracts of bone collagen from the OI-dog showed a similar mobility shift and on tandem mass spectrometry the chains were post-translationally overmodified. The bone collagen had a higher content of pyridinoline than control dog bone.
The SERPINH1 mutation in this naturally occurring model of OI impairs how HSP47 acts as a chaperone in the ER. This results in abnormal post-translational modification and cross-linking of the bone collagen.

Testing the association between rs689, rs680, rs3767140, rs1800469 polymorphisms and the 2d:4d ratio in diabetic patients

A. Tudor[1], *C. Cristescu*[2], *M. Niculescu*[3], *A. Craciun*[4], *D. Stefan*[4], *C. Serafinceanu*[4], *A. Alexiu*[1], *S. Spandole*[1], *D. Cimponeriu*[1];
[1]*University of Bucharest, Bucharest, Romania,* [2]*Titu Maiorescu University, School of Medicine and Pharmacy, Bucharest, Romania,* [3]*2Titu Maiorescu University, School of Medicine and Pharmacy, Bucharest, Romania,* [4]*NIDNMD N. Paulescu, Bucharest, Romania.*

Introduction: The 2d:4d ratio was considered a multifactorial trait, showing sexual dimorphism. In men the 2nd finger is shorter than the 4th finger, whereas in women the two fingers have approximately the same length. Insulin, IGF2, TGFb and HSPG gene products are involved in body growth, development and shaping, mainly during fetal development. Patients with diabetes present altered microcirculation and impaired matrix and bone mineral density. The aim of this study was to test the association between rs689, rs680, rs3767140, rs1800469 polymorphisms and the2d:4d ratio in patients with T1DM, T2DM and control subjects.
Materials and Methods: The study involved 320 individuals distributed into 4 groups: T1DM (80 patients with T1DM; 25,9 ± 4,1 years), HC1 (80 clinically and paraclinically healthy subjects, 26.4 ± 3.9 years),T2DM (80 patients with T2DM; 54,7 ± 3,3 years), HC2 (80 clinically and paraclinically healthy subjects, 53.6 ± 3.4 years). The two sexes were similarly distributed within the groups. Finger length was measured using digital callipers. Blood from each subject was collected and used for DNA extraction (Wizard®Genomic DNA Purification Kit), that was later used for polymorphisms genotyping, by PCR-based methods.
Results: The AA genotype of the rs689 polymorphism was strongly associated with T1DM (AA OR = 4.26; p <0.0001). The 2d:4d ratio was associated only with gender in T1DM and HC1 lots (p= 0.0001). This ratio was associated only with rs680 în T2DM and HC2 lots (p= 0.001).
Conclusions: The 2d:4d ratio was significantly associated with gender in T1DM patients and control subjects, and with IGF2 Apa polymorphism in T2DM patients.

A Recessive Skeletal Dysplasia, Novel Type, Results from a Mutation of NEK1 (Never in Mitosis Gene A-Related Kinase 1)

S. T. Bozdogan[1], *E. Karaca*[2], *O. O. Yuregir*[3], *H. Aslan*[4], *D. Pehlivan*[2], *O. Sezer*[5], *Y. Bayram*[2], *S. N. Jhangiani*[6], *M. M. Atik*[2], *T. Gambin*[2], *A. Bisgin*[7], *R. A. Gibbs*[6], *J. R. Lupski*[2];
[1]*Mersin University, Medical Faculty, Dept. of Medical Genetics, Mersin, Turkey,* [2]*Baylor College of Medicine, Dept. of Molecular&Human Genetics, Houston, TX, United States,* [3]*Genetics Diagnosis Center, Adana Numune Training and Research Hospital, Adana, Turkey,* [4]*Eskişehir Osmangazi University, Medical Faculty, Dept. of Medical Genetics, Eskisehir, Turkey,* [5]*Samsun Training and Research Hospital, Dept. of Medical Genetics, Samsun, Turkey,* [6]*Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, United States,* [7]*Cukurova University, Faculty of Medicine, Medical Genetics Dept. of Balcali Clinics and Hospital, Adana, Turkey.*

Introduction: This study is the analysis of a nuclear consanguineal family with two affected (13 year old girl and a 7 year old boy) and one 3 month old boy with similar clinical features identified an autosomal-recessive form of skeletal dysplasia. There were no other cardiological and abdominal assessment findings. On the basis of the clinical features and laboratory findings, we performed whole-exome sequencing for one subject.
Materials and Methods: Two affected children were characterized by dysmorphological findings as narrow forehead, hypertelorism, pectus excavatum, prominent eyes. There were unique constellation of radiographic findings including biconcave vertebrae, coxa vara, enlarged humerus diaphysis and femur metaphysis in both affected children that the boy had more severe features. Chromosomal analysis revealed normal karyotypes. Furthermore, we performed whole-exome sequencing for one subject and identified a novel mutation (c.3630+1G>C and c.G3498T:p.K1166N) in the NEK1 (Never in Mitosis Gene A-Related Kinase 1, OMIM *604588) gene. We have confirmed this homozygous mutation in other affected children; where as, the heterozygous mutation cosegregated with other family members.
Conclusion: NEK1 (Never in Mitosis Gene A-Related Kinase 1) gene is located on 4q33 that encodes a protein kinase and its‘ defects cause short rib-polydactyly syndrome type 2. According to the findings, we have suggested that this is a new type skeletal dysplasia, indicating autosomal recessive inheritance.

Case presentation: A one year old girl with the diagnosis of Cutis Laxa syndrome

S. Akbaroghli[1,2], *A. Kariminejad*[3], *M. Mansouri*[1,2], *S. Tonekaboni*[1,2];
[1]*Mofid Children's Hospital, Tehran, Iran, Islamic Republic of,* [2]*Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [3]*Kariminejad & Najmabadi Pathology and Genetics Center, Tehran, Iran, Islamic Republic of.*

• A one year old girl with respiratory distress, tachypnea, cough, fever, coarse crackles, hypotonia and developmental delay. She was the consequence of first cousins marriage. She had a healthy older brother. Her clinical manifestations were: H.C = 41.5 cm, length= 69 cm, weight: 6200, deep set eyes, brachycephaly, mild mid face hypoplasia, micrognathia, long eyelashes, frontal bossing, hyperextensible joints (joint hyperlaxity), flexion deformities in hands (fingers) and wrists, hypotonia, transverse palmar crease, umbilical hernia, cranial sutures overriding, soft and doughy skin, cutis laxa, easy bruising, mongolian spot (right flank), short neck, wide nipples. Her paraclinical findings were: normal echocardiography, normal brain MRI, normal metabolic screening.
The differential diagnoses for this patient were:
1. Ehler Danlos Syndrome (Dermatosparaxis type, AR)
2. The Collagen related Myopathies such as Ullrich Congenital Muscular Dystrophy (AR)
3. Inherited Cutis Laxa (AR)
The result of molecular study for the most probable diagnosis (Cutis Laxa) was positive and she was homozygote for mutation in PYCR1 gene.

J04.13

Two DMP1 synonymous mutations in a Malaysian hypophosphatemic rickets patient

N. N. RAZALI, *T. H. TING, K. THILAKAVATHY;*
UNIVERSITI PUTRA MALAYSIA, SELANGOR, Malaysia.

Hypophosphatemic rickets (HR) is a rare disorder of bone mineralization due to defective phosphate reabsorption in the renal tubules. *PHEX*, *FGF23* and *DMP1* are the associated genes of familial HR that contribute to X-linked dominant, autosomal dominant and autosomal recessive HR, respectively. This study is aimed to identify the underlying genetic mutation in a four-year-old girl who manifested clinical features of HR and affirmed by biochemical tests and radiological analysis. Her parents did not show any clinical symptoms of HR. Mutational analyses of *PHEX*, *FGF23* and *DMP1* were carried out by polymerase chain reaction and direct sequencing of coding exons and flanking intronic regions. No mutations were found in *PHEX* and *FGF23*. However, synonymous mutations were found in the patient at two different locations of exon 6 in *DMP1*; c.1322C>T, and c.1334G>A. These mutations did not change the amino acids; S406S and E410E, respectively. RNAfold, a software that predicts the secondary structure of RNA, foretells that these synonymous mutations affect the secondary structure of mRNA, resulting in lower stability and translation efficiency. The presence of two synonymous mutations in exon 6 of *DMP1* is possibly the cause of this disorder in the child. Genetic testing for HR patients is necessary for correct early diagnosis, treatment intervention, counseling and to help improve patient clinical care and management.

J04.14

The study of *IL1A* gene polymorphisms as risk factors for Psoriatic Arthritis in Romanian population

O. M. Popa[1], *M. Cherciu*[1], *M. I. Dutescu*[2], *M. Bojinca*[1], *T. Mazdrag*[1], *C. Bara*[1], *L. O. Popa*[3];
[1]*University of Medicine anf Pharmacy ,Carol Davila', Bucharest, Romania,* [2]*"Prof. Dr. C. T. Nicolau" National Institute of Blood Transfusion, Bucharest, Romania,* [3]*Grigore Antipa National Museum of Natural History, Bucharest, Romania.*

Introduction. Psoriatic arthritis (PsA) is a chronic disorder characterized by skin psoriasis and the inflammation of the peripheral joints and/or spine. PsA belongs to the group of spondyloarthritides and shows strong association with SNPs in the major histocompatibility complex region, but genes outside this region have also been implicated in disease pathogenesis. Interleukin 1 alpha (IL-1α) is a proinflammatory cytokine involved in the regulation of immune responses and inflammatory processes.
Genetic variations of IL1 locus have been associated with the risk of spondyloarthritides.Our aim was to investigate two IL1A gene SNPs for association with PsA.Materials and methods. The study included 97 PsA patients and 160 healthy unrelated controls, all of Romanian origin. The two SNPs of IL1A gene rs1800587 (-889C>T) and rs17561 (Ser114Ala) were genotyped by TaqMan Allelic Discrimination Assay (7300 Real time PCR System, Applied Biosystems, USA). Alleles, genotypes and haplotypes frequencies were compared using the software PLINK v 1.07 and p values ≤0.05 were considered significant. Results. There was no statistically significant difference in allelic, genotypic or haplotypic frequency distribution between cases and controls. We also tested whether the investigated SNPs were associated with clinical features, but no significant differences were detected. Conclusions. Our results suggest that the two IL1A gene markers do not influence the risk of PsA

in Romanian population. However, the number of individuals analysed could be insufficient to evaluate small genetic effects. Additional studies with enlarged sample size are needed to clarify the role of IL1A polymorphisms in PsA.Grant support: SOP HRD/159/1.5/S/135760

Pycnodysostosis : Report of three Tunisian cases

M. Trabelsi, *F. Maazoul, L. Kraoua, R. Meddeb, I. Ouertani, R. Mrad;*
Service des maladies congénitales et héréditaires, EPS Charles Nicolle, tunis, Tunisia.

Pycnodysostosis is an autosomal recessive lysosomal disorder due to CTSK gene (1q21) mutations. This rare skeletal dysplasia is characterized by short stature, acroosteolysis of distal phalanges and frequent fractures due to bone fragility. Cranio-facial dysmorphy including a delayed suture closure with open anterior fontanelle, an exophthalmia, a prominent nose, an obtuse angle mandible and dental anomalies is commonly noted.
In this report, we describe the clinical and radiological features of three Tunisian patients (one familial and one sporadic case) with pycnodysostosis.
These patients were referred to the authors' department for evaluation of a short stature and a facial dysmorphy.
All were girls, born from consanguineous parents and their ages ranged from 9 to 12 years. The eldest of two sisters had, at the age of 9, a fracture of the right tibia which occurred after a trivial injury. All of our patients had normal psychomotor development and were normally schooled.
The clinical examination revealed a height between -4 and -5 SD, short and stubby fingers, and dysmorphic features including frontal bossing (3/3), open anterior fontanelle (3/3), exophtalmia (3/3), a prominent nose (3/3), hypoplasia of the mandible (3/3), malapposed teeth (2/3) and narrow palate (1/3).
Skull and hands radiographies showed open sutures and acroosteolysis of terminal phalanges, respectively.
These clinical and radiologic features enabled us to retain the diagnosis of pycnodysostosis and consequently to offer an appropriate genetic counseling and an adequate orthopedic and stomatologic follow up. However, CTSK gene analysis should also be realized in order to determine the molecular profile of Tunisian patients with pycnodysostosis.

Polymorphism rs 3134069 OPG gene in postmenopausal women with osteoporosis

M. Mydlárová Blaščáková[1], *J. Poráčová[1], L. Blaščáková[2], J. Bernasovská[1], I. Boroňová[1], E. Petrejčíková[1];*
[1]Presov University in Presov, Faculty of Humanities and Natural Sciences, Department of Biology, Presov, Slovakia, [2]Pavol Jozef Šafárik University in Košice, Faculty of Science, Department of Biophysics, Košice, Slovakia.

Introduction: Osteoporosis is a common disease that is characterized by low bone mineral density (BMD), deterioration in bone microarchitecture, and increased fracture risk.
Materials and Methods: The aim of this study was to find distribution of genotypes of polymorphisms T245G (rs3134069) OPG gen in control group of postmenopausal women (n=104) and in osteoporotic group of postmenopausal women (n=105). Genomic DNA was isolated from leucocytes of peripheral blood using standard methods. Genotyping was realized by TaqMan SNP genotyping assay (Applied Biossystem) on basis of standard protocol. Fluorescence was detected by Real-Time PCR method using apparatus StepOne™ Real-Time PCR System.
Results: Distribution of surveyed genotypes in osteoporotic group was: TT (80,00%), TG (20,00%), GG (0,00%). Distribution of genotypes in control group was: TT (85,58%), TG (13,46%), GG (0,96%). Statistical significance between behalf of genotypes of control and osteoporotic group was not found.
Conclusion: Molecular-genetic research represents the best way in order to create complex view over genetic conditionality of osteoporosis.
Acknowledgement: The thesis was furthered by Agency of Ministry of Education, Science, Research and Sport SR, project ITMS:26110230100.

Autosomal recessive congenital ichthyoses in the Czech Republic

L. Fajkusova[1,2], *R. Borska[1], H. Noskova[1], L. Kopeckova[1], P. Silerova[1], H. Buckova[3], J. Kyrova[4], R. Gaillyova[5], J. Nemeckova[5];*
[1]Centre of Molecular Biology and Gene Therapy, University Hospital Brno, Brno, Czech Republic, [2]Central European Institute of Technology, Masaryk University, Brno, Czech Republic, [3]Pediatric Clinic, University Hospital Brno, Brno, Czech Republic, [4]Pediatrc Clinic, University Hospital Brno, Brno, Czech Republic, [5]Department of Medical Genetics, University Hospital Brno, Brno, Czech Republic.

Introduction: Autosomal recessive congenital ichthyosis (ARCI) is a heterogeneous group of disorders of epidermal cornification caused by mutations in one of at least nine genes. Methods: ARCI families presenting at our laboratory over a period of 3 years were assessed using PCR-direct sequencing and/or Sequence Capture and Targeted Resequencing. The genetic results were complemented by analysis of missense mutations using homology modelling on the basis of known 3D protein structures.
Results: The genetic analyses were performed in 34 Czech ARCI probands: 11 patients carry mutations in ALOX12B, 6 patients in ALOXE3, 6 patients in NIPAL4, 4 patients in CYP4F22, 3 patients in TGM1, 1 patient in ABCA12, and 3 patients are without causal mutations despite that all known genes up to now associated with ARCI were analysed. Totally, mutations were identified in 31 patients (91.2%). In silico analysis of missense mutations in ALOX12B, ALOXE3, and TGM1 genes revealed various structural defects while no defects were associated with known polymorphisms.
Conclusions: Besides identification of the spectra of mutations in Czech EB patients, the study present new method implemented into genetic diagnostics of genodermatoses in the Czech Republic - sequence capture and targeted resequencing - that provides more complete diagnosis than a classical gene-by-gene approach. Parallel analysis of known genes in a patient (or in multiple patients) enables fast and cost-effective identification of gene mutations.
Currently, we are able to perform analysis of 81 genes associated with different inherited skin disorders.
The work was supported by the project IGA MZČR NT14585-3 and TAČR TE02000058.

Molecular genetic analysis of Fibrodysplasia ossificans progressiva in Russian patients.

A. L. Chukhrova, **I. G. Sermyagina**, *A. V. Polyakov;*
Research Centre for Medical Genetics, Moscow, Russian Federation.

Fibrodysplasia ossificans progressiva (FOP, MIM 135100) is a rare disease with autosomal dominant inheritance, characterized by genetically determined ossification of the connective tissue of muscles, fascia and tendons different localization. FOP different progressive course, leads to significant violations of the functional state of the musculoskeletal system, profound disability of patients, up to complete immobilization. Attempts to surgical removal of ossification cause new recurrence of the pathological process.
ACVR1 mutations responsible for the development of FOP. This gene localized in the locus 2q23-q24. In the laboratory our Center is searched ACVR1 gene mutations in patients with FOP by direct analysis of DNA sequencing of all exons and exon-intron junctions. 37 patients were examined. Found 13 mutations. In 11 cases revealed the most common mutation c.617G>A (p.Arg206His). In two other cases found mutations c.619C> G (p.Gln207Glu) in exon 7 and c.1067G>A (p.Gly356Asp) in exon 10 of the gene ACVR1. The investigations of this gene are in progress now.

J04.19
Unbalanced translocation associated with acrania in two subsequent pregnancies

E. Hlavova, *D. Smetanova, M. Hynek, M. Dolezal, J. Horacek, N. Jencikova, M. Trkova, V. Becvarova;*
GENNET s.r.o., Praha 7, Czech Republic.

Objectives: The aetiology of NTDs is heterogeneous.
Method: Ultrasound evaluation, karyotype analysis, SNP array (Illumina), IVF with PGD, IUI with donor sperm
Results: 25-year-old primigravida in 2010 with high level of MSAFP and ultrasound finding of acrania in the 16th week of pregnancy. Amniocentesis was performed with abnormal karyotype 46,XY,add(1)(p 36). Subsequent parental karyotype analysis revealed paternal balanced translocation 46,XY,t(1;3)(p36.3.;p24.2) de novo. In 2011 the second spontaneous pregnancy was checked in the 12th week by ultrasound and a fetus with acrania was detected again. We went on with SNP array analysis. The result was the deletion of 3Mb in the region 1p36.33- p36.32 and the duplication of 22.6Mb in the region 3p26.3-p24.3. It meant an involvement of great amount of genes with different functions. Then in 2012 the couple decided to undergo IVF with PGD. Based on this treatment, 5 embryos were created, all were unbalanced. The subsequent pregnancy in 2012/2013 was performed by IUI with a donor sperm, without any invasive investigation, which led to a successful birth of a healthy boy.
Conclusions: Despite the implementation of new genetic technologies, our family delivered a healthy child only due to a donor sperm. A key role for the detection of a fetus with acrania is the first trimester ultrasound examinati-

on. Later detection includes a high level of MSAFP in the second trimester.

J04.20
N- terminal region of human low-molecular weight salivary mucin gene (MUC7) N80K polymorphism may be a biomarker for dental caries.

L. Koc Ozturk[1], *K. Ulucan*[2], *A. Yarat*[1], *S. Akyuz*[3], *H. Furuncuoglu*[3];
[1]*Marmara University, Faculty of Dentistry, Department of Biochemistry, Istanbul, Turkey,* [2]*Marmara University, Faculty of Dentistry, Department of Medical Biology and Genetics, Istanbul, Turkey,* [3]*Marmara University, Faculty of Dentistry, Department of Pedodontology, Istanbul, Turkey.*

Purpose: Human low- molecular- weight salivary mucin (MUC7), also known as MG2, is a small, secreted glycoprotein that functions to help salivary defence against oral bacteria by masking their surface adhesins and thereby inhibiting colonization. In this study, we aimed to identify the N- Terminal region of MUC7 gene polymorphisms between individuals with and without caries.
Methods: 44 Healthy dental students were included in this study. 24 of them were classified to have dental caries (DMF-T=5,6) according to the World Health Organisation (WHO) and 20 of them were caries- free (DMF-T=0). Salivary total protein was measured by Lowry method, salivary buffer capacity (SBF) by Ericsson's method. Saliva flow rate and pH was also calculated. Genotyping procedure was carried out by PCR- direct sequencing.
Results: We detected a transversition of C to G, which causes a change asparagine to lysine in codon 80 (N80K). This alteration was found 33,3% and 42,1% in with and without caries groups, respectively. There was no statistically significant difference between caries and non- caries group in the terms of biochemical and genetic results.
Conclusion: The SNP found in this study may be a specific polymorphism affecting Turkish population. Further studies with more numbers of individuals are necessary in order to clarify this finding.

J04.21
Interdisciplinary management of a young patient with hypodontia :a orthodontic-restorative-surgical approach

A. Bud, *D. Esian, C. Bică, S. Pop, E. Bud;*
UMF Targu-Mures, targu-mures, Romania.

Hypodontia represents the congenital lack of one or a few teeth and is an autosomal inherited dominant trait. Although a lot of progress has been made in understanding the causes of hypodontia, knowledge of the exact aethiology remains poor. Genetic studies discovered mutations in 3 genes in patients with familial hypodontia or oligodontia: MSX1, PAX9 and AXIN2.
The patient, a 22 years old male was referred to the Department of Orthodontics, University of Dentistry Tîrgu-Mures, with a chief complaint of missing permanent teeth. Extraoral examination revealed a well-balanced face with normal facial profile and normal skeletal dental base relations. Intraoral examination revealed a mixed dentition. Radiographic examination confirmed that the following teeth were developmentally missing: 4.2,3.3,4.1,1.2,1.5.
A multidisciplinary team involving an orthodontist and a prosthodontists established the treatment plan and the clinical management of this case. A combined orthodontic-restorative-surgical approach was adopted. The aim of the orthodontic treatment was dental allignement and creation of space for placement of implants. Orthodontic treatment was conducted using a fixed staight-wire appliance for 12 months. Implants were placed and after five months the final prosthetic restauration was performed.
Young patients with congenitally missing teeth need an early refferal to a dentistry team for optimal management. This case report shows the need for a multidisciplinary team approach for the establishment of the treatment plan. The two main objectives for patients with hypodontia, namely improved esthetics and restoration of masticatory function, were achieved in this case.

J04.22
Deregulated expression of genes involved in extracellular matrix regulation in tendons of patients with rotator cuff tear

M. F. Leal, *P. S. Belangero, E. A. Figueiredo, C. Cohen, L. C. Loyola, F. S. Alves, W. H. Yanaguizawa, M. C. Smith, C. V. Andreoli, A. C. Pochini, M. T. S. Alves, B. Ejnisman, M. Cohen;*
Universidade Federal de São Paulo, São Paulo, Brazil.

Rotator cuff tear is one of the most common shoulder dysfunction. Gene expression analysis is a useful tool for understanding tendon tears. TGFβ1 is a cytokine that seems to be involved in tendon differentiation. TGFβR1 is one of the main receptor of the TGFβ pathway. GDF5 and KFL6 are members of the TGFβ family. Moreover, FN1 and TNC glycoproteins seems to have a role in the tendon healing. No previous study evaluated the mRNA expression of these genes in tendons of patients with rotator cuff tears. We evaluated TGFβ1, TGFβR1, GDF5, KFL6, FN1 and TNC expression in 28 ruptured supraspinatus tendon samples of patients with rotator cuff tears and in 8 normal supraspinatus tendon samples by reverse-transcription quantitative polymerase chain reaction. HPRT1, TBP and ACTB were selected as reference genes for gene expression normalization. We observed that FN1, TNC and TGFβR1 expression was increased in tendon samples of cases compared with controls (p=0.002, p=0.025, p=0.020, respectively). Increased FN1 (p=0.025) and TNC (p=0.014) expression was detected in smokers in relation to non-smoker patients. Samples with microcyst presented increased TNC expression in relation to samples without microcysts (p=0.046). Samples with microcysts also tented to present higher FN1 expression. (p=0.054). Samples with myxoid alterations presented reduced GDF5 expression (p=0.029). In conclusion, FN1, TNC and TGFβR1 expression were deregulated in tendons of patients with rotator cuff tears. These molecular alterations may lead to modifications of tissue structure and of the healing process, as well as to tendon ruptures.

FOXL2 mutations in Iranian patients with blepharophimosis-ptosis-epicanthus inversus syndrome

M. T. Akbari[1,2];
[1]*Tarbiat Modares University, Tehran, Iran, Islamic Republic of,* [2]*Tehran Medical Genetics Laboratory, Tehran, Iran, Islamic Republic of.*

Blepharophimosis-ptosis-epicanthus syndrome (BPES) is a rare genetic disorder with autosomal dominant inheritance. There are two distinct phenotypes: BPES type I, which is associated with female infertility or premature menopause due to ovarian resistance to gonadotropins, whereas in type II only eyelid abnormalities are present. Mutations in the forkhead transcription factor 2 (FOXL2) gene are responsible for both types of BPES. The purpose of this study was to identify mutations in FOXL2 in Iranian patients with BPES.
The peripheral blood was collected from the patients of two families and genomic DNA was extracted. Direct sequencing of all exons of FOXL2 gene was performed.
Two mutations in FOXL2 were identified in two familial cases c.102-103 ins A (p.G35R fsx), a novel mutation, and c.855-871 dup (17-bp insertion), a known disease-causing mutation were found in FOXL2 gene. These mutations cause truncated protein and envisaged to have severe phenotypic impact in harmony with type I phenotype seen in the patients.
The role of FOXL2 gene in the etiology of infertility is still unclear, but several studies suggested that it plays a central role in follicle development. Our results expand the spectrum of FOXL2 mutations and confirm the mutations association with eyelid abnormalities and female infertility.

Cathepsin K mutation is responsible for pycnodysostosis in a Turkish family

K. Ulucan[1], **B. Sisinoglu Capan**[2], *S. Akyüz*[2];
[1]*Marmara University, Faculty Dentistry, Department of Medical Biology and Genetics, Istanbul, Turkey,* [2]*Marmara University, Faculty of Dentistry, Department of Pedodontology, Istanbul, Turkey.*

Introduction: Pycnodysostosis (PKND) is a rare, autosomal recessive disease characterized by short stature, severe bone fragility, exophthalmus and oral manifestations such as micrognathia. It usually demonstrates typical craniofacial deformities, such as hypoplastic midface, anterior cross-bite, grooved palate and dental crowding. The aim of this case report is to investigate the role of cathepsin K (CTSK) for pycnodysostosis in an effected Turkish family.
Material- Method: Family applied to Marmara University, Department of Pedodontology for treatment of PKND. Three of five siblings had PKND whereas the other two siblings were PKND-unaffected. All the siblings' detailed clinical and radiological examinations were performed.
Results: Taking into consideration the fragility in these patients, appropriate restorative treatments and protective applications were preferred. Patients were given oral hygiene education. Recall visits occurred in every 3 months during the 18-month follow-up period. For mutational analysis, genomic DNA was isolated from buccal cells. Seven exons, including exon- intron

boundaries of CTSK were directly sequenced after amplification in all family members.
Conclusions: Early diagnosis and treatment is important with PKND patients, since bone fractures easily occur during dental treatment and limited mouth opening makes it difficult to access the treated area. Frequent recalls should be planned for PKND patients. Regular oral care and early preventive treatments ensure the patients a better life quality. Genetically, all the affected members carried L7P variation as homozygous state, whereas unaffected had the heterozygous state of the same condition. Conclusively, we suggest that L7P mutation is important for the onset of this anomaly.

J04.25
Familial recurrence of lethal neonatal coagulopathy: Novel mutation in arysulfatase-E suggests severe phenotype of x-linked chondrodysplasia punctata

V. H. McKay[1], *J. S. Sibbring*[2], *C. Dewhurst*[3], *D. Rigden*[4], *K. L. Greenhalgh*[5], *N. Hall*[2];
[1]*Department of Clinical Genetics, Cheshire & Merseyside Regional Clinical Genetics Service, Liverpool, United Kingdom,* [2]*Centre for Genomic Research, University of Liverpool, Liverpool, United Kingdom,* [3]*Neonatal Intensive Care Unit, Liverpool Women's Hospital, Liverpool, United Kingdom,* [4]*Department of Biochemistry, Institute of Integrative Biology, University of Liverpool, Liverpool, United Kingdom,* [5]*Department of Clinical Genetics, Cheshire & Merseyside Regional Clinical Genetics Service, Liverpool, Liverpool, United Kingdom.*

Two male babies were born to identical twin mothers and both mothers were completely deficient in vitamin K. Both patients were born in extremely poor condition with disseminated intravascular coagulopathy (DIC) and dysmorphic features; small noses with depressed nasal bridges and midface hypoplasia. Radiographs revealed stippled epiphyses and tracheal ring calcification. Both infants died in the neonatal period from haemorrhagic sequelae.
Targeted sequencing of X chromosome exons revealed both patients to be hemizygous for a novel mutation (c.1692C>G) in exon 11 of arysulfatase-E (*ARSE*), encoding the Golgi enzyme arylsulfatase-E. The mutation was carried by both mothers and was demonstrated to have arisen *de novo*. The mutation is predicted to destabilise the ARSE protein and reduce overall protein activity.
X-linked recessive chondrodysplasia punctata (CDPX1) refers specifically to mutations in *ARSE* leading to the clinical features of distal phalangeal hypoplasia, stippled epiphyses and typical dysmorphic facial features (Binder face). Mutations in *ARSE* are found in 50% of patients with CDP, suggesting that in the remaining patients, clinical features are caused by mutations in other genes or, more commonly, by non-genetic phenocopies.
Our data supports the pathogenicity of this novel mutation and clinical features are consistent with a lethal phenotype of CDPX1. Three further cases are reported in the literature of neonatal haemorrhage associated with mutations in *ARSE*; this suggests that a severe sub-group of CDPX1 exists. The substrate for ARSE is currently unknown but our patients provide more evidence for the role of vitamin K in this pathway and potential therapeutic targets.

Missing heritability in Primary Osteoarthritis: the EXORHUM project

C. BAUGE[1,2], *J. AURY-LANDAS*[1,2], *S. LECLERCQ*[3], *C. MARCELLI*[4], *K. BOUMEDIENE*[1,2];
[1]*UNICAEN, EA4652 MILPAT, Caen, France,* [2]*Normandie Univ, Caen, France,* [3]*Service de Chirurgie orthopédique, Hôpital privé Saint Martin, Caen, France,* [4]*Service de Rhumatologie, CHU, Caen, France.*

Osteoarthritis (OA) is the most common joint disease observed worldwide and affects nearly 10 million adults in France and 27 million adults in USA. OA is mainly characterized by the gradual loss of the articular cartilage, particularly affecting the knee, hip, spine, hand and foot. Although the multifactorial nature of the vast majority of OA cases is well recognized, genetic risk factors have been found to be strong determinants of the disease. About 50% of hip and hand OA may be genetically determined. However, currently, only few genetic alterations responsible for OA determinism have been identified mostly in genes involved in the cartilage extracellular matrix. These alterations have been mainly detected in patients with syndromic early-onset OA like pseudoachondroplasia, multiple epiphyseal dysplasia or spondyloepiphyseal dysplasia tarda.
The EXORHUM project is based on the recruitment of a well clinically characterized cohort of patients with non syndromic early-onset OA. The main aim is to identify new genetic alterations, exclusive to primary OA in patients with a familial presentation, strongly suggestive of a genetic determinism. Exome sequencing will be performed on two distant affected family members without known alterations. The sub aim is to assess the prevalence of known mutations in primary non syndromic OA.
In conclusion, the EXORHUM project will help us to improve the understanding of molecular processes involved in pathogenesis of OA and to better understand the complexity of OA. This is essential to improve patient diagnosis and to identify new therapeutic targets.

Premature ovarian failure and Madelung deformity in a woman with a Xq25→qter deletion

S. Lanciotti[1,2], *D. Postorivo*[2], *E. Pisaneschi*[3], *A. Angioni*[3], *A. Nardone*[1,2], *C. Di Rosa*[2], *F. Sangiuolo*[1,2], *G. Novelli*[1,2], *F. Brancati*[2,4];
[1]*Department of Biomedicine and Prevention, Section of Genetics, School of Medicine, Tor Vergata Univ, Rome, Italy,* [2]*Medical Genetics Unit, Policlinico Tor Vergata University Hospital, Rome, Italy,* [3]*Bambino Gesù Pediatric Hospital IRCCS, Rome, Italy,* [4]*Department of Medical, Oral and Biotechnological Sciences, Gabriele D'Annunzio University, Chieti, Italy.*

Madelung deformity (MD) is a congenital anomaly of the wrist with subluxation of the ulna head. MD may be part of Léri-Weill dyschondrosteosis featuring short stature and mesomelic shorting of the limbs caused by SHOX gene alterations. MD may also be present in monosomy X and, more rarely, in other monogenic disorders such as Albright hereditary osteodystrophy in association to brachydactyly.
We report a 48-year-old woman with MD, short stature (148 cm but in her target height) and premature ovarian failure (age at last menses 38 years) in the absence of brachydactyly, other endocrine anomalies, or abnormal skin pigmentation. SHOX gene mutations and rearrangements were excluded by molecular techniques. Conventional cytogenetic analysis demonstrated euploid female karyotype with a deletion of the long arm of one X chromosome in band q24→qter. To better characterize the rearrangement, we performed array-CGH analysis that showed a deletion extending about 33 Mb with breakpoints in Xq25→q28.
Distal Xq deletions are a well-known cause of premature ovarian failure (POF1) but we failed to identify other women with MD and such deletions in the literature. This patient reinforces the concept of genetic heterogeneity in MD suggesting the existence of other, yet unrecognized factors in its pathogenesis, including terminal Xq deletions.

J04.28
Mutations spectrum at autosomal recessive congenital ichthyosis in patients from Russian Federation.

N. N. Vasserman, *A. V. Polyakov;*
Research Center for Medical Genetics, Moscow, Russian Federation.

Autosomal recessive congenital ichthyosis (ARCI) is a heterogeneous group of disorders of keratinization. It characterized by abnormal skin scaling and sometimes it is associated with erythema. It divides on several types the main of which are lamellar ichthyosis (LI) and nonbullous congenital ichthyosiform erythroderma (NCIE), although phenotypic overlap within the same patient or among patients from the same family. Mutations in several genes can lead to both LI and NCIE.
We performed analysis DNA from patients from 40 families on mutations in TGM1 and Alox12B genes. We found mutations in 7 families in TGM1 gene. 7 mutations were novel: p.Trp61Term, p.Val115Met, p.Tyr134His, p.Gly296Arg, p.Pro474Leu, p.Ser691Leu, and one deletion c.566delG. There are no frequent mutations in this gene.
We detected mutations in Alox12B gene in 13 families. There were 6 novel mutations: p.Tyr97Term, p.Ser125Term, p.Gly265Arg, p.Ala412Asp, p.Ser502Asn, p.Asn594His. Two mutations were frequent: p.Ala597Glu at exon 14 was found in 9 families, p.Tyr521Cys at exon 12 was detected in 6 families. Together both mutations were found in 12 families or 92% families with mutations in Alox12B gene.
Thereby among 40 families diagnosis ARCI was confirm for 20 families or 50%: 17.5% families have mutations in TGM1 gene and 32.5% - in Alox12B gene.

A novel MSX1 gene splice mutation due to an intronic nucleotide substitution is the cause of congenital tooth agenesis in a Japanese family

T. Tatematsu, 1986.01.04[1], *M. Kimura*[1], *M. Nakashima*[2], *J. Machida*[3], *S. Yamaguchi*[1], *A. Shibata*[1], *H. Goto*[1], *A. Nakayama*[4], *Y. Higashi*[5], *H. Miyachi*[1], *K. Shimozato*[1], *N. Matsumoto*[2], *Y. Tokita*[5];
[1]*Department of Maxillofacial Surgery, Aichi-Gakuin University School of Dentistry, Nagoya, Japan,* [2]*Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan,* [3]*Department of Oral and Maxillofacial Surgery, Toyota Memorial Hospital, Toyota, Japan,* [4]*Department of Embryology, Institute for Developmental Research, Aichi-Human Service Center, Kasugai, Japan,* [5]*Department*

of Perinatology, Institute for Developmental Research,Aichi-Human Service Center, Kasugai, Japan.

Congenital tooth agenesis is caused by mutations in the *MSX1*, *PAX9*, *WNT10a*, or *AXIN2* genes. Here, we report a Japanese family with nonsyndromic tooth agenesis caused by a novel nucleotide substitution in the intronic region between exons 1 and 2 of the *MSX1* gene. Because the mutation is located 9 bp before exon 2 (c.452-9G>A), we speculated that the nucleotide substitution would generate an abnormal splice site. Using cDNA analysis of an immortalized patient blood cell, we confirmed that an additional 7-nucleotide sequence was inserted at the splice junction between exons 1 and 2 (c.451_452insCCCTCAG). The consequent frameshift generated a homeodomain-truncated MSX1 (p.R151fsX20). We then showed a subcellular localization of the mutant MSX1 in the cytoplasm of transfected COS7 cells, suggesting deletion of the nuclear localization signal, which is mapped to the MSX1 homeodomain. These results indicate that this novel intronic nucleotide substitution is the cause of tooth agenesis in this family. To date, most MSX1 variants isolated from patients with tooth agenesis involve single amino acid substitutions in the highly conserved homeodomain or deletion mutants caused by frameshift or nonsense mutations. We here report a rare case of an intronic mutation of the *MSX1* gene responsible for human tooth agenesis. In addition, the missing tooth patterns were slightly but significantly different between an affected monozygotic twin pair of this family, showing that epigenetic or environmental factors also affect the phenotypic variations of missing teeth among patients with nonsyndromic tooth agenesis caused by an *MSX1* haploinsufficiency.

A novel intragenic duplication of FBN1 exons 36-46 in a spontaneously aborted fetus with features of Marfan syndrome.

H. L. Savage, *S. Cottrell, H. Gosrani, A. Perez-Caballero, S. Moore, L. Reed, R. Taylor; St George's University Hospitals NHS Foundation Trust, London, United Kingdom.*

Introduction: Marfan syndrome (MFS) is a connective tissue disorder caused by mutations in FBN1. It affects ~1/5,000 people and 75% of cases are inherited. A spectrum of mutations are reported to cause disease; however, to date there have been no reports of large intragenic duplications causing MFS. Here, we report a de novo duplication of exons 36-46 of FBN1 in a fetus with bilateral talipes, enlarged cisterna magna, an unfolded aorta and long, thin, overlapping fingers.

Methods: Sanger sequencing and MLPA of exons 1-65 of FBN1 in the fetal sample, and MLPA analysis of both parental samples were completed.

Results: Sequencing analysis of the entire coding region of FBN1 did not detect any pathogenic mutations. However, FBN1 MLPA analysis detected a heterozygous duplication of exons 36-46. Neither unaffected parent was found to be heterozygous for this mutation, supporting likely pathogenicity of this change.

Conclusion: To our knowledge, intragenic duplications involving multiple exons of FBN1 have not been previously reported in humans. If this is an intragenic tandem duplication it would be predicted to cause a frameshift and therefore would likely be pathogenic.

Although intragenic duplications have not been previously described in humans, the tsk mouse has an intragenic tandem duplication of FBN1 (exons 17-30) and demonstrates cardiac hypertrophy, tight skin and skeletal features associated with MFS (Siracusa et al (1996) Genome Research 6:300-313).

This novel duplication is likely to be the cause of the abnormalities seen in this fetus, and expands the range of pathogenic mutation types detected in MFS.

Variants within the COL5A1 3'-untranslated region (UTR) may contribute to the aetiology of musculoskeletal soft tissue injuries

M. N. Laguette, *S. Prince, M. Collins; University of Cape Town, Cape Town, South Africa.*

A polymorphism (rs12722, C/T) within the COL5A1 3'-UTR is associated with musculoskeletal soft tissue injuries. COL5A1 encodes for the α1 chain of type V collagen, an important regulator of fibril assembly. Variants in the 3'-UTR may regulate synthesis of the α1(V) chain and type V collagen production thereby influencing the mechanical properties of the tissues. Functional differences were established between the COL5A1 3'-UTR cloned from participants with a severe chronic Achilles tendinopathy (TEN) phenotype and healthy asymptomatic control individuals. Indeed, two major forms, the C- and T-allelic form, were identified and additional variants were shown to be associated with TEN. To further investigate these functional differences and to start mapping the regions responsible for the tendinopathic phenotype, skin biopsies from donors having a known genotype at rs12722 were taken and primary fibroblast cell lines were established to quantify COL5A1 and COL1A1 expression in a pilot study. Site-directed mutants were generated for two implicated variants, namely rs12722 and rs71746744. Lastly, in preliminary RNA EMSAs, biotinylated C- and T-allelic RNA probes for a 57bp region were incubated with either nuclear/cytoplasmic protein extracts to investigate putative distinguishing RNA:RBP complex formation. An overall higher relative mRNA expression of both COL5A1 ($p<0.001$) and COL1A1 ($p=0.0015$) were observed in the presence of rs12722 TT genotype compared to CC. Although the rs71746744 and rs12722 variants appeared to be functional, they did not independently contribute to the tendinopathic phenotype. However, a unique RNA:RBP complex was identified with the C-allelic probe. These novel results have implications for our understanding of the molecular basis of musculoskeletal soft tissue injuries.

NGS panel makes new diagnoses in Ehlers-Danlos syndrome & related HDCT

R. A. Weerakkody[1,2], *J. Vandrovcova[1], C. Kanonidou[1,2], M. Mueller[1], P. Gampawar[1], A. Abdullah[1], Y. Ibrahim[1], P. Norsworthy[1], J. Biggs[1], D. Ross[1,2], H. A. Black[2], N. J. Cheshire[1], G. Sobey[3], N. Ghali[4], A. Vandersteen[4], F. M. Pope[4], T. J. Aitman[1,2];*
[1]Imperial College London, London, United Kingdom, [2]Institute of Genetics & Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom, [3]National Ehlers Danlos Syndrome Diagnostic Service, Sheffield Children's Hospital, Sheffield, United Kingdom, [4]National Ehlers-Danlos Diagnostic Service, Northwick Park Hospital, London, United Kingdom.

Background

Ehlers-Danlos syndrome (EDS) is a significant inherited cause of morbidity and mortality, often presenting at a young age with significant vascular complications. There is wide genetic and phenotypic heterogeneity and overlap with other hereditary disorders of connective tissue (HDCT). The spectrum of mutations in known genes and correlation with phenotype in a mixed cohort of EDS remains to be characterised.

Methods

We used a multiplex-PCR targeted NGS (Fluidigm/MiSeq) assay to sequence the coding regions of COL1A1, COL1A2, COL3A1, COL5A1, COL5A2, FBN1, TGFBR1, TGFBR2, SMAD3, MYLK, MYH11, ACTA2 in a cohort of 177 deeply-phenotyped unrelated patients referred with suspected EDS (mean age 33.8 years, 66% female: 7% Classical, 10%Vascular, 42% Hypermobile, 17% other EDS, 24% other HDCT).

Results

The NGS assay identified 24 pathogenic mutations and 21 variants of uncertain significance (VUS) in the collagen genes and 7 mutations in FBN1, TGFBR1, TGFBR2, SMAD3. Ten high-priority rare variants were found outside the expected genotype-phenotype relationship. Four pathogenic variants (COL3A1, COL5A1, FBN1) and two possible pathogenic VUS (TGFBR2, TGFBR1) represented new diagnoses, not previously detected, in addition to 18 newly identified VUS.

Conclusions

Unbiased targeted sequencing using NGS in combination with current clinical phenotyping can increase the rate of molecular diagnosis in EDS and will enhance our understanding of genotype-phenotype relationships in EDS and other hereditary disorders of connective tissue.

Localization of the pathogenic gene of accessory fagus phenotype in a Chinese Han family

Y. Cao[1], *Z. Fan[2];*
[1]Beijing Stomatology Hospital, School of Stomatology, Capital Medical University., Beijing, China, [2]Molecular Laboratory for Gene Therapy and Tooth Regeneration, Beijing Key Laboratory of Tooth Regeneration and Function Reconstruction, Capital Medical University School of Stomatology, Beijing, China.

Introduction:To localize the pathogenic gene of Accessory fagus phenotype in a Chinese Han family. Material and Methods: A five-generation family consisting of 56 individuals with or without Accessory fagus phenotype was found in Chinese Han people. Genescan, Linkage analysis and haplotype analysis were used to map the candidate gene by Microsatellite genetic marker.

Results: Genescan and Linkage analysis indicated that the pathogenic gene was located either between d18s462~d18s70, the heretary distance was 6.00cM,LODZMAX =1.83(d18s462,θ= 0.06), or located between d7s2546 and d7s550, the hereditary distance was 8.94cM, LODZMAX =2.74(d7s2546,θ=0.05). Further haplotype analysis narrowed the pathogenic gene between d7s2546~d7s550,the hereditary distance was 5.38cM.

Conclusion:the pathogenic gene of the Accessory fagus phenotype this family was located between d7s2546~d7s550 in chromosomes 7q36.1~7q36.2.

Introduction: Hypophosphatemic rickets (HR) comprises a rare group of inherited diseases. Very recently, mutations in the dentin matrix protein 1 (DMP1) gene were identified in patients with an extremely rare autosomal recessive form of HR (ARHR). To date, very few cases of these mutations were reported.
Materials and methods: A Lebanese consanguineous family with 2 affected sisters was studied. Patients aged 45 and 47 years old presentedwith short stature, severe genu varum, cranial hyperostosis and a very high bone density that led to a diagnosis of a familial sclerosing bone dysplasia. Molecular analysis of known genes involved in osteopetrosis showed normal results. A combination of genotyping and exome sequencing was performed in order to elucidate the genetic basis of this pathology.
Results: Biochemical analysis was consistent with normal serum calcium and 1-25(OH)2D levels, low to normal serum phosphorus and elevated PTH values. Serum c-terminal FGF-23 was elevated in one of the two patients. A homozygous mutation disrupting the initiation codon of the DMP1 gene (OMIM 600980), NM_001079911.2: c.1ANG, p.Met1Val, was identified by exome sequencing and confirmed by Sanger sequencing.
Conclusion:We report here a family of ARHR secondary to aDMP1mutation located in the first coding exon of the gene. Our cases show that some ARHR cases may develop with age an unaccountable increase in bone density and bone overgrowth.

New clinical presentation of tooth agenesis associated with p.Phe228Ile WNT10A mutation

M. Haddaji Mastouri[1]*, A. Ben Salem Saied[2], A. Zaghbani[3], S. Trabelsi[1], M. Chourabi[1], D. H'mida-Ben Brahim[1], P. De Coster[4], P. Coucke[5], A. SAAD[1];*
[1]Departement of Human Cytogenetics, Molecular Genetics and Reproductive Biology, Farhat Hached University Hospital, Sousse, Tunisia, [2]Departement of Orthodontics, Farhat Hached University Hospital, Sousse, Tunisia, [3]Departement of Oral Surgery, Farhat Hached University Hospital, Sousse, Tunisia, [4]Departement of Restorative Dentistry and Endodontology, Ghent University Hospital, Ghent, Belgium, [5]Department of Medical Genetics, MRB, Ghent University Hospital, Ghent, Belgium.

Tooth development is under strict genetic control and mutations of genes regulating early stages of tooth formation have been found to cause tooth agenesis, i.e. congenital absence of teeth.
In our study we sequenced the WNT10A, PAX9, AXIN2 and MSX1 genes in a patient presenting agenesis of mandibular and maxillary second premolars in order to identify potential mutations. The patient carries a heterozygous missense mutation c.682T>A (p.(Phe228Ile)) in the WNT10A gene. This mutation is predicted to be damaging with a Polyphen score of 0.999 and a Global MAF of 0.010 (allele A). This coding variant has previously been reported in 2 patients with odonto-onychodermal dysplasia and in one family with variable hypodontia involving lateral incisors and premolars. Another study revealed that this variant is the most prevalent in the WNT10A gene and represent13% of all oligodontia alleles detected in their cohort.
In our study, we report a novel dental phenotype associated with the (p.(Phe228Ile)) coding variant in the WNT10A gene involving agenesis of all second premolars. In the absence of other systemic anomalies, and based on current insights into the interacting signaling pathways at the initiation stage of tooth development, we hypothesize that this new phenotype might be caused by additional polymorphisms observed in the PAX9, AXIN2 or MSX1 genes.

Prevalence of CYP2C8*3 and CYP2J2*7 in Bulgarian patients with coronary artery disease and hypertension

R. Tzveova[1]*, G. Naydenova[2], T. Yaneva[3], G. Dimitrov[3], D. Pendicheva-Duhlenska[4], S. Vandeva[5], Y. Matrozova[5], I. Popov[1], C. Naydenov[6], O. Beltcheva[1], S. Zacharieva[5], R. Turnovska-Kadreva[3], G. Nachev[7], V. Mitev[1], R. Kaneva[1];*
[1]Medical University, Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Sofia, Bulgaria, [2]Second Department of Cardiology, UMBAL „Dr. G. Stranski", Pleven, Bulgaria, [3]Clinic of Cardiology, UMHAT "Aleksandrovska", Sofia, Bulgaria, [4]Department of Experimental and Clinical Pharmacology, Dermatology and Venereology, Medical University, Pleven, Bulgaria, [5]Clinical Center of Endocrinology and Gerontology, Medical University, Sofia, Bulgaria, [6]Medical University, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria, [7]University National Specialized Hospital for Active Treatment Hospital "Sv. Ekaterina", Sofia, Bulgaria.

The cytochrome P450 epoxygenases are important enzymes metabolizing arachidonic acid to different vasoactive metabolites.
We conducted a case-control study to determine the prevalence of polymorphic variants in epoxygenase - related genes CYP2C8 (rs1050968; CYP2C8*3) and CYP2J2 (rs890293; CYP2J2*7) in the Bulgarian population and to evaluate whether these genetic variants are associated with increased risk of coronary artery disease (CAD) and /or essential hypertension (EH) in the studied cohort.
The current analysis included 192 unrelated hypertensive patients, 261 patients with angiographically documented CAD (153 with myocardial infarction and 108 without myocardial infarction) and 496 population - based controls. The CYP2C8*3and CYP2J2*7 polymorphisms were genotyped by TaqMan SNP Genotyping Assay (Applied Biosystems). PLINK version 1.07 was used for the statistical analysis.
The frequency of -50T mutant allele of CYP2J2*7 was significantly higher in male with angiographically documented CAD without history of myocardial infarction (OR 2.16 95%CI 1.04-4.48 p=0.035) compared to population control group, but this association did not survive after Bonferroni correction (padj=0.07). A significant association of a CYP2C8*3 allele with increased risk of EH was found in men (OR 2.12 95%CI 1.18-3.81 p=0.015) and this relationship remained significant after adjustment for multiple comparisons (padj=0.02).
In conclusion, these results could be due to the great impact of sex hormones such estrogens on the vascular tone and CYP2J2/CYP2C8 gene expression. Therefore, the protective effect is more evident in females compared to males.

Distribution of angiotensin-I converting enzyme insertion/ deletion and α-actinin- 3 codon 577 polymorphisms in Turkish male soccer players

K. Ulucan[1]*, C. Sercan[1], T. Biyikli[2], D. Kirac[3], A. I. Güney[4];*
[1]Marmara University, Faculty of Dentistry, Department of Medical Biology and Genetics, Istanbul, Turkey, [2]Gelisim University, School of Physical Education and Sports, Department of Coach Training, Istanbul, Turkey, [3]Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey, [4]Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey.

Angiotensin-1 converting enzyme gene (ACE) and α-actinin- 3 gene (ACTN3) polymorphisms are considered to be the most important candidate genes for genetic predisposition to human performance . In the present study, we aimed to analyze the distribution of ACE and ACTN3 polymorphisms in male Turkish soccer players In this prospective study, our cohort consisted 25 professional players, all with Turkish ancestry. Genotyping protocol were carried out by polymerase chain reaction- restriction length polymorphism (PCR- RFLP) for ACTN3 and PCR for ACE. 16%, 44% and 40% of the players had II, ID and DD genotype, respectively, for ACE genoype; whereas 20% had XX, %36 had RX and %44 had RR genotypes for ACTN3. When we examined the allelic percentages, for ACE, D allele was recorded as 62 and I as 38; and for ACTN3, R allele was 62 and X was 38. Our results were in agreement with the previous reports, indicating the presence of D allele and X allele in soccer players. We suggest that ACE and ACTN3 genotypes are important biomarkers for genetic counseling for the individuals who are prone to be successful in soccer.

Genetic tests help to choose a therapeutic step with high complication rate in a family with hypertrophic cardiomyopathy: a case report.

K. Arvai[1]*, V. Horvath[2], B. Balla[1], B. Tóbiás[1], G. Kirschner[2], Z. Putz[2], Z. Nagy[2], I. Takács[2], L. Környei[3], H. Vágó[4], A. Tóth[4], I. Likó[5], G. Fekete[6], B. Merkely[4], P. Lakatos[2], J. Kósa[1];*
[1]Semmelweis University PentaCoreLab, Budapest, Hungary, [2]Semmelweis Universty, 1st Dept. of Medicine, Budapest, Hungary, [3]Gottsegen György National Institute of Cardiology, Budapest, Hungary, Budapest, Hungary, [4]Semmelweis University, Heart and Cardiovascular Center, Budapest, Hungary, [5]Hungarian Academy of Science, "Lendület" Research Group of Inherited Endocrine Tumors, Budapest, Hungary, [6]Semmelweis University, 2nd Dept. of Pediatrics, Budapest, Hungary.

Genetic testing is becoming a more valuable tool in clinical decision making. Here, we discuss the case of a family with hypertrophic cardiomyopathy where the generally used diagnostic approaches did not give enough information for a correct decision of implanting an implantable cardioverter defibrillator (ICD). A 7 year old female child was transported to a critical care center after a short reanimation which was carried out after she had collapsed without prodromal signs during a regular physical activity. The father had typical MRI signs for HCM while the mother's MRI did not show any change characteristic for HCM. The sudden cardiac death together with the diagnosed HCM indicated the implantation of ICD. The detailed analysis of Holter, ECG and MRI did not show typical signs that could have indicated ICD implantation for the 2 older sisters. Genetic testing was offered to the family and we have identified two disease-causing heterozygous mutations in the MYBPC3 gene (p.R495Q and p.S593fs*11) in the children. This information finally helped to make the decision of implanting ICD into both sisters as primary prevention, despite of the associated average of 25% complication rate of the procedure in children. Later, the father (carrying the p.R495Q mutation) also received an ICD after a 30 second collapse with unknown origin. Since the mother (carrying the p.S593fs*11 mutation) - for the time being - does not have any morphological or clinical sign of HCM, ICD implantation was not indicated in her. This case further supports the importance of genetic testing in clinical practice.

J05.04

Compound and individual effect of heterozygous missense mutations in long QT syndrome

A. V. Polyakova, *L. I. Shagam, R. A. Ildarova, M. A. Shkolnikova, V. S. Sukhorukov; Pediatric Clinical Research Institute of Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

Congenital long QT syndrome (LQTS) is a rare heart disorder that is characterized by prolonged QT interval, syncopes, seizures and/or sudden death. Up to now, 13 LQTS genes have been identified.

We have developed a gene panel for targeted resequencing of the 13 genes based on AmpliSeq™ technology. The panel covers coding exons and adjacent 5 bp parts of introns. We performed clinical and genetic characterization of two unrelated LQTS family trios. The first proband (child in family #1) harbours 2 missense mutations inherited from his mother and father, respectively: KCNH2 c.526C>T, p.(R176W) and KCNQ1 c.775C>T, p.(R259C); the second proband - KCNH2 c.526C>T, p.(R176W) and KCNE1 c.253G>A, p.(D85N) from his mother and father. Both patients suffer severe LQTS with significantly prolonged (>500 ms) QT intervals and have cardioverter-defibrillator implanted.

Effect of the KCNH2 mutation (rs36210422) found in both probands is known to be controversial. Here, we report two phenotypically healthy women harbouring this mutation (with normal QTc). Pathogenicity of the KCNE1 mutation (rs1805128) is also known to be controversial. Here, we report a phenotypically healthy man harbouring the mutation with slightly prolonged QTc (~450 ms). The KCNQ1 mutation (rs199472719) that affects the structure of an evolutionally conservative intracellular linker of S4-S5 protein domains and is reported to be pathogenic by multiple authors also demonstrates no strong phenotypic effect itself (QTc ~450 ms in father of proband #1).

Our results support the concept of severe effect of compound heterozygous mutations in LQTS with the effect of solitary mutations being usually ambiguous.

J05.05

Mitochondrial DNA control region heteroplasmy in carotid atherosclerotic plaques and blood cells

M. V. Golubenko[1,2,3], *M. Y. Glushkova[3], M. S. Nazarenko[1,3], A. A. Sleptsov[1,3], A. V. Frolov[2], O. L. Barbarash[2], V. P. Puzyrev[1,4,3];*
[1]Research Institute for Medical Genetics, Tomsk, Russian Federation, [2]Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation, [3]Tomsk State University, Tomsk, Russian Federation, [4]Siberian State Medical University, Tomsk, Russian Federation.

Atherosclerosis is characterized by increased oxidative stress which can induce DNA damage. Mitochondrial DNA is particularly subjected to oxidative damage. So mtDNA mutations in somatic cells could be a result of oxidative stress and, in turn, may lead to uncoupling of oxidative phosphorylation through their effect on mtDNA-encoded proteins (further stress increasing). To study possible somatic mutations in mtDNA during atherosclerotic plaque development, we sequenced control region of mtDNA (16024-400) in 24 patients who have undergone surgery on carotids. DNA was isolated from the plaques and blood leucocytes. Sanger sequencing (allowing detection of 10% heteroplasmy level) was performed on ABI 3730 analyzer. In total, we have detected 5 heteroplasmic transitions in 4 individuals (16.7%). In addition, common heteroplasmy in polycytosine tracts 16184-16193 and 302-309 has been registered in 17% and 70% patients, respectively. While comparing plaque and blood samples for each patient, 3 of the heteroplasmies were common for the plaque and blood of the individuals, whereas two heteroplasmic positions were detected only in the plaques, so they could be result of somatic mutations. The results support the assumption that atherogenesis is accompanied by mtDNA damage.

The study is supported by Russian Science Foundation, grant no. 14-15-00305.

Molecular analysis of the BMPR2 gene in patients with Pulmonary Arterial Hypertension: preliminar data of an Italian study

D. Degiorgio[1], *S. Ghio[2], F. Ornati[3], S. Plumitallo[3], C. Olivieri[3], E. Zammataro[1], E. Di Buduo[1], G. Maggi[2], S. De Servi[1,2], L. Scelsi[2];*
[1]Laboratory of Molecular Cardiology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [2]Coronary Care and Cardiology Unit, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [3]Department of Molecular Medicine, University of Pavia, Pavia, Italy.

Pulmonary arterial hypertension (PAH) is a rare disorder of the small pulmonary arteries that determines proliferative and fibrotic changes characterized by progressivity, leading to vessel blockage, right heart failure and death. The major gene associated to PAH, according to an autosomal dominant inheritance pattern, is BMPR2 that encodes the 'bone-morphogenetic-protein-receptor, type II (serine/threonine-kinase)'. At our Cardiology Unit, a Center of Excellence for diagnosis and therapy of PAH, within the project concerning the BMPR2 screening in PAH patients, to date, we (LS, SG) enrolled 30 probands. The BMPR2 analysis by direct sequencing of the 13 coding exons has been completed in 26 (19 female): 6 (23%) patients, 3 (43%) male and 3 (16%) female, showed a private mutation; these nucleotide changes were absent in dbSNP141, 1000Genomes and Exome-Variant-Server dataset. In four patients a BMPR2-haploinsufficiency is predictable, because the mutation leads to a premature termination codon; in other two were identified the mutations p.(Cys117Gly) (not described) and p.(Arg491Gln) (Deng Z et al., 2000) that, by use of Blastp, have been located within the consensus CCX{4-5}CN (hydrophilic-cysteine-rich-ligand-binding domain) and in the 'Catalytic domain of the Serine/Threonine-Kinases', rispectively. The cysteine substitution in the ligand-binding domain is plausibly causative of retention of the protein in the endoplasmic reticulum (Rudarakanchana N et al., 2002). This abstract describes preliminary data of the first Italian study aimed to characterize the genetic basis of PAH in a large number of patients; this will ensure a more focused and effective clinical management of PAH patients together with the goal to move toward application of personalized medicine.

Desmosomal gene mutations in dilated and arrythmogenic cardiomyopathy

F. Russo[1], *W. Serra[1], N. Gaibazzi[1], M. Zardini[1], G. Gonzi[1], M. F. Notarangelo[1], C. Manzalini[2], V. Caporale[1], P. A. Merlini[3], D. Ardissino[1], N. Marziliano[1];*
[1]Azienda Ospedaliero Universitaria di Parma, PARMA, Italy, [2]University of Bologna, BOLOGNA, Italy, [3]Azienda Ospedaliera Ospedale Niguarda Cà Granda, MILANO, Italy.

Desmosome proteins defects are associated with right ventricular (fibro)-fatty replacement of myocardial tissue (Arrythmogenic Right Ventricular Cardiomyopathy/Dysplasia, ARVC/D, MIM #609040 and #107970). The causative genes are: JUP (17q21), PKP2 (12p11), DSC2 (18q12.1), and DSG2 (18q12.1-q12.2), DSP (6p24), TGFB3 (14q24.3), TMEM43 (3p25.1), CTNNA3 (10q21.3). We screened the eight genes in a consecutive series of 45 ARVC/D patients and 25 DCM patients with arrhythmias. The corresponding mean age was 42.3±11.3 years and 45± 8.7 years. The ARVC/D was diagnosed on McKenna et al. criteria, the DCM according to the WHO criteria. The selected genes were analysed by targeted NGS (PGM, Life Technologies). We identified 54 mutations in 70 patients (30 of the 45 ARVC/D patients and 24 of the 25 DCM patients), with 12 patients carrying a double/compound heterozygous mutation and 6 patients carrying a triple mutation. The segregation of the gene defects with the phenotype in the family was confirmed in 3 probands (who fulfilled the McKenna criteria of ARVC/D). The recurrence of double/triple mutants in these patients raise serious problems in molecular diagnosis and family study, in particular the prediction of the development of the disease in young mutation carriers. The desmosome gene defects associated phenotypes include DCM with ventricular arrhythmias. The screening of the candidate genes should not stop when finding a mutation and the segregation of the phenotype with the defect is essential to help the correct interpretation of the molecular genetic data. Due to the current uncertainties, healthy mutation carriers should undergo

regular clinical monitoring.

Association of allelic polymorphisms of matrix Gla protein system genes with acute coronary syndrome in the Ukrainian population

V. Harbuzova, *A. Ataman, O. Obukhova;*
Sumy State University, Sumy, Ukraine.

Normal;heading 1;heading 2;heading 3;heading 4;heading 5;heading 6;heading 7;heading 8;heading 9;toc 1;toc 2;toc 3;toc 4;toc 5;toc 6;toc 7;toc 8;toc 9;caption;Title;Default Paragraph Font;Subtitle;Strong;Emphasis;Table Grid;

Background - The matrix Gla-protein (MGP) has an important role in vessel protection against ectopic calcification; its presence in tissues prevents initiation and spread of a pathological calcification. It gave a reason to talk about MGP functional system that yields, except for the MGP protein, such factors as vitamin D receptor, enzymes involved in biochemical transformations of MGP, vitamin K epoxide reductase and vitamin K-dependent gamma-glutamyl carboxylase, including bone morphogenetic protein-2.

Methods - The association between acute coronary syndrome (ACS) and 10 polymorphic variants of MGP-system genes was analysed. Venous blood of 118 patients with ACS and 234 healthy individuals was used for genotyping. Polymorphisms of MGP-system genes were examined with PCR-RFLP methodology.

Results - The risk of ACS in carriers of minor allele A/A (G-7A) in 2.8 times higher; B/B (BsmI) in 2.1 times higher; Gln/Gln (Arg325Gln) and C/C (T2255C) twice higher than in carriers of the major allele. The best classification model is a two-component model that includes polymorphisms MGP gene G-7A and Thr83Ala. The coincidence of similar orientation genotypes variants for chosen polymorphism was associated with a high risk of developing ACS.

Conclution - There is an association between the ACS and some polymorphic variants of genes of MGP system.

Grant reference: The study was a part of scientific project "Association ectopic calcification genes polymorphisms with widespread cardiovascular diseases and their complications" supported by the Ministry of Education and Science of Ukraine, 2013-2014 (No 0113U000132).

ROS1, TAS2R50, ZNF627, MIAF3 genes, 16q23.1, 6p24, 9p21 chromosomal regions and myocardial infarction in siberia caucasians

P. Orlov[1,2], *V. Maksimov*[1,2], *V. Gafarov*[2], *S. Malyunina*[2], *A. Kuimov*[3], *M. Voevoda*[1,2];
[1]*Laboratory Molecular Genetics of Human The Institute of Cytology and Genetics the Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation,* [2]*Laboratory molecular genetic studies of therapeutic diseases Federal State Budgetary Institution of Internal and Preventive Medicine SB RAMS, Novosibirsk, Russian Federation,* [3]*Department of Faculty Therapy Novosibirsk State Medical University Novosibirsk, Novosibirsk, Russian Federation.*

The purpose: aim of the study to test SNP identified in recent genome-wide association studies on the suitability as risk markers of myocardial infarction in the Siberian population Caucasians.

Materials and Methods: The study had taken two groups: myocardial infarction 275 people and a control group 420 people, comparable in sex and age differences are formed on the basis of population sample of 45-69 year old residents of Novosibirsk, established under the international project HAPIEE. Genomic DNA was isolated from venous blood by phenol-chloroform extraction. Gene polymorphism was tested by real-time PCR according to the protocol of the manufacturer (probes TaqMan, Applied Biosystems, USA) on the instrument ABI 7900HT. The study included the following single nucleotide polymorphisms: rs499818, rs619203, rs10757278 and rs1333049, rs1376251, rs2549513, rs4804611, rs17465637.

Summary of the results: For rs1376251, we have shown that the CC genotype was associated with MI OR = 1.37 (95% CI 1.005-1.888 CCvs. CT + TT p = 0.05). For rs499818 was shown that the AA genotype has a protective effect OR = 0.3 (95% CI 0.103-0.883 AAvs. AG + GG p = 0.025). Considering rs10757278 genotype GG shown predisposing OR = 2.1 (95% CI 1.47-3.05, p = 0.001), and CC genotypes in rs1333049 CC OR = 2.1 (95% CI 1.47-3.05, p = 0.001)

Conclusions: We identified a significant association between rs1376251, rs499818, rs10757278, rs1333049 and myocardial infarction.

J05.10

The molecular genetic markers of myocardial infarction and sudden cardiac death in a Russian population.

A. A. Ivanova[1], *V. N. Maksimov*[1,2], *P. S. Orlov*[1,3], *D. E. Ivanoshchuk*[1,3], *S. V. Savchenko*[4,2], *M. I. Voevoda*[1,2];
[1]*Federal State Budgetary Institution of Internal and Preventive Medicine SB RAMS, Novosibirsk, Russian Federation,* [2]*Novosibirsk State Medical University, Novosibirsk, Russian Federation,* [3]*Institute of Cytology and Genetics SB RAS, Novosibirsk, Russian Federation,* [4]*Novosibirsk Regional Office of Forensic Medical Examination, Novosibirsk, Russian Federation.*

Motivation and Aim: Recent genome-wide studies have detected the association of some single nucleotide polymorphisms (SNPs) with an increased risk of myocardial infarction. According to ICD-10, sudden cardiac death (SCD) does not include the death of myocardial infarction; however, the clinical picture and the mechanism of fatal outcome development in sudden cardiac death and myocardial infarction are rather similar. So the aim of this work is investigate the association of rs17465637 gene MIAF3 (1q41), rs1376251 gene TAS2R50 (12p13), rs4804611 gene ZNF627 (19p13), rs619203 gene ROS1 (6q22), rs1333049 (9p21), rs10757278 (9p21), rs2549513 (16q23), rs499818 (6p24) associated with myocardial infarction available from the international genome-wide studies with SCD in a case study of a Russian population.

Methods and Algorithms: A sample of SCD cases (n = 285) was formed using the WHO criteria; the control sample (n = 421) was selected according to sex and age.

Results: No statistically significant differences in the genotype and allelic frequencies of rs17465637, rs2549513, rs1376251, rs4804611, and rs619203 polymorphisms between SCD cases and control were detectable. Genotypes CC of rs1333049 and GG of rs10757278 are associated with an increased SCD risk in men (p=0.019, OR=1.7, 95%CI 1.1-2.8; p=0.011, OR=1.8, 95%CI 1.2-2.8, respectively). Genotype AG of rs499818 is associated with an increased SCD risk in the women over 50 years old (p=0.009, OR=2.4, 95%CI 1.3-4.6).

Conclusion: Polymorphisms rs1333049 and rs10757278 are associated with SCD in men and rs499818 in the women aged over 50 years.

J05.11

Molecular-genetic analyses of single nucleotide polymorphism in the ZBTB17 gene in Slovak patients with dilated cardiomyopathy

I. Boronova[1], *J. Bernasovska*[1], *J. Kmec*[2], *A. Kisko*[3], *P. Ferenc*[1], *V. Szabadosova*[1];
[1]*University of Prešov, Prešov, Slovakia,* [2]*Cardiocentre, Faculty Hospital of J.A.Reyman, Prešov, Slovakia,* [3]*Cardiology, Reimanus, Prešov, Slovakia.*

Dilated cardiomyopathy (DCM) is a primary myocardial disease and genetically heterogeneous disorder. It represents a major cause of cardiovascular morbidity and mortality and is characterized by systolic dysfunction, dilation, and impaired contraction of the ventricles, often leading to chronic heart failure and eventually requiring cardiac transplantation. Mutations in both sarcomeric and cytoskeletal genes have been implicated in DCM. Recently, a GWAS study on DCM indicated that rs10927875 single nucleotide polymorphism (SNP) in ZBTB17 gene was associated with DCM. The aim of the study was to analyze the distribution of SNP rs10927875 in ZBTB17 gene in 150 Slovak subjects, 55 patients with DCM (51.7±6.9 years) and 95 healthy controls (51.7±6.9 years) using the Custom Taqman®SNP Genotyping assays. The distribution of ZBTB17 gene rs10927875 polymorphism in Slovak patients with DCM was as follows: CC (36.4%), CT (58.2%), TT (5.4%), in controls: CC (44.2%), CT (51.6%), TT (4.2%). There was no difference in genotype or allele frequencies in ZBTB17 gene rs10927875 polymorphism (OR=0.75, 95% CI=0.46-1.23, P=0.25) between DCM patients and control subjects. Further studies in numerous files and additional functional investigations are needed to fully understand the roles of genetic associations. Knowledge of the genetic risk factors for DCM is important to initiate treatment prior to symptomatic onset of the disease to delay its occurrence or possibly halt its progression.

This study is the result of implementation of the project APVV-0644-12.

J05.12

GENES KIAA1462, CDKN2BAS1, LIG1, ADAMDEC1, APOA2 IN PREDISPOSITION TO MYOCARDIAL INFARCTION

I. A. Goncharova[1,2], *O. A. Makeeva*[1,2], *M. V. Golubenko*[1,2], *N. V. Tarasenko*[1], *A. V. Markov*[1], *V. P. Puzyrev*[1];
[1]*Scientific Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Reserch Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation.*

A set of SNPs in genes related to fibrogenesis and cardiovascular diseases was investigated in the sample of patients with myocardial infarction (IM), which were collected in Tomsk and Kemerovo cities in West Siberia (Russians). The patients were divided into two subgroups according to presence or absence of co-existing diseases: (1) patients with IM and without other diseases of cardiovascular continuum (hypertension, hypercholesterolemia, type 2 diabetes mellitus) - "isolated IM" (n=60); (2) patients with IM and all

the pathologies, mentioned above - "syntropy of cardiovascular disease continuum" (syntropy CDC) (n=96). As a control, population sample of Tomsk residents (n=300) was considered. Altogether, 58 SNPs were genotyped by mass-spectrometry (Sequenom MassARRAY).
Comparing genotype frequencies between patients and controls, we found following significant associations: (1) rs1333049 in CDKN2BAS1: allele C (OR=1.35 (1.00-1.82), p=0.024); CC+CG vs GG (OR=1.68 (1.00-2.83), p=0.047); (2) rs20579 in LIG1: allele C (OR=1.78 (1.11-2.81), p=0.010); CC vs CT+TT (OR=1.69 (1.00-2.72); p=0.009); (3) rs3739998 in KIAA1462: allele C (OR=1,66 (1.23-2.23), p=0.001); CC vs CG+GG (OR=2.46 (1.48-4.08), p=0.0002); (4) rs5082 in APOA2: allele T (OR=1.45 (1.07-1.96), p=0.015), TT vs TC+CC (OR = 1.76 (1.13-2.70), p=0.032).
Association analysis in the subgroups of patients has revealed differences in the genetic predisposition to the isolated IM and syntropy CDC. The KIAA1462 (rs3739998) association is common for both groups. LIG1 (rs20579) and ADAMDEC1 (rs3765124) are associated with the isolated IM. CDKN2BAS1 (rs1333049) and APOA2 (rs5082) are associated with the syntropy CDC.

J05.13
The frequencies of mutation in the prothrombin (FII G20210A) gene and factor V Leiden (FVL) in the Russian endurance elite athletes.

N. K. Vereina[1], *D. A. Dyatlov*[2], *Y. E. Pushkareva*[1], *E. F. Orekhov*[2], *V. P. Pushkarev*[2,1];
[1]*South-Ural State Medical University, Chelyabinsk, Russian Federation,* [2]*Ural State University of Physical Culture, Chelyabinsk, Russian Federation.*

Endurance athletes represent a group of risk of arterial and venous thromboses. Cases of coronary thrombosis in marathon, VTE in triathlon were described (Albano AJ, 2012; Tao K, 2010; Hull CM, 2014). It is caused by several factors: dehydration with haemoconcentration, pharmacological stimulators, injuries, immobilization at traveling, etc. The role of a hereditary thrombophilia at this contingent is studied a little.
PURPOSE. To investigate the frequencies of FII 20210A and FVL mutations in sample of Russian endurance athletes.
METHODS. 559 unrelated Caucasians were studied. Athletes: 264 persons, age: 26,3±10,3 years (±SD), including 152 ice hockey players, 62 biathlonists, 18 triathlonists, 14 walkers, 3 runners, one cyclist. 87 athletes were winners of the international competitions (elite). Sedentary control: 295 persons, age of 31,2±10,4 years. All participants gave the written informed consent. Biological samples: buccal epithelium. gDNA was extracted by sorbent method. Genotyping: TaqMan® SNP Genotyping Assays, StepOne™ Real-Time PCR System (LifeTechnologies, USA).
RESULTS. All participants had no the burdened thrombotic anamnesis. Pathological homozygotes were absent. Frequencies of heterozygotes (±95% confidence interval) are present in Table.

	FII 20210A	FVL
Controls	2,4±1,7	1,7±1,5
Athletes, all	3,0±2,1	4,5±2,5
Athletes, elite	6,9±5,3	4,6±4,4

Frequencies of heterozygotes didn't differ significantly between groups of athletes (pooled and elite level) and controls. Aerobic conditions accompany endurance sports, stimulate fibrinolysis and provide antithrombotic effect.
CONCLUSIONS. Observed frequencies of FVL and FII 20210A in sample of Russian endurance athletes didn't differ from sedentary control. Endurance sports didn't increase thrombotic risk for young carriers of FVL and FII 20210A heterozygotes.

J05.14
ACE Gene I/D Polymorphism in the Czech population

M. Bittóová, *J. Kalinaj, M. Koudová, R. Alánová, M. Hrabíková, M. Zobaníková, V. Králíková, T. Votíková;*
GHC GENETICS, Prague, Czech Republic.

Angiotensin converting enzyme (ACE) is a part of RAAS system, which regulates blood pressure, management of water and minerals and has behavioral effects (thirst, taste, memory and learning regulation). The enzyme is coded by ACE gene, the most frequent Polymorphism I/D determinates the presence of insertion (I) or deletion (D) of 287bp Alu repeat sequence in intron 16. This polymorphism regulates plasma level of enzyme which decreases from DD to II genotype. The aim of our study was to determinate allele/genotype frequencies of this polymorphism in Czech population.
940 individuals (470 F, 470M, age 18-69 years) of the Czech population were tested. DNA was isolated from oral mucosa or blood using MagCore HF16. ACE Gene I/D Polymorphism was tested by the End-point PCR and agarose electrophoresis with visualization under UV light, verification was performed by strip assay reverse hybridization method.
Allele I was detected in 47,2%, allele D in 52,8% of samples. The frequency of genotypes: II - 21,8% (21,3% F, 22,6% M), ID- 50,8% (51,7% F, 49,5% M) a DD- 27,4% (27,0% F, 27,9% M).
According to published data of the European populations, the Czech population with slight predominance of allele D and risk DD genotype (+5,6 %) surprisingly correlates with Hungarian and Turkish population, while it differs from the Polish population. Because there are significant differences among populations, it is important that the control group of Czech population was made for further genetic studies of this polymorphism in relation to diseases and pathological conditions of Czech patients.

J05.15
Prevalence of NOTCH1 signalling pathway mutations in subjects with bicuspid aortic valve

N. Marziliano[1], **N. Gaibazzi**[1], *C. Siniscalchi*[2], *W. Serra*[1], *V. Caporale*[1], *C. Manzalini*[3], *P. A. Merlini*[4], *F. M. Notarangelo*[1], *D. Ardissino*[1];
[1]*Azienda Ospedaliero Universitaria di Parma, PARMA, Italy,* [2]*University of Parma, PARMA, Italy,* [3]*University of Bologna, BOLOGNA, Italy,* [4]*Azienda Ospedaliera Ospedale Cà Granda Niguarda, MILANO, Italy.*

The bicuspid aortic valve (BAV) (OMIM #109730) is the commonest congenital cardiac malformation, occurring in ~2% of the population. Missense mutations in the NOTCH1 gene have been shown to be associated with calcific aortic valve disease plus BAV. However mutations in the NOTCH1 gene only partially explain the presence of BAV in the absence of other syndromic features (i.e. Marfan Syndrome, Loeys Dietz Syndrome type I and II and Ehlers Danlos type IV Syndrome). In this study we analysed 50 patients with true BAV assessed by cardiac imaging (none of them with syndromic feature), for mutations in genes (n=48) belonging to the NOTCH1 signalling pathway (http://pathcards.genecards.org/pathway/1766) by means of massive parallel sequencing (My Seq, Illumina). In 35 patients (70%), we identified novel de novo mutations in NOTCH1, 15 (30%) patients inherited rare gene variants in FOXC2, FOXL1, PSEN2, ADAM17, DTX2 and DTX4. Some of the identified variations (n=26, 52%) coexisted in the same patient. The biological significance of such rare variations is unknown, but our findings strengthen the role of NOTCH pathway in cardiac valve development, indicating that BAV is, at least in part, an inherited familial disorder. This report strengthens the use of massive parallel sequencing to provide insights in common disorders. Moreover, the coexistence of multiple rare variants suggests in some cases a cumulative effect, as shown for other complex disease.

J05.16
Alport syndrome and cardiovascular abnormalities. D. Shentseva, O. Groznova, L. Shagam, A. Polyakova, V. Sukhorukov, N. Konkova, V. Dlin. Pirogov Russian National Research Medical University (RNRMU).

D. Shentseva, *O. Groznova, L. Shagam, A. Polyakova, V. Sukhorukov, N. Konkova, V. Dlin;*
Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Alport syndrome (AS) is a genetically determined glomerulopathy that is caused by mutations in type IV alpha collagen chain genes (COL4A3, COL4A4or COL4A5) and clinically characterizedby hematuria, proteinuria andend-stage kidney disease (ESRD). The syndrome is often combined with sensorineural hearing loss and ocular pathology.
We examined 21 children with Alport syndrome, the diagnosis was verified by molecular genetic studies. In 83% cases the mutation COL4A5 was determined, and X-linked version of the SA was verified.
By echocardiography we observed in children with X-linked AS up to 9 years of age dimensions of the aortic root and fibrous ring of the aortic valve does not exceed the normative values (up to 95 percentile according to body surface area). In older children (10-17 years) in 62% of cases of aortic root dilatation, followed by dilation of the aortic annulus and diastolic aortic valve prolapse.
The of the aorta in Alport syndrome is still poorly understood. To date, there is no doubt that a significant proportion of patients have manifestation of vascular disease.

J05.17
Hypoplastic left heart syndrome in a case with partial 18p monosomy and partial 20q trisomy

B. Aleksiūnienė, *A. Matulevičienė, E. Benušienė;*
Department of Human and Medical Genetics, Vilnius University, Vilnius, Lithuania.

Chromosomal deletions and duplications have been associated with a variety of congenital cardiac malformations. We report on a patient with prenatally diagnosed congenital left ventricular hypoplasia syndrome, born to healthy non-consanguineous parents with complicated family history (two

miscarriages). After surgery for the condition, bradycardia suddenly developed leading to a fatal outcome on 3rd day of his life. The following dysmorphic features were present in the patient: frontal bossing, prominent nasal bridge, thin lips, oversized ears, left preauricular pit, ear lobe creases on both ears, a single transverse palmar crease on the left palm). X-ray showed thoracic hemivertebrae and 13 rib pairs.
Chromosome analysis of peripheral blood lymphocytes of proband revealed normal karyotype. Whole genome genotyping analysis of the patient showed an unbalanced translocation of paternal origin: a deletion in the region 18p11.32 - 18p11.31 (12,842-4,652,432) and a duplication in the region 20q13.2 - 20q13.33 (50,208,036-62,909,908) of 4.6 Mb and 12.7 Mb in size, respectively. The clinical cardiac characteristics of patient could be associated with combination of both chromosomal aberrations, containing 27 OMIM annotated genes in total. Combination of genes in these regions could contribute to the development of the cardiac malformation in our patient.

J05.18

Multidisciplinary diagnostic workup in cardiovascular patients

E. Manfredini[1], *P. Primignani*[1], *F. Turazza*[2], *M. Friferio*[2], *G. P. Gesu*[1], *S. Penco*[1];
[1]*ospedale Niguarda, Medical genetics unit, Milan, Italy,* [2]*ospedale Niguarda, department of Cardiology, Milan, Italy.*

Since February 2012 we recruited a cohort of 380 cardiovascular patients from the Medical Genetic Unit and the Department of Cardiology of Niguarda Ca' Granda Hospital of Milan (Italy) in a multidisciplinary diagnostic workup including cardiologic evaluation and genetic counseling.
After clinical and instrumental evaluation all patients received a genetic counselling and signed an informed consent to the genetic study; we tested 18 gene by Sanger sequencing analysis
We report here a summary of the results: 109 patients presented Hypertrophic cardiomyopathy (HCM), 71 Dilated cardiomyopathy (DCM), 47 Arrhythmogenic Right Ventricular cardiomyopathy (ARVC), 16 Fabry disease, 37 Marfan syndrome, 19 Loeys-Dietz, 20 Noonan/Leopard syndrome, 15 Left/Right Ventricular non-Compaction (LVNC/RVNC) and 46 Channelopathies (35 Brugada and 11 Long QT).
In HCM affected subjects we found causative mutation as follows: 24,7% MYBPC3, 9,1% MYH7, and 1,8% TNNT2 genes; in DCM patients: 19,7% in LMNA and 2,8% in SCN5A genes; in Brugada patients: 28,5% SCN5A gene; in LQ patients: 18%mutations in KCNH2 gene; in ARVC patients: 31.9% in PKP2 and 2.1% in JUP genes; in Marfan patients: 27% in FBN1 and 2.7% in TGFBR2 genes; in Noonan /Leopard syndrome patients: 25% in PTPN11gene and in LVNC patients: 13.3% in LDB3 gene.
Search for causative mutations is an integral part of the cardiomyopathy diagnosis. The finding of a causative mutation in a patient permits the identification of family members who may have the disease in an asymptomatic way or who may develop disorders in the future and may in turn transmit the mutation to their offspring.

J05.19

Association of VDR gene polymorphisms with hypertension in patients with atherothrombotic ischemic stroke in Ukrainian population

O. Obukhova, *V. Harbuzova, A. Ataman;*
Sumy State University, Sumy, Ukraine.

Background - Recently genes, which depend on the intensity and direction of the calcium-phosphorus metabolism in the body as a whole and in certain tissues, have been named among factors that influence the damage of blood vessels. These includes vitamin D receptor gene (*VDR*). Furthermore, according to clinical trials, there is an inverse correlation between low level of vitamin D and factors, such as blood pressure (BP), coronary atherosclerosis and various cardiovascular diseases, arterial hypertension in particular.
Materials and methods - Venous blood of 170 patients with atherothrombotic ischemic stroke (AIS) and 124 healthy individuals (control group) was used for genotyping. Four polymorphisms (*Fok*I, *Bsm*I, *Apa*I, *Taq*I) of gene *VDR* were examined with PCR-RFLP methodology.
Results - The association between genotypes of polymorphic variants *Fok*I, *Bsm*I, *Apa*I and *Taq*I *VDR*-gene with the development of atherothrombotic ischemic stroke in people with normal and high blood pressure was found (Table).

Table - The distribution of individuals with different genotypes for polymorphic variants of *VDR* gene in the control group and patients with AIS depending on the blood pressure

BP	*FokI*		*BsmI*		*ApaI*				*TaqI*	
	F/F		*b/b*		*a/a*		*a/A*		*T/T*	
	Control group	Stroke case	Control group	Stroke case	Control group	Stroke case	Control group	Stroke case	Control group	Stroke case
BP(-) (*n*)	16 (48.5%)	6 (15.0%)	23 (41.1%)	16 (22.5%)	17 (43.6%)	7 (15.6%)	21 (42.0%)	22 (25.9%)	21 (39.6%)	15 (22.1%)
BP(+) (*n*)	17 (51.5%)	34 (85.0%)	33 (58.9%)	55 (77.5%)	22 (56.4%)	38 (84.4%)	29 (58.0%)	63 (74.1%)	32 (60.4%)	53 (77.9%)
χ^2	9.629		5.055		8.046		3.768		4.396	
P	0.002		0.025		0.005		0.052		0.036	

Note: n – the number of people, BP(-) – normal blood pressure, BP(+) – high blood pressure, P – level of significance by χ^2 test.

Conclusion – In patients with genotype F/F, b/b, a/a, a/A, and T/T polymorphic variants *Fok*I, *Bsm*I, *Apa*I, *Taq*I of *VDR* gene the association between presence of hypertension and development of atherothrombotic ischemic stroke was established.
Grant reference: The study was a part of the scientific project "Association ectopic calcification genes polymorphisms with widespread cardiovascular diseases and their complications" supported by the Ministry of Education and Science of Ukraine, 2013-2014 (No 0113U000132).

Mutations in *TAX1BP3* cause Dilated Cardiomyopathy with Septo-Optic Dysplasia

E. Reinstein[1,2];
[1]*Rabin Medical Center, Petach Tikva, Israel,* [2]*Tel Aviv University, Tel Aviv, Israel.*

We describe a Bedouin family with a novel autosomal recessive syndrome characterized by dilated cardiomyopathy and septo-optic dysplasia. Genetic analysis revealed a homozygous missense mutation in *TAX1BP3,* which encodes a small PDZ-containing protein implicated in regulation of the Wnt/β-catenin signaling pathway, as the causative mutation. The mutation affects a conserved residue located at the core of TAX1BP3 binding pocket and is predicted to impair the nature of a crucial hydrophobic patch, thereby interrupting the structure and stability of the protein, and its ability to interact with other proteins. *TAX1BP3* is highly expressed in heart and brain and consistent with the clinical findings observed in our patients, a knockdown of *TAX1BP3* causes elongation defects, enlarged pericard and enlarged head structures in zebrafish embryos. Thus, we describe a new genetic disorder that expands the monogenic cardiomyopathy disease spectrum and suggests that *TAX1BP3* is essential for heart and brain development.

Hypoplastic left heart syndrome (HLHS) is one of the most common and lethal congenital cardiac anomalies, characterized by an underdeveloped left ventricle, mitral valve and aorta. Despite strong evidence of an underlying genetic aetiology, only a minority of cases can be explained on genetic bases. Using genomics as well clinical studies, our work aims to identify new genes contributing to HLHS pathogenesis and explaining clinical and anatomical variability. We identified by exome sequencing novel de novo mutations in genes not previously associated to HLHS. In silico studies suggested that these genes are potentially involved in cardiac morphogenesis, and molecular 3D modeling highlighted the potential pathogenic effect of the identified mutations. Furthermore, we performed in vitro functional characterization of one of these variants falling in low density lipoprotein receptor-related protein 6 (LRP6) gene. The preliminary results suggest that the mutation in LRP6 impairs the WNT signaling required in the induction of endothelial to mesenchymal transition (EndMT) during ventricular chambers formation. Further studies are required to confirm the mechanism by which LRP6 is involved in HLHS pathogenesis.
In conclusion, due to genetic heterogeneity and phenotypic variability, elucidating the causes of HLHS remains challenging. The development of this multidisciplinary approach will help to better understand HLHS by uncovering the multiple genetic mechanisms. Others patients are needed to find new genes.
Funding sources:This work was supported by fellowship from Fondazione Umberto Veronesi to M.E.S.

Complex analysis of predisposition to essential hypertension: differential expression and multigene associations of chemokine genes

Y. Timasheva, *T. Nasibullin, O. Mustafina;*

Institute of Biochemistry and Genetics Ufa Science Centre Russian Academy of Sciences, Ufa, Russian Federation.

Essential hypertension (EH) is a complex disease that arises from an interaction between environmental and genetic factors. It is been hypothesized that systemic inflammation plays a role in the pathogenesis of hypertension. We aimed to investigate expression profiles of inflammatory mediator genes in patients with EH and to analyze an association between these genes and the development of hypertension.

We performed the analysis of gene expression in peripheral blood leukocytes of patients with EH (N=57) and healthy individuals (N=51) using microarray technology (RT2ProfilerTM PCR Array, SABiosciences Corporation, Qiagen) with subsequent validation of the obtained results by quantitative real-time RT-PCR. The results have confirmed significant differences in transcriptional activity of CCL2, CCL8, CCL18, CX3CR1, CXCL1, CXCL13, CCR5, IL10, IL13, XCR1, and CCR2 genes in cases and controls (p=0.001).

Next, we performed genotyping of polymorphic loci in genes with altered expression profile in the group of patients with EH (N=216) and healthy individuals (N=314). Allelic combinations associated with the disease were identified using Markov chain Monte-Carlo approach (APSampler).

We identified three allelic combinations of chemokine and chemokine receptor genes associated with the increased risk of EH: CCL2 *T+CCR2*I+CX3CR1*M+CCR5*I+CXCR2*T (OR=6.342, FDR=0.04); CCR2*I+ CX3CR1*M+CXCL1*G+CXCR2*T (OR=4.48, FDR=0.04); CCR2*V+CXCL8*A+CCR5*I+ XCR1*T/T (OR=3.11, FDR=0.04).

The results of our study suggest that chemokines and chemokine receptors may play a role in the development of essential hypertension, and demonstrate that the interplay of the polymorphic loci may influence susceptibility to the disease.

The study was supported by the RFBR grants 13-04-01561_a, 14-04-01169_a.

Role of peroxisome proliferator-activated receptor- γ coactivator -1 α gene polymorphisms and association of type II diabetes mellitus in south Indian population

S. Dayakar[1,2,3], *S. Purna Prasad*[4], *M. Sadhnani*[5];
[1]*Laboratory Medicine & Molecular Diagnostics,Rajiv Gandhi Centre For Biotechnology, Thiruvananthapuram, India,* [2]*Department of Clinical Biochemistry, Institute of Genetics and Hospital for Genetic Diseases,Osmania University, Hyderabad-500016, India,* [3]*Apollo Hospitals Educational And Research Foundation, Hyderabad, India,* [4]*Anglia Ruskin University, Cambridge, United Kingdom,* [5]*Department of Clinical Biochemistry, Institute of Genetics and Hospital for Genetic Diseases,Osmania University, Hyderabad, India.*

Background In the present study we aim to investigate if variability in the peroxisome proliferator-activated receptor-gamma coactivator-1(PGC-1) gene is associated with Type II (non-insulin-dependent) diabetes mellitus. The objective of study was to explore the relationship between SNPs of PGC-1 α and type 2 diabetes in the south Indian population

Methods The SNPs in all exons of the PGC-1 gene was investigated in 50 type II diabetic patients using PCR-single strand conformational polymorphism (PCR-SSCP) .183 type II diabetic patients and 195 healthy controls were genotyped by restriction fragment length polymorphism -polymerase chain reaction (RFLP-PCR).

Results Three frequent SNPs (Thr394Thr, Gly482Ser and Thr528Thr) were found in exon of the PGC-1α gene. Only the Gly482Ser variant had a different distribution between diabetic patients and healthy subjects, with the 482Ser allele more frequent in patients than in controls(40.1% vs 29.3% P <0.01) .In controls ,the 482Ser(A) carriers were more likely to have higher levels of total cholesterol and low-density lipoprotein cholesterol than the 482 gly(G) carriers. The 394-482G-528A haplotype was associated with protection from diabetes, while the 394A-482A-528A was associated with the diabetes.

Conclusions The results suggested that the 482Ser variant of PGC-1 α conferred the susceptibility to type II diabetes in south Indian population

Kearns-Sayre syndrome and a mtDNA deletion in Bulgarian patient

T. Todorov[1], *I. Litvinenko*[2], *D. Stamatov*[2], *A. Todorova*[1,3];
[1]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [2]*Child neurology clinic, Department of pediatrics, University Pediatric Hospital, Sofia, Bulgaria,* [3]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria.*

Kearns-Sayre syndrome (KSS) is a mitochondrial disease characterized by progressive external ophthalmoplegia, pigmentary retinitis and an onset before the age of 20 years. Common additional features include bilateral sensorineural deafness, cerebellar ataxia, heart block, skeletal muscle myopathy, intestinal, endocrine disorders and renal failure. Patients with KSS have a large deletion of mtDNA, ranging from 1,000 to 10,000 nucleotides. The condition is rare and most cases are sporadic. The risk of the mother being carrier of a large mtDNA deletion and transmitting it to her child has been estimated to be less than 4%.

Here we report a male patient with KSS. The first clinical findings dated from the age of 8 years and include bilateral ptosis, ophtalmoplegia. Around the age of 10 years the patient muscle weakness, dysmetria in climbing stairs and uprising, ataxic gait and tremor. The affected patient also showed positive test of Romberg and reflex of Babinski.

The molecular genetic testing by MLPA (SALSA MLPA P125-B1 mitochondria) revealed large deletion encompassing a number of mitochondrial genes *COX1*, *COX2*, *ATP6*, *COX3*, *ND3*, *ND4*, *ND5* (the location of the deleted probes along the mitochondrial genome 7146 - 13168). The deletion covers the genes involved in the oxidative phosphorylation pathway. The deletion is heteroplasmic ~ 50%.

We detected a classical heteroplasmic mtDNA deletion associated with KSS, but atypical clinical picture. Our patient did not show pigmentary retinitis, MRI showed normal bilateral optic nerve. No sensorineural impairment is detected. Our results showed that there is no simple genotype/phenotype correlation in KSS.

Identification of a Novel N-acetylgalactosamine-6-sulfate sulfatase Gene Mutation in an Iranian twin with Mucopolysaccharidosis Type-IVA

L. Mahootipour, *M. Noruzinia, G. Bahrami Monajemi, M. Ahmadvand;*
Sarem Cell Research Centre-SCRC, Tehran, Iran, Islamic Republic of.

Background:mucopolysaccharidosis Type IVA or Morquio A Syndrome, which is inherited as an autosomal recessive trait, is a lysosomal storage disorder and results from the deficiency of N-acetylgalactosamine-6-sulfate sulfatase activity. This deficiency leads to lysosomal accumulation of keratin sulfate and chondroitin 6-sulfate. In this study, GALNS mutation analysis was performed on Iranian twin patients.

Methods: Mutation screening of the GALNS gene was performed by PCR and direct sequence analyses using genomic DNAsamples.

Results: Sequencing analysis revealed a novel homozygous missense mutation in theGALNS gene at c.148G>A [p. G50R] in Iranian twin MPS-IVA Patients.

Conclusion:this data may be useful for carrier detection and prenatal diagnosis in informative families whose specific mutations have not been identified.

The clinical and lab manifestations of the onset of Methylmalonic aciduria

D. Blanita[1], *A. Nicolescu*[2,3], *V. Sacara*[1], *V. Petrovici*[1], *S. Garaeva*[4], *I. Tarcomnicu*[5], *D. Stambouli*[5], *L. Balogh*[6], *C. Deleanu*[2,3], *N. Usurelu*[1];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*"Petru Poni" Institute of Macromolecular Chemistry of the Romanian Academy, Iasi, Romania,* [3]*"C. D. Nenitescu" Centre of Organic Chemistry of the Romanian Academy, Bucharest, Romania,* [4]*Institute of Physiology and Sanocreatology of Academy of Science of Moldova, Chisinau, Moldova, Republic of,* [5]*"CytoGenomic" Medical Laboratory, Bucharest, Romania,* [6]*1st Department of Pediatrics, Semmelweis University, Budapest, Hungary.*

Introduction: Methylmalonic aciduria (MMA) comprises a group of diverse inherited disorders causing methylmalonic acid (MMAc) accumulation in body fluids. The total incidence estimates to 1:48,000-100,000 newborns.

Material: We report on 5 Moldavian children diagnosed with MMA (3 newborns, 7 and 30 mo old). Amino acids by liquid chromatography (blood/urine), NMR spectroscopy (urine for organic acids) and tandem MS/MS were used for diagnosis.

Results: In three cases the clinical manifestations occurred in the neonatal period by: body weight loss [-15%], dehydration, generalized hypotonia, recurrent vomiting, seizures, frequent apnoea, precoma, severe metabolic acidosis: anion gap[17-26mmol/L], low pH[7.23-7.33], hyperlactacidaemia[2.6-8.0mmol/L], hypoglycaemia[1.8-2.8mmol/L], hyperammonaemia[126-390µmol/L], ketonuria. In one case clinical signs debuted in the first week of life, but not being diagnosed he continued to present frequent precoma, ketoacidosis and sings of pancreatitis being defined as a MMA at 30 mo old. In another case, patient presented late onset from 7 mo old associated with similar symptoms as the previous case. In all cases there were identified: high level of MMAc in urine, positive C3[6.49-21.39,ref.val<4.4] and C3/C2[0.33-1.05,ref.val.<0.2]. In four children with neonatal clinical onset the urine MMAc was over 19 mol/molCrea when diagnosed with severe clinical evolution, while in the late onset child the urine MMAc was under 2 mol/molCrea with mild evolution. There was no apparent correlation between

urine MMAc and C3. All children required a special diet.
Conclusion: The results support the need to develop a system for early diagnosis of IEM in Moldova. The neonatal onset is predictive for severe evolution of disease.

J06.05

A novel mutation of GALNS gene in mucopolysaccharidosis type 4A

S. Seyedhassani[1], *M. Neshan*[1,2], *M. Yavari*[1,3], *S. Asadollahi*[1], *F. Harazi*[1];
[1]Dr. Seyedhassani Genetic Center, Yazd, Iran, Islamic Republic of, [2]Yazd welfare organisation, Yazd, Iran, Islamic Republic of, [3]Yazd science university, Yazd, Iran, Islamic Republic of.

Mucopolysaccharidosis type IVA is an autosomal recessive lysosomal storage disease characterized by intracellular accumulation of keratan sulfate and chondroitin-6-sulfate. Key clinical features include short stature, skeletal dysplasia, dental anomalies, and corneal clouding. Intelligence is normal and there is no direct central nervous system involvement, although the skeletal changes may result in neurologic complications. There is variable severity, but patients with the severe phenotype usually do not survive past the second or third decade of life. N-acetylgalactosamine 6-sulfatase (GALNS) enzyme activity is recommended as the first diagnostic test, especially when clinical findings strongly indicate MPS IVA and urine GAG analysis is normal. GALNS enzyme activity can be measured in cultured fibroblasts or leukocytes.
Case Report: The case was a 12 years old boy born from consanguineous marriage due to normal pregnancy and delivery. He had normal growth and development until 2 years old. Then appeard spinal muscle weakness leading to kyphoscoliosis. The other clinical manifestations were ankle valgum, genu valgum, hip dysplasia and spinal cord compression that was operated 4 years ago.Molecular Genetic Testing: DNA sample of the proband was investigated for the mutation in coding exons of GALNS gene, and then the findings were compared with parents. A homozygous mutation at codon 181 TAC>TGC (Y>C) was found. The parents were heterozygous at this position. This mutation was not been reported yet. The result was analyzed by online PolyPhen-2 software too. Thus, this mutation could be considered as a pathogenic mutation for inducing the disease.

J06.06

Effect of sevoflurane anaesthesia on serum glutathione S-transferase concentration and the association with the CYP2E1, GSTA1 and GSTP1 genetic variants.

O. Zakerska-Banaszak[1,2], *M. Skrzypczak-Zielinska*[2], *B. Tamowicz*[3], *M. Skibinska*[4], *M. Szalata*[5], *A. Mikstacki*[3], *R. Slomski*[2,5];
[1]The NanoBioMedical Centre, Poznań, Poland, [2]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland, [3]Department of Anaesthesiology and Intensive Therapy, Regional Hospital, Poznan, Poland, [4]Department of Genetics in Psychiatry, Medical University in Poznan, Poznan, Poland, [5]Department of Biochemistry and Biotechnology, University of Life Sciences, Poznan, Poland.

Introduction: The serum glutathione S-transferase alpha (α-GST) concentration has been discovered as a marker of hepatocellular integrity after sevoflurane anaesthesia and mild impairment was observed. The role may play genetic polymorphism of genes, coding for enzymes involved in the metabolism and detoxification process o sevoflurane - CYP2E1, GSTA1 and GSTP1. GSTA1*B (-567T>G, -69C>T, -52G>A) allele is linked with reduced promotor activity, GSTP1*A, *B, *C are characterized by two amino acid substitutions Ile105Val (c.313A>G) and Ala114Val (c.341C>T), which also decrease the enzyme activity, while the variant -1053C>T in CYP2E1 gene is responsible for increased enzyme activity.
Materials and methods: 86 unrelated Polish patients undergoing sevoflurane general anaesthesia, were enrolled into the study. Measurement of serum α-GST concentrations in three time points: before anaesthesia, directly after and 24 hours after the end of anaesthesia was performed using ELISA. Molecular analyzes included sequencing of GSTA1 gene fragments and pyrosequencing for CYP2E1 and GSTP1 changes genotyping.
Results: The increase of α-GST concentration at the end of anaesthesia was observed in 54.7% of patients and 24 h later in 31.4% of subjects, but in all cases the increase was not statistically significant. Frequency of GSTA1*B was 43%, whereas the GSTP1 gene alleles 313G, 341T were found in 28% and 10% respectively. The CYP2E1-1053T variant was observed with 1% frequency. None of analyzed SNPs were significantly associated with the enzyme level.
Conclusions: We not observed any significant hepatotoxic effect in Polish patients after sevoflurane anaesthesia and the α-GST enzyme level was not associated with analyzed variants.

A rare case of TMAU associated with suspected Currarino triad

C. Scimone[1], *C. Rinaldi*[1], *G. Nicocia*[2], **F. Greco**[1], *L. Donato*[1], *R. D'Angelo*[1], *A. Sidoti*[1];
[1]Department of Biomedical Sciences and Morphofunctional Images, Division of Biology and Genetics, Uni, Messina, Italy, [2]Department of Experimental Sciences Medical-Surgical, Specialist and Odontostomatologic, University of Messina, Messina, Italy.

Trimethylaminuria (TMAuria; MIM 602079) is a metabolic disorder caused by failed N-oxygenation of the odorous compound trimethylamine (TMA) due to FMO3 gene dysfunctions. Several polymorphic variants of *FMO3* have been identified and, individually, these have little or no effect on enzyme activity. However, the haplotype with two polymorphisms in cis seems to cause a reduction of enzyme activity. Non-oxygenated TMA is a very strong-smell substance that is, than, expelled through urine, breath and sweat. The result is a severe body odor and associated psychosocial condition (1). Currarino triad (MIM 176450) is a multiple congenital anomalies syndrome characterized by three distinct clinical aspects: anal atresia, sacral anomalies and presacral mass. Genetic causes are mutations at *HLXB9*, a Homeobox gene encoding for a sequence-specific DNA binding protein implicated in the control of gene expression in both developing and adult tissues (2). Here we present a case of a 64 years-old woman that shows a severe fish-like body odor and all the malformations peculiar of Currarino syndrome. We described the first case in literature of TMAU syndrome in association with Currarino triad.

CTLA-4and PTPN22 genes expression as risk factorin egyptisn patient with typr 1diabeted

r. M. Issa;
institute of genetic engineering and biotechnology, Cairo, Egypt.

Diabetes mellitus type 1 or T1DM; form of diabetes that results from the autoimmune Insulin action is the consequence „The CTLA4 gene is found on chromosome 2q33. Cytotoxic T-lymphocyte-associated protein 4 (CTLA4) is expressed only on activated T lymphocytes, and downregulates T cell function, limiting both activation and expansion. CTLA-4 is a surface molecule found on activated T cells which produces a negative signal by inhibiting the T cell receptor signaling interactions (blocks binding of CD80 and CD86). It is thought that inherited changes in CTLA-4 gene expression can increase T cell self-reactivity and therefore play an important role in autoimmune diseases such as type 1 diabetes(Protein tyrosine phosphatase, non-receptor type 22): PTPN22 The single nucleotide polymorphism located in the PTPN22 gene has been associated with autoimmune disorders, including an increased risk of Type 1 DiabetesThis work aims to report the prevalence and frequency of CTLA4 and PTPN22 genes expression as a risk factor in patients with Type-1 diabetes by Real-Time PCR and correlate the genes expression to each other anopportunities for early testing and diagnosis, .This study will include 100 patients with Type-1 Diabetes divided into two groups: 50 patients having Diabetes type-1 (Controlled) and 50 patients having Diabetes type-1 (insulin resistance); Together with 50 healthy age and sex matched controls.
These patients will be subjected to the following: Full Clinical evaluation Complete blood count and routine lab tests (FBS, PPBS, HbA1C and the Glucose curve).>3. Genetic analysis includes: Five (5) ml of blood on EDTA will be withdrawn, RNA extraction and quantitative assessment of CTLA4 and PTPN22 .

Association analysis of BDNF gene Val66Met polymorphism and obesity: Case-control study

A. BEŞTEPE[1], **M. A. SÖZEN**[2], *A. GENÇ*[2], *K. Üçok*[2], *L. AKGÜN*[3], *K. HEKİMLER ÖZTÜRK*[2], *N. İMİRZALIOĞLU*[2];
[1]Family Medical Center, Afyonkarahisar, Turkey, [2]Medical Faculty, Afyonkarahisar, Turkey, [3]State Hospital Obesity Clinic, Afyonkarahisar, Turkey.

Introduction: The brain-derived neurotrophic factor (BDNF) is one of the candidate genes for obesity. There is evidence that Val66Met polymorphism may be involved in the pathophysiology of obesity. In the present study, we investigated the relationships between this polymorphism and obesity and obesity-related clinical phenotypes in a population from Turkey.
Materials and Methods: A functional Val66Met polymorphism of BDNF gene was studied in patients with obesity (n=88) and non-obese controls (n=80). Genotyping of the Val66Met polymorphism of BDNF was performed by po-

lymerase chain reaction amplification and restriction fragment length polymorphism.
Results: The data showed that the BDNF Val66Met genotypes and their allele distributions did not differ between patients with obesity and the controls ($\chi 2$=0.06, df=2, p=0.806 and p=0.109, df=1, respectively). We also investigated the association between the BDNF Val66Met polymorphism and obesity-related clinical phenotypes; however, no significant association was observed.
Conclusions: Our data do not provide evidence that the BDNF Val66Met polymorphism may be involved in the etiology of obesity in a population from Turkey. So,our results do not support a significant role for the BDNF Val66Met polymorphism in the development of obesity in the population studied. The results of the present study suggest that the BDNF gene Val66-Met polymorphism do not play major roles in conferring susceptibility to obesity in a western population from Turkey. However, further studies with larger sample sizes assessing the associations between the BDNF gene polymorphisms and obesity should be performed in several other ethnic populations.

Phenylketonuria frequency and PAH gene spectrum mutations in Rostov Region

M. A. Amelina[1], *S. S. Amelina*[1,2], *A. A. Stepanova*[3], *A. V. Polyakov*[3], *S. I. Kutsev*[3,4], *R. A. Zinchenko*[3,4,5];
[1]*Academy of Biology and Biotechnology of Southern Federal University, Rostov-on-Don, Russian Federation,* [2]*The Rostov State Medical University, Rostov-on-Don, Russian Federation,* [3]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [4]*Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [5]*Scientific and Practical Center of medical care for children, Moscow, Russian Federation.*

Phenylketonuria (PKU, MIM#261600) is an autosomal recessive hereditary disease referred to a group of enzyme defects. PKU frequency and PAH gene spectrum mutations varies between populations. Aim: To investigate PKU clinical and genetics characteristics in patients from Rostov Region (RR). Methods: Epidemiological, PCR, sequencing and MLPA.
Results: Within a more general framework of genetic and epidemiology study of RR population PAH gene mutations frequencies and PAH gene spectrum mutations for Russians in RR. There are 221 PKU patients in a RR Hereditary Diseases Register. PKU frequency in RR according to the data of the neonatal screening is estimated as 1:4978. Russians are the most substantial ethnic group composing a patients' sample (90.05%). Comprehensive DNA diagnostics detect PAH mutations in Russian PKU patients (90 people, 180 chromosomes). 27 different mutations represent the spectrum, 9 mutations are frequent. The most prevalent is R408W (71.11%), second-frequent - IVS12+1G>A mutation (5%), it is followed by P281L and R158Q (2.2% cases for each mutation). The R252W mutation occurs in 1.67% cases, IVS4+5G>T, IVS10-3C>T and EX5DEL - in 1.1%.cases for each mutation. A300S and R297H are revealed in two patients from one family with a mild form of PKU. The rest 16 mutations (A342T, A403V, E280K, F39del, F299C, IVS2+13T>G, IVS7+1G>A, IVS9+5G>A, IVS10-11G>A, K363fsdelG, R176X, R408Q, Y268C, p.N133_Q134>Rfs, c.47_48delCT, p.V245A) are detected in single cases (8.89% in total). PAH gene mutant alleles diversity is revealed in population of one ethnic affiliation (people, who class themselves to Russians), PAH mutations frequency profiles might vary considerably. The study was partially funded by the RFBR grant 14-04-00525.

Cystic fibrosis related bone disease

I. M. Ciuca[1], *L. L. Pop*[1], *Z. L. Popa*[2], *D. I. Onet*[3,4], *L. A. Tamas*[5];
[1]*Pediatric II Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [2]*Obstetrics and Gynecology Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [3]*Radiology Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [4]*Clinical County Hospital, Timisoara, Romania,* [5]*Biochemistry Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania.*

Cystic fibrosis (CF) is the most frequent monogenic genetic disease, autosomal recessive transmitted, characterized by important clinical polymorphism and significant lethal prospective. CF related bone disease occur frequently in adults with CF and the childhood is the period of bone formation, children being more susceptible to low bone density. Several factors like pancreatic insufficiency, hormone imbalance and physical inactivity contribute to CF bone disease development and their revealing would be important for prophylactic attitude against bone disease occurrence.The study was observational, transversal, with a cross-sectional design.
Objective: Evaluation of CF bone disease presence and identification of its risk factors in our CF children population. Subjects and methods: Study included 68 children with cystic fibrosis, genotyped and monitored in the National CF Centre. At the annual assessment, besides clinical examination, biochemical evaluation for pancreatic insufficiency, diabetes, a subgroup of 26 children were evaluated for bone mineral density using dual energy x-ray absorptiometry (DXA).
Results: Twenty-six patients, aged over 10 years were diagnosed with CF bone disease, without significant gender gap. Bone disease was frequent in patients aged over 10 years with exocrine pancreatic insufficiency, carriers of severe mutations and CF liver disease.
Conclusion: CF children carriers of a severe genotype who associates pancreatic insufficiency and CF liver disease were more likely predisposed to low bone mineral density. Further studies should discover other significant influences in order to prevent the development of CF bone disease and an improved life quality in CF children.

Cystic fibrosis and Clostridium

L. L. Pop[1], *I. M. Ciuca*[1], *Z. L. Popa*[2], *C. Pienar*[1], *L. A. Tamas*[3];
[1]*Pediatric II Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [2]*Obstetrics and Gynecology Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [3]*Biochemistry Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania.*

Background:Children with cystic fibrosis are, unfortunately, candidates at multiple antibiotic courses,having a potential increaserisk for pseudomembranous colitis with Clostridium difficile. The aim of the paper was to evaluate the frequency of Clostridium difficile infection among children with cystic fibrosis(CF).
Methods: Retrospective analysis over a ten years period was done, using the information from our CF center`s database. In all the patients, only presentation with diarrhea occurred during antibiotherapy were taken into consideration. Diagnosis test for Clostridium difficile infection was performed by enzyme immunoassay for detection of toxins A and B.
Results: Over a ten years period, 308 patients with cystic fibrosis were admitted in our clinic; only five of them(1.62%) were diagnosed with Clostridium difficile infection. Patients were diagnosed in the last 4 years, by the detection e of toxin A or toxin A and B(in 2 patients) in the presence of diarrhea; they had a favorable outcome, with a good response to treatment(metronidazole in 3 cases, metronidazole and vancomycine in 2 cases). All patients had chronic Pseudomonas aeruginosa infection and received more than fourteen days of antibiotics.
Conclusion: Clostridium difficile infection should be consider for evaluation in cystic fibrosis patients with diarrhea who receive antibiotics. Special attention is necessary when antibiotherapy is given for a long time, as commonly reccomended in cystic fibrosis patients.

J06.13
Familial intrahepatic cholestasis: new approaches to diagnosis

I. Giovannoni[1], *F. Callea*[1], *E. Bellacchio*[2], *G. Torre*[3], *J. De Ville De Goyet*[4], *R. Boldrini*[1], *P. Francalanci*[1];
[1]*Dept. Pathology and Molecular Histopathology, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy,* [2]*Research Laboratories, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy,* [3]*Dept. Hepatology, Gastroenterology and Nutrition Unit, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy,* [4]*Dept. Pediatric Surgery and Transplantation, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy.*

***Introduction*:** Familial intrahepatic cholestases (FICs) are a heterogeneous group of autosomal recessive disorders of childhood with cholestasis of hepatocellular origin. Three distinct forms are described: FIC1, FIC2 and FIC3 due to mutations in *ATP8B1*, *ABCB11* and *ABCB4*, respectively. Different mutations in these genes may cause either a "malignant" progressive familial intrahepatic cholestasis (PFIC) or a benign recurrent intrahepatic cholestasis (BRIC). Liver histology is important, but not specific, for diagnosis. Genotyping is conclusive. To exclude rare forms of transmission, the study of parents is required and to sort out the meaning of the novel mutations a molecular study of healthy controls and protein modelling are mandatory
Methods: For the purposes of the present study we genotyped 27 children with intrahepatic cholestasis, diagnosed on either a clinical or histological basis.
Results: Three BRIC, 22 PFIC and 2 BRIC/PFIC were identified. Thirty-four different mutations were found of which 16 were novel. One was a 2Mb deletion (5'UTR- exon 18) in *ATP8B1*. In another case microsatellite analysis of chromosome 2, including *ABCB11*, showed uniparental disomy. Two cases were compound heterozygous for BRIC/PFIC2 mutations. The occurrence of mutations in the same genes in PFIC and BRIC indicates a *continuum* in severity of the involved mutations, mostly exemplified by intermediate BRIC/PFIC form.
Conclusion: Our results highlight the importance of the pathogenic role of

novel mutations in the three genes, the unusual modes of their transmission and the recognition of an intermediate BRIC/PFIC form as a specific entity.

Are we ready to translate therapies targeting mitochondrial dysfunction to people with Down syndrome?

A. Izzo[1], R. Cicatiello[1], C. Procaccini[2], N. Mollo[1], M. Nitti[1], C. Tordino[1], F. Cesaro[1], D. Faicchia[2], G. Cali[2], P. Pinton[3], G. Matarese[2], A. Conti[1], **L. Nitsch***[1];*
[1]University of Naples Federico II, Naples, Italy, [2]Institute of Experimental Endocrinology and Oncology, Naples, Italy, [3]University of Ferrara, Ferrara, Italy.

Mitochondrial dysfunction is consistently observed in Down syndrome (DS). It possibly contributes to determine DS mental retardation as well as other phenotypic abnormalities including Alzheimer's disease, type2 diabetes, obesity, and hypertrophic cardiopathy. In human DS cells we demonstrated that mitochondrial dysfunction is associated to the downregulation of nuclear encoded mitochondrial genes (NEMGs). We identified the nuclear receptor interacting protein 1 (NRIP1/RIP140), a gene mapping to the chromosome 21 and overexpressed in DS cells, as a good candidate for NEMG downregulation. We further demonstrated that NRIP1 transient attenuation is able to counteract mitochondrial dysfunction in DS fibroblasts. NRIP1 is known to affect oxidative metabolism and mitochondrial biogenesis by negatively controlling mitochondrial pathways regulated by PGC-1α.
Based on this background, we are pursuing a project to correct mitochondrial alterations in DS by pharmacologically modulating the activity of the NRIP1 targets PGC-1α and PPARs. To this aim we have supplemented cultures of fibroblasts from DS human fetuses with drugs affecting respectively PGC-1α and PPAR activity, namely metformin and pioglitazone, to evaluate their modulatory impact on mitochondrial function and morphology. We found this strategy effective on rescuing mitochondrial function in terms of oxygen consumption, ATP production and mitochondrial biogenesis.
Counteracting mitochondrial dysfunction in DS will open new therapeutic perspectives to improve the DS neurological phenotype and to prevent DS associated pathologies. The results of this study may be easily extended to other neurodegenerative disorders associated to mitochondrial dysfunction.

J06.15
Mutation spectrum of phenilketonuria in Karachay-Cherkessia

P. Gundorova*[1], A. A. Stepanova[1], R. A. Zinchenko[1,2], A. V. Polyakov[1];*
[1]Federal State Budgetary Institution „Research Centre for Medical Genetics", Moscow, Russian Federation, [2]Pirogov Russian National Research Medical University, Moscow, Russian Federation.

The prevalence of phenylketonuria in Russia is 1:8000-10000 infants. The prevalence of phenylketonuria in Karachay-Cherkessia is about 1: 3000. We have compiled and analyzed the results of a comprehensive population and medical genetic studies of ten districts and two cities in Karachay-Cherkess Republic, and found 36 unrelated patients with phenylketonuria.
All patiens were assayed for the presence of mutations in the PAH gene by the following algorithm. Initially, we searched for 8 frequent mutations by MLPA-analysis. This system has an efficiency up to 81% for Russian patients. The most common R408W mutation in the PAH gene for the Europeans met 3 times (4.2%), mutations R158Q and IVS10-11G> A met once (1.4%). It was further used MLPA-analisis of 10 recurring mutations. R261X mutation met at 50 chromosomes (69.4%), Y414C and L48S met once (1.4%). The detections of the second mutation in some patients was conducted using Sanger sequencing of the PAH gene. R413P mutation was found on 6 chromosomes (8,3%), P211T on 3 chromosomes (4,2%), F331S on 2 chromosomes (2.8%), mutations P211L, S349P, s.664_665delGA, c.1089delG met once (1.4%).
Mutations frequent for the Europeans were found only in Russians by nationality. For indigenous people of the republic - Karachai, Circassians, Abasins - frequent mutations are R261X, R413P, P211T, F331S, which according to the results of our study have met more than once. Widespread of R261X mutation can be explained by a high inbred of Karachay-Cherkessia population, and probably a founder effect.
This work was partially funded by RFBR grants 14-04-00525 and 15-04-01859.

J06.17
Expression analysis of genes related to inflammation in patients with Gout disease

D. V. Nesheva*[1], P. G. Pavlova[2], B. B. Rukova[1], S. Karachanak - Yankova[1], V. Damyanova[1], Y. S. Zdravkova[2], Z. Hammoudeh[1], R. Staneva[1], O. Antonova[1], I. Dimova[1], S. Hadjidekova[1], V. D. Paskaleva - Peitcheva[2], D. I. Toncheva[1];*
[1]Department of Medical genetics, Medical University of Sofia, Sofia, Bulgaria, [2]Department of Rheumatology, University Hospital „St. Ivan Rilski"- Sofia, Sofia, Bulgaria.

Introduction: Gout is a multifactorial disease characterized by recurrent attacks of acute inflammatory arthritis. It is characterized by elevated levels of uric acid in the blood leading to deposition of uric acid crystals in joints, tendons and surrounding tissues. This condition increases the risk of hypertension, diabetes, metabolic syndrome, renal and cardiovascular disease. The Gout become more common in recent decades, affecting more than 2% of the populations.
Materials and methods: We have performed an expression analysis of 34 Bulgarian male patients with Gout disease and 34 healthy controls. RNA was isolated from blood samples and Real Time PCR analysis using Custom RT2 Profiler PCR Array kit, containing 11 genes (NOD2, NLRP3, PYCARD, IL1B, MYD88, P2RX7, NFKB1, CASP1, CASP5, TRAF1, IRAK1) was applied.
Results: The obtained results showed an increased expression of genes NOD2 and IL1B. The Nod2 is cytosolic receptor and its role is related to modulate the cytokine production by Th1 cells. The Il-1β is an important mediator of the inflammatory response and is involved in cell proliferation, differentiation and apoptosis. The Il-1β predominantly derived from the innate immune cells and Th1 cells. The higher expression of these genes is connected to the acute inflammatory reaction.
Conclusion: New data about the role of NOD2 and IL1B in the pathophysiology of the Gout disease have been received.

J06.18
Sequence Analysis of MT-ND Genes from Iranian Patients with Leber's Hereditary Optic Neuropathy

M. Houshmand*, Z. Rezvani, ,. Didari, A. Arasteh, V. Ghodsinejad, O. Aryan, B. Kamalidehghan;*
National Research Center forGenetic &Biotechnology, Tehran, Iran, Islamic Republic of.

Background. Leber's hereditary optic neuropathy (LHON) is an optic nerve dysfunction due to mutations in mitochondrial DNA (mtDNA) which is transmitted in a maternal pattern. It is caused by three primary point mutations, G11778A, G3460A and T14484C, in the mitochondrial genome. These mutations are sufficient to induce the disease, accounting for the majority of LHON cases, and affect genes that encode for different subunits of mitochondrial complexes I and III of the mitochondrial respiratory chain. Other mutations, called secondary mutations, are ordinarily associated with primary mutations. There is currently no effective treatment for LHON.
The purpose of this study was to determine MT-ND variations in Iranian patients with LHON.
Methods. In order to determine the prevalence and distribution of mitochondrial mutations in the LHON, the mtDNA was studied through PCR amplification and DNA sequence analysis.
Results. In 35 LHON patients, MT-ND gene sequencing revealed a total of 44 nucleotide variations (30 types) in the twenty-seven LHON patients, but eight patients had no changes in the ND genes. Of the 30 types of changes, 50% were previously reported and 50% were novel changes.
Conclusion. This clustering of mutations is therefore useful to extend the mtDNA polymorphism database of Iranian patients and should facilitate definition of disease-related mutations in human mtDNA. This research may help to understand the disease mechanism and may open up new experimental and therapeutic opportunities of LHON for diagnostic testing and for future investigations.

J06.19
The prevalence of Melanocortin-4 receptor gene mutations in Slovak obese children and adolescents

E. Polák*[1], E. Vitáriušová[2], P. Celec[3], Z. Pribilincová[2], L. Košťálová[2], A. Hlavatá[2], L. Kovács[2], L. Kovács[2], L. Kádaší[4];*
[1]Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, [2]Faculty of Medicine, 2nd Department of Paediatrics, Comenius University, University Children's Hospital, Bratislava, Slovakia, [3]Institute of Molecular Biomedicine, Comenius University, Bratislava, Slovakia, [4]Institute of Molecular Physiology and Genetics, Slovak Academy of Science, Bratislava, Slovakia.

Introduction: Melanocortin-4 receptor (MC4R) deficiency is the most frequent monogenic form of obesity. The contribution of MC4R mutations on Slovak population has not been investigated as yet.
Material and methods: 210 unrelated Slovak obese patients were analysed. Body weight and height were recorded for this cohort group, SDS BMI was counted and subsequent standard biochemical protocols assessed their glucose, triglycerides, total cholesterol and lipids blood levels. The coding region of MC4R gene was screened by sequencing analysis. Multifactorial statistical analysis was performed in order to determine the influence of genotypes on standard biochemical blood markers.

Results: Four different mutations in four patients were identified giving a detection rate of 1.9%. Of these, three were missense mutations previously identified and characterized by other research groups (p.R7C, p.S127L and p. R305W, respectively). One was a novel nonsense mutation p.W174* detected in a severely obese 7 years old boy. This mutation was further analysed in family segregation analysis and exhibited variable penetrance. Two known amino acid polymorphisms (p.V103I and p.I251L) were also identified in 7 subjects of our cohort group. No significant influence was observed in carriers of DNA variants on tested parameters.
Conclusions: MC4R mutations in Slovak obese children and adolescent seem to appear with low incidence of 1.9%. We identified three missense mutations and one novel nonsense mutation, which was further studied in family segregation analysis. Our findings support variable penetrance of the MC4R gene variations and also agree with age-dependent manifestation manner. Not all of the mutation carriers fulfilled the typical symptoms of MC4R deficiency.

The gene expression of SIRT1 ,SIRT3 and SIRT4 in patients with type 2 diabetes mellitus: The probable association with its related complications

S. Emamgholipour[1,2], *Z. Maghbooli*[2], *A. Hossein-nezhad*[2];
[1]*Clinical Biochemistry, School of Medicine,Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [2]*Osteoporosis Research Center, Endocrinology and Metabolism Research Institute ,Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of.*

Introduction: Sirtuins are NAD +-dependent deacetylases that have been linked to cellular energy metabolism, survival and the redox state. Among them, SIRT1, SIRT3 and SIRT4 have important roles in this regard. Since dysregulation of energy metabolism, oxidative stress and aging have been implicated in the pathophysiology of diabetes and its associated complications; we aimed to measure SIRT1, SIRT3 and SIRT4 mRNA levels in patients with type 2 diabetes based on either with or without retinopathy and /or nephropathy.
Methods: A total of 38 patients with type 2 diabetes were included in the study. The participants were categorized into two separate groups: Patients with retinopathy and/or nephropathy (group1) (n=19) and patients without retinopathy and/or nephropathy (group2) (n=19). We compared mRNA levels of SIRT1, SIRT3 and SIRT4 in PBMCs isolated from participating subjects using real time RT-PCR.
Results: The patients in two group were matched in term of age (p=0.09), sex (p=0.1) and BMI (p=0.08),whereas the duration of diabetes was significantly (p=0.004) higher in group1 (16.37± 5.6 years)compared with group2 (9.9±7.1 years). We found a significant (p=0.001) increase in relative SIRT1 gene expression in group 1 in comparison with the group 2, while SIRT4 mRNA levels were significantly (p=0.013) lower in group 1. In this study, there was no significant difference in SIRT3 mRNA levels between two groups.
Conclusions: It seems that the relative expression of SIRT1 and SIRT4 may be involved in an etiological process that leads to diabetes associated complications.

J06.21
Clinical and molecular characteristic of X-linked adrenoleukodystrophy, reporting of 9 new cases including one novel mutation from Iran

Y. Shafeghati, *Z. Hadipour, F. Hadipour, S. Shafeghati;*
Med. Genet. Dept., Sarem Women Hospital, Tehran, Iran, Islamic Republic of.

X-linked adrenoleukodystrophy (X-ALD) is a rare peroxisomal disorder resulting in progressive cerebral demyelination, axonal dysfunction, and adrenal insufficiency. It is the most common peroxisomal disorder with an estimated birth incidence of about 1 out of every 20,000. There is no ethnic predominance.
The age of onset and morbidity are highly variable and progression is unpredictable. Male hemizygotes may initially present with neurological symptoms in two different forms: (X-ALD) with childhood presentations, and Adrenomyeloneuropathy (AMN) that presents in adulthood.
Primary manifestations of X-ALD are moderate cognitive deficits followed by diminished visual acuity, central deafness, cerebellar ataxia, hemiplegia, convulsions and dementia leading to a neurovegetative state or death within mostly in two years.
X-ALD is inherited in an X-linked manner and mainly affects 4 to 8 year old boys. About 93 to 95% of index cases have inherited the ABCD1 mutation from their carrier mothers, and 5 to 7% of individuals have a de novo mutation. ABCD1 is the only gene known to be associated with this entity.
The diagnosis of X-ALD is based on clinical findings. MRI is always abnormal in males with neurologic symptoms and often provides the first diagnostic clue. Plasma concentration of very long chain fatty acids (VLCFA) is abnormal in 99% of males with X-ALD.
Here we report 8 affected boys with X-ALD from Iran. VLCFA was increased strongly, and MRI images were typical in all of them. Molecular analysis of ABCD1 gene confirmed the diagnosis in 4 of the patients and we detected 1 novel mutation in an index case.

Examine to evaluate serological applications of *Toxoplasma gondii* rhoptry protein1 antigen
Fatemeh keshavarzi[1], Azad fattahy rad[2]
[1]Department of biology, Sanandaj Branch, Islamic Azad University, Kurdistan, Iran
[2]Tohid Hospital, Kurdistan University of Medical Sciences, , Sanandaj, Iran
Abstract
Objective: Toxoplasma gondii is distributed across a worldwide and infects most species of warm-blooded animals, including humans. The heavy incidence and severe or lethal damage caused by *T. gondii* infection clearly indicates the need for the development of a vaccine. The current study goals were to evaluate serological applications of *Toxoplasma gondii*rhoptry protein 1 (ROP1) antigen.
Materials and methods: We constructed DNA vaccines by using the eukaryotic plasmid pROP1. Purification by one-step metal affinity chromatography allowed recovery of milligram amounts of pure recombinant proteins per liter of culture. The usefulness of this antigen for diagnosis of human infections was provided and tested on 77 serum samples which are obtained during routine diagnostic tests.
Results: A panel of 20 serum samples from patients with acute toxoplasmosis was compared to a panel of 35 serum samples from individuals with chronic toxoplasmosis. The results indicated that ROP1 recombinant antigen detected antibodies more frequently in samples from individuals with acute infections (96%) than in samples from individuals with chronic infections (17%). These results suggest that an immunoglobulin G antibody against ROP1 antigen is produced during the acute stage of toxoplasmosis but are uncommon in the chronic phase of the infection.
Conclusion: Hence, this recombinant protein can be used as specific molecular markers to differentiate between acute and chronic infections
.
Key words:Toxoplasma gondii, rop1, recombinant antigen

Antibiotic resistance

A. Fattahy rad[1], *f. keshavarzi*[2];
[1]*Tohid Hospital, Kurdistan University of Medical Sciences, Sanandaj, Iran, sanandaj, Iran, Islamic Republic of,* [2]*Department of biology, Sanandaj Branch, Islamic Azad University, sanandaj, Kurdistan, Iran, sanandaj, Iran, Islamic Republic of.*

The prevalence of Antibiotic resistance and corresponding resistance genes in clinical isolates of staphylococci from Kurdistan hospitals
Azad Fattahy Rad[1], Fatemeh Keshavarzi [2]
[1]Taohid Hospital, Kurdistan University of Medical Sciences, Sanandaj, Iran
[2]Department of biology, Sanandaj Branch, Islamic Azad University, sanandaj, Kurdistan, Iran
Background and Objectives: Staphylococcus aureus is one of important etiology of contagious infections in hospital. Aminoglycosides still play an important role in anti staphylococcal therapies, although emerging resistance amongst staphylococci is widespread. This study was conducted to further our understanding of aminoglycoside resistance in Kurdistan hospitals of Iran.
Materials and Methods: we tested 212 clinical isolates of *Staphylococcus aureus* for susceptibility to penicillin, erythromycin, clindamycin, tetracycline, vancomycin and methicillin. All of these isolates were screened for the presence *ermA ermB ermC mphC msrA, van A, tet K, tet M, tet L, tet O* and *mecA* genes.
Results: The highest rates were seen in treatment with *penicillin (93%), Methicillin (77/33%), tetracycline (61/33%), clindamycin (58/6%), erythromycin (54/6%)* while the lowest sensitivity was observed in *vancomycin(12%)*.

Foremore, The most prevalent gene was *mecA* followed by *ermA*, *tetK* , *ermC*, ermB, tetM,msrA, mphC, *tetL* and *tetO* and *van(A)* didn't see in any isolated.
Conclusion: This study indicates that resistance to erythromycin and tetracyclines are mainly by efflux pumps mediated by *ermA* ,*ermC* and *tetK* genes in S. aureus in Kurdistan province, respectively. Our results also revealed the need for further investigations using a higher number of specimens representing a wider variety of locations to determine the antibiotic resistance patterns in our state more precisely.

Cytokines genotypes as predictors of disease outcomes in HIV-1 infected Ukrainians

A. Piddubna;
Sumy State University, Sumy, Ukraine.

Background. Cytokines genes single nucleotide polymorphisms (SNPs) influence clinical course of HIV infection in different population groups. The objective of the research was to determine cytokines genotypes association with outcomes of the disease in Ukrainians with HIV-1.
Methods. We examined promoter SNPs in IL-4 (rs 2243250), IL-10 (rs 1800872), TNF-α (rs 1800629) among 78 naive HIV-1 infected European Ukrainians (68 % male, 32 % female; age at diagnosis (33,35±0,76) years) and 100 healthy controls using PCR-RFLP. Patients with HIV-1 were distributed into groups depending on implications of bacterial, viral, fungal and parasitic infections.
Results. All detected cytokines SNPs showed no significant deviation from the Hardy-Weinberg equilibrium in controls (p≥0.1). The dissimilarity in cytokines genotypes frequencies among HIV-1 infected persons with different clinical course of the disease was determined. We found the association of C/A IL-10 with bacterial (OR=0.74, p≤0.05), C/C IL-10 and G/A TNF-α - viral (OR=0.65, p≤0.05; OR=0.53, p≤0.05 appropriately), C/T IL-4 - fungal (OR=0.44, p≤0.05) infections. Cytokines genes variants played a protective role in patients with HIV-1: A/A IL-10 genotype in fungal (OR=3.98, p≤0.05), C/A IL-10 in viral (OR=1.93, p≤0.05), G/G TNF-α in viral and parasitic opportunistic infections (OR=1.83, p≤0.05, OR=1.79, p≤0.05 appropriately).
Conclusions. Our results demonstrate that cytokines genes polymorphisms may be used as clinical markers to predict outcomes of HIV-1 infection and warrant further studies in the host genetic factors sphere.

Trials for Defining the Mutation Spectrum in Egyptian FA patients

R. M. Mosaad, *M. M. Eid, G. Y. El-Kamah;*
National Research Centre, Cairo, Egypt.

Introduction: FA-A is the most frequent complementation group representing approximately two-thirds of the patients in the majority of countries.
Aim of the work: screening the most internationally reported mutations of FANCA gene in the Egyptian (FA) Fanconi anemia patients and evaluate a correlation between clinical and cytogenetic results.
Subjects and Methods: Fourty five cases, descending from unrelated consanguineous pedigrees were recruited from the hereditary blood disorders (HBD) clinic, NRC. All patients had positive chromosomal breakage studies with diepoxybutane (DEB) confirming the diagnosis of FA. Amplification of FANCA gene exons of interest by PCR, Multiplex PCR, Restriction Analysis, DNA sequencing for patients and controls was done.
Results: 13 % (6/45) of our patients had homozygous deletion of exons (12-31) of the FANCA gene, these patients presented with severe phenotype, 70% were born with low birth weight. All patients had cafe´ au lait spots, hyper pigmentation, and 86% suffered skeletal abnormalities. Increased chromosomal breakages by DEB with an average of 12.5 break/cell were detected among those patients. No 2574C to G (S858R) mutation in exon 27or c.3788_3790 del TCT mutation in exon 38 in the FANCA gene was detected in our studied patients. No new mutations were detected in exons 34 and 43 of the FANCA gene. **Conclusion**: This is the first step in defining the mutation spectrum of FA. 13 % (6/45) of our patients had homozygous deletion of exons (12-31) of the FANCA gene, these patients presented with severe phenotype. Further studies on a larger number of patients are recommended to be able to define Egyptian FA mutations' spectrum.

J07.05
Investigation of IL-12p40, IL-12Rβ1, IFNγR1, IFNγR2 gene mutations in childhood tuberculosis

M. Saka Guvenc[1], *H. Onay*[2], *F. Ozkinay*[2];
[1]*Osmangazi University Faculty of Medicine, Department of Medical Genetics, Eskisehir, Turkey,* [2]*Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey.*

Background: Tuberculosis is a necrotizing, chronic infection caused by a group of mycobacteria known as Mycobacterium tuberculosis complex (MTC). About 9.0 million newly diagnosed tuberculosis cases and 1.5 million tuberculosis deaths are estimated to occur worldwide in 2013. Mycobacterium Tuberculosis is responsible for almost 99% of the cases. Clinically apparent infections occur in only 5 to 10% of all cases. Ethnic differences, twin studies, animal models and family segregation analyses support the hypothesis of genetic susceptibility to tuberculosis. Mendelian susceptibility to mycobacterial diseases (MSMD) is a rare congenital disease, characterized by hereditary immunodeficiency causing mycobacterial infections. Mutations in IFN-γ-IL-12 pathway are considered to play a role in MSMD. Identifying MSMD mutations may contribute to explore molecular mechanisms in host's immune response. Aim: To investigate the role of mutations in IFNGR1, IFNGR2, IL12B and IL12RB1 genes for developing MSMD in pediatric patients with extrapulmonary tuberculosis
Methods: Mutations were investigated in IFNGR1, IFNGR2, IL12B and IL12RB1 genes by sequencing in 30 pediatric patients with extrapulmonary tuberculosis.
Results: No mutation was detected in four genes which are involved in IFN-IL12 pathway. However, we found polymorphisms which might cause susceptibility to tuberculosis: rs7749390 in IFNGR1 gene , rs9808753 in IFNGR2 gene, rs11575926 in gene IL112B , rs3212227 and rs436857 polymorphism in IL12RB1 gene.
Conclusıon: In this study, we report genetic analysis of IFN-IL12 pathway on MSMD cases for the first time in the Aegean region of Turkey. Determining the frequencies of these polymorphisms in control samples and performing functional studies might elucidate the exact roles of these polymorphisms in TB infection in Turkish children.

J07.06
The impact of Xmn1-HBG2 , BCL11A, HBS1L-MYB, age and sex on HbF variation among Iranian hematologicaly normal individuals

M. Neishabury[1], *M. Jafari Vesiehsari*[1], *S. Talebi Kakroodi*[1], *E. Keyhani*[1], *K. Kamali*[2];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitaion Sciences, Tehran, Iran, Islamic Republic of,* [2]*2. Department of Public Health, School of Public Health, Zanjan University of Medical Sciences, Tehran, Iran, Islamic Republic of.*

The impact of HbF on disease severity of Sickle cell and Beta thalassemia is well documented. Xmn1-HBG2, BCL11A and HBS1L-MYB SNPs have been introduced as the most important factors causing variation in HbF levels. However the impact of these factors on HbF variation could be population specific and depends on the frequency of the HbF boosting allele (minor allele) in each population. Determining the effect of these factors in Iran, where thalassemia is the most common genetic disorder, is important. In here we genotyped 8 SNPs including Xmn1-HBG2, 5'HS4, 2 BCL11A and 4 HBS1L-MYB SNPs in 122 Iranian hematologically normal individuals, including 51 male and 71 female. HbF values ranged from 0.3%-1.3% with a mean of 0.74 ± 0.21. Multivariate linear regression analysis was used to evaluate the association between HbF and these SNPs. No association was observed between these SNPs and HbF levels of the normal individuals. This study could suggest that these HbF modifying factors are not able to explain common HbF variations in the Iranian normal population. In support of this controversy, the ability of SNPs in these three loci, in explaining the total HbF variation has been considerably different between European healthy adults (44%) and African patients with SCA (16-20%). Therefore, to further study the major regulators of common HbF variation in normal population of Iran, studies with larger population sizes and more number of SNPs are proposed. This study was funded by the Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran.

Mutation screening of the KLF1 gene by using SSCP in a cohort of Iranian B-thalassemia patients

B. Zaker Kandjani;
Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran, Islamic Republic of.

Krűppel-Like Factor 1(KLF1) is an essential erythroid-specific transcription factor. Mutations in the human KLF1gene have different phenotypic effects, ranging from increased HbF levels to the disruption of erythropoiesis. Here, we have screened 227 Iranian β-thalassemia (β-thal) patients for the presence of KLF1mutations by using the single-strand conformational polymorphism (SSCP) approach. Our aim was to assessthe potential effect of these mutations on the β-thal disease severity. After screening, two variants were found. One patient carried a potentially deleterious variant (Polyphen-2) in

exon 2 (p.F182L). Another patient was homozygous for a previously unreported intronic variant (c.911+84A>G). The patient with the p.F182L variant (c.544 T>C) had noticeably high HbA 2 levels (7.6%), consistent with the phenotypic effect of several previously characterized KLF1mutations in the same exonic region.
In addition,he had higher platelet counts(1069000/µl)compared to other patients in the cohort

Genetic Predisposition In Aggressive Periodontitis Expressed By Interleukine-1 Gene Polymorphism

A. A. Martinescu[1], *V. Badea*[2], *C. Nuca*[2], *L. C. Petcu*[2], *D. P. Balaban*[2], *A. Caraiane*[2], *M. Grigorian*[2];
[1]*Ovidius university, Faculty of medicine, Constanta, Romania,* [2]*Ovidius university, Faculty of dentistry, Constanta, Romania.*

Introduction: Aggressive periodontitis has a complex multifactorial etiology, genetic predisposition being one of the risc factors. Among the inflammatory mediators in aggressive periodontitis, interleukine-1, codified by IL-1A and IL-1B genes, has an important role in tissue destruction. The aim of this study is to identify if there is an association between interleukine-1 gene polymorphism with the aggressive periodontitis.
Materials and Methods: We comprised into our study 54 subjects (by clinically orodental examination): 17 healthy subjects and 37 patients with aggressive periodontitis. For the genetic polymorphism of IL-1 gene we used PCR reaction - GenoType IL-1 (HAIN Lifescience, Germany). It detects IL-1A-889 and IL-1B+3953 from epithelial cells on buccal mucous (collected using sterile swabs). Statistical analysis was made using ANOVA test and Pearson correlation coefficient.
Results: Regarding IL-1A-889 we found heterozygous (C/T) and homozygous (T/T) profile at 9 (52.9%) heathy subjects, who will require special monitoring for possible onset of aggressive periodontitis, and at 27 (72.9%) patients. We identified significant difference in the frequence of the positive genotype between the healthy subjects and patients: for C/T p=0.023 and for T/T p=0.0006. Also, IL-1B+3953 polymophism was found at 7 (41.2%) heathy subjects and 30 (81.1%) patients and we also identified a significant difference for C/T p=0.001 and for T/T p=0.0001 between the study groups.
Conclusions: Our study demonstrates that the IL-1 gene polymorphisms are associated with aggressive periodontitis. Single nucleotide polymorphisms at IL-1A-889 and IL-1B+3954 loci identified at healthy subject may be useful as risk markers in producing aggressive periodontitis.

J07.09
Molecular analysis of MEFV gene polymorphisms and mutations in rheumatoid arthritis in the Azeri population of Iran

M. A. Estiar[1], *A. Khabbazi*[2], *S. Kolahi*[2], *F. Zolrahim*[2], *E. Sakhinia*[3];
[1]*Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [2]*Connective Tissue Disease Research Center, Tabriz University of Medical Sciences, Tabriz, Iran., Tabriz, Iran, Islamic Republic of,* [3]*Department of Medical Genetics, School of Medicine, Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of.*

Objective: The aim of our study was analyzing the Mediterranean fever (MEFV) gene polymorphisms and mutations on exon 2 and 10 in patients with rheumatoid arthritis and to then compare disease activity between mutation carriers and non-carriers in the Azeri population of Iran.
Methods: In this cross sectional study we considered the MEFV gene polymorphisms and mutations in exons 2 and 10 in 50 Iranian Azeri patients with rheumatoid arthritis by polymerase chain reaction and direct sequencing.
Results: Thirty three out of 50 RA patients were found to carry MEFV polymorphisms and mutations. The most common were the D102D, G138G, and A165A polymorphisms. In comparison with the normal Azeri population the carrier state of MEFV mutations in our study patients was higher. No significant difference was seen in the disease activity between carriers and non-carriers.
Conclusion: MEFV mutations may act as a genetic susceptibility factor for RA. However, it has no major effect on the activity of disease in the Azeri population of Iran.

J07.10
The molecular basis of Thalassemia intermedia in central Iran

Z. Sajadpour, *M. Motovali-Bashi;*
Department of Biology, School of Sciences, University of Isfahan, Isfahan, Iran, Islamic Republic of.

Thalassemia intermedia is a clinical entity characterized by moderate, non-transfusional anemia and hepatosplenomegaly. To elucidate the mild phenotype of many patients with thalassaemia intermedia we screened three predominant mutations (IVSII.1 G:A, IVSI.110 G:A and IVSI.5 G:C mutations) in β-globin gene , deletion in α-globin genes, XmnI polymprphism and RFLP haplotypes at β-globin gene cluster in 50 thalassemia intermedia patient. 58% (29) of patients were associated with mentioned mutations. None of 29 patients parents had an elevated level of Hb F. IVSII-1 (G→A) mutation was linked to haplotype +-++ (57.69%). This haplotype is in linkage desequilibrium with Xmn –I polymorphism (C →T - 158) and has been associated with increased expression of HbF in thalassemia intermedia patients. Relatively mild clinical course was shown with homozygosity for this haplotype. Xmn I polymorphism was found in association with this prevalent mutation and was detected in the homozygous state in majority of the of the patients homozygous for the IVS-II-1 (G → A) mutation. Homozygoutes for Xmn-I (+) polymorphism have milder disease than heterozygotes. One patient had a single α-globin gene deletion (-$\alpha^{3.7}$ kb deletion). The main factor in mild phenotype thalassemia intermedia patienes was linkage of a XmnI(T) polymorphism with mutation IVSII-1 (80.76%),. which were associated with increased production of fetal hemoglobin and co-inheritance haplotype +-++ with thalassemia intermedia, especially with homozygous IVSII-I mutation Molecular basis of thalassemia intermedia as defined in this study explains the involvement of different factors that tend to develop the disease phenotype.

Polymorphisms in the tumor necrosis factor receptor genes affect the expression levels of membrane-bound receptors

F. F. Vasilyev[1], *A. N. Silkov*[2], *S. V. Sennikov*[2];
[1]*North-Eastern Federal University (NEFU); Yakut scientific center of CMP, Yakutsk, Russian Federation,* [2]*Research institute of fundamental and clinical immunology, Novosibirsk, Russian Federation.*

Tumor necrosis factor (TNF) is a pro-inflammatory cytokine involved in a wide range of physiological processes. The biological activity of TNF is dependent on the expression level of its membrane-bound receptors. The aim of this study was to establish associations between single nucleotide polymorphisms (SNPs) in the TNF receptor genes (TNFRSF1A, TNFRSF1B) and membrane-bound TNF receptor expression levels on subpopulations of peripheral blood mononuclear cells (PBMC) and to determine the serum levels of soluble TNF receptors (sTNFRs) in healthy individuals and patients with multiple sclerosis (MS). Determining the expression level of membrane-bound TNF receptors on PBMCs was performed by flow cytometry using BD QuantiBRITE calibration particles. Serum levels of sTNFRs were determined via ELISA and genotyping was carried out using PCR-RFLP.
Individuals with genotype TT in SNP TNFRSF1A rs4149570 showed lower levels of sTNFR1 compared to GG genotype carriers. The genotype CC in SNP TNFRSF1B was associated with a lower percentage of CD14+ cells expressing TNFR2 compared to individuals with the CT genotype. The frequencies of alleles and genotypes of TNFRSF1A and TNFRSF1B SNPs had no statistically significant differences in MS patients and healthy individuals.
Polymorphisms in the TNF receptor genes represent one mechanism affecting the expression levels of membrane-bound receptors and TNF-mediated signaling.
The research was supported by „Scientific and Educational Foundation for Young Scientists of Republic of Sakha (Yakutia)“ (2014-01-0011).

J07.12
Cystic fibrosis and mannose binding lectine

Z. L. Popa[1], *I. M. Ciuca*[2], *L. L. Pop*[3], *S. Tanasescu*[2], *C. Pienar*[2], *B. Almajan-Guta*[4];
[1]*Obstetric and Gynecology Department, UMF Victor Babes, Timisoara, Romania,* [2]*Pediatric II Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [3]*Pediatric II Department, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania,* [4]*Physical Education and Sport Department, West University, Timisoara, Romania.*

Background: Mannan-binding lectine (MBL) is a protein implicated in immune response in children. Children are more prone to develop pathologies like infection, autoimmune disease, cystic fibrosis, liver disease. The aim of the study was to evaluate the MBL serum levels in children with cystic fibrosis and liver disease, compared to controls. Material and methods: Patients with cystic fibrosis and liver disease were aged matched with controls, blood samples were collected. MBL was determined by solid-phase enzime-linked immunoabsorbent assay. Results: In the group of patients with liver disease associated with cystic fibrosis, the average was 2061.99 ng/ml , almost 50% lower than average level in the controls group (3986.827 ng.ml), being significantly low among children with cystic fibrosis and liver disease.

In our study MBL values ranged from 2.3 ng/ml to 5432 ng/ml. Conclusion: Determining of MBL levels in children is suggestive for certain diseases, like cystic fibrosis liver disease and could be used as a predictive factor for early diagnosis.

J07.13

The investigate of the biological association between atopic bronchial asthma and tuberculosis

E. Bragina[1], *M. Freidin*[1], *E. Tiys*[2], *L. Koneva*[1], *V. Ivanisenko*[2], *V. Puzyrev*[1];
[1]*Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Institute of Cytology and Genetics, Novosibirsk, Russian Federation.*

Atopic bronchial asthma (BA) and tuberculosis (TB) have become two of the most important global public health problems. Co-existence of BA and TB is extremely uncommon in the same individual (dystropic). We hypothesize that dystropic relationships between diseases are caused by shared proteins/genes that suspend simultaneous development of diseases.
Using system biology analysis we have determined of shared proteins/genes for BA and TB, assuming that the rare co-occurrence can be attributed to shared biological mechanisms.
Two associative protein networks of BA and TB were reconstructed using the ANDCell software. We found the 19 proteins associated with both BA and TB. Among the shared proteins identified in the study is gene *SPP1* previously not studied for TB, genes *CXCL10*, *TNFRSF1B* are not studied for BA, and genes *CD4*, *CD79A* are not studied for both BA and TB in "case-control" studies.
The identified shared proteins have been classified for Gene Ontologies using BiNGO plug-in of the Cytoscape platform. GO enrichment analysis for 19 shared proteins revealed 1262 statistically significant biological processes. Top 10 processes were related to immune response with "positive regulation of immune system process" being the most significant (p-value=$4.31 \bullet 10^{-16}$). The study has also identified shared genes related to crucial biological processes for life including of immune processes. One possible explanation for BA and TB appear to be inversely associated is that shared proteins operate mainly in area of immune processes which important for both diseases.
The reported study was partially supported by RFBR, research project № 15-04-05852.

J07.14

Results of molecular analysis of NLRP3, MVK and TNFRSF1A genes in patients with autoinflammatory diseases and juvenile arthritis

E. Kamenets[1], *E. Zaharova*[1], *S. Salugina*[2], *Y. Fedorov*[2], *M. Kaleda*[2];
[1]*Reseach Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Children, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation.*

Background: Human autoinflammatory diseases (HAIDS) are a group of rare heterogeneity genetic determined disorders caused by primary dysfunction of the innate immunity. More than 25 causative genes are known. The most common are NLRP3, TNFRSF1A and MVK. Systemic onset juvenile arthritis (soJA) has similar features so it's belonging to HAIDS is discussed.
Objectives: To discover contribution of mutations of NLRP3, TNFRSF1A and MVK to HAIDS in Russian patients. To define presence of the same defects in patients with soJA.
Material and methods: We recruited 40 patients with assumption of HAIDS and 39 pts with soJA. Selection criteria were persistent fever, maculopapular rash, arthralgia/arthritis, acute-phase markers. Diagnosis of soJA was based on ILAR criteria. DNA samples were extracted from whole blood and analyzed by direct automatic sequencing.
Results: Among HAIDS patients 9 cases were confirmed (22,5%). Six patients are heterozygous for mutations in NLRP3, 2 - in TNFRSF1A and 1 is compound heterozygote for mutations in MVK, included the new mutation c.1126G>C. Among arthritis pts 4 show genetic defects (10,3%): 2 of them are heterozygous for mutations in NLRP3, 1 - in TNFRSF1A, 1 is compound heterozygote for mutations in MVK.
Conclusion: We confirmed different HAIDS in 22,5% of suspected cases. Also 10,3% of arthritis patients had HAIDS defects. Our findings demonstrate that patients with clinical diagnosis of soJA may suffer from autoinflammatory diseases missed because of similar symptoms. We recommend screening of mutations in NLRP3, MVK and TNFRSF1A for all patients with HAIDS-like clinical findings.

J07.15

The first report of dominantly inherited beta-thalassemia caused by a novel elongated β-globin chain

S. Farashi, *N. Faramarzi Garous, M. Ashki, S. Vakili, F. Zeinali, H. Imanian, A. Azarkeivan, H. Najmabadi;*
Kariminejad-Najmabadi Genetics and Pathology Center, Tehran, Iran, Islamic Republic of.

A distinct set of mutations in the β-globin gene leads to the dominantly inherited β-thalassaemia that is associated with a disease phenotype even when presents in a single copy. We describe the molecular and the hematological characteristics of a novel elongated beta globin chain in combination with a known hemoglobin variant (Hb N-Baltimore) in cis. This novel β-globin variant has eight extra residues in the second exon of beta globin gene. This was determined by sequencing of amplified DNA. The produced highly unstable hemoglobin variant gives rise to typical features of major or intermedia β-thalassaemia in two members of a family depends on their genotype of alpha globin genes. The mutant beta allele of mother is transmitted in an autosomal dominant fashion to her daughter. They resemble severe forms of β-thalassaemia due to the ineffective erythropoiesis. Similar clinical features have been identified in families of dispersed ethnic origins but none in Iran. Taken together with previously published data, this result indicates that dominantly inherited β-thalassaemia should be regarded as a phenotypic term of hemoglobinopathies caused by β-chain variants that are highly unstable.

J07.16

Detection of c.657_661del5 mutation in NBN gene in patients suspected of Nijmegen breakage syndrome from Serbia and Montenegro

S. S. Cirkovic, *D. Radivojevic, M. Miskovic, N. Ilic, S. Pasic, J. Vukajlovic, B. Dobric, A. Jovanovic, M. Djurisic;*
Mother and Child Health Care Institute of Serbia "Dr Vukan Cupic", Belgrade, Serbia.

The Nijmegen breakage syndrome (NBS) is a rare DNA repair disease with high risk of malignancy. The patients affected with NBS usually have microcephaly at a birth and later, growth retardation and immunodeficiency. The main cellular feature of NBS is an increased sensitivity to radiation and radiomimetic agents such as bleomycin (BLE). *NBN* gene mapped in 8q21 region is found to be disease-causing with the major founder mutation c.657_661del5, which is the mostly present in Slavic populations. The study included 10 children with clinical symptoms of NBS, who were diagnosed and treated at the Mother and Child Health Care Institute of Serbia from July 2005 to January 2012. Molecular analysis for the presence of the c.657_661del5 mutation was carried out in all patients, using modified PCR method with sequence specific primers, on PAGE gel. Homozygosity for the c.657_661del5 mutation was detected in 7 of 10 children. Cytogenetic analysis, performed on peripheral blood cultures using BLE (1μg/ml), further revealed that there were no increases in chromosomal fragility of the rest three patients without the mutation, when compared with healthy individuals. Hence, four of 7 patients carrying the mutation, showed elevated BLE-induced chromosomal breakage (0.27 -0.81 vs. 0.02-0.13 breaks/cell) with various aberrations involving chromosomes 7 and 14. The authors propose fast and reliable PCR method for the c.657_661del5 mutation detection in patients with NBS symptoms, at first. In case when this mutation is not found, cytogenetic analysis is strongly recommended, helping with differential diagnosis of other chromosomal instability disorders.

J07.17

Crohn's disease susceptibility genes and tuberculosis

A. Rudko[1], *F. Vannberg*[2], *E. Bragina*[1], *V. Puzyrev*[1], *M. Freidin*[1], *A. V. S. Hill*[2];
[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.*

Genome-wide association studies (GWASs) are currently a standard tool in human genetics which allow identifying new candidate genes of susceptibility to complex diseases. Taking into account shared mechanisms of pathogenesis, the results of GWAS for immune-mediated diseases can be used to look for new candidate genes of susceptibility to tuberculosis (TB). Based on this hypothesis, we carried out an analysis of association between TB in ethnically different Siberian populations (Russians and Tuvinians) and genetic polymorphisms associated with Crohn's disease according to results of a GWAS (Nature, 447:661-678). Overall, 453 Russians (304 TB patients and 149 controls) and 501 Tuvinians (238 TB patients and 263 controls) were recruited. Genotyping of single nucleotide polymorphisms (SNPs) associated with Crohn's diseases in published GWASs was done using iPLEX mass-spectrometry assays. In a pilot analysis, in Russians, five polymorphisms were nominally associated with TB (p = 0.008-0.021), including rs2872507 (ORMDL3), rs3810936 (TNFSF15), rs10192702 (ATG16L1), rs9286879 (1q24.3), and rs10507523 (13q14.11). In Tuvinians, an association between TB and two SNPs, rs1407308 (TNFSF15) and rs1736135 (21q21.1), was identified (p = 0.002-0.003). The associations become non-

significant after stringent Bonferroni correction for multiple testing; however, none of the polymorphisms was previously known to be associated with TB, and their further studies in extended samples may be fruitful. Thus, the analysis of the polymorphisms associated with Crohn's disease can help identify new TB candidate genes.

J08.01
Clinical and molecular delineation of the emerging 10q22.1q22.3 microdeletion syndrome

E. Preikšaitienė, *Ž. Čiuladaitė, B. Tumienė, A. Utkus, V. Kučinskas;*
Dept. Human and Medical Genetics, Vilnius University, Vilnius, Lithuania.

Five patients with interstitial 10q22 deletion have been reported so far. We report on the characterisation of an overlapping interstitial 10q22.1q22.3 microdeletion. The patient, a 2.5-years-old female, was born from the uncomplicated pregnancy at full term in a normal delivery. Her birth weight was 3156 g, length 50 cm, the Apgar scores 9/10. Hypotonia and ptosis were observed from birth. Internal hydrocephaly was diagnosed in infancy. The patient's psychomotor and language development was delayed - she could sit unsupported at age of 9 months, and still does not walk independently. During the physical examination at age of 2.5 years her height was 79 cm (<3 centile), weight 12 kg (3 centile), OFC 50 cm (75 centile). The phenotype was remarkable for ptosis, hypertelorism, epicanthus, short palpebral fissures, low set and rotated ears, short nose, and umbilical hernia. The elevated concentrations of lactate and alanine in plasma were detected. Array CGH (105K) revealed a de novo 5.18 Mb deletion of 10q22.1q22.3 (position 74236933-79422266, build GRCh37). The deletion involves 49 genes. MICU1 and MRPS16 genes are associated with mitochondrial function and their haploinsufficiency might be the cause of mitochondrial phenotype. These clinical and molecular findings increase our understanding of the clinical presentation of 10q22.1q22.3 microdeletion.

The work was funded by the Lithuanian-Swiss cooperation programme to reduce economic and social disparities within the enlarged European Union under project agreement No. CH-3-ŠMM-01/04, UNIGENE project and the World Federation of Scientists (Geneva, Switzerland) under the Lithuanian National Scholarship Programme.

Whole exome sequencing in a Tunisian family with unsuspected Cohen syndrome

I. REJEB[1], *H. JILANI*[1], *Y. ELARIBI*[1], *L. HILA*[2], *S. HIZEM*[1], *J. LAUER ZILLAHRDT*[3,4,5], *J. CHELLY*[3,4,5], *L. BENJEMAA*[1];
[1]*Service des Maladies Congénitales et Héréditaires, La Marsa, Tunisia,* [2]*Laboratoire de Génétique Humaine, Faculté de Médecine de Tunis, Tunis, Tunisia,* [3]*Institut Cochin, Université Paris-Descartes, CNRS (UMR 8104), Paris, France,* [4]*Inserm, U1016, Paris, France,* [5]*Pôle de biologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France.*

Cohen syndrome is an autosomal recessive disorder associated with multiple clinical manifestations including developmental delay, acquired microcephaly, myopia, pigmentary retinopathy, joint hypermobility, truncal obesity, friendly disposition and intermittent neutropenia. In young patients, the diagnosis is difficult, because several of the characteristic features may not be present until school age or later years and the intermittent neutropenia is not always detectable. In Cohen Syndrome only the *VPS13B* (vacuolar protein sorting 13, yeast, homologue of B) gene is known to harbour causative mutations including nonsense, missense, indel and splice-site variants. *VPS13B* is required for Golgi integrity and is involved in intracellular protein trafficking. We describe the application of whole exome sequencing (WES) in a Tunisian family with two young children with developmental delay, hypotony, ptosis and thick hair and eyebrows. WES identified the presence of compound heterozygous mutation in *VPS13B* inherited from healthy heterozygous parents, confirming an unsuspected clinical diagnosis of Cohen Syndrome. In conclusion the diagnosis of Cohen Syndrome remain very difficult because of the heterogeneity of clinical manifestations in fact the introduction of exome sequencing approaches improves the diagnosis of rare diseases and helps clinicians in elucidating their etiologies.

J08.03
Leukemia inhibitory factor gene polymorphism rs929271 is associated with mild intellectual disability

R. V. Gulkovskyi[1,2], *L. S. Volkova*[1,2], *L. A. Livshits*[1,2];
[1]*Institute of Molecular Biology and Genetics of NASU, Kyiv, Ukraine,* [2]*Educational and Scientific Centre „Institute of Biology", Kyiv, Ukraine.*

The causes of intellectual disability (ID) vary with the severity of the condition: moderate-to-severe ID (IQ<50) is much more likely to be due to a single pathological cause (genetic or environmental) whereas mild ID (IQ 50-70) is rather complex condition in origin.

Leukemia inhibitory factor (LIF) was found to regulate the neuronal phenotype and coordinate astrocyte, oligodendrocyte, microglia, and inflammatory cell responses. The T to G transversion rs929271 is located in the 3`-UTR of the LIF gene and suggested to reduce mRNA stability. Previous reports demonstrated that rs929271 may produce susceptibility to hebephrenic schizophrenia and deterioration of working memory function.

Aim of this study is to evaluate the possible association of LIF gene polymorphism rs929271 with mild ID. The group of mild ID patients consisted of 64 individuals including 40 (62.5 %) males and 24 (47.5 %) females, where previous extensive genetic investigations revealed no abnormalities. The control group consisted of 238 healthy volunteers. It was determined that total frequency of hetero- and homozygous carriers of LIF minor allele (G), is reliably higher (p=0.01) in the ID patients group (71.9%) compared to the control group (55%). The G-allele occurred less frequently 0.328 - in the control group than 0.445 - in the ID patients group (p=0.02). It was shown that the risk of mild ID development increased for both hetero- and homozygous carriers of minor G-allele and the odd ratio was 2.09 (95% CI: 1.14-3.81).

Therefore, we propose LIF as a new marker of genetic susceptibility for intellectual disability.

Influence of mutation type and X chromosome inactivation on Rett syndrome phenotype in Czech patients

D. Zahorakova[1], *P. Lelkova*[1], *A. Baxova*[2], *A. Zumrova*[3], *M. Simandlova*[4], *J. Hadac*[5], *P. Martasek*[1];
[1]*Department of Pediatrics and Adolescent Medicine, Charles University in Prague, First Faculty of Medicine and General University Hospital, Prague, Czech Republic,* [2]*Institute of Biology and Clinical Genetics, Charles University in Prague, First Faculty of Medicine and General Teaching Hospital, Prague, Czech Republic,* [3]*Department of Paediatric neurology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic,* [4]*Department of Biology and Medical Genetics, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic,* [5]*Department of Pediatric Neurology, Thomayer Hospital, Prague, Czech Republic.*

Introduction: Rett syndrome (RTT) is a severe X-linked dominant neurodevelopmental disorder caused by mutations in MECP2 gene. The severity of clinical features is highly variable and tends to depend on specific mutations. Variation in X chromosome inactivation (XCI) is another factor, often causing milder or more severe phenotypes.

The purpose of this study was to examine whether specific mutations and XCI pattern can explain different clinical manifestations in selected Czech patients with RTT.

Subjects and methods: The severity of clinical features was evaluated in two pairs of patients with a confirmed mutation: P1 and P2 had a "mild" mutation p.Arg133Cys; P3 and P4 had a "severe" mutation p.Arg255*. XCI analysis was performed by a common human androgen receptor assay.

Results and discussion: Both patients with p.Arg133Cys had random XCI (49:51 and 43:57). P1 presented with a more severe classic form of RTT, while P2 had a mild variant typical for this mutation. P3, carrying p.Arg255*, had skewed XCI (17:83) and in comparison with P4, who had random XCI (59:41), had considerably milder phenotype regarding the age at onset of symptoms and absent epilepsy. Both patients with the p.Arg255* mutation were more severely affected than patients with the p.Arg133C mutation.

Conclusions: Our results support the hypothesis that specific MECP2 mutations and XCI influence the clinical severity of RTT phenotype, but not in all cases. Exceptions to the rule point out the need to proceed with caution in clinical prognosis and suggest that other modifying factors are involved in RTT pathology.

Supported by NT13120-4/2012, UNCE204011/2012, MZCR-RVO-VFN64165/2012.

α-ketoglutarate dehydrogenase mutations may predispose Alzheimer's disease

E. Bányász[1], **K. Pentelényi**[1], *V. Hársfalvi*[1], *M. Palkovits*[2], *V. Ádám-Vizi*[3], *M. Molnár*[1];
[1]*Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary,* [2]*Human Brain Tissue Bank and Laboratory, Semmelweis University, Budapest, Hungary,* [3]*Department of Medical Biochemistry, Semmelweis University, Budapest, Hungary.*

Introduction: α-ketoglutarate dehydrogenase (αKGDH) enzyme is a key enzyme of Krebs cycle and its mutations are known to result in extensive oxidative stress and cell damage. The hereditary mutations lead to a variety of phenotypes, extending from the lethal infant-type enzyme defect to the elderly's chronic diseases. Reduced enzyme activity has been reported in Alzheimer's patients' fibroblasts. Our objective was the mutation analysis

of the αKGDH enzyme.
Materials and Methods: Dihydrolipoamide S-succinyltransferase (DLST) and dihydrolipoyl dehydrogenase (DLD) genes (E2 and E3 components of αKGDH) were sequenced from 22 Alzheimer's patients' blood samples, from 11 Alzheimer's patients' post mortem brain tissues, and from 2 control samples.
Results: We found 4 pathogenic mutations in 3 of 11 Alzheimer patients' brains: Arg263His missense mutation in DLD gene, Pro204Leu, Leu394Met and Leu453His missense mutations in DLST gene. No mutations were present in the blood samples.
Conclusions: The presence of the 4 pathogenic mutations in the αKGDH may indicate that this enzyme is a keyplayer in the pathogenesis of Alzheimer disease. Further studies are needed to support our hypothesis.

J08.06
Breakpoint within the minimum critical region of the 15q24 microdeletion syndrome in a patient with an inherited rearrangement

M. Moreno-Igoa, *B. Hernández-Charro, L. Morales-Garófalo, A. Bengoa-Alonso, A. Pérez-Juana, M. A. Ramos-Arroyo;*
Complejo Hospitalario de Navarra, Pamplona, Spain.

Introduction
The 15q24 microdeletion syndrome is major characterized by global developmental delay, mild-moderate intellectual disability, facial dysmorphisms, genital and digital anomalies and growth retardation. We here present a father and his daughter bearing an inversion breakpoint within the minimum critical region of this syndrome.
Patients and Methods
Both patients shared facial dysmorphic features (long face, wide forehead, depressed nasal base, pointed chin) and showed intellectual disability, more severe in the daughter. Additionally, the father manifested hiposmia and the daughter had behavioural/relation problems. Conventional and molecular karyotypes were performed. FISH experiments were completed using BAC clones for breakpoints approach at chromosome 15q.
Results
The daughter´s karyotype was 46,XX,inv(15)(q21q24)pat. aCGH revealed no genomic imbalances. FISH analysis showed that the RP11-586G22 BAC probe spanned the translocation breakpoint at 15q24.2, involving 5 genes (COMMD4, NEIL1, MAN2C1, SIN3A and PTPN9). At 15q21.1 band, the breakpoint was delimited between RP11-138E16 and 142O17 BAC probes, involving 4 genes (SECISBP2L, COPS2, GALK2 and FAM227B).
Conclusion
We speculate on the potential pathogenicity of the genes contained in 15q24.2 region that are likely to be disrupted by the inversion breakpoint and responsible for specific clinical features of the 15q24 microdeletion syndrome. Loss of NEIL1 has been reported to cause defects in olfactory function in mice, as found in the father. In neurons, SIN3A has been described to participate in learning and memory processes. The impairment of this gene might be implicated in the intellectual disability presented in our patients and those affected by the 15q24 microdeletion syndrome.

Array CGH approach for neurodevelopmental disorders in Romania

A. Chirita-Emandi[1], *O. Adam*[1], *S. Dumitriu*[2], *M. Papa*[1], *M. Puiu*[1];
[1]*University of Medicine &Pharmacy Victor Babes, Timisoara, Romania,* [2]*UCL- Institute for Child Health, Department of Genes, Development and Diseases, London, United Kingdom.*

Background: Array-CGH approach has dramatically increased the detection rate of genomic imbalances, increasing the diagnostic yield also in neurodevelopmental disorders; however in Romania it is in most cases expensive or unavailable. This approach can be challenging with regard to interpretation of copy number variants of uncertain significance or variants with reduced penetrance.
Aim: We audited the results from array CGH in a series of Romanian children with neurodevelopmental disorders, to assess the proficiency of the method considering its costs.
Method: The Array CGH analysis of DNA were carried out in London, using oligonucleotide arrays with ~60,000 probes across the genome of 20 Romanian children with neurodevelopmental disorders. This work was done under the frame of European Social Fund, Human
Resources Development Operational Programme 2007-2013,project POSDRU/159/1.5/136893.
Results: The overall diagnostic yield of causal abnormalities was 30%. The overall yield of noncausal abnormalities was 10%. 20% came back without abnormality, while 40 % located findings that may represent a benign copy number variant, however genetic counselling was considered appropriate and blood samples from patents were requested.
Conclusion: When interpreting a result form array CGH, distinguishing the characteristics of copy number changes in relation to their clinical relevance is essential. Nonetheless, the method provided a better understanding the genetic architecture of the heterogenic neurodevelopmental disorders, thus advancing diagnosis, prognosis, and counselling for patients and families.

Molecular cytogenetic characterization of terminal 14q32 deletion

A. Hovhannisyan[1,2], *S. Midyan*[1];
[1]*Center of medical genetics and primary health care, Yerevan, Armenia,* [2]*National Bureau of Expertises, Yerevan, Armenia.*

Detailed molecular-cytogenetic studies combined with clinical characterization are needed to establish genotype-phenotype correlations for specific deletion syndromes. Although many patients with subtelomeric deletions have been reported, the phenotype map for the terminal deletion 14q syndrome is only slowly emerging. A 14q32.3 terminal deletion with the breakpoint 14q32.31-14q32.33 only has been reported in nine cases. Here, we report on a 3 year old patient with partial monosomy of 14q32.3. She was born of healthy non-consanguineous parents, at 38 weeks'of gestation with a birth weight and length of 2300g and 44cm respectively. Head circumference at 3 years old was 44.5cm. Deletion size determined by molecular karyotyping (aCGH) is 14:102254905- 107240840 ~ 5Mb, which was confirmed by FISH. Major clinical features were presented with profound mental retardation and dysmorphisms, including broad forehead, depressed nasal bridge, pointed chin, hypotonia, epicanthus, excessive knee points extension in the standing position and walking ataxia, weakness of ligamentous apparatus. Based on our findings and review of the literature, we refine the phenotype map for typical clinical findings of the terminal deletion 14q including exclusively 14q32.31-14q32.33 bands. There is a phenotypic discrepancy in few reported so far cases, where the minimal region was 0.3Mb. Our patient hasn't congenital heart defects, genitourinary malformations and coloboma. Combining this phenotype map with benign copy-number variation data available from the Database of Genomic Variants, we propose terminal deletion 14q involving approximately 75 annotated genes. These findings should contribute to delineate the emerging phenotype in terminal 14q32 deletion but need further data.

J08.09
Microdeletions Screening of Bulgarian Patients With Developmental Delay

S. Bichev[1], *R. Vazharova*[2], *S. Andonova*[1], *A. Yosifova*[1], *A. Savov*[1];
[1]*University Hospital Of Obstetrics and Gynecology; National Genetics Laboratory, Sofia, Bulgaria,* [2]*University of Sofia; Medical Faculty; Department of Biology, Medical Genetics and Microbiology, Sofia, Bulgaria.*

Introduction: Microdeletions and microduplications are known cause for developmental delay (DD) and mental retardation (MR). MR/DD affect 1 to 5% of the general population. Establishing a genetic diagnosis in patients with MR/DD is a challenge. These small changes are not always detectable by routine karyotyping. Nowadays new molecular genetic approaches such as MLPA and array CGH allow precise detection of specific submicroscopic deletions or duplications. Next generation sequencing (NGS) could clarify diagnosis of patients with normal aCGH profile.
Materials and Methods: Over a period of 4 years 355 patients with syndromic MR of different severity were screened for deletions/duplications with MLPA. We used MLPA probe mixes P245 for microdeletion syndromes and P070/P036 for subtelomeric regions. Further analysis with aCGH was performed for 29 patients. Two patients were additionally analyzed by Illumina TruSight Inherited Diseases panel.
Results: In 56 patients (15.5%) out of 355 we were able to establish a genetic diagnosis. 44 of all aberrations (12.4%) were detected by MLPA and 4 of them were further characterized by aCGH. In 10 cases (2.8%) aberrations were detected exclusively by aCGH. Among 29 patients screened by aCGH pathogenic CNVs were detected in 14 cases (48%). In 2 additional patients diagnosis was established by NGS.
Conclusion: We present MLPA as an adequate screening procedure for clinically recognizable conditions. Array CGH presents an opportunity to investigate cases with appropriate chromosomal phenotype, where MLPA was insufficient. In our study, aCGH allowed detection of several pathogenic CNVs outside known regions. NGS provides an opportunity to diagnose cases, outside the scope of MLPA or aCGH.

Research on development of children with genetic pathologies associated to mental deficiencies

M. L. Sprincean[1,2], *E. P. Nicolaescu*[3], *E. Halabudenco*[1], *N. Barbova*[1,2], *E. Paladi*[1];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*State University of Medicine and Pharmacy "N. Testemitanu", Chisinau, Moldova, Republic of,* [3]*Universitatea Hyperion, Bucureşti, Romania.*

Introduction: Hereditary mental deficiencies (HMD) represent a group of genetic illnesses with different level of mental retardation. Most characteristic for HMD is decreasing or substantial reducing of psychical activities witch determine a row of deregulations of adaptation processes and mechanisms of organism and its existence in society. Medical-genetic and psycho-pedagogic assistance should have priority among all resources of amelioration of state of persons affected by mental deficiencies of genetic etiology.
Scope of research consists in studying of development process of children with genetic pathologies associated to mental retardations in first three years of their life, using medical, psychological and pedagogic resources of amelioration.
Materials and methods: The study included children diagnosed with genetic pathologies associated to mental retardations in first three years of life.
Results: Research results demonstrate persistence of severe retardation of children with genetic pathologies in psycho-medical aspect, related to insufficient development of all psychical processes and spheres. Psycho-physical retardation of children with genetic pathologies is not so clear during first year of life, comparing with normal children, due to biological resources and to inborn potential of individuals. Deficiency of children with genetic pathologies becomes more evident after the age of one year old. Cognitive-verbal behavior is most affected to children with genetic syndromes, followed by psycho-motional and social-affective behaviors.
Conclusion: Development of psycho-motional sphere represents an important premise for achieving sustainable increasing of formation-development of other neuro-psychic spheres. Psycho-pedagogic models of early differentiated development, including psycho-pedagogic individual program of formation, had a fundamental contribution to development of motricity, of social - affective sphere and of speech.

J08.11

15q11.2(BP1-BP2) deletion as neurocognitive disease risk factor

N. Passon, **P. Dello Russo***, E. Demori, D. Romagno, F. Baldan, L. Allegri, D. Fabbro, G. Damante;*
AZ. OSP.UNIV S. MARIA DELLA MISERICORDIA, UDINE, Italy.

Microdeletions occurred between BP1 and BP2 of 15q11.2 Prader-Willi/Angelman critical region are described in literature as the novel Burnside-Butler Syndrome.
There are four highly conserved and unimprinted genes within the 15q11.2(BP1-BP2) region:*TUBGCP5,CYFIP1,NIPA1, and NIPA2*.
TUBGCP5 is expressed in subthalamic nuclei, *NIPA1*, *NIPA2* and *CYFIP1* are expressed in central nervous system.
Haploinsufficiency for *TUBGCP5*, *NIPA1*, *NIPA2* and *CYFIP1*, without Prader-Willi syndrome, can explain some clinical features as delayed motor and speech development, dysmorphism and behavioural problems.
We describe a case of a 5 old boy with a BP1-BP2 microdeletion of 443kb spanning these four genes.
He had developmental delay, awkwardness of motor skills, behavioural problems, speech and language impairment and was referred for autism clinical suspicion.
No dysmorphism was observed in the patient.
aCGH showed a 15q11.2 microdeletion flanked by BP1 and BP2.
MLPA analysis, performed on the trios, confirmed the microdeletion in the patient and his normal mother.
The penetrance of15q11.2(BP1-BP2) deletion is estimated about at 10%. Our case provide a further evidence to support this CNV as a susceptibility locus for a spectrum of neurodevelopmental disorders.

J08.12

A NOVEL ANKRD11 MUTATION CAUSE MILD KBG SYNDROME

M. Cassone[1,2], *M. Bengala*[1,2], *F. Sangiuolo*[1,2], *G. Novelli*[1,2], *M. Tekin*[3], *F. Brancati*[1,4];
[1]*Genetics Unit, Policlinico Tor Vergata University Hospital, Rome, Italy,* [2]*Department of Biomedicine and Prevention, Section of Genetics, School of Medicine, Tor Vergata University, Rome, Italy,* [3]*Dr. John T. Mc Donald Foundation Department of Human Genetics, Miller School of Medicine, University of Miami, Miami, FL, United States,* [4]*Department of Medical, Oral and Biotechnological Sciences, Gabriele D'Annunzio University, Chieti, Italy.*

Background: KBG syndrome is an autosomal dominant disease characterized by intellectual disability, seizures, short stature, skeletal anomalies and distinct craniofacial features. It is caused by mutations in ANKRD11 gene. So far, nearly 30 mutated KBG patients are reported but the range of neurologic manifestations appears extremely broad.
Methods: during regular genetic counseling we have seen an outpatient, aged 28 years, with macrodontia and distinct craniofacial dysmorphism. Direct sequencing of ANKRD11 coding regions was performed by Sanger method.
Results: a novel c.2130delG heterozygous mutation leading to a premature frameshift p.Trp710Cysfs*9 was identified in ANKRD11. Detailed clinical features included macrodontia of upper incisors, sensorineural/mixed hearing loss, hypoplastic lower ribs, brachydactyly with fifth finger clinodactyly, bicuspid aortic valve. Surprisingly, his neurologic evaluation did not reveal cognitive delay and he was of normal stature.
Conclusion: in nearly all patients with KBG intellectual disabilities are in the mild to moderate range. Single mutations in ANKRD11 have been also reported in idiopathic intellectual disability highlighting a major role for this gene in cognitive impairment and brain disorders. The present patient emphasizes the variability, especially with respect to the neurologic phenotype, related to ANKRD11 mutations allowing more accurate genetic counseling for our patients and their families.

J08.13

Challenges in medical genetics: exome sequencing uncovers recessive mutations in two cases with de novo cnv.

E. Giorgio[1], *V. Caputo*[2], *A. Ciolfi*[3,4], *E. Di Gregorio*[5], *A. Calcia*[1], *C. Mancini*[1], *S. Cavalieri*[5], *E. Belligni*[6], *E. Biamino*[6], *C. Molinatto*[6], *M. Cirillo*[6], *G. Ferrero*[6], *M. Tartaglia*[3], *A. Brusco*[1,5];
[1]*University of Torino-Dep Medical Sciences, Torino, Italy,* [2]*Sapienza University of Rome-Department of Experimental Medicine, Rome, Italy,* [3]*Istituto Superiore di Sanità-Department of Hematology Oncology and Molecular Medicine, Torino, Italy,* [4]*Sapienza University of Rome-Department of Molecular Medicine, Rome, Italy,* [5]*Città della Salute e della Scienza University Hospital-Medical Genetics Unit, Torino, Italy,* [6]*University of Torino-Department of Public Health and Pediatrics, Torino, Italy.*

De novo CNV may represent a challenge for the clinical geneticist. We report on two cases with non-syndromic intellectual disability and developmental delay (ID/DD) carrying a de novo rearrangement involving a single gene: a deletion spanning the ARHGAP12 gene, and a duplication spanning the CNOT6 gene. ARHGAP12 encodes for a member of a large family of proteins that activate Rho-type GTPase. Other genes of the same family are involved in ID or play a role in the developing axons and growth cones, suggesting ARHGAP12 was a candidate for the disease. CNOT6 encodes a subunit of the Carbon Catabolite Repressor Protein 4 (CCR4-NOT) core transcriptional regulation complex. Given the role of regulatory complexes in the pathogenesis of ID/DD, and the widespread expression of this gene, we considered its duplication as a variant of unknown significance. Because of parents consanguinity, we decided to perform a whole exome sequencing (WES). In the first family, we found a reported nonsense mutation p.Arg377* in TRAPPC9, encoding a protein implicated in NF-kB activation. Mutations in TRAPPC9 cause non-syndromic ID associated with a small head circumference, mild cerebral white matter hypoplasia, and corpus callosum hypoplasia. Our patient presents a compatible phenotype. In the second family, we identified a missense homozygous change c.154C>T (p.Cys52Arg) in VLDLR predicted as deleterious. Mutations in this gene have been reported to cause cerebellar ataxia, mental retardation and disequilibrium syndrome type 1, with a phenotype overlapping that of our patient. Our data suggest that de novo array-CGH variants should be looked suspiciously in consanguineous cases, where WES may become mandatory in future.

J08.14

Combined analysis of linkage and exome sequencing identifies a novel elongation factor associated with intellectual disability and delayed motor development

E. Yucesan[1], *F. Tuncer*[1], *F. Kesim*[1], *M. Çalık*[2], *A. İşcan*[3], *S. Ugur Iseri*[1], *U. Ozbek*[1];
[1]*Institute for Experimental Medicine, Istanbul, Turkey,* [2]*Harran University, Faculty of Medicine, Department of Pediatric Neurology, Sanliurfa, Turkey,* [3]*Bezmialem Vakif University, Faculty of Medicine, Department of Pediatric Neurology, Istanbul, Turkey.*

Introduction:
Combined analysis of homozygosity mapping and whole exome sequencing (WES) has served as a powerful tool to detect pathogenic variants associated with recessive disorders. Herein, we applied a two-step approach,where linkage analysis and homozygosity mapping were used to limit exome variants to specific chromosomal regions.
Material and Methods:
We ascertained a consanguineous family from Turkey with three affected children having intellectual disability (ID) and delayed motor development. Whole genome SNP genotyping was conducted for all available family mem-

bers followed by linkage analysis. WES was performed only for one affected individual.
Results:
Two linkage peaks on chromosomes 8 and 9 were obtained with maximum LOD scores of 2.65 and 2.25, respectively. Homozygous haplotypes with identical by descent inheritance were valid only for chromosome 8. Variants were filtered from WES data solely for the linkage region on chromosome 8. Amongst, novel variants with pathogenic affect on protein were prioritized. This combined effort has led to identification of one nonsense and two missense variations in three distinct genes. All variants segregated with the condition in the family and none of them were detected in almost 480control individuals from Turkey. In silico analyses predicted benign effect for the missense variants. We therefore identified the most likely variant that caused an early stop codon in a translation elongation factor.
Conclusions:
We have identified a novel gene that encodes a translation elongation factor associated with ID delayed motor development and seizures using linkage analysis and WES.
This study was supported by TUBITAK and IU-BAP (Project Numbers: 113S331 and 11021)

J08.15
Identification of a nonsense mutation in PIDD in Pakistani families with non-syndromic autosomal recessive intellectual disability using exome sequencing

N. Vasli[1], *A. Mikhailov*[1], *A. Mir*[2], *M. Ayub*[3,4], *J. B. Vincent*[1,5,6];
[1]*Molecular Neuropsychiatry and Development Lab, The Campbell Family Brain Research Institute, The Centre for Addiction & Mental Health (CAMH), Toronto, ON, Canada,* [2]*Human Molecular Genetics Lab, Department of Bioinformatics and Biotechnology, FBAS, International Islamic University, Islamabad, Pakistan,* [3]*Department of Psychiatry, Queen's University, Kingston, ON, Canada,* [4]*Lahore Institute of Research & Development, Lahore, Pakistan,* [5]*Department of Psychiatry, University of Toronto, Toronto, ON, Canada,* [6]*Institute of Medical Science, University of Toronto, Toronto, ON, Canada.*

Intellectual disability (ID) is a genetically heterogeneous neurodevelopmental disorder affecting 1-3% of the general population. It is characterized by deficits in memory skills and language development with difficulty in learning and problem solving. Today, more than 50 genes were detected in patients with ID. In an effort to identify the disease-causing mutations in patients with non-syndromic autosomal recessive ID (NS-ARID) using homozygosity mapping following by exome sequencing, we detected a homozygous nonsense mutation, c.2587C>T, p.Gln863*, in the gene PIDD in two large consanguineous Pakistani families. Sanger sequencing analysis showed complete segregation within the two families with multiple affected individuals. Analysis of cryptic relatedness was performed on a set of 73,306 independent autosomal markers in PLINK version 1.07. The pair-wise PI_HAT values between members of two families were less than 0.10 indicating that these two families were not closely related. P53-Induced Death Domain Protein (PIDD) is a Leucine-rich repeat and death domain-containing protein expressing in brain, with a key role in DNA damage/stress response. It acts as a cell-fate switch through interacting with a pro-survival molecule, RIP1 and activation of NF-kB signaling to repair and survive the lesions, or via interacting with a pro-death factor, RAIDD and activation of caspase-2 and apoptotic cell death. The p.Gln863*mutation was in the death domain (DD), through which PIDD interacts with other DD proteins such as RIP1 or RAIDD. Functional studies are ongoing to establish the mechanism of pathogenicity of the variant detected. Our finding suggests the involvement of new pathways, i.e. PIDD-related pathways, in the etiology of intellectual disability.

J08.16
A missense variant in Oligophrenin-1 segregating with intellectual disability without cerebellar hypoplasia and distinctive appearance in males from a large pedigree

A. ZIEGLER, *A. GUICHET, E. COLIN, D. BONNEAU;*
Service de Biochimie et Génétique, CHU Angers, Angers, France.

X-linked intellectual disability (XLID) is a heterogeneous condition with more than 110 genes identified. Oligophrenin-1 is a protein with a Rho-GTPase-activating domain required in theregulation of the G-protein cycle. Mutations in the oligophrenin-1 coding gene, OPHN1,usually cause XLID with cerebellar hypoplasia and distinctive facial appearance.
We studied a large pedigree including 8 males affected with moderate intellectual disability. All affected males had no distinctive dysmorphic features and the MRI showed a normal cerebellum. We first performed a haplotype-sharing analysis using SNP-array in affected males, followed by whole exome sequencing in one affected male. Four deleterious mutations were evidenced in 4 distinct genes,namely FAAH2, MAGEE1, TAF9B and OPHN1, located in the haplotypic minimal region shared by affected males. After Sanger sequencing, only one variant in OPHN1,namely R243W,was found to be co-segregated with the disease in all affected males and was absent in normal males. This variant altered a highly conserved residue located between the BAR and the PH domains of the oligophrenin protein,was predicted to be damaging by SIFT and Polyphen and was not listed in the EXAC database. Although there is currently no functional test to definitively validate the deleterious effect on the oligophrenin function of this variant, we suggest that this variant is pathogenic, expanding the spectrum of OPHN1 variants to non-syndromic XLID.

J09.01
Novel and recurrent mutations in NF1 gene causing neurofibromatosis in Bulgarian patients

M. Glushkova[1,2], *I. Yordanova*[2], *T. Todorov*[2], *A. Todorova*[1,2], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemitry, Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria.*

Neurofibromatosis type 1 (NF1) is characterized by skin pigmentation (cafe-au-lait spots), Lisch nodules and growth of tumors along nerves in the skin, brain, and other body parts. NF1 is an autosomal dominant disorder, caused by mutations in the *NF1* gene (17q11.2). The produced nonfunctional neurofibromin cannot properly regulate cell growth and division. Segmental NF (NF5) is a rare form in which multiple neurofibromas are restricted to a single body part without the typical characteristics of neurofibromatosis.
Here we report 15 Bulgarian NF1 cases and one segmental NF5 case. All but one of NF1 cases presented „café au lait" macules. Plexiform neurofibroma(s), Lisch nodules, sphenoid wing dysplasia and freckling in the axillary and inguinal regions were reported in some cases. The segmental neurofibromatosis case suffered by multiple neurofibromas formation in the right thenar hand, engaging thumb and middle finger. The age of onset is early after birth.
Mutations in the *NF1* gene were detected in nine patients (56%). Three mutations are novel, two germline and one somatic. The germline mutations were detected in blood: a splice site mutation c.4725-1G>A and deletion of exons [41-52]⋯56. The case with segmental neurofibromatosis was tested negative for *NF1* mutations in blood but a somatic deletion of exons [1-12] was detected in fresh neurofibrom biopsy.
In conclusion, the detection of mutations in *NF1* gene allows family planning, better genetic counseling and prenatal diagnostics in affected families. The cases with segmental neurofibromatosis must be genetically interpreted with caution, as they are caused by somatic mutations in neurofibroms.

J09.02
Novel mutation in SPG4 gene in patients with spastic paraplegia from Bashkortostan Republic (Russia)

A. Akhmetgaleyeva[1], *I. Khidiyatova*[1], *E. Saifullina*[2], *R. Idrisova*[2], *R. Magzhanov*[2], *E. Khusnutdinova*[1];
[1]*Institute of biochemistry and genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

Hereditary spastic paraplegias (HSP) - is a genetically and clinically heterogeneous group of neurodegenerative disorders characterized by progressive spasticity of the lower limbs. The major pathological feature of HSP is degeneration of pyramidal tracts. Autosomal dominant (AD), recessive (AR), or X-linked inheritance were described. To date, 30 causative genes and 50 loci have been identified. Mutations in the SPG4 gene are responsible for about 45% of the pure AD type of HSP and for 12-18% of the sporadic cases. SPG4 codes for spastin - AAA (ATPase associated with diverse cellular activities) family protein. Over 300 mutations have been described.
The HSP frequency in Bashkortostan Republic (BR) is 3,5:100000. We examined HSP patients from BR and detected one mutation in patients from one large Bashkir family in SPG4 gene. This previously undescribed frameshift mutation is deletion of ten nucleotides in exon 6 leading to the formation of a premature stop codon in 15 codons after mutation codon (c.885del10 (p.Thr295ThrfsX16)). Disorder in this family has autosomal dominant mode of inheritance. The disease in proband and his relatives manifestated at the beginning of the third decade of life. The first symptoms were lower extremity spasticity and gait disturbance. Clinical examination revealed lower central spastic paraparesis with increasing hypertonicity at the initiation of movement in proband at the age of 47 years. An absence of any other neurological symptoms allowed concluding that there is pure form of HSP in this family. The mutation was not revealed in the control group of Bashkir ethnicity.

J09.03

A severe neurological syndrome of ventriculomegaly, agenesis of corpus callosum, psychomotor retardation and seizures mapped to a locus on chromosome 12.

Y. Perez[1], *H. Flusser*[2], *O. Birk*[1];
[1]*The Morris Kahn Laboratory of Human Genetics and the Genetics Institute, Soroka Medical Center, Ben-Gurion University of the Negev, Beer Sheva, Israel,* [2]*Zussman Child Development Center, Soroka Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel.*

Large consanguineous Bedouin family of the Negev area of southern Israel presented with an autosomal-recessive severe neurological syndrome of ventriculomegaly, agenesis of corpus callosum, psychomotor retardation and seizures. Patients karyotype, chromosomal microarray and metabolic workup were normal. Homozygosity mapping using Affymetrix 250K SNP arrays identified a single ~7Mb disease-associated locus on chromosome 12 between rs10734905 and rs903770. Multipoint LOD score was calculated and yielded a score of 3.82 at rs7312321. Within the pre-defined locus are some genes associated with neuronal development. Mutations in these genes are known to cause severe phenotypes similar to those presented by our patients: HSPB8 (MIM#158590), COX6A1 (MIM#616039), ACADS (MIM#201470), C12orf65 (MIM#615035), EIF2B1 (MIM#603896) and TCTN2 (MIM#603896). Whole exome sequencing was performed and data analysis is being processed.

J09.04

Familial pericentric inversion 18: A new recombinant child

A. Acar[1], *M. Balasar*[2], *P. Taşdemir*[2], *Ö. Balasar*[3];
[1]*İstanbul Bilim University, Department of Molecular Biology and Genetics, İstanbul, Turkey,* [2]*Necmettin Erbakan University,Medical Faculty, Department of Medical Genetics, Konya, Turkey,* [3]*Konya Dr. Faruk Sükan Women And Children Hospital, Department Of Medical Genetics, Konya, Turkey.*

Introduction
The pericentric inversions frequency of the population is 1-2%. In most of the inversion carrier, the phenotype is normal, but carriers of inversions are at risk of having unbalanced offspring due to meiotic crossing-over. The risk of having an abnormal child is about 5-10 %. Here, an unbalanced offspring whose mother is pericentric inversion 18 carrier was presented.
Material and Methods
Cytogenetic analysis and SNP Array were performed on the patient's peripheral blood.
Findings
1 year old female patient had minor dysmorphic feature and epilepsy. Her mother had oligohydramnios in prenatal period. The neuro-motor development was normal. She was diagnosed with epilepsy when she was 8 month old. The patient's mother was known to be familial inversion 18 carrier.
Cytogenetic analysis was performed on the patient's peripheral blood by GTG banding method. Her karyotype was 46,XX,inv(18)(p11,2;q21) like her mother. SNP Array was performed on the patient's peripheral blood and a heterozygote deletion which was 1,177,294 base pairs in size on 18p11.31 chromosomal region was found. This region contains C18orf42, LINC00526, LINC00667, ZTBD14, EPB41L3, LOC645355, MIR3976, TMEM200C, L3MBTL4, MIR4317, C18orf64, ARHGAP28, LINC006, LAMA1 genes. It is suggested that this heterozygote deletion is responsible for the patient's clinical findings. There were children with severe abnormalities and died early due to inv18 in this family. Genetic counseling was given to family. PGD was recommended in subsequent pregnancies.
Conclusion
18p11.31 deletion is associated with normal phenotype to mild dysmorphic feature, autism, epilepsy and intellectual disability in the literature. Our findings were similar to the literature.

J09.05

The clinical peculiarities of congenital malformation of the brain

E. Paladi[1], *M. Sprincean*[1,2], *E. Halabudenco*[1], *N. Barbova*[1,2], *V. Egorov*[1];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*State University of Medicine and Pharmacy "N. Testemitanu", Chisinau, Moldova, Republic of.*

Introduction: Cerebral malformations represent a great problem in neurogenetics. More than 2000 different congenital malformations of the brain have been described in the literature, and their incidence is reported to be about 1 percent of all live births. In congenital brain malformations development involved several factors: genetic factors, vitamin deficiency, infections, irradiation factors, medications, etc.
Materials and methods: The study included 55 patients (25 girls and 30 boys) aged between 2 week - 12 month, diagnosed with congenital brain malformation (CBM).
Results: All the children included in the study were examined by complex neurological examination and supplementary investigation: neurosonography, computed tomography (CT) - brain and magnetic resonance imaging (MRI). It was concluded that agenesis of the corpus callosum was the most common congenital brain malformation in children aged under 1 year (42%), microcephaly (27%), agenesis of the septum pellucidum (11%). The most rare congenital brain malformations were: hydranencephaly (5%), anencephaly (5%), hemimegalencephaly (2%) and microgiria (2%). The most common clinical manifestations were: neuropsychic retardation of varying degrees (91%), disorders of muscle tone (50%), partial seizures / infantile spasms (36%).
Conclusion: A congenital malformation affects neurological development and reduces the ability of the children. The prognosis of the children with CBM varies depending on the type and severity of the defect: some congenital defects causing minor neurological disorders, others are so severe that they are fatal before or soon after birth.

Analysis of solute carrier family 6 member 4 gene promoter polymorphism in young Turkish basketball players.

K. Ulucan[1,2], **C. Sercan**[1], *S. Yalcin*[3], *B. Akbas*[3], *F. Uyumaz*[3], *M. Konuk*[2];
[1]*Marmara University, Faculty of Dentistry, Department of Medical Biology and Genetics, Istanbul, Turkey,* [2]*Üsküdar University, Faculty of Engineering and Natural Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey,* [3]*Doga Foundation Schools, Department of Biology, Istanbul, Turkey.*

Serotonin transporter (5-hydroxytryptamine transporter, 5- HTT) gene (SLC6A4) is considered to be one of the most important candidate genes for genetic involvement in psychiatric conditions like anxiety, self- confidence and motivation. In the present report, we aimed to analyze the distribution of SLC6A4 promoter long and short (L and S, respectively) polymorphism in young Turkish basketball players. We enrolled 24 players in the study, 17 were females and 7 were males. 12%, 35% and 53% of the females had SS, LS and LL genotype, respectively; whereas 28,5% of the males had SS and the same percentage of them had LS, and 43% had LL genotype. When we examined the allelic counts, L allele was recorded as 71% in females and 57% in males; S allele was 29% in females and 43% in males. Our results were in agreement with the previous ones, indicating the presence of L allele in individuals dealing with sport. We suggest that SLC6A4 promoter analysis is important for genetic counseling for the individuals who are prone to be successful in sports.

Methylation status and calorimetric profiles of serum proteins in schizophrenia patients

B. B. Rukova[1], *R. Staneva*[1], *S. Hadjidekova*[1], *S. Krumova*[2], *S. Todinova*[2], *I. Dimova*[1], *S. Karachanak-Yankova*[1], *Z. Hammoudeh*[1], *O. Antonova*[1], *D. Nesheva*[1], *V. Milanova*[3], *S. Taneva*[2], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University, Sofia, Sofia, Bulgaria,* [2]*Institute of Biophysics and Biomedical Engineering, Bulgarian Academy of Sciences, Sofia, Bulgaria,* [3]*Department of Psychiatry, Medical University, Sofia, Sofia, Bulgaria.*

Background: Schizophrenia is severe chronic psychiatric disorder. It has multifactorial etiology. Epigenetic factors such as DNA methylation could be involved in the schizophrenia pathogenesis. Environmental factors could modify the gene expression and change the thermodynamic behavior of blood sera.
Materials and Methods: We have performed high-resolution genome-wide methylation array analysis on pool samples consisted of 220 patients and 220 healthy controls to determine the methylation status of 27,627 CpG islands. The effect of environmental factors on gene expression was analyzed by differential scanning calorimetry (DSC) applied on 92 patients and 21 controls.
Results: We found 394 differentially methylated regions (DMRs) between schizophrenia patients and control DNAs. In the promoters were discovered 146 CpG islands (96 hyper- and 50 hypomethylated). The potential new discovered candidate genes with DMRs participate in transcription regulation, neurotransmission, cell motility and adhesion and nervous system development. Significant thermodynamic modifications in blood sera behavior of schizophrenia patients were revealed. The calorimetric profiles were classified in four distinct groups, reflecting different thermal stabilization of the high-abundance portion of the serum proteome.
Conclusion: Our data revealed substantial differences in methylation and calorimetric profiles between schizophrenia patients and controls. It is proposed that a combination of DNA methylation microarray analysis and calorimetric analysis of proteins is a perspective strategy for a comprehensive study of schizophrenia.

Analysis of several loci from genome-wide association studies in Parkinson's disease in three ethnic groups from Bashkortostan Republic of Russia

I. Khidiyatova[1], *G. Akhmadeeva*[1], *I. Gilyazova*[1], *A. Baytimerov*[2], *R. Magjzanov*[2], *E. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

We performed replication of genome-wide association analysis (GWAs) with Parkinson's disease (PD) in three ethnic groups from Bashkortostan Republic on 550 PD patients (Russians - 215, Tatars - 243, Bashkirs - 90) and 622 controls (Russians - 190, Tatars - 338, Bashkirs - 94). The study included analysis of 15 polymorphic loci: rs356219, rs356165, rs2737020, rs2619364 and rs6532194 in SNCA gene; rs11012, rs2942168, rs393152, rs1724425, rs12373139 and rs1981997 in chromosomal region of MAPT gene (17q21.31); rs1491942, rs1907632, rs34778348 (G2385R) associated with LRRK2 gene, and rs7077361 - in ITGA8 gene.
The results of the analysis in three ethnic groups were different. Genetic markers of the increased risk of PD development in Russians were alleles: rs356219*G (p = 0,006; OR = 1,58), rs356165*G (p = 0,003; OR = 1,64) of SNCA gene, rs11012*A (p = 0.007; OR = 2,12) of MAPT- region; in Tatars - rs6532194*T (p = 0,04; OR = 1,40) of SNCA gene; rs2942168*C (p = 0,02; OR = 1,60), rs393152*A (p = 0,001; OR = 1,92), rs1724425*C (p = 0,04; OR = 1,3), rs1981997*C (p = 0,01; OR = 1,72) of MAPT- region; rs7077361*T (p = 0,005; OR = 1,74) of ITGA8 gene. Polymorphsm rs34778348*G/A (G2385R) of LRRK2 gene was found only in PD patients of Tatar ethnic origin (0.6%). In Bashkirs association with PD development was confirmed only for rs1491942l in LRRK2 gene: genotype *G/G was protective against PD development of (p = 0,01; OR = 0,07).

Genetic association of 5-HT1A and 5-HT1B gene polymorphisms with OCD in the Turkish population

S. Aldemir[1], *M. Acar*[2], *Z. Ocak*[3], *E. Dalbudak*[1], *M. Yiğitoğlu*[4], *E. Gündüz*[2];
[1]*Department of Psychiatry, Faculty of Medicine, Turgut Ozal University, Ankara, Turkey,* [2]*Department of Medical Genetics, Faculty of Medicine, Turgut Ozal University, Ankara, Turkey,* [3]*Department of Medical Genetics, Istanbul Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey,* [4]*Department of Medical Biochemistry, Faculty of Medicine, Turgut Ozal University, Ankara, Turkey.*

Objectives: Obsessive-compulsive disorder (OCD) is a common neuropsychiatric disorder with complex genetic etiology. We investigated the possible roles of C-1019G promoter region polymorphism of the 5-HTR1A and G861C coding region polymorphism of the 5-HTR1B receptor genes in the susceptibility to OCD in the Turkish population.
Methods: Two single nucleotide polymorphisms that are the 5-HTR1A (rs6296) and the 5-HTR1B (rs6295) receptor genes were genotyped in 76 OCD patients and 57 healthy control groups that are unrelated age-matched and sex-matched by using the PCR-RFLP.
Results: We did not observe any difference in the genotype distributions of the rs6296 and rs6295 between the OCD patients and the control groups.
Conclusions: To the best of our knowledge, our study is the first to confirm the association of the variant rs6296 that is related to HTR1A with OCD in the Turkish population. As a result of our study, polymorphisms of rs6296 and rs6295 receptor genes are possibly a weak candidate that will contribute in determination of the relationship between 5-HT1A, 5-HTR1B receptor genes and OCD.

J09.10

Association of ADARB1 gene with suicide attempt risk in patients with major psychiatric disorders

J. Karanović[1], *S. Šviković*[1], *M. Pantović*[2], *S. Durica*[1], *G. Brajušković*[1], *A. Damjanović*[2,3], *V. Jovanović*[4], *M. Ivković*[2,3], *S. Romac*[1], *D. Savić Pavićević*[1];
[1]*Center for human molecular genetics, Faculty of biology, University of Belgrade, Belgrade, Serbia,* [2]*Clinic for Psychiatry, Clinical Centre of Serbia, Belgrade, Serbia,* [3]*Medical School, University of Belgrade, Belgrade, Serbia,* [4]*Department of Genetic Research, Institute for Biological Research „Siniša Stanković", University of Belgrade, Belgrade, Serbia.*

Introduction: Adenosine-to-inosine RNA editing, catalyzed by ADAR and ADARB1, is widely used to fine-tune the functional properties of proteins key to neurotransmission, and is thought to be essential for behavior and cognition. Changes in the editing of some target transcripts and changes in ADARB1 mRNA expression were demonstrated in the brains of psychiatric suicide victims. Transgenic mice misexpressing the rat's ADARB1 isoform is a model of endogenous depression, indicating that genetically determined differences in ADARB1 expression may be involved in psychiatric pathologies. To test this, we performed an association study of common variants in ADARB1 gene with suicide attempt (SA) in psychiatric patients.
Materials and Methods: 165 suicide attempters and 188 suicide non-attempters, suffering from major depressive disorder, bipolar disorder or schizophrenia were genotyped for 11 selected tag-variants mapping in ADARB1 region coding deaminase domain and 3'-untranslated region. Associations were tested using Pearson's $\chi 2$-test and logistic regression adjusted by psychiatric diagnoses. Multiple testing bias was corrected by applying a 10e6 permutation test.
Results: Rs9983925 minor allele T decreased the risk for SA (P=0.028, OR=0.705), while the rs4819035 minor allele G increased the risk (P=0.028, OR=1.495). The genotypic tests revealed significant result only for the additive model (rs9983925: P=0.032, OR=0.710; rs4819035: P=0.042, OR=1.437). The observed associations were confirmed with permutation test.
Conclusion: This is the first study showing the association of ADARB1 with SA in psychiatric patients, implying genetically determined involvement of RNA editing in SA. The identified risk variants overlap putative 3'-regulatory regions of ADARB1 and may influence its expression.

Association Study of a Brain-Derived Neurotrophic Factor genetic polymorphism Val66Met and Major Depression Disorder in Colombian population

A. M. Gaviria-Manrique, *C. Cañizares-Escobar, M. C. Lattig-Matiz, Y. Gomez-Maquet; Universidad de los Andes, Bogotá, Colombia.*

Major Depression Disorder(MDD) affects morbility, mortality and quality of life of many people around the world(1). This disease has heritability between 30% and 40%, indicating an important genetic component(2). Otherwise, it has been suggested that the Val66Met polymorphism of the brain-derived neurotrophic factor gene (BDNF) could be associated to this disorder(3). During the present investigation a case-control approach was carried out in order to determine the genotype of clinical Colombian population and their match controls. For this, a cognitive diagram of each individual was evaluated using the standard psychological tests M.I.N.I, STAI, IDER, and YSQ SF, then genotyping was performed by qPCR and data was analyzed using R software. Association studies show no effect between these variants and MDD (OR=1 Y P-value= 0,99). When psychological data was analyzed, a strong association between abuse and depression phenotype was found (OR=0.11, p=0.00036). When analyzing for interactions, between the BDNF variants and childhood abuse we observed that individuals with the Val allele and childhood abuse where more prone to develop MDD (LOD=2.83). These results suggest that Val66Met variant per se has no influence over the MDD but people with the genotype Val/Val could be more vulnerable to develop a depressive disorder when they have been abused in their childhood.

Symmetrical progressive calcification of brain basal ganglia:symptomatic or idiopathic

K. Hovhannesyan[1], *A. Hakobyan*[1], *T. Sargsyan*[1], *L. Servais*[2];
[1]*Center of medical genetics and primary health care, Yerevan, Armenia,* [2]*Institute of Myology, Paris, France.*

Different perinatal pathologies, as well as pseudohypoparathyroidism (PHP) and genetic disorder known as Fahr's disease can cause calcification of brain hemispheres in the early childhood. In our studies of rare disorders to a special interest came a condition such as PHP, when high concentration of parathyroid hormone in the blood is associated with resistance of the organism towards biological activity of the hormone, namely, patients have hypocalcemia and hyperphosphatemia. Modern molecular-genetic methods play a significant role in child neurology clinic in relation to both diagnostics and treatment. Our presented case likely to be PHP type 1b (male, 16yo), who has developed his first partial epileptic seizures at age 13. Brain CT performed at age 15 showed symmetrical calcification in the region of basal ganglia. Mild neurological signs were observed (mild muscle hypoto-

nia, slowness in movements, a little euphoric, low school performance and restricted interactions with peers). Oral intake of carbamazepine was not effective, valproate sodium as second drug has improved seizures' control. The second CT performed at age 17 showed progression of calcification including frontal lobe. Biochemistry and molecular genetic exams confirmed a rare pathology - PHP type 1b which is characterized by molecular defect in the GNAS1 gene which is responsible for the renal resistance to PTH. The seizures identified as symptomatic and require additional treatment with active form of vitamin D3 and IV calcium to normalize blood calcium level and prevent progression of brain tissue calcification and finally decrease epileptic activity and enhance seizure control.

Cocaine dependence is a complex psychiatric disorder with both genetic and environmental factors involved. The involvement of different neurotransmitter systems in cocaine effects makes the molecular machinery that controls the release of neurotransmitters to the synaptic cleft a good candidate for participating in the development of the dependence. In a previous work we identified a risk haplotype for cocaine dependence in the gene encoding the N-ethylmaleimide Sensitive Factor (NSF), which is essential for synaptic vesicle turnover. Recently, another study identified a large polymorphic copy-number variant (CNV) that encompasses the first 13 exons of the *NSF* gene. We examined the possible contribution to cocaine dependence of this CNV in the *NSF* gene. For this purpose, we performed a case-control association study in a discovery sample of 359 cocaine-dependent patients and 356 sex-matched controls. Using qRT-PCR technology we genotyped individuals and analyzed the results considering two genotype groups: low number of copies (2 and 3) and high number of copies (4, 5 and 6), and identified an association between cocaine dependence and the CNV (P=0.013). We then performed a replication study consisting of a new sample of 508 cocaine-dependent patients and 569 controls, and the association persisted (P= 7.1 e-03). Finally, we did a pooled analysis and the association also remained significant (P= 1.8 e-04) with a higher frequency of individuals with low number of copies in cases (70.6%) than in controls (62.2%). These results, together with the ones obtained in a previous study from our group, support a role for the *NSF* gene in the susceptibility to cocaine dependence.

Universitat de Barcelona (UB), Barcelona, Spain,* [9]*Mental Health Division, Fundació Althaia, Hospital Sant Joan de Déu, Manresa, Spain,* [10]*Psychiatric Genetics Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Drug addiction is considered a disorder of neuroplasticity in brain reward and cognition systems that results from aberrant activation of gene expression programs in response to prolonged drug consumption. Non-coding RNAs (ncRNAs), such as microRNAs (miRNAs), are key regulators of almost all aspects of cellular physiology. Recently, miRNAs were shown to play key roles in the drug-induced remodelling of the brain reward system that likely drives the emergence of addiction. In this work we aim at exploring the role of miRNAs in drug addiction. Using a case-control association approach we evaluated, in a sample of 735 drug-dependent patients and 739 sex-matched controls, the possible contribution to drug dependence predisposition of 62 SNPs in the 3'UTR of several genes expressed in the central nervous system that are predicted to alter the binding of miRNA molecules. Seven polymorphic variants were found nominally associated with drug addiction. We subsequently assessed these seven SNPs in a replication sample of 663 drug-dependent patients and 667 sex-matched controls and found association between rs1047383 in the PLCB1 gene and drug dependence. This association remained significant when we analyzed the results in the whole sample (1,392 cases and 1,403 controls), with a higher frequency of carriers of the C allele in cases (40%) than in controls (35.5%). Our results suggest that the PLCB1 gene may participate in the susceptibility to drug dependence.

Lack of association between mitochondrial DNA T4216C variation and multiple sclerosis in an Iranian population

S. Andalib[1], *M. Talebi*[1], *E. Sakhinia*[2], *M. Farhoudi*[1], *H. Sadeghi-Bazargani*[3], *A. Gjedde*[4];
[1]*Neurosciences Research Center, Imam Reza Hospital, Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of,* [2]*Division of Regenerative Medicine, School of Medicine, Faculty of Medical and Human Sciences, the University of Manchester, Manchester, United Kingdom,* [3]*Department of Public Health Sciences, Karolina Institute, Stockholm, Sweden,* [4]*Department of Neuroscience and Pharmacology, University of Copenhagen, Copenhagen, Denmark.*

Multiple Sclerosis (MS) affects nerves in the brain and spinal cord and has been the topic of global research; yet there is no commonly accepted cause and no cure for the disease. Mounting evidence supports the role of genetics in susceptibility to MS. From this perspective, a current effort focuses on the neurogenetics of the complex pathogenesis of MS in relation to factors such as mitochondrial DNA (mtDNA) variations or mutations. The present study tested whether mtDNA T4216C variation in the ND1 mtDNA gene is associated with MS in an Iranian population.
Blood samples were collected from 100 patients with MS and 100 unrelated healthy controls, and DNA extraction was carried out by means of a salting-out method. By means of appropriate primers, polymerase chain reaction (PCR) amplification was carried out for the mtDNA fragment. Afterwards, the PCR products were digested using Nla III restriction endonuclease enzyme for analysis of Restriction Fragment Length polymorphism (RFLP) in mtDNA T4216C variation. With electrophoresis by means of 3% agarose gel and *safe DNA gel stain, we imaged restriction products in a UV transilluminator.* The accuracy of genotyping procedure was confirmed by sequencing the mtDNA fragment.
No significant statistical difference in the frequency of the T4216C mtDNA variation was found between the patients (24 %) and the control subjects (21 %) (P=0.61). Logistic regression analysis showed an OR of 1.1 (95% CI=0.5-2.4).
The present study revealed no association between the T4216C variation in mitochondrial ND1 gene, and MS.
This study was supported by Neurosciences Research Center, Tabriz University of Medical Sciences.

A family history of dementia influences the development and the progression of late-onset Alzheimer's disease

R. M. Corbo[1,2], *G. Gambina*[3], *E. Broggio*[3], *D. Scarabino*[4];
[1]*La Sapienza University, Rome, Italy,* [2]*CNR Institute of Molecular Biology and Pathology, Rome, Italy,* [3]*Department of Neuroscience, University and Hospital of Verona, Verona, Italy,* [4]*CNR Institute of Cellular Biology and Neurobiology, Monterotondo Scalo, Rome, Italy.*

Late onset Alzheimer's disease (AD) has no recognizable Mendelian pattern of inheritance but its development may be linked to a family history of dementia (FH). We investigated the possible role of FH in AD susceptibility, age at AD onset (AAO) and cognitive decline in a sample of Italian subjects (504 AD patients and 265 controls). FH was ascertained by interview. FH was found in 28% of AD patients and 15% of controls (p=0.0001). The degree of relationships among relatives with dementia was collected for 97 patients . Logistic regression analysis showed that FH carries an increased risk of AD (OR= 1.9,C.I. 1.3-2.8) independent from the presence of APOE e4 allele, and that FH in first-degree relatives (parents and siblings), is an even higher risk (OR= 5.97,C.I. 2.8-12.7). Among the AD patients with one parent affected, the ratio of mother-to-father with dementia was 1.7/1, confirming that maternal FH may impact on AD development. Among the AD patients with a first-degree FH, mean AAO (±sd) was lower among those with affected parents (73.6±6.8 years) than in those with affected siblings (77.2±5.7,

p=0.02). Cognitive decline (MMSE test scores) was lower in patients with affected parents (17.4 ±5.1) than in those with affected siblings (20.3 ±3.6, p=0.02). AAO and cognitive decline were lower in patients with an affected mother (73.0±7.8 and 16.6±5.3 respectively) than those with an affected father (75.0±5.2 and 18.3±4.9, respectively). In conclusion FH influences AD development and quantitative traits reflecting disease severity, including AAO and cognitive impairment.

J09.17
Case report of Prader -Willi syndrome

G. Zukauskaite[1], *D. Serapinas*[1,2];
[1]*Lithuanian university of Health sciences, Kaunas, Lithuania,* [2]*Mykolas Romeris university, Vilnius, Lithuania.*

Prader-Willi syndrome (PWS) is a complex genetic disorder, characterized by neonatal hypotonia, delayed development, short stature, childhood obesity, hypogonadism, characteristic facial features, and other features . It can be considered to be an autosomal dominant disorder and is caused by deletion or disruption of a gene or several genes on the proximal long arm of the paternal chromosome 15 or maternal uniparental disomy 15, because the genes on the maternal chromosome 15 are virtually inactive through imprinting. This region contains genes that are epigenetically imprinted. We report 12-years old girl with Prader-Willi syndrome. At the day of her birth, she had severe hypotonia, her physiological reflexes were very indolent, also she could not suck or swallow herself. At the age of 12 the patient was admitted for genetic counselling. All laboratory tests for newborns were performed which showed normal results, including karyotipe test (46XX). Neurosonography showed asymetrical, rounded ventricles which suggested hypoxic ischemic changes in the brain. Phenotypically, almond-shaped eyes, prominent nasal bridge and brachydactyly were observed. Moreover, defects in the internal organs, retardation and cysts in the brain were also observed. After the consultation, fluorescent in situ hybridization (FISH) cytogenetic test was carried out to verify the hypothesis of Prader-Willi syndrome. The results showed 15q11 region deletion in 100% of interphase nuclei of lymphocyte culture. The phylogenetic tree was constructed and it showed that patient's father is a carrier. This case shows the importance of genetic testing when patients are suffering from severe hypotonia.

Analysis associations of cognitive performance genes revealed by GWAS with intellectual features in Russian population of West Siberian region

A. V. Marusin[1], *A. N. Kornetov*[2], *A. V. Bocharova*[1], *M. G. Swarovaskaja*[1], *V. A. Stepanov*[1];
[1]*Institute for Medical Genetics, Tomsk, Russian Federation,* [2]*Siberian State Medical University, Tomsk, Russian Federation.*

The research of genetic factors influencing to cognitive function of healthy adults arouse of great interest. All genes that determine the intellectual abilities still have not identified.Genetic researches are based on GWAS revealed genetic variants associated with cognitive performance. The aim of this study was analyze the associations of 5 SNPs (rs8020441, rs2247572, rs2616984, rs2252521, rs2229741) are reported in GWAS with personal intellectual properties that are determined with help (16PF) Cattel's test.This traits included the following factors: B - Reasoning, M - Abstractedness, N - Privateness and Q1 - Openness to Change. Cognitive performance according to recent GWAS studies were genotyped by real-time PCR in Russian healthy adults (N = 150; 111 - women and 11 men; mean age was 22,8+/-0,10). DNA samples were genotyped using TaqMan® SNP Genotyping Assays (Applied Biosystems) under condition recommended by the manufacturer. The relationship of genotypes with quantitative factors B, M, N and Q1 of 16PF was estimated by Kruskal-Wallis ANOVA test. The associations of rs2247572 in KCNB2 gene and rs2252521 in CSMD1 gene with factor B were revealed (p<0,05). The association both SNPs with cognitive performance was reported in GWAS by Cirulli et al., 2010. Also there were established moderate associations (p<0,01) of ZNF804A gene with abstractedness (factor M) and NRIP1 gene with openness to change (Q1). Our findings are support the association of genetic variability KCNB2 and CSMD1 genes with cognitive performance in Russians.The identified associations presuppose substantial contribution of genetic variability in individual mental constitution perhaps.

J09.19
The case of combination of Glutaric acidemia type II and hyperhomocysteinemia

O. Khmil, *Y. Grechanina, E. Zdybskaya, L. Molodan;*
KSMGC, Kharkiv, Ukraine.

Background. Glutaric acidemia type II is characterized by multiple acyl-CoA dehydrogenase deficiencies resulting in significant excretion of glutaric acid, as well as lactic, ethylmalonic, butyric, isobutyric, 2-methyl-butyric and isovaleric acids.
Case report. A., 4 year old girl, with seizures, severe delay in the psycho-speech development, is not able to sit, stand and walk, holds her head badly, chokes with liquids.
The child of 3rd pregnancy, that progressed under condition of maternal preeclampsia, threat of miscarriage. The child was born with respiratory failure, hyperthermia, and convulsions.
The survey found high levels of ammonia, hydrothorax, gidroperitoneum, MRI Dandy Walker cyst. Anticonvulsant, detoxification and antibiotic therapy did not ensure any improvement.
Phenotype: microcephaly, microangiopathy, muscle hypertonia, hepatomegaly, nephroptosis.
In the pedigree: cardiovascular and oncological diseases.
In urine increased concentration of 2-ketoglutaric acid, 3-hydroxybutyrate, 3-hydroxypropionic acid and 4-hydroxyphenylacetate, glutaric acid, ethylmalonic acid and lactate.
Blood test:
C12-0,35 (result 0.469 mM/m) -acylcarnitine
C12: 1-0,24 (0.469 mM/m) -dodekspaylcarnitine
C4-0,1 (1.58 mM/m) -izobutirylcarnitine
C5-0,6 (1,16 mM/m) -valeril-2-methyl-butylcarnitine
C6-0,24 (0.691 mM/m) -geksanaylcarnitine
C8-0,3 (0.461 mM/m) -oktancarnitine.
Homocysteine - ↑ 17,5 mmol/l
Diagnosis: Organic aciduria, glutaric acidemia type II, hyperhomocysteinemia
Conclusions: A diet with a sharp restriction of fats and proteins (1 g/1 kg of body weight), energotropic therapy and correction of metabolic disorders have significantly improved the condition of the child. Ammonia and homocysteine levels in blood have normalized; the child began to swallow normally.

J09.20
Down regulation of antioxidant enzymes in SCA28

S. Squadrone[1], *C. Mancini*[2], *A. Brusco*[2];
[1]*Istituto Zooprofilattico, Turin, Italy,* [2]*University of Turin, Turin, Italy.*

Introduction:
Autosomal dominant spinocerebellar ataxias (SCAs) are genetically heterogeneous neurological disorders characterized by cerebellar dysfunction mostly due to Purkinje cell degeneration. Spinocerebellar ataxia 28 (SCA28) is caused by heterozygous mutation in the *AFG3L2*
gene, on chromosome 18p11.22-q11.2. This gene encodes a component of the conserved m-AAA metalloprotease complex involved in the maintenance of the mitochondrial proteome. Altered oxidative stress response has been supposed for SCA28 as well as for other neurodegenerative conditions. In eukaryotes, antioxidant enzymes involved in reactive oxygen species (ROS) response include superoxide dismutase (SOD) enzymes, which catalyze the conversion of superoxide anions to hydrogen peroxide, and catalase (CAT), a H_2O_2-degrading enzyme. The Cu/ZnSOD or SOD1, is a cytosolic enzyme, the predominant SOD in most cells and tissues, accounting for 70-80 % of the total cellular SOD activity; the MnSOD or SOD2, is a key mitochondrial antioxidant enzyme. Materials and methods: We evaluated in SCA28 patients vs. controls lymphoblastic cell lines (LCLs) mRNA levels of CAT, and SOD2.
Results: We found that CAT and SOD2 expression were down-regulated in SCA28 patients of 20% and 15% respectively (p=0.0118; p= 0.0004). The analysis of enzymatic activity showed a 10% of reduction of SOD1
activity in SCA28 LCLs vs. controls. Conclusions: Major emphasis has been given on the role of oxidative stress and free radical chemistry with respect to major neurodegenerative disorders (e.g., AD, PD, and
ALS). Here we further suggest the role for oxidative stress in the pathogenic mechanism of more rare neurodegeneration disease such as SCA28.

Analysis of mutation distribution for focused groups of children with epileptic encephalopathy

M. Belenikin, *S. Zhilina, T. Meshcheryakova, G. Mutovin, S. Ayvazyan, A. Prityko;*
Research Center for Children Medical Care, Moscow, Russian Federation.

Background: Epilepsies are highly heterogeneous with a genetic contribution. The variety of nonspecific and overlapping syndromic and nonsyn-

dromic phenotypes often hampers a clear clinical diagnosis and genetic testing, however thorough focusing patient groups can help overcome this difficulty. The aims of study: high-throughput sequencing of genes associated with epileptic encephalopathy and mental retardation (thirty-four genes in panel; focused children groups; 100 persons, including controls/parents); searching for de novo mutations and analysis of mutation distribution among studied genes. Particular attention is given to patients of first years of life with epileptic encephalopathy, resistant to anticonvulsants. Methods: DNA isolation: MagNA Pure LC2, targeted genomic enrichment: NimbleGen SeqCap system, sequencing: 454 GSJunior. All steps of the sample preparation/sequencing were performed according to the manufacturer's protocols. Results: The structure of the gene variants (are listed only missense-mutations with MAF less 0,5% or unknown) (gene/persons/mutations): SCN1A/15/10 (3 of them are nonsense-mutations; 9 are unannotated (NCBI)), SCN1B/3/1, SCN2A/2/2, SCN9A/1/1, NRXN1/8/4, ZEB2/2/1, TREX/1/1, CNTNAP2/3/2, DLGAP/6/5, SPTAN1/2/2, GRIN2A/4/4, GRIN2B/1/1, RNASEH2A/1/1, RNASEH2B/3/2, CDKL5/1/1, PCDH19/1/1, UBE3A/2/1. An about half of revealed missense-mutations are unannotated (NCBI). Long 454 reads revealed some extended structural features undetectable from NGS with shorter reads: deletions (75b.p. (SCN1A); 59b.p. (SLC9A6)), inversions (311b.p. (NRXN1)). Conclusions: The data obtained allowed to confirm clinical diagnosis for most patients studied. The research was supported by the Department of Health of Moscow.

J09.22
The role of gene x environment interactions in anxiety-related traits in healthy individuals

R. F. Kanzafarova[1], *A. V. Kazantseva*[2], *N. Yamangulova*[1], *A. Kulbaeva*[1], *A. R. Farahtdinova*[1], *E. K. Khusnutdinova*[1,2];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics Ufa Science Centre of RAS, Ufa, Russian Federation.*

Anxiety appears to be the endophenotype of affective disorders caused by gene-environment interactions. Despite multiple studies focused on associations of serotonergic system genes with anxiety-related traits, there is some controversy since multiple genes of small effect are involved. Recently, the involvement of genes encoding contactin associated protein like 2 (CNTNAP2) and neurexin 1 (NRXN1) in anxiety-related phenotypes was published (Stein et al., 2011; Grayton et al., 2013). The aim of this study is to examine the role of NRXN1 (rs4971648, rs1045881) and CNTNAP2 (rs2710102) polymorphisms contributing into anxiety variations under gene-environment interactions.

The study involved 520 healthy individuals of Russian, Tatar, Bashkir, Udmurt populations from Russia (75% women) (mean age 20,3 ± 3,87 years) without any history of psychopathologies subjected to state (SA) and trait anxiety (TA) assessment using State-Trait Anxiety Inventory . SNPs genotyping was performed via PCR-RFLP. Statistical analysis was conducted with Plink v.1.07.

Linear regression analysis revealed GxE models determining variations in anxiety. The association of CNTNAP2 rs2710102 G-allele and lower TA was observed in individuals reared by mothers with the older age (P=0.035), while CNTNAP2 rs2710102 G/G-genotype was associated with lower TA in individuals who have several sibs (P=0.0049). Moreover, higher SA was found in individuals with NRXN1 rs4971648 A-allele who were younger children in family (P=0.036) and with NRXN1 rs1045881 A-allele with high income level (P=0.031).

These findings suggest that environmental factors modulate the association of NRXN1 and CNTNAP2 genes with variations in anxiety.

This study was supported by Russian Foundation for Humanities (13-06-00583a, 15-16-02007a(r)).

Association analysis of Vitamin D Receptor Gene rs4334089 polymorphism with Parkinson's disease in Iranian Subjects

a. fazeli, *b. emamalizadeh, a. movafagh, h. darvish;*
shahid beheshti university of medical sciences, tehran, Iran, Islamic Republic of.

Introduction: Parkinson disease (PD) is a neurodegenerative disorder with both contributions of genetic and environmental factors. Protective functions of vitamin D and then vitamin D receptor (VDR) in PD have been declared recently. With this regards in this study we investigated the association of VDR rs4334089 allele gene polymorphism in Iranian PD patients. Method and materials: DNA was extracted from 520 PD patients and 520 unrelated Iranian subjects. Evaluation of rs4334089 allele polymorphisms were done by PCR-RFLP method using NalIII restriction enzyme. PD was characterized by UK Parkinson's disease Society Brain Bank Clinical Diagnostic Criteria and study protocol was approved by our institution ethics committee. Results: Analysis of data showed that rs4334089 AA genotype (OR=1.487, 95% CI: 1.130-1.956, P = 0.003) and rs4334089 A allele (OR=1.251, 95% CI: 1.053-1.486, P = 0.011) were significantly more frequent in PD patients in compare to control group. Conclusion: Our findings suggest that VDR rs4334089 AA genotype and A allele could be important risk factors for PD in Iranian subjects. So, considering of this genetic background point could be helpful to achieve an appropriate schema for PD management.

De novo case of a mosaic ring supernumerary marker chromosome leading to trisomy of 8p11.22-q11.23 in a boy with development delay and corpus callosum hypoplasia

D. Vansevičiūtė, *Ž. Čiuladaitė, B. Tumienė, A. Utkus, V. Kučinskas;*
Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

Small supernumerary marker chromosomes (sSMC) are structurally abnormal parts of the karyotype. ~70% of people with sSMC grow and develop normally, while 30% show different clinical signs and symptoms. We present the clinical and cytogenetic findings in a 6-year-old male referred for genetic evaluation because of developmental delay, behavior problems, *corpus callosum* hypoplasia, minor dysmorphic features. Cytogenetic analysis of GTG banded metaphases revealed a *de novo* supernumerary ring chromosome in 50 % of the analyzed cells. aCGH indicated a 13.8 Mb gain of 8p11.22-q11.23 including 85 RefSeq genes.

Based on gene expression and function analysis in databases, we suggest that developmental delay and *corpus callosum* hypoplasia may be caused by overdose of the *NKX6-3*, *THAP1*, *POMK*, *UBE2V2* genes. *NKX6-3* encoded protein is transcriptional repressor involved in early stages of neural crest development. The neural localization of THAP1 and its nuclear compartmentalization suggests that it may control neuronal gene transcription. The highest expression of *POMK* gene in human fetal and adult brain suggests an important role in brain development. *POMK* encoded protein-O-mannose kinase is involved in O-glycosylation and neuronal migration processes. *Ube2v2* expressed ubiquitin-conjugating enzyme is distributed widely in the rat brain in the late embryonic developmental stage and appears to have an important role in brain development and neural differentiation.

Nocivelli Institute for Molecular Medicine, Spedali Civili, Brescia, Italy,* [5]*Department of Medical, Oral and Biotechnological Sciences, Gabriele D'Annunzio University, Chieti, Italy.*

Kostmann syndrome (KS) or autosomal recessive severe congenital neutropenia 3 (OMIM #610738) is a rare primary immunodeficiency presenting with early childhood onset of recurrent life-threatening infections due to a lack of mature neutrophils. Nearly half of patients also display neurological symptoms, ranging from mild to severe developmental and cognitive delay often associated with epilepsy. Mutations in *HAX1* gene have been identified as the cause of KS. Notably, two transcripts of HAX1 exist (the shortest one missing part of exon 2) and only mutations affecting both of them are preferentially associated with the additional neurological phenotype. We report the third Italian patient with KS. DNA sequencing identified two novel compound heterozygous mutations: c.487C>T (p.Q163*) and c.557-2A>G. At age 22 years, our patient presents with a neuropsychiatric profile characterized by mild intellectual disability, reduced adaptive capacity associated to social anxiety and consequent impairment of social relationship. We focused on the neurobehavioral aspects of KS and recorded neurological symptoms in 26 additional patients from the literature. Comprehensive evaluation was available only for 16 of them, presenting with mild (38%), moderate (31%) and severe (31%) intellectual disability. Three patients showed a severe neurological phenotype associated with psychomotor regression. Seizures (primary or secondary generalized and usually responsive to antiepileptic drugs) were a common finding, being present in more than half of patients.

Motor clumsiness (19%), brain abnormalities (19%), and attention deficit (12%) were also found. This work expands the allelic spectrum of HAX1 and outlines high clinical variability of the neurobehavioral phenotype of KS.

Schizophrenia as a genetic disorder: novel risk factors of neuroinflammation

R. Zakharyan, *S. Atshemyan, A. Boyajyan;*
Institute of Molecular Biology NAS RA, Yerevan, Armenia.

Introduction: Schizophrenia is a chronic incurable mental disorder. Despite several studies suggest a key role of genetic factors in disease development, molecular genetic markers of this disease are still undetermined. Here, we aimed to assess the role of genetic variations neuroinflammatory proteins in schizophrenia:
Materials and methods: For this purpose, a total of 500 chronic schizophrenia patients (ICD-10 code: F20.0, DSM-IV-TR code: 295.30) and healthy subjects unrelated Caucasian individuals of Armenian nationality were genotyped for the IL-6 rs1800795, TNF-a rs1800629, MCP-1 rs1024611, BDNF rs6265, NGF rs6330 and NGFR rs11466155, rs2072446 single nucleotide polymorphisms was performed using polymerase chain reaction with allele-specific primers (PCR-SSP).
Results: The distributions of genotypes for all selected SNPs both in patients and controls were in Hardy-Weinberg equilibrium. Our results showed that the rs1800795*C, rs1800629*A, rs1024611*G, rs6265*A, rs6330*T , and rs11466155*T, rs2072446*T alleles of the IL-6, TNF-α, MCP-1, BDNF, NGF, NGFR genes, respectively, are overrepresented in the group of patients compared to controls ($p<0.05$).
Conclusions: The findings obtained suggest that IL-6, TNF-a, MCP-1, BDNF, NGF, NGFR are among the candidate genes of schizophrenia and their rs1800795*C, rs1800629*A, rs1024611*G, rs6265*A, rs6330*T, rs11466155*T, rs2072446*T alleles might be nominated as risk factors for this disorders. This work was partly made possible by a research grant from the Armenian National Science and Education Fund (ANSEF#molbio-3125) based in New York, USA.

Association study of 45 SNPs in Russian patients with schizophrenia.

A. Bocharova[1], *A. Marusin*[1], *O. Fedorenko*[2], *A. Semke*[2], *S. Ivanova*[2], *V. Stepanov*[1];
[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Mental Health Research Institute, Tomsk, Russian Federation.*

Although the clinical features of schizophrenia (SCZ) were described over one hundred years ago, our knowledge of the molecular and genetic mechanisms of pathophysiology remains very incomplete. The aim of this study was to analyze associations of 45 SNPs reported in GWAS with SCZ in Russian population of Siberian region. In this study 389 patients with SCZ and 674 healthy controls, matched to the patients by age, gender, and ethnicity were included. 15 SNPs were genotyped by real-time PCR using TagMan assay (Applied Biosystems) and 30 SNPs were genotyped by MALDI-TOF mass-spectrometry using MassARRAY Analyzer 4 (Sequenom). Allele-specific ORs and associated p values were calculated. We found six significant associations of SNPs with SCZ in Russian patients of Siberian region: rs12807809 at NRGN gene (OR = 0.55, p=0.000001), rs2247572 at KCNB2 gene (OR = 0.77, p= 0.03), rs2229741 at NRIP1 gene (OR = 0.81, p=0.02), rs11064768 at CCDC60 gene (OR = 1.79, p=0.001), rs16887244 at LSM1 gene (OR = 0.77, p=0.02) and rs7004633 at being between loci LOC100129100 and LOC100509857 (OR = 0.74, p= 0.01). These genetic markers were previously reported in GWAS associated with cognitive performance (rs2247572 KCNB2 gene, rs2229741 NRIP1 gene) and schizophrenia (rs12807809 NRGN gene, rs11064768 CCDC60 gene, rs16887244 at LSM1 gene, rs7004633 LOC100129100/LOC100509857). Genetic markers of NRGN, KCNB2, NRIP1, CCDC60, LSM1 and rs7004633 are associated with SCZ but their role in pathogenesis of the disease is not clear. Our findings also demonstrate that genetic variability in schizophrenia and cognitive performance has overlapping genetic background.

SCA28 is one of the 31 known subtypes of autosomal dominant Spinocerebellar Ataxias (SCA) and it is caused by mutations in the *AFG3L2* gene, encoding for m-AAA metalloprotease (mitochondrial ATPases Associated with a variety of cellular Activities).
We generated a knockin (KI) mouse model carrying the p.M665R mutation (corresponding to human p.M666R, showing the earliest onset in patients). Homozygous $Afg3l2^{M665R/M665R}$ mice were lethal perinatally; $Afg3l2^{M665R/+}$ heterozygous mice showed a significant motor impairment starting from 18 months of age. Number and dendritic structure of Purkinje cells, and the thickness of molecular and granular layers were almost identical in $Afg3l2^{M665R/+}$ and wild-type (WT) mice.
We studied mitochondrial dynamics in Mouse Embryonic Fibroblasts (MEFs) from KI and WT embryos: (i) we detected an increased amount of short OPA1 forms and the complete absence of the long bands in $Afg3l2^{M665R/M665R}$ MEFs; (ii) mitochondrial network morphology by mitoRED staining suggested a complete fragmented pathway in homozygous KI and an intermediate tubular/fragmented network in heterozygous MEFs; (iii) preliminary data revealed no differences in mitochondrial membrane potential in the three genotypes, despite a reduced ability of $Afg3l2^{M665R/M665R}$ MEFs in TMRM probe up-take, suggested by decreased basal fluorescence intensity. No others fission/fusion proteins was shown altered.
These data are in accordance with the cellular phenotype described in *Afg3l2* knockout mouse model, corroborating the idea that SCA28 mutations hitting the peptidase domain negatively impact on m-AAA complex function, probably acting as hypomorphic.
This work is supported by Italian Telethon Foundation Grant GGP12217.

Association of mutations in 5´end of NF1 gene with a specific phenotype

M. Nemethova[1,2], *A. Bolcekova*[3], *Z. Pysova*[3], *D. Ilencikova*[3], *S. Pozgayova*[2], *A. Hlavata*[3], *L. Kadasi*[1,4], *L. Kovacs*[3], *A. Zatkova*[4];
[1]*Faculty of Natural Sciences,Comenius University, Bratislava, Slovakia,* [2]*Laboratory of Clinicaly and Molecular Genetics 2nd Department of Pediatrics, Comenius University Medical School University and Children´s Hospital, Bratislava, Slovakia,* [3]*2nd Department of Pediatrics, Comenius University Medical School University and Children´s Hospital, Bratislava, Slovakia,* [4]*Laboratory of Genetics, Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia.*

Autosomal domaminant disorder neurofibromatosis type 1 is one of the most frequent. It is causing by mutations in one of the biggest gene, in NF1 gene, consist of 60 exons. Gene product neurofibromin is a negative regulator of protooncogene Ras. Patients usually fulfill at least two of seven consensus clinical features: "café au lait" macules, freckling, Lish nodules, bone dysplasia, glioma of optical pathway, different types of neurofibromas and the first degree relative with confirmed NF1. In our cohort of 126 unrelated Slovak patients we identified 48/126 (38%) frameshift, 22/126 (17,5%) nonsense, 27/126 (21 %) splicing 16/126 (12,5%) missense mutations, 7/126 (5,5%) large deletions, 5/126 (4%) deletion of entire gene type I, and 2/126 (1,5%) small in frame deletions. Untypical splicing mutation we observed in 44,4% (12/27) patients. This mutations were identified deeper in intronic sequence or directly in exons as missense or nonsense mutations. We also followed position of mutations in NF1 gene. At 5´end which forms exons 1-16 (1-26 at new classification) we observed 43,8% (53/121) small mutations, by absence of mutations of entire gene. In patients with small mutation at 5´end we also observed significantly higher presence of Lish nodules, optical glioma and neurofibromas. This findings help us by desigining optimal diagnostic protocol and it confirms the advantage of using RNA based method. Complete mutation analysis in the first-degree relatives was performed in 61 families. Interestingly, we showed that 62% (38) of the patients from these families carry de novo NF1 mutation.

Role of SCN2A, SCNB1, GABRG2 and PCDH19 in SCN1A-negative epileptic patients

M. Surovy[1], *A. Soltysova*[1,2], *M. Kolnikova*[3], *P. Sykora*[3], *D. Ilencikova*[4], *A. Ficek*[1], *L. Kadasi*[1,2];
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [2]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia,* [3]*Department of Child Neurology, Children´s Faculty Hospital, Bratislava, Bratislava, Bratislava, Slovakia,* [4]*2nd Pediatric Department of the Comenius University, Medical School and University Children's Hospital, Bratislava, Slovakia.*

Introduction: Epilepsy is a large, phenotypically and genetically diverse group of disorders. Tens of different genes are linked to genetically determi-

ned forms. However, except for SCN1A, there is no other evident candidate locus with higher observed mutation frequency. In clinical practice, there is often an urgent demand for complete analysis of epileptic genes panel, as many patient express unclear phenotype. Therefore, there is need for genotype/phenotype correlation studies to search for associations, which can be used in diagnostic gene prioritization.
Materials and Methods: In 64 Slovak patients with a broad range of epilepsy phenotypes with no identified SCN1A mutation we sequenced the whole coding region and surrounding intron sequences of candidate genes SCN2A, SCN1B, GABRG2 and PCDH19 (27 females).
Results: In SCN2A, we have identified one causative variant (p.G211C) in patient with Lennox-Gastaut (LG) syndrome and one splicing-affecting nucleotide variant in GABRG2 (c.327+1G>A) in patient with complex partial seizures with generalization. No other disease-causing changes in selected genes were observed.
Conclusions: Since there were only two SCN2A and GABRG2 causative variants identified and neither SCN1B, nor PCDH19 causative variants were observed in any of 64 analyzed patients enrolled in the study, we can assume that there is no evident "gene hierarchy" in etiology of the disease.
This contribution is the result of the project implementation: Comenius University in Bratislava Science Park supported by the Research and Development Operational Programme funded by the ERDF. Grant number: ITMS 26240220086 and by VEGA 1/1288/12.

rs1063843 polymorphism within CAMKK2 is associated with an increased risk of schizophrenia and bipolar disorder in Iranian population

S. Rahimi-Aliabadi, *H. Darvish;*
shahid beheshti university of medical science, tehran, Iran, Islamic Republic of.

Background: A recent large-scale study have reported that rs1063843 located within the gene CAMKK2 is highly associated with schizophrenia in European and Han Chinese populations. Accumulating evidence shows that schizophrenia and bipolar disorder have common genetic variance. Here we evaluated the association of this variant with schizophrenia and bipolar disorder in Iranian population.
Methods: Genomic DNA was extracted from peripheral blood of Five hundred schizophrenic patients, 500 bipolar patients and 500 normal controls and all were genotyped for the rs1063843 using a PCR-RFLP method.
Results: The allele frequency of rs1063843 was significantly different in both schizophrenia and bipolar patients comparing to control group (P=<0.001, OR=1.4 and P=<0.00.1, OR=1.39 respectively).
Conclusion: For the first time we showed that rs1063843 is highly associated with bipolar disorder, although more replication studies are needed to confirm our findings. Our result also support the findings of previous studies suggesting an association between rs1063843 and schizophrenia.

Gene x environment interactions in personality: the role of ER-stress involved genes

A. Kazantseva[1], *R. Kanzafarova*[2,1], *S. Koks*[3], *T. Traks*[3], *S. Malykh*[4], *M. Lobaskova*[5], *E. Khusnutdinova*[1,2];
[1]*Institute of Biochemistry and Genetics Ufa Scientific Center of Russian Academy of Sciencies, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation,* [3]*Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia,* [4]*Psychological Institute, Russian Academy of Education, Moscow, Russian Federation,* [5]*Udmurt State University, Izhevsk, Russian Federation.*

Personality traits are predictors of life outcomes as well as endophenotypes for major psychiatric disorders. Wolframin 1 (encoded by WFS1 gene located at 4p16.1 was previously linked to bipolar disorder) is involved in endoplasmic reticulum (ER) stress response. WFS1 gene polymorphisms were associated with psychiatric disorders and personality traits.
We aimed to examine gene-environment (GxE) and gene-gene (GxG) interaction models based on genes encoding proteins involved in ER stress: wolframin 1 (WFS1) and neighboring 4p16.1 region, activating transcription factor 6 (ATF6) and X-box binding protein 1 (XBP1) gene polymorphisms contributing into personality traits variation in healthy individuals.
In total, 1018 healthy individuals (68% women) from Russia (mean age±SD: 19.81±2.65 years) without any history of psychopathologies were subjected to personality traits assessment via TCI-125 and EPI. Involved individuals are Caucasians from Russian (N=409), Tatar (N=290), Bashkir (N=130) and Udmurt populations (N=189). Socio-demographic data including gender, order and season of birth, prenatal solar activity (SA), place of residence, childhood maltreatment were obtained. Genotyping of 48 SNPs was performed with SNPlexTM platform (Applied Biosystems). Statistical analysis was conducted with PLINK v.1.07 corrected via FDR-procedure for multiple comparisons.
The following GxE models have been revealed: ATF6 rs12045480*SA (PFDR=0.044) and WFS1 rs6828983*SA (PFDR=0.038) interactions affected neuroticism and Self-directedness, respectively. No significant GxG models were observed after FDR-correction. Accordingly, solar activity (measured as sunspots number) within gestation appears to modulate the effect of ER-stress related genes on personality. The possible mechanism of this modulation refers to epigenetic modifications occurred depending on high/low solar activity.

Identification and functional characterisation of a novel dopamine beta hydroxylase gene variant associated with ADHD

J. Tong[1], *L. McKinley*[1], *T. Cummins*[1], *B. Johnson*[1], *N. Matthews*[2], *A. Vance*[3], *H. Heussler*[4], *M. Gill*[5], *L. Kent*[6], *M. Bellgrove*[1], *Z. Hawi*[1];
[1]*Monash University, VIC3800, Australia,* [2]*Queensland Brain Institute, Brisbane, Australia,* [3]*University of Melbourne, VIC3000, Australia,* [4]*Mater Research Institute, South Brisbane, Australia,* [5]*Trinity College, Dublin, Ireland,* [6]*University of St Andrews, Scotland, United Kingdom.*

Dysregulation in neurotransmitter signalling has been implicated in the aetiology of ADHD. Polymorphisms of the gene encoding dopamine beta hydroxylase (DBH), a key player in catecholamine signalling, have been shown to be associated with increased risk for ADHD. Previous genetic studies of ADHD have reported associations with a range of DBH gene variants (rs2519152, rs1611115, rs1108580 and rs6271) however small sample sizes have led to inconsistency. Here we conducted TDT analysis in a large ADHD sample of 794 nuclear families to re-examine the relationship between DBH and ADHD. Although we did not replicate associations of rs2519152 and rs1611115 with ADHD, we identified a significant association with rs129882 (pcorrected = 0.02). Further, gene reporter assays of DBH rs129882 showed a significant impact of the ADHD-associated C allele on luciferase expression in a human neuroblastoma cell line, SH-SY5Y. These data demonstrate for the first time that a DBH gene variant which confers risk to ADHD is also associated with reduced in vitro gene expression.

Functional genetic polymorphism of c-Jun in ischemic stroke

K. Tadevosyan[1], *A. Boyajyan*[2];
[1]*Institute of Molecular Biology, National Academy of Sciences, Republic of Armenia, Armenian-Russian (Slavonic) University, Yerevan, Armenia,* [2]*Institute of Molecular Biology, National Academy of Sciences, Republic of Armenia, Yerevan, Armenia.*

Synaptic plasticity plays a key role in recovery of patients after progression and outcome of ischemic stroke. c-Jun is one of the most important transcription factors and is involved in regulation of transcription of genes involved in synaptic plasticity including formation of long-term memory. In present study we, for the first time, evaluated potential association of functional polymorphism of c-Jun encoding gene (JUN) with IS. For the purpose of study, genomic DNA samples of 125 patients with first episode acute IS and 153 healthy subjects (controls) with no family or past history of any mental, cerebrovascular or cardiovascular disorders were genotyped for JUN single nucleotide polymorphism (SNP) by polymerase chain reaction with sequence-specific primers (PCR-SSP).The primer sequences for the rs11688 polymorphism were as follows: forward 5′-TCCGCCTTGATCCGCTCC-3′ for standard allele, forward 5′- TCCGCCTTGATCCGCTCT-3′ for minor allele, and constant reverse 5′- AACCCAGGCGCGCTGAGC -3′. The results obtained demonstrated that the rs11688*T minor allele was significantly more frequent in controls than in patients (0.49 vs 0.31, P<0.0001, OR=2.6, 95% CI: 1.5-3.1), and the carriers of this allele were overrepresented in controls compared to patients (0.77 vs 0.51, P<0.0001, OR=3.3, 95% CI: 1.9-5.6). In summary, this study revealed that rs11688 functional polymorphism of JUN gene is negatively associated with IS and T minor allele of this locus may have a protecting effect against the development of IS.

Pontine segmental cap dysplasia (PTCD) among five Egyptian patients suggests dominant de novo mutation

M. S. Zaki, Female[1], *G. M. H. Abdel Salam*[1], *M. Y. Issa*[1], *J. G. Gleeson*[2];
[1]Clinical Genetics Department, National Research Centre, Dokki,, Egypt, [2]2Laboratory of Pediatric Brain Disease, Howard Hughes Medical Institute, The Rockefeller University, New York, NY, United States.

Pontine tegmental cap dysplasia (PTCD) is a rare recently delineated mid-hind brain anomalies first described in 2007 by Barth and co-workers. It is characterized by a unique neuroimaging feature compromises the vaulted pontine tegmentum, which projects posteriorly into the fourth ventricle forming a "cap. It is associated with a variety of neurological features and cranial nerves affection likely a result of brain wiring defects. Skeletal, cardiac and gastro-intestinal malformations are variably associated. Herein, we describe 5 Egyptian patients, each from different families, presented MRI evidence of PTCD. Patients were all males and in 3 there was parental consanguinity, but no recurrence. All presented with hypotonia, cognitive and motor impairment and bilateral deafness. Corneal clouding due to anesthesia was in 3, which notably recurred in one after corneal transplantation. Other cranial neuropathies including trigeminal nerve affection with lack of pain sensation demonstrated clearly in one who lost his nasal collumella. Dysmorphic features in the form of preauricular tags, small ears and unilateral hypoplasia of mandibles was in one who had bilateral talipus. None of our probands had other systemic involvement and chromosomal studies were normal in all. This is the largest series from a single ethnic group with PTCD. We present clinical phenotype, compared previously described cases, aiming for more delineation of their clinical spectrum. The lack of recurrence suggests a *de novo* mutation in an unknown gene.

L-2-hydroxyglutaric aciduria (L2HGA) is an autosomal recessive neurometabolic disorder characterized essentially by the presence of elevated levels of L-2-hydroxyglutaric acid (LGA) in plasma, cerebrospinal fluid and urine. L2HGA is caused by a deficiency in the L2-Hydroxyglutaric dehydrogenase (L2HGDH) enzyme involved in the oxidation of LGA to the alpha 2-ketoglutarate. LGA has been proposed as an endo-and exogenous cytotoxic organic acid which induces free radical formation and generation of reactive oxygen species (ROS). In this report, we analyzed 14 L2HGA patients belonging to 6 unrelated consanguineous families originated from the south of Tunisia. The patients were diagnosed with L2HGA disease confirmed on the presence of high level of LGA in urine. We analyzed the L2HGDH gene in all probands and identified the same c.241A>G homozygous mutation. We also used intragenic SNPs and two extragenic microsatellites flanking the L2HGDH gene to confirm the founder effect of c.241A>G mutation in the fourteen studied cases. In addition, we carried out the measurement of the oxidative stress parameters in plasma of L2HGA patients which revealed a significant increase in the malondialdehyde levels (MDA), a biomarker of lipid peroxydation, and the reduced glutathione (GSH). A diminution of the antioxidant enzymes activities including superoxide dismutase (SOD), glutathione peroxidase (GPx) was also observed.

A clinical variant in SCN1A inherited from a mosaic father cosegregates with a novel variant to cause Dravet syndrome in a consanguineous family

F. N. Tuncer[1], *Z. Gormez*[2], *M. Calik*[3], *G. Altiokka-Uzun*[4], *M. S. Sagiroglu*[2], *B. Yuceturk*[5], *B. Yuksel*[5], *B. Baykan*[4], *N. Bebek*[4], *A. Iscan*[6], *S. A. Ugur-Iseri*[1], *U. Ozbek*[1];
[1]Istanbul University, Institute of Experimental Medicine Department of Genetics, Istanbul, Turkey, [2]The Scientific and Technological Research Council of Turkey (TUBITAK-BILGEM), Advanced Genomics and Bioinformatics Research Center, Kocaeli, Turkey, [3]Harran University, Faculty of Medicine, Department of Pediatric Neurology, Sanliurfa, Turkey, [4]Istanbul University, Istanbul Faculty of Medicine, Department of Neurology, Clinical Neurophysiology Unit, Istanbul, Turkey, [5]The Scientific and Technological Research Council of Turkey (TUBITAK-MAM), Genetic Engineering and Biotechnology Institute, Kocaeli, Turkey, [6]Bezmialem Vakif University, Faculty of Medicine, Department of Pediatric Neurology, Istanbul, Turkey.

Introduction: A consanguineous family from Turkey having two children with intellectual disability exhibiting myoclonic, febrile and other generalized seizures has been recruited to identify the genetic origin of this phenotype.
Materials and Methods: Physical and neurological examinations of all family members were performed and magnetic resonance imaging and electroencephalography recordings were analyzed with information on family history. A combined approach of SNP genotyping and exome sequencing were employed both to screen identified genes of Dravet syndrome and to detect homozygous variants common to affected sibs assuming a recessive inheritance model due to consanguinity in the family. The exome data analysis was extended further to potentially compound heterozygotes in the affected sibs.
Results: The study identified two paternally-inherited genetic variants in SCN1A (rs121917918; p.R101Q and p.I1576T), one of which was previously implicated in Dravet syndrome. Interestingly, the previously reported clinical variant (rs121917918; p.R101Q) displayed mosaicism in the blood and saliva of the father.
Conclusion: The study supported the genetic diagnosis of affected children as Dravet syndrome possibly due to the combined effect of one clinically associated (rs121917918; p.R101Q) and one novel (p.I1576T) variants in SCN1A gene. This finding is important given that heterozygous variants may be overlooked in standard exome scans of consanguineous families. Thus, we are presenting an interesting example, where the inheritance of the condition may be misinterpreted as recessive and identical by descent due to consanguinity and mosaicism in one of the parents.
This study was supported by TUBITAK (Project Number: 113S331).

Determination of the Frequency of Spinocerebellar Ataxia (SCA) Types 1, 2, 3, 6 and 7 in northwest of Iran

M. R. Ranjouri[1], *P. Aob*[1], *M. Shekari Khaniani*[2], *S. Mansoori Derakhshan*[2];
[1]Zanjan University of Medical Science, zanjan, Iran, Islamic Republic of, [2]Tabriz University of Medical Science, Tabriz, Iran, Islamic Republic of.

* Introduction: Spinocerebellar Ataxia(SCA) is an inherited disorder of brain function. It is characterized by increasing problems with coordination that often affect the legs, hands and speech. Since there is no information on the frequency of SCA in northwest Iran, the aim of the present study is to determine the frequency of common types of SCA disease (SCA1,2,3,6 and 7) and the number of CAG-trinucleotide repeats in the northwest iranian population.
* Material and Methods: Genomic DNA was extracted from the blood samples by salting-out. DNA samples were analyzed to determine the number of CAG trinucleotide repeats within each allele of the five causative genes. an abnormally large number of CAG repeats which is a diagnostic factor for the disease was detected by polymerase chain reaction(PCR) and agarose gel electrophoresis.
* Results: Of 118 cases,10, 8, 6, 8 and 3 cases were positive for SCA1,SCA2, SCA3, SCA6 and SCA7, Respectively. The range of the expanded CAG trinucleotide repeat was 39-75, 36-51, 50-84, 21-29 and 39-86 in SCA1, SCA2, SCA3, SCA6 and SCA7, Respectively.
* Conclusion: In this study for the first time in Northwest of Iran, the Frequency of common types of SCA(1, 2, 3, 6 and 7) was determined. Results show that the most common form was SCA1(8.4%) followed by SCA2(6.7%), SCA6(6.7%), SCA3(5%), SCA7(2.5%), respectively.

Homozygous CCTG-repeat mutation in myotonic dystrophy type 2 in Russian patient.

V. V. Zabnenkova[1], *N. M. Galeeva*[1], *S. I. Dedaev*[2], *G. E. Rudenskaya*[1], *A. V. Polyakov*[1];
[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Moscow Centre of Myasthenia, Moscow, Russian Federation.

Myotonic dystrophy is a clinically and genetically heterogeneous autosomal dominant disorder. Myotonic dystrophy type 2 (DM2) is caused by unstable DNA sequences comprising CCTG-repeat in the first intron of the ZNF9 gene located at chromosome 3q21.
We present a rare case of DM2 with the expansion on both alleles of the ZNF9 gene.
The patient is a 72 year old man with mild DM2 phenotype. Onset of proximal arm weakness began at age 70 years (weakness during press-up), proximal leg weakness - at age 71 years (troubles with walking up the stairs). He has myalgia and hand stiffness, weakness of facial muscles, of deltoid, triceps and biceps brachii muscles (MRC 3/5), the elbow flexors (MRC 4/5),

elbow extensors (MRC 4/5), iliopsoas (MRC 3/5). The patient was operated on for immature cataract twice at age 67 and 68 years. He has no diabetes mellitus. A mild atrophy of muscles of gridle of superior extremities, of the quadriceps femoris are notable. EMG showed myotonic runs in limb muscles. Creatine kinase level is increasing since age 65 years and ranging between 600 and 1000 U/l. In addition, patient has sporadic episodes of arrhythmia, early balding. He has five clinically healthy children.
This is the first case of homozygous CCTG-repeat mutation in myotonic dystrophy type 2 described in Russian patients.

J10.02
A family with complicated hereditary spastic paraplegia-case study

D. Stoicanescu[1], *M. Cevei*[2];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania.*

Hereditary spastic paraplegias comprise a group of rare neurodegenerative disorders characterized by slowly progressive muscle weakness, spasticity and hyperreflexia of the lower limbs. In different populations the reported incidences vary from 1.3 to 9/100 000 individuals. We present a 39 years-old male patient, born from healthy unrelated parents. Since the age of 19 he suffered progressive motor deficit of the lower limbs, initially with fatigue and irritability, evolving to paraparesis, spasticity, reduced muscle strength of upper train, neuropathic pain, back pain, bladder disorder, dysarthria. Neurological examination revealed marked spasticity with clonus and inability to maintain sitting position, muscle retraction, sensation of cold feet. Brain MRI was normal. Electromyography was also normal. The family history showed the existence of an affected brother, in whom the motor deficit was present only at 30 years of age, but of much lower intensity. The physical examination also revealed ataxia, moderate spasticity, orthostatism with support on the tip of the toes still possible, urinary urgency, normal sensitivity, obesity, mental retardation. The only other affected member of the family was a young woman, first degree cousin, with bilateral lower extremity spasticity, bilateral extensor plantar responses, hypertonic urinary bladder, onset of the symptoms was at the age of 23 years. They were considered to have complicated hereditary spastic paraplegia, with autosomal recessive inheritance. Clinical heterogeneity of the disease is revealed by variety and complexity of symptoms in the affected family members.

J10.03
Cognitive impairment and emotional instability-onset signs of isolated hypoplasia of corpus callosum

M. Cevei[1], *D. Stoicanescu*[2];
[1]*University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania,* [2]*University of Medicine and Pharmacy „Victor Babes", Timisoara, Romania.*

Hypoplasia of the corpus callosum is a developmental disorder with complex biological basis. The prevalence was estimated at 2.05 per 10,000 live births in a study performed in southeastern Hungary. The precise incidence is difficult to establish, since many isolated cases are asymptomatic. It's etiology is complex, may be part of a syndrome or may occur isolated. We report a sporadic case with isolated hypoplasia of corpus callosum. The 26 years-old woman was born from healthy unrelated parents, after an uneventful pregnancy. The onset was insidious, six years ago, with cognitive disturbances, emotional lability, fatigue followed by progressive muscle weakness. Drug therapy and medical rehabilitation started immediately, but the evolution was rapidly progressive. She presented in our clinic complaining of motor deficit, hypoesthesia and paresthesia in lower limbs, cognitive impairment, concentration and emotional problems, anxiety, crying easily, dysarthria, posture and gait disturbances. Physical examination revealed body anteflexion, impaired balance and coordination, could not perform transfers from bed to chair or roll in bed, involuntary movements, muscle strength could not be assessed due to spasticity, spastic gait. Abdominal reflexes were abolished. Laboratory examinations were normal. Standard chromosomal analysis revealed normal karyotype. Brain MRI revealed isolated hypoplasia of corpus callosum. Spine MRI detected discrete medium dorsal spinal cord atrophy and intraspongious disk herniation D7-D9. The diagnosis was spastic tetraparesis due to hypoplasia of corpus callosum. The peculiarity of the case: although the defect was present at birth, she was diagnosed quite late, the only early symptoms were cognitive impairment and emotional problems.

J10.04
Homozygosity mapping data and exome data analysis of a family affected with a form of spastic paraplegia

A. H. Alkhayat Alshehi, *F. A. Alsalmi, A. Alfetaisi, R. Koul, F. Almamari;*
Sultan Qaboos University, Muscat, Oman.

Hereditary Spastic Paraplegia is a heterogeneous group of inherited neurodegenerative diseases affecting the motor neurons, characterized clinically with the spasticity and weakness in the lower limbs. A family from Oman was identified with two affected boys to have an inherited form of Spastic Paraplegia. The parents are first cousins. The first child, born in January 2004, his parents noticed that he was developing normally till the age of six to seven months, when stiffness in lower limbs was observed. Overtime he was late in gaining gross motor milestones. There was weakness of both upper and lower limbs and severe spasticity of lower limbs, limiting his ability to sit and even walk. The other affected child, born in 2006, has similar symptoms which started developing around the same age of onset for his elder brother.
Homozygosity mapping is a versatile technique to investigate the genetic cause of autosomal recessive disorders. Children of consanguineous parents share regions identical by decent. To study the genetic basis of the disease in this family we analyzed SNP genotypes for the two affected family members and their parents generated by 330k SNP array from Illumina platform. None of the known SPG genes was identified using this approach. Exome sequencing data for the same family excluded all known SPG genes. Novel variants identified by exome sequencing in the homozygous regions are being investigated for genetic segregation in the family and for the possibility of being causative in this family.

J10.05
Neonatal detection in Sprintzen-Goldberg syndrome

C. P. S. R. Sonia del Carmen, *C. P. S. R. Sonia;*
Juarez's Hospital Secretaria de Salud, México DF, Mexico.

The syndrome of Shprintzen-Goldberg (SGS) is a little described entity (less than 60 cases reported), is suspected in individuals in the presence of craneosisnostosis, proptosis, retrognathia, micrognathia, cardiovascular malformations, marfanoid habitus, slight hypotonia to moderada, among others, rarely is it to diagnose neonatalmente.
Case: Our purpose is a male without product of second feat unprecedented importance for the current condition who from birth struck severe hypotonia, narrow suture, low implantation of ears, proptosis, ogival palate, retromicrognatia, arachnodactyly and marfanoid habitus. Methodology: The patient did not comply with the characteristics for Marfan syndrome and Loeys-Dietz syndrome, was the mutation bussqueda in TGFβ in peripheral blood and fibroblasts
Marfan síndrome (MFS) is a relatively common connective tissue disease with predominant involvement of the ocular, cardiovascular and musculoeskeletal systems. Experimental findings from mouse models of MFS have indicated that promiscuous latent TGFβ signaling. This group of MFS-related conditions includes Loeys-Dietz syndrome (LDS). Shprintzan- Goldber syndrome (SGS, aneurysms-osteoarthritis syndrome (AOS and syndromic TAA (sTAA). Common involvement of the TGFβ therapy may represent a general strategy to delay or even prevent dissection and rupture of the aortic wall in this group heritable disease.
The increasing recognition of exon-specific mutations in certain conditions, like Shprintzen-Goldberg syndrome, will likely allow the development of more efficient exon-targeted clinical diagnostic testing. Additionally, while exome sequencing is becoming increasingly valuable in the diagnosis or rare disorders, some genes such as SK1,are no well detected by existing technology. The current limitations of exome analysis and the continuing utility of Sanger-based sequencing

J10.06
Do ubiquitous herpesvirdae infections play any role in spinal muscular atrophy? Case series analysis.

A. V. Shatillo;
Institute of Neurology, Psychiatry and Narcology of NAMS of Ukraine, Kharkiv, Ukraine.

Spinal muscular atrophy (SMA) is a disorder caused by mutation in the *SMN1* gene, characterized by selective degeneration of lower motoneurons, and consecutively muscle weakness and atrophy. Despite simple and uniform mutation type, disease phenotype spans from neonatal death to ambulant cases with normal lifespan. Classification by types I, II, and III reflects this SMA's clinical polymorphism. *SMN2* copy number, *NAIP* mutation and several others are shown to be phenotype modifiers; however, phenotype correlation with these genetic factors is not strong.
In this, mainly cross-sectional, analysis we collected serological profiles (IgM, IgG) for most prevalent herpesviruses (HSV I/II, CMV, EBV) in patients of different ages and SMA types.
Results. Beside SMA type I infants (N=2) whose 100% abnormal serological

profiles and antibody origin require additional investigation, about 80% of type II (N=5) and 85 % of type III (N=7) patients have definite serological profile abnormalities characteristic for infectious state or, irrelevant to their age, clinical signs and/or epidemiologic history.
Conclusions. Very high proportion of abnormal serological profiles in all SMA groups may be relevant to phenotype severity. Herpesviruses are ubiquitous infections, which are capable of latent persistency and interaction by multiple pathways with motoneurons/myocites. Thus, detailed evaluation of SMA-viral interaction in longitudinal and experimental studies is warranted, because they could provide us with important insights of SMA pathogenesis.

J10.07
The role of immunohistochemistry and western blotting for dystrophinopathies management

G. Chelu;
National Institute of Research Development in the Pathology Domain and Biomedical Sciences Victor Babes, Bucharest, Romania.

Introduction: Dystrophinopathies are a group of two recessive X-linked genetic diseases determined by gene mutation for dystrophin: Duchenne muscular dystrophy (DMD) and Becker muscular dystrophy (BMD). The diagnosis for one of the two forms is based on immunohistochemical and western blot analysis of bioptic muscle tissue.
Matherial and methods: The study was performed in a family in which both boys have presented suggestive symptoms for dystrophinopathy. For a proper diagnosis, clinical and paraclinical examination, electromiography, have been completed with dystrophin genetic analysis, also immunohistochemistry and western blotting.
Results: The late onset and mild simptomatology innitially suggested a diagnosis of BMD but in time a very different pattern of symtoms have developed for the patients. Genetic analysis showed the same mutation for both brothers and their mother: 45-47 exon deletion, classically correlated with BMD. More severe clinical evolution for only one of the brothers raised the suspicion of a quantitative difference of dystrophin between the two cases. IHC and WB. have identified the complete absence of immunostaining for Dys 1 and 3 and a partial reduction for Dys 3 immunostaining in the case of the more affected brother, while the less affected, expressed only a diminished expression of Dys 2 and 3 in all muscle fibers and a reduction of Dys 1 immunostaining in some fibers.
Conclusions: Although genetic analysis is the only test which establish the diagnosis, based on genotip-fenotip international correlation studies between the two forms of the disease , analysis of dystrophin by IHC and WB turns into an important asset for prognosis and symptoms management.

GJB1 gene mutation c.34G>A in a Lithuanian family

B. Burnyte[1], *I. Uktveryte*[1], *A. Vaitkevicius*[2], *L. Ambrozaityte*[1], *V. Kucinskas*[1], *A. Utkus*[1];
[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Center of Neurology, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.*

Charcot-Marie-Tooth disease type 1X (CMT1X) is an X-linked dominant hereditary motor-sensory peripheral neuropathy, which results from mutations in the GJB1 gene and comprises approximately 10% of CMT cases. The GJB1 gene codes for connexin 32 (Cx32), a gap-junction (GJ) forming protein expressed by Schwann cells and oligodendrocytes. We report a Lithuanian family carrying the c.34G>A (p.Gly12Ser) mutation in the GJB1 gene. A 21-yr-old woman presented with distal weakness, unsteady walking, running difficulties and cognitive impairment. Physical examination revealed normal muscle strength, normal deep tendon reflexes and no apparent sensation dysfunction. Nerve conduction velocity (NCV) studies showed distal symmetrical sensorimotor axonal neuropathy with more prominent lesion in lower limbs. Brain MRI was not performed. Her father aged 56-yr-old complained of gait unsteadiness with bilateral hand weakness, muscle atrophy and contractures. Physical examination revealed tetraparesis with more prominent distal weakness (graded 2 score in distal muscles and 3-4 score in proximal muscles in both upper and lower limbs on the MRC scale) and distal muscle atrophy, severe sensory impairment in the pin-prick and vibration, sensitive ataxia, proximal hyporeflexia and distal areflexia. There were no cranial nerve disturbances, and no sign of dysautonomia. NCV studies showed severe distal symmetrical mixed type sensorimotor neuropathy. Heterozygous and hemizygous genotypes of the known c.34G>A (p.Gly12Ser) mutation (HGMD CM930318) were identified for daughter and father respectively in the GJB1 gene. Identified mutation is located in N-terminus cytoplasmic tail. This family report confirms that CMTX1 is a clinically heterogeneous group, with great variability in phenotypes, possible severe involvement in females with clinical features of cognitive impairment.

J10.09
Searching for mutations in the genes PARK2, PARK8, VPS35 in Slovak Parkinson's disease patients

C. Bognár[1], *M. Baldovic*[1], *A. Zatkova*[2], *L. Kadasi*[1,2];
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratsilava, Slovakia,* [2]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences Vlárska 5, Bratislava, Slovakia.*

The Parkinson's disease (PD) is the second most common progressive neurodegenerative brain disorder caused by loss of nigrostriatal dopaminergic neurons, which affect the control of body movements, with formation of inclusions (Lewy bodies) in surviving neurons. Mutations in the PARK2 (parkin) and PARK8 (LRRK2) gene are those most frequently identified among patients with Parkinson's disease. The p.Asp620Asn (c.1858G>A) mutation in VPS35 was discovered as a new cause of PD in two independent exome sequencing studies. VPS35 encodes the vacuolar protein sorting 35 homolog, which is a part of the retromer complex involved in endosomal-lysosomal trafficking.
The aim of this study was to detect the prevalence of mutations within selected exons in LRRK2 (exons 24, 25 and 29), parkin (all exons except 2, 6, 7) and VPS35 (exon 15) genes in 146 Slovak patients with idiopathic Parkinson´s disease with both familial and sporadic forms of disease.
By sequencing the 15.exon of VPS35 gene we identified only a common synonymous single nucleotide polymorphism (rs168745, c.1938C>T, p.H646H). We did not find the c.1858G>A mutation in Slovak patients. In the selected exons of gene the LRKK2, we did not observe any mutations after sequencing. In parkin we found two coding polymorphisms and two probably pathogenic mutations.
In conclusion, the frequency of PARK2, PARK8, VPS35 (p.Asp620Asn) mutations in our Slovak population is low and does not play major role in pathogenesis of PD.
This study was supported by GUK/245/2015.

J10.10
Clinical study of patients with hereditary motor and sensory neuropathy from Republic Bashkortostan with novel mutation in GDAP1 gene.

E. Saifullina[1], *R. Magzhanov*[1], *I. Skachkova*[2], *I. Khidiyatova*[2], *E. Khusnutdinova*[2];
[1]*Bashkir State Medical University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa, Russian Federation.*

The Russian family with novel c.934G>A (p.Ala312Thr) mutation in the *GDAP1* gene displayed an autosomal-dominant pattern of inheritance. The onset of the disease was in the first or the second decade of the patient's life. The initial symptoms were pain, muscle weakness and wasting of distal extremities, gait disorder. The proband was a man 34 years old; his clinical picture was presented by slowly progressive moderate weakness and wasting of distal extremities, absent tendon reflexes, distal pan-modal sensory loss, bilateral *pes equinovarus* deformity. The proband's mother and sister had mild clinical symptoms of hereditary motor and sensory neuropathy: gait disorder, weakness and wasting of distal extremities, absent ankle reflexes. 11-year-old proband's daughter and 9-year-old nephew had complaints of pain in the calf muscles. Their clinical picture was presented by gait disorder and absent ankle reflexes. Neurophysiological data were available from the proband: median motor conduction velocities (MCV) were 35-38 m/s, the M-amplitude was 0.2-0.4 mV.
Thus, clinical and electrophysiological data of this family were presented by moderate or mild form of hereditary motor and sensory neuropathy with slowly progressive course of the disease.

J10.11
Correlation of copy number of the SMN2, SERF1A and NAIP genes with severity of spinal muscular atrophy in Serbian patients

M. Brkušanin[1], *A. Kosac*[2], *V. Jovanović*[3], *J. Pesovic*[1], *G. Brajusković*[1], *N. Dimitrijević*[4,5], *S. Romac*[1], *V. Milić Rašić*[2,5], *D. Savić Pavićević*[1];
[1]*Centre for Human Molecular Genetics, Faculty of Biology, Belgrade, Serbia,* [2]*Clinic for Neurology and Psychiatry for Children and Youth, Faculty of Medicine, Belgrade, Serbia,* [3]*Department of Genetic Research, Institute for Biological Research, Belgrade, Serbia,* [4]*Department of Neurology, University Children's Hospital, Faculty of Medicine, Belgrade, Serbia,* [5]*Faculty of Medicine, Belgrade, Serbia.*

Introduction: Spinal muscular atrophy (SMA) is caused by deficiency of the SMN protein due to homozygous absence of the *SMN1* gene in 96% of patients. Despite genetic homogeneity, SMA is marked by extensive phenotypic variability, indicating the existence of disease modifiers. The *SMN1* gene re-

sides in the telomeric part of 5q13.3 segmental duplication enriched in genes and prone to various unequal rearrangements. Copy number polymorphism (CNP) of 5q13.3 centromeric counterpart of the *SMN1* gene, *SMN2*, is the main modifier of SMA phenotype, but the influence of rearrangements of other genes at 5q13.3 segmental duplication (*SERF1A* and *NAIP*) still remain elusive.
Materials and Methods: CNP of the 5q13.3 genes was determined in 99 Serbian patients with homozygous absence of *SMN1* (23 with severe type I, 37 with intermediate type II and 39 with mild type III), and 122 patients' parents by MLPA. Correlation of *SMN2*, *SERF1A* and *NAIP* CNP with disease severity, indicated by the type of SMA, was performed by Spearman rank test, while their joint effect was fitted using generalised linear models.
Results: Strong inverse correlation was observed between *SMN2*, *SERF1A* and *NAIP* CNP and SMA type (ρ=0.85, p=2.2e-16; ρ=0.659, p=6.661e-15; ρ=0.523, p=1.403e-08, respectively). Starting with full model including the *SMN2*, *SERF1A* and *NAIP* CNP and their interactions, the best minimal model describing SMA phenotypic variability included *SMN2* CNP (p<2e-16), *SERF1A* CNP (p<2e-16) and their interaction (p=0.02628).
Conclusion: Obtained results stress out that unequal rearrangements of 5q13.3 segmental duplication significantly contribute to phenotypic variabilityof SMA.

J10.12
effect of the VDR gene polymorphisms on susceptibility to Parkinson's disease in Iranian population

b. emamalizadeh, *m. motallebi, a. movafagh, h. darvish;*
shahid beheshti university of medical sciences, tehran, Iran, Islamic Republic of.

Objectives: Parkinson's disease is one of the common and complex neurodegenerative disorders being affected by environmental and genetic factors. Vitamin D receptor (VDR) gene encodes a nuclear transcription factor that may play a role in neurological disorders. Recently, evidences in support of the effect of vitamin D receptor on development of PD have been increased significantly. In the present study, we investigated the association between three polymorphic sites related to VDR gene (Bsmi, G/A, Taq C/T, and Fok C/T) with the risk of the development of PD in Iranian population.
Methods: We analyzed 520 PD patients and 520 healthy control for three mentioned single nucleotide polymorphisms using polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP).
Results: Our results demonstrated that the BsmI and TaqI polymorphisms of the VDR gene among patients and healthy individuals had no significant differences in genotype and allele distributions. but we observed an association between the FokI C/T polymorphism and the Parkinson's disease (pValue= 0/001).
Conclusion: we showed that the FokI polymorphism of the VDR gene may have a role in the susceptibility to Parkinson's Disease in Iranian patients.

HMSN-P is a new type of neuronopathy caused by mutation in TFG gene

A. Alavi[1], *E. Elahi*[1], *H. Shamshiri*[2], *S. Nafissi*[2], *A. Moghadam*[1];
[1]*University of Tehran, Tehran, Iran, Islamic Republic of,* [2]*University of Tehran, Dept. of Biotechnology, College of Science, Tehran, Iran, Islamic Republic of.*

Introduction: Hereditary motor and sensory neuropathy with proximal predominance (HMSN-P) is considered a form of HMSN, so far identified only in families from the Far East.
Aims: Identify genetic cause of a neuromuscular disease in a large Iranian pedigree, delineate the disease, and describe presentations.
Methods: Linkage analysis and exome sequencing were performed. Thirteen individuals were studied. Two candidate sequence variations were tested for segregation with disease and screened in 420 controls. Subjective, biochemical, nerve conduction, electromyography, and muscle MRI data were obtained.
Results: A mutation in TFG was identified as cause of disease. The same mutation had been reported as cause of HMSN-P in patients of Far East ancestry. Phenotypic and genetic analysis revealed that the Iranian patients were also affected with HMSN-P. Three different haplotypes were recognized for the mutated alleles. The unreported or less common features of the Iranian patients include usual asymmetric initial presentation, involvement of abdominal muscles, and predominant paroxysmal dry coughing. Urinary dysfunction and rapid progression were sometimes observed. Hyperlipidemia was not common. Nerve conduction studies suggested sensory nerves are prominently affected. Muscle MRIs and clinical examinations revealed parallel involvement of both proximal and distal muscles.
Conclusions: HMSN-P, which is a misnomer, is not confined to the Far East and may have not been diagnosed in other populations. Absence of identity by descent in its only known mutation suggests at least three independent origins. There is clinical variability. Sensory nerves are prominently affected. Proximal and distal muscles are involved. The disease is a neuronopathy.

J10.14
Exceptional cases of choreic states in Russia: two cases report

T. B. Milovidova, *V. V. Zabnenkova, A. V. Polyakov;*
Research centre for medical genetics, Moscow, Russian Federation.

Chorae (choreic hyperkinesis) is the form of a hypermotility which is shown involuntary fast, chaotic, spasmodic, not stereotypic twitchings of various muscular groups. The reason of chorea's development are pathological changes of the corpus striatum. Character and localization of a pathological process are defined by features of a disease, degree of expressiveness and prevalence of diffusion and focal changes of a brain. One of exceptional cases with choreic hyperkinesis are choreoathetosis and congenital hypothyroidism with or without pulmonary dysfunction (CAHTP) and choreoacanthocytosis (CHAC).
CAHTP is an autosomal dominant disease with infancy onset of these clinical features, muscular hypotonia followed by the development of chorea, athetosis, dystonia, ataxia, and dysarthria. The reasons of CAHTP are mutations in NKX2-1 gene. We survey two patients of the age three months and one year with specific clinical features. New mutations c.344delG of NKX2-1 gene was revealed at the one-year-old boy. Normal sequence of NKX2-1 gene was detected for second patient.
CHAC is an autosomal recessive disease with red cell acanthocytosis, progressive neurodegeneration and onset in the third to fifth decade of life. The reasons of CHAC are mutations in VPS13A gene. We investigate 39-year-old man with acanthocytosis and neurologic abnormalities: progressive orofacial dyskinesia, dysarthria, dysphagia and choreic hyperkinesis of the trunk and limbs. Two new mutations c.85_86delCT and c.799C>T in compound heterozygous position were detected in VPS13A gene.
These two cases are first molecular confirmed cases of CAHTP and CHAC in Russia.

J10.15
Molecular genetic study of anoctaminopathy in a cohort of Russian LGMD patients.

M. V. Bulakh, *O. P. Ryzhkova, A. V. Polyakov;*
Federal State Institution "Research Centre of Medical Genetics", Moscow, Russian Federation.

Limb girdle progressive muscular dystrophy (LGMD) are group of clinically and genetically heterogeneous polymorphic diseases characterized by primary lesion of pelvic and shoulder girdles.
LGMD 2L is an autosomal recessive slowly progressive disease characterized by late-onset proximal lower-limb weakness (mean onset age 35 years; range 11-50 years), asymmetric atrophy of the quadriceps femoris and subsequent atrophy of the biceps brachii. LGMD 2L development is determine by mutations in the anoctamin-5 gene (ANO5).
This form is the one of the most common autosomal recessive LGMD in Europe. It's prevalence in Finland is 2:100000, in northern England is 0.26:100000. We analyzed 295 DNA-samples in a cohort of Russian LGMD patients without mutations in CAPN3 and FKRP on the presence of frequent mutations in ANO5: c.191dupA (p.Asn64delinsLys) and c.2272C> T (p.Arg758Cys). The mutation c.2272C> T was found in 3 patients in heterozygous state and 1 patient in the homozygous state. The mutation c.191dupA wasn't found.
In the results of coding sequence assay in two patients with c.2272C>T mutation in heterozygous state other mutations weren't detected. It proposed that the second mutation is localized in non-coding and promoter sequences or it's an extended deletion / insertion. One patient have undescribed earlier nonsense-mutation p.Glu138Stop.
In analyzed samples the proportion of patients LGMD 2L was 1.4%.

J11.01
EP300 deletion: cause of Rubinstein-Taybi Syndrome 2

A. Klímová;
Department of Medical Genetics, Ústí nad Labem, Czech Republic.

We present a family, where deletion EP300 was diagnosed. Genetic counseling was recommended because of mental retardation and dysmorphic features in the boy. He was also operated because of posterior urethral valve and he was observed because of multiple renal stones. He had aortic valve stenosis and autoimmune thrombocytopenia. IQ score was 47. There

were dysmorphic features - hypertelorism, downslanted palpebral fissures, lower-set prominent ears, high palate, hands and feet were normal except hallux valgus.
We started genetic examination and we found normal karyotype 46,XY. Molecular genetic examination excluded X-Fragile syndrome, Prader-Willi-Angelman syndrome and Noonan syndrome. Microarray comparative genomic hybridisation (aCGH) identified a 1,5-Mb interstitial deletion of chr.22q13.1-q13.2, which included the EP300 gen connected with Rubinstein-Taybi syndrome 2. It was confirmed by fluorescent in situ hybridisation. Parents were examined and no mutation was found. Rubinstein-Taybi Syndrome is inherited in an autosomal dominant manner. Most of all mutations are de novo. Rubinstein-Taybi syndrome (RSTS) is a multiple congenital anomaly syndrome characterized by mental retardation, postnatal growth deficiency, microcephaly, usually with broad thumbs and halluces, and typical dysmorphic facial features with grimacing smile. About 50% of patients have RSTS1 due to mutation in the CREBBP gene and about 3% of patients have RSTS2 (OMIM # 613684) due to mutation in the EP300 gene. RSTS2 is usually associated with a milder phenotype than RSTS1. Our case was complicated because of normal skeletal findings with no classic malformations on both hands and feet in the boy. Grimacing smile was not so evident. Microarray comparative genomic hybridisation helped us identified the mutation and managed treatment/care.

Cystathionine beta synthase mutations in patients with hyperhomocysteinemia and developmental and severe ocular problems

R. Qamar[1], *M. P. Iqbal*[2], *S. Ibrahim*[2], *S. Maqbool*[1], *M. Azam*[1];
[1]*COMSATS Institute of Information Technology, Islamabad, Pakistan,* [2]*Department of Biological and Biomedical Sciences, Aga Khan University, Karachi, Pakistan.*

Introduction: Three children from three different nuclear families had hyperhomocysteinemia, developmental delay, lens dislocation and glaucoma in the first decade of life. DNA sequence variations in methylene tetrahydrofolate reductase (*MTHFR*) and cystathionine beta synthase (*CBS*) have been reported to cause hyperhomocysteinemia-associated anomalies. *MTHFR* and *CBS* genes were therefore screened, to identify the genetic cause of hyperhomocysteinemia and ocular anomalies in these patients.
Materials and Methods: Hyperhomocysteinemia associated *MTHFR* polymorphisms C677T and A1298C were initially screened by restriction fragment length polymorphism method in the three families. *CBS* exonic sequences along with consensus splice sites were then Sanger sequenced. Mutation segregation in the parents and available family members was also confirmed through sequencing.
Results: *MTHFR* C677T and A1298C polymorphisms were found not to be associated with hyperhomocysteinemia, developmental delay and ocular phenotype. However, *CBS* sequencing resulted in identification of two novel mutations, a missense change (c.467T>C; p.Leu156Pro) in exon 7, an in-frame deletion (c.808_810del; p.Glu270del) in exon 10, and a recurrent missense mutation (c.770C>T; p.Thr257Met) in exon 10 of the *CBS* gene. The three different mutations in these three different patients were homozygous, which they had inherited from respective carrier parents.The identified mutations segregated with the phenotype in respective families.
Conclusions: This is the first report of *CBS* mutations from Pakistan where we identified two novel and a recurrent mutation. The persons carrying these mutations have developmental delay, early onset hyperhomocysteinemia along with severe ocular complications.

Introduction: High throughput, large-scale parallel sequencing (next generation sequencing, NGS) technology has been installed in clinical laboratories for generate massive amount of sequence data from entire human genome in a short time with low cost as an ideal approach for the mutation analysis of hard-to-diagnose genetic diseases. This study presents an undiagnosed Iranian family with three affected members showing severe intellectual disability, distinctive facial features short philtrum, facial hypotonia, down slanting palpebral fissures and almond-shaped eyes, decreased visual acuity, narrow hands and feet and mild scoliosis.
Materials and Methods: Mutation analysis in one of affected patients was performed by NGS and validated by Sanger sequencing for confirmation in all three affected patients and parents.
Results: Exploration of obtained sequence data revealed new missense mutation in the homolog of the yeast vacuolar protein sorting 13 genes (VPS13B) as disease-causing mutation. So that all three patients shared the same homozygote genotype for this new mutation whereas parents was heterozygous.
Conclusions: In conclusion, since VPS13B have been reported as a cause of Cohen syndrome, this strategy was led to the clinical diagnosis of patients in this family with a phenotype strongly suggestive of Cohen syndrome. Thus, this study is a best example that demonstrated the incorporation of NGS and Sanger sequencing to identifying the etiology of such rare complex genetic diseases in short time.

2q21.1 deletion and 1q42.2 duplication in a girl with developmental delay, dysmorphic features and epilepsy, Further characterization of 2q21.1 deletion.

D. Gieruszczak-Białek[1,2], *M. Kucharczyk*[2], *I. Sawionek*[1], *A. Skorka*[1,2], *M. Kugaudo*[1,2], *M. Krajewska-Walasek*[2], *K. Chrzanowska*[2];
[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*Institute of Mother and Child, Warsaw, Poland.*

The availability and use of CGH with high-resolution microarrays has greatly improved the detection of micro-deletion and duplications in patients with developmental delay and congenital anomalies.
Here we report the molecular karyotyping and phenotypic description of a new patient with 2q21.1 deletion and 1q42.2 duplication. Our patient presented with developmental delay, epilepsy, abnormal brain MRI and dysmorphic features. 2q21.1 deletion encompassing 28 genes (some of these genes are expressed in the brain) seems to be responsible for the clinical phenotype in the presented case. Duplications of 2q21.1 are rare with only a few cases reported to date in the literature. The phenotypic and genetic findings of our patient will be compared with those of previously reported individuals. We indicate the possible candidate genes, providing new data supporting further genotype-phenotype studies. Our results suggest that haploinsufficient genes within the deleted region, especially ARHGEF4 and GPR148, could underlie the developmental delay/intellectual impairment and epilepsy
Because of lack of the literature data, it is difficult to determine the clinical significance of the 1q42.2 (SIPA1L2, KIAA1383, NTPCR, PCNXL2 genes) duplication at this time.
This study was supported by the MNiSW Grant No. 0193/IP1/2013/72.

10p15 deletion and 10p11-15 duplication in a patient with developmental delay and dysmorphic features

M. Balasar[1], *P. Taşdemir*[1], *A. Acar*[2];
[1]*Necmettin Erbakan University Medical Faculty, Department of Medical Genetics, KONYA, Turkey,* [2]*İstanbul Bilim University, Department of Molecular Biology and Genetics, İstanbul, Turkey.*

Introduction
The multiple birth defects and mental retardation are associated with the unbalanced structural chromosomal rearrangement in proportion at 5%. The rate of deletions and duplications in all the chromosomal aberrations is 10%. We present here the patient who had unbalanced structural chromosomal rearrangement and dysmorphic feature.
Material and Methods
Cytogenetic analysis was performed on the patient's peripheral blood. Array CGH method was used for detection of deletion and duplication region.
Results
The 3-year-old female patient had motor mental retardation, dysmorphic feature, operated cleft lip, operated polydactyly, hearing loss and inability to walk and speak. Head circumference and length of the patient was <3p. She had dry hair, broad nasal root, telecanthus, upslanting palpebral fissures, micrognathia, high palate, crowded teeth, small low-set ears, joint hyperlaxity, hypotonia, dry skin and hirsutism.
It was reported that the patient was born in time with anoxia and cyanosis and hospitalized for 15 days due to sepsis. Her birth weight was 1900 gr. Her parents were not relatives. She was using drugs for congenital hypothyroi-

dism. The patient's karyotype analysis was 46,XX,add(10p13). Her parent's karyotype analysis were normal. The patient was thought to be de-novo. Array CGH was performed and it was detected that 10p15.3→15.1 region was deleted and 10p15.1→11.21 region was duplicated.
Conclusions
It was considered that 10p15 region was deleted and the region of 10p15 up to centromeres was duplicated , inverted and reinserted [inv dup (10) (p15.1- >p11.2)].
To our knowledge, this is the first and only report in which 10p15 deletion and 10p duplication occur together in a patient.

J11.06

Terminal deletion of 8p23.1 and terminal duplication of 8q22.1: San Luis Valley Syndrome with normal parental karyotype

T. Tos[1], M. Y. Alp[2], **H. Aydın**[3];
[1]Dr.Sami Ulus Women's and Children's Research and Training Hospita, Department of Medical Genetics, Ankara, Turkey, [2]Dışkapı Yıldırım Beyazıt Research and Training Hospital Genetic Diagnostic Center, Ankara, Turkey, [3]Zeynep Kamil Women's and Children's Research and Training Hospital, Department of Medical Genetics, İstanbul, Turkey.

Recombinant chromosome 8 syndrome, San Luis Valley Syndrome, is characterized by duplication of 8q22.1-qter and deletion of 8pter-p23.1. It was first described by Fujimoto et. al in a Hispanic girl with multiple anomalies, including tetralogy of Fallot and minor anomalies due to the maternal pericentric inversion, inv(8)(p23.1q22.1). Characteristic features of rec(8) syndrome are congenital heart disease (conotruncal and septal defects), dysmorphic craniofacial features included hypertelorism and thin upper lip, anteverted nares, wide face, abnormally low-set ears, downturned mouth, low posterior hairline, micrognathia, brachycephaly, midface hypoplasia, and thick lower lip, developmental delay, mental retardation, and mild genitourinary tract malformations. Here we described a 3 year-old girl patient with developmental delay, facial dysmorhism, skeletal malformations, and unilateral hydronephrosis. Chromosome analysis from peripheral blood of the patient revealed a derivative chromosome 8. Parents had normal karyotype. Array CGH analysis detected 9.5 Mb deletion of 8p23.1-pter, and 47 Mb duplication of 8q22.1-qter. To the best of our knowledge this is the first report of the rec(8) syndrome with normal parental karyotype.

J11.07

Identification of a denovo novel mutation in FOXL2 gene in a Turkish patient with BPES

E. Arslan Ates[1], *A. Aykut[2], A. Durmaz[2], H. Onay[2], F. Ozkinay[2];*
[1]Sevket Yilmaz Training and Research Hospital, Bursa, Turkey, [2]Ege University Faculty of Medicine, Izmir, Turkey.

Introduction: Blepharophimosis, ptosis, and epicanthus inversus syndrome (BPES) is a rare genetic syndrome which is characterised by eyelid malformation. Narrow palpebral fissures, ptosis, epicanthus inversus and telechantus are the main features of BPES. It is inherited in an autosomal dominant manner. In BPES Type I premature ovarian insufficiency is present with eyelid malformation. BPES Type II includes only eyelid malformation. Heterozygous mutations in FOXL2 gene which is located on chromsome 3q22.3 are responsible for both types of BPES. Chromosomal rearrangements involving this location also were repoted in BPES cases. In this study we report a case which was diagnosed as BPES and a novel mutation was detected .
Method: By evaluation of clinical findings and sanger sequencing of FOXL2 gene the case was diagnosed as BPES and discussed in the light of literature.
Case Report: A one year-old boy was referred us because of blepharophimosis. He had scaphocephaly, frontal bossing, ptosis, telechantus, narrow palpebral fissures, epicanthus inversus, flat nasal bridge, full cheeks, low set, big ears and clinodactyly of fifth toe. His parents' clinical examinations were normal. We sequenced FOXL2 gene and detected c.871_872insC variation. This variation was not reported previously, and seems to be resulting in an elongated protein. The variation was not detected in parents. Also in silico analysis of the variation was indicated that it is a damaging mutation.
Conclusion: Here we reported a novel denovo mutation in a BPES case. Fuctional studies and more reports are required to understand the affect of the mutation and for genotype-phenotype correlation.

J11.08

Alfi syndrome - cytogenetic study, FISH and clinical findings

C. GUG[1,2], *V. Plaiasu[3], D. Roman[4], M. Pantea[4], I. Velea[5];*
[1]Dept. Medical Genetics, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [2]Private Medical Practice and Genetics Laboratory Dr. Cristina Gug, Timisoara, Romania, [3]IOMC „Prof. Dr. Alfred Rusescu", Bucuresti, Romania, [4]University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [5]Pediatric II Dept, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania.

Alfi syndrome is a rare chromosomal anomaly that has an incidence of 1:50.000 newborns, but the incidence in Romania is unknown. We report a 5 year old girl with Alfi syndrome (a partial deletion 9p syndrome) a clinical entity as rare as it is well-defined. The clinical phenotype mainly consists of a distinct craniofacial dimorphism featuring, trigonocephaly, abnormal rotate ear, midfacial hypoplasia, arched eyebrows, down slanting palpebral fissures, small flat nose, anteverted nostrils, long philtrum, poor muscle tone and psychomotor retardation with language delay. A multidisciplinary evaluation was performed. It was observed that the patient presented female external genitalia, with agenesis of minor labia and no signs of virilization. The singularity of this case consists of the fact that the patient does not present hypothyroidism. Cytogenetic studies have been performed from peripheral lymphocytes by GTG banding in agreement with the standard procedure and ISCN 2013. A homogenous karyotype can be seen: 46,XX,del(9)(p22-pter). The anomaly is "de novo" because the normal karyotypes of the parents exclude balanced translocations. For the FISH testing probes have been used: Cytocell Aquarius Subtelomere Specific Probes: 9p (clone 43N6) - red (Marker STS: 9ptel30) and 9q (clone 112N13) - green (Marker STS: 9qtel33). The FISH probes have confirmed this deletion: 46,XX.ish del(9)(p22-pter)(43N6-,112N13+). In Romania, other 3 cases have been reported, but this is the first case to be documented using the FISH method. The early diagnosis of rare syndromes confers prognostic evaluation, counseling of the parents and better case management.

J11.09

A Case of Sotos Syndrome with a Novel Mutation of NSD1 Gene

H. Simsek, B. B. Geckinli, **K. Delil**, *M. A. Soylemez, A. Turkyilmaz, A. I. Guney, P. Ata, A. Arman;*
Department of Medical Genetics, Marmara University School of Medicine, İstanbul, Turkey.

Sotos Syndrome or Cerebral Gigantism, is an overgrowth syndrome without endocrinological abnormalities. It is characterized by tall stature, advanced bone age, macrocephaly, prognathism, large hands and feet, neurological symptoms including mental retardation and characteristic facial signs. It is inherited in a autosomal dominant manner and is caused by heterozygous NSD1 gene mutations or deletions of 5q35 region including NSD1 gene. More than 95% of individuals have a de novo mutation.
We described a 5-year-old girl with Sotos Syndrome who has acromegalic symptoms, prognatism, strabismus, mental retardation and gait disturbance. DNA sequence analysis of the patient showed a de novo heterozygous c.5920 G>A (p.Glu1974Lys) mutation of NSD1 gene. This mutation is a novel mutation that has not been previously described. We have reported our patient to contribute to genotype-phenotype correlations in Sotos syndrome.

J11.10

Particular features in a cohort of Down Syndrome patients

G. S. Doros, *C. Olariu, M. Puiu, A. Popoiu, M. Gafencu;*
Victor Babes University of Medicine and Pharmacy, Timisoara, Romania, Timisoara, Romania.

Aim: to present particular features associated in classic Down syndrome patients.
Material and methods: A 38 patients with Down Syndrome were diagnosed during a 5 year period, 49 % boys and 51 % girls. Six cases presented particular features. All patients performed complex investigations.
Results: From the selected 6 cases, one male infant was coming from a twin pair, both with Down syndrome, but the sister without heart malformation. All the 6 patients presented congenital heart disease: 3 cases with Fallot Tetralogy and 3 cases with atrioventricular septal defect(AVSD). The particular features in the Fallot Tetralogy were: in one case, association of aortic arch anomaly, with left subclavian artery emerging from left pulmonary artery, dolicocephaly, and cutis marmorata congenita, the second Fallot presented severe combined pectus carinatum and pectus escavatum and aneurysm of the pulmonary artery trunk at bifurcation, mimicking three branches emerging from the trunk; the third Fallot associated severe hypoplasia of the pulmonary trunk and branches, previous interventional dilated, but still waiting for stenting. The other 3 patients with AVSD, associated particular features as: congenital ectropion and cataracts in one case, grade IV right kidney hydonephrosis, neurogenic urinary bladder, right patellar and bilateral congenital hip luxation in another case and the third case associated cutis marmorata congenita, mimicking the shock.
Conclusions: particular heart and vascular malformations associated with the classic ones, cutis marmorata congenita, patellar and bilateral hip luxa-

tion, severe hydronephrosis, neurogenic urinary bladder, congenital ectropion and cataracts, all are particular features associated with Down syndrome, isolated described.

J11.11
Clinical and genetic characteristics Russian Marfan patients

A. Semyachkina[1], *T. Adyan*[2], *P. Novikov*[1], *A. Polyakov*[2];
[1]*Research Institute for Clinical Pediatrics Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [2]*Research Center for Medical Genetics, Moscow, Russian Federation.*

Marfan syndrome (MFS), a relatively common autosomal dominant hereditary disorder of connective tissue with prominent manifestations in the skeletal, ocular, and cardiovascular systems, is caused by mutations in the glycoprotein gene fibrillin-1 (FBN1). In MFS, there is a continuum of clinical presentations ranging from mild isolated features to severe progressive disease affecting multiple organ systems.
We herein present the results of the first direct DNA diagnosis in 9 Russian unrelated patients with MFS aged from 2 to 52 years. Eight 8 different heterozygous mutations in 8 probands was found (of which 6 were novel) and 1 patient had a substitution with unknown clinical significance described in SNP as rs112287730 with the incidence 0.02% (family analysis has shown its association with the disease in this family). Mutations were distributed along the length of the FBN1 gene. In contrast to the literature data, most of the mutations were null mutations: 3 frame shift, 3 splice site, 1 nonsense.
Most of the detected mutations (7 of 9) lead to the severe clinical presentation. Genotype-phenotype correlation analysis showed that mutations in exons 24-32 of FBN1 gene are associated with a high risk of a severe cardiovascular disease with a poor prognosis of life for all ages. Two patients with mutations in terminal exons 62 and 66 had severe changes in the skeletal, ocular, and cardiovascular systems (that diverges with the literature data).
Our results expand the spectrum of FBN1 mutations causing MFS and further confirm the role of FBN1 in the pathogenesis of MFS.

J11.12
Bilateral internal carotid artery agenesis associated with growth hormone deficiency, developmental delay and renal anomalies: a novel clinical entity?

T. S. E. Tan[1], *Z. Mohamed*[2], *J. Clayton-Smith*[3], *I. Banerjee*[2];
[1]*Manchester Medical School, The University of Manchester, Manchester, United Kingdom,* [2]*Department of Paediatric Endocrinology, Royal Manchester Children's Hospital, Manchester, United Kingdom,* [3]*Manchester Centre For Genomic Medicine, St Mary's Hospital, Central Manchester University Hospitals Foundation Trust, Manchester, United Kingdom.*

Internal carotid artery (ICA) agenesis is rare but is often syndromic and appears clinically heterogenous. It is associated with panhypopituitarism, velocardiofacial syndrome, Athabaskan-syndrome (AS), Bosley-Salih-Alorainy-Syndrome (BSAS) and PHACE syndrome. Here, we report a novel paediatric occurence of bilateral ICA agenesis.
A 4 year-old boy, born at term to a non-consanguineous British couple, was investigated for short stature (height: 82cm, -5SDS). He presented with facial dysmorphology (frontal bossing, hypertelorism, short nose, stellate bright blue irides and sclera), hypotonia and bilateral hearing impairment without any obvious focal neurology. He also has a dysplastic ectopic left kidney and developmental delay. Microarray analysis revealed a de-novo chromosome 11q14 microdeletion involving a single gene DLG2 encoding a synaptic protein. Pituitary function tests established isolated GHD (peak GH: 0.7mcg/L, IGF-1: 20ng/ml) and brain magnetic resonance (MR) imaging revealed a hypoplastic anterior pituitary and ectopic posterior pituitary. Bilateral agenesis of the ICAs with basilar artery ectasia was also confirmed by MR angiogram. CHARGE syndrome was excluded by analysis of the CHD7 gene. Other syndromes associated with ICA were considered unlikely on clinical grounds.
Hence, this case highlights a possible unidentified syndromic presentation of bilateral ICA agenesis. The loss of DLG-2 may account for developmental delay, but the basis of facial dysmorphology, renal dysplasia and visual abnormalities remain genetically unexplained. Homozygous HOXA1 mutations have been observed with ICA agenesis causing a phenotype overlapping BSAS and AS. However, its characteristic features (i.e. cardiac malformations, 6th nerve palsy and gaze abnormalities) are absent in our index case. Thus, further genetic investigation with whole exome sequencing may identify a genetic basis.

J11.13
Chromosome 4, Partial Trisomy 4q- case report

M. Boia[1], *A. Manea*[1], *D. Cioboata*[2], *M. Dobre*[3];
[1]*University of Medicine and Pharmacy Timisoara, Timisoara, Romania,* [2]*Clinic Emergency Hospital for Children „L. turcanu", Timisoara, Romania,* [3]*Clinic Emergency Hospital for Children „L. Turcanu", Timisoara, Romania.*

Introduction:
Chromosome 4, Partial Trisomy 4q is a rare chromosomal disorder in which a portion of the fourth chromosome appears three times (trisomy) rather than twice in body cells . Associated symptoms and findings may vary from case to case. In most cases, the trisomy appears to result from a balanced chromosomal rearrangement in one of the parents; rarely, it is thought to arise from spontaneous (de novo) errors early in embryonic development occured for unknown reasons (sporadically).
Methods:
Case report of a 2 weeks old new born infant , with facial dysmorfism, swallowing disorders, 3rd left space parasternal intense ejection systolic murmur , generalized hypotonia.
From the anamnestic dates we retain: healthy 28 years old parents; gestational age 37 weeks, birth weight=2040g, Apgar score 9 at 1 minute, monitored pregnancy with oligoamnios.
Results:
The cardiologic consult and ultrasound revealed a congenital heard disease without cyanosis, congestive heart insufficiency type Ross III.
Karyotype - 46XXder(12)dup(4)(q31.2-qter)100%. Abnormal derivated chromosome identificated der(12). The abnormally chromosomial structure is a duplication of the distal region of the long arm of the 4th chromosome from the q31.2 until telomere. This unbalanced arrangement represents a partial trisomy (4)(q31.2-ter).
The evolution was unsatisfied and because of the swallowing disorders the child presented repeated respiratory problems, slowly upward weight curve and even bacterial endocarditis.
Conclusions:
Extremely rare disease in medical practice; investigated on the mother's side history, we discovered that both, mother and grandmother, have the same type of translocation, but only in this case we could make a correlation between the clinical manifestation and the chromosomal abnormality.

J11.14
Radio-ulnar synostosis, microcephaly and scoliosis in a 9 years boy - hallmarks of Giuffrè - Tsukahara syndrome

C. Coldea, *I. Secheli, M. Coman, N. Dumitriu, M. Secheli;*
Clinical Emergency Hospital for Children "MS Curie", Bucharest, Romania.

In 1994 Giuffré et al reported a new genetic condition with microcephaly and radio-ulnar synostosis. Scoliosis, short stature and mental retardation were described, additionally, by Tsukahara (1995) and Udler (1998), in another syndrome. In 2005, clinical overlapping between those two conditions were suggested by Selicorni et al.
We report here a new case of a 9 years boy with short stature, mild facial dysmorphism consisting in microcephaly, proeminent eyes, flat malar region, thick uppper lip and micrognathia. He also had bilateral radio-ulnar synostosis, dorso-lumbar scoliosis, short stature (-2,24 SD) and mental retardation. These features oriented us to the Giuffré - Tsukahara syndrome. Less then 20 cases are reported in literature, most of them being familial. Our patient is a new case in the family. Bilateral cryptrochidism imposed a differential diagnosis with Noonan Syndrome. This particular phenotype brings additional evidence of the clinical overlapping beetween this two rare genetic conditions. The moleclar basis of the disease has not been identified.

J11.15
New mutation of the *TCOF1* gene in a patient with Treacher Collins syndrome

M. Martins, *P. Botelho, M. Souto, R. Arantes, O. Moutinho, R. Pinto Leite;*
Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal.

Treacher Collins syndrome (TCS), is a well know syndrome first described in 1900. The estimated incidence is 1/50000 live births, with 60% of the cases resulting from a de novo mutation. It is characterised by a congenital disorder of craniofacial development with a combination of bilateral symmetrical oto-mandibular dysplasia and various head and neck defects. The characteristic facial dysmorphism includes bilateral and symmetrical hypoplasia of the malar bones and infra-orbital rim (80% of cases) and of the mandible (78%) (retrognathia, retrogenia). External ear malformation such as microtia or anotia, atresia of the external auditory canal and anomalies of the ossicular chain are often present (60%) with bilateral conductive hearing loss.

With an autossomic dominant transmission, the TCOF1 gene mutations are the most common cause of the disorder, accounting for 81 to 93% of all cases. POLR1C and POLR1D gene mutations are responsible for an additional 2% of cases.
The present work describes a new TCOF1 mutation in a 26 year old TCS patient, in a study done in order to provide prenatal diagnosis in a future pregnancy.
PCR amplification and DNA analysis through sequencing of all exons of TCOF1 gene and the contiguous intronic sequences were performed.
A new mutation c.2507del(p.Pro836Glnfs*37) in heterozygosity in TCOF1 gene was detected.
Every new information of a genetic condition should be reported in order to allow a more precise genetic counselling.

J11.16
Monitoring of congenital anomalies in the population of Republic of Moldova

N. I. Barbova, *V. V. Egorov, M. L. Sprincean, E. A. Halabudenco;*
National Center of Human Reproduction and Medical Genetics, Chisinau, Moldova, Republic of.

Introduction: Congenital anomalies (CA) took second place in the Republic of Moldova among the causes of child mortality. Regular monitoring of the CA is held since 1991. Relevant is the prevention of multiple congenital malformations (MCA) that require costly surgical treatment and characterized by a high mortality rate.
Materials and Methods: Was carried out the analysis of MCV in National Register of Congenital Anomalies of the Republic of Moldova for the period from 2009 to 2013.
Results: The prevalence of CA for concerned was 17.5 per 1000 newborns. The prevalence of MCA was 7.19 per 1000 newborns. Maximum prevalence of MCV was recorded in 2013, and minimal in 2012 (9.14 and 4.23 for 1000 newborns, respectively). MCV occupied the leading position in the overall structure of the CA (25,24±2,24%). During the reporting period, was mentioned the steady trend of increasing the prevalence of congenital anomalies from 19.8% in 2009 to 31.0% in 2013. The leading position occupied unclassified complexes of MCV - 47%, which manifested by congenital heart defects (CHD) with defects of musculoskeletal system, as well as CHD plus anomalies of the nervous system. Chromosomal syndromes (Down syndrome, Patau syndrome etc.) were in 38% of cases. Monogenic syndromes have been detected in 9% of children with MCV, and 6%of MCV were consequences of intrauterine infection and other diseases of the mother.
Conclusions. The above data of surveillance allow us to plan and carry out preventive measures to reduce the frequency of children's' birth with MCV in Moldova.

J11.17
A CASE WITH TETRASOMY 9p

S. Eren Keskin, *B. DOGRUOGLU, D. Sunnetci Akkoyunlu, Z. İLKAY, E. Gumuslu, N. CINE, H. SAVLI;*
Kocaeli University, Faculty of Medicine, Medical Genetics Deparment, KOCAELİ, Turkey.

Introduction: Tetrasomy of short arm of chromosome 9 constitutes a clinically recognizable chromosomal syndrome.Tetrasomy of 9p is frequently caused by meiosis II nondisjunction followed by rearrangements leading to duplication of the short arm and loss of the long arm. Phenotypic abnormalities of tetrasomy 9p are ranging from mild developmental delay to multiple anomalies including intrauterine growth retardation, cerebral ventriculomegaly, dysmorphic facial features, cleft lip or palate, abnormal genitalia and renal anomalies. We present a new case of i(9p) that presented to us with dismorphic features such as hypertelorism, frontal bossing,corpus collosum agenesis.
Material Methods:Chromosomal analysis were performed on peripheral blood lymphocytes. Fluorescent in situ hybridization (FISH) studies were applied in order to confirm the origin of the extra chromosome.
Results: Chromosome analysis revealed tetrasomy 9p karyotype on GTL banding studies. Parental karyotypes were normal. Fluorescent in situ hybridization (FISH) studies confirmed the origin of the extra chromosome
Results: Here in, we diagnosed a case of tetrasomy 9p by classical cytogenetic methods combined with chromosome analysis and FISH.

J11.18
A further case with Macrocephaly-Capillary Malformation Syndrome

G. Ozgen, *E. Arslan Ates;*
Sevket Yilmaz Training and Research Hospital, Bursa, Turkey.

Introduction: Macrocephaly-capillary malformation syndrome (M-CM, #602501) is characterized by a spectrum of anomalies including megalencephaly, prenatal overgrowth, brain or body asymmetry, cutaneous vascular malformations and distal limb anomalies such as polydactyly or syndactyly. The syndrome is frequently associated with structural brain abnormalities. Mosaicism of chromosomal abnormalities in skin biopsies and somatic mutations of PIK3CA gene was reported in M-CM cases in literature. In this study, we report a case with M-CM, diagnosed clinically and radiologically.
Materials and Methods: We present a case who was diagnosed as M-CM, and discuss the clinical and radiological findings.
Results: A 14 months old boy was referred to our clinic because of macrocephaly and Chiari 1 malformation. He had macrocephaly, prominent metopic ridge, hypertelorism, body asymmetry, capillary malformations on trunk, back of the neck and philtrum, and syndactyly of toes. Brain MRI revealed hydrocephaly and whole spinal MRI revealed Chiari 1 malformation and tethered cord. Peripheral blood karyotype analysis was normal, karyotype analysis from skin fibroblast culture was planned. Sequence analysis of PTEN gene revealed no mutations.
Conclusions: The case was diagnosed as M-CM according to clinical and radiological findings. Somatic mutations of PIK3CA gene are known to be responsible for M-CM syndrome, however, we could not perform molecular genetic diagnosis for this patient.

J11.19
A de novo 13.7 Mb interstitial deletion at 7q21.2 in a child with mental retardation, microcephaly, hearing loss and cerebral cavernous malformation

M. Y. Alp[1], **T. Tos**[2], *H. Aydın[3];*
[1]Dışkapı Yıldırım Beyazıt Research and Training Hospital Genetic Diagnostic Center, Ankara, Turkey, [2]Dr. Sami Ulus Women's and Children's Research and Training Hospital, Department of Medical Genetics, Ankara, Turkey, [3]Zeynep Kamil Women's and Children's Research and Training Hospital, Department of Medical Genetics, İstanbul, Turkey.

7q21 microdeletion is a very rare chromosomal abnormalities characterized with mental retardation, short stature, microcephaly, and hearing loss. Additional features are split hand and foot anomalies and cerebral cavernous malformation. Her we described an eleven year-old male patient referred to the department of medical genetics because of microcephaly, sensorineural hearing loss, and facial dysmorphism. Cranial MRI revealed multiple cerebral cavernous hemangiomas and cortical dysplasia. Abdominal USG, echocardiography, cranial CT and X-Ray examinations were normal. Chromosome analysis of the patient from peripheral blood demonstrated an interstitial deletion at 7q21. Parental karyotypes were normal. Array CGH analysis showed 13.7 mb deletion at 7q21.2.

J11.20
Patau syndrome with mild phenotypic expression

M. Jurkute[1], *D. Serapinas[1,2];*
[1]Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Patau syndrome is a genetic disorder which causes an infant to have three copies of genetic material of chromosome 13. Full trisomy 13 is caused by nondisjunction of chromosomes during meiosis. The extra genetic material disrupts the normal course of development, causing complex organ defects. Those individuals may have heart defects, polydactyly, intellectual disability, microphthalmia or anophthalmia, cleft lip, cleft palate, hypotonia, low-set ears, scalp defects, microcephaly, myelomeningocele, abnormalities of fingers, respiratory difficulcies and hypoglycemia.There is a possibility to stay alive, but most infants with the syndrome die within the first three months after birth.
Case report: We report 7 months old girl with Patau syndrome. She had low-set ears, flattened nose, wider then usual area between eyebrows, cataracts, coloboma and heart defects. Genetical tests were made two times during pregnancy, but higher risk for Patau syndrome was not shown . What is more fetus was tested with ultrasound but there were not found any abnormalities either. Trisomy 13 was confirmed by examining the infant's chromosomal pattern through karyotyping. Also it is important to highlight the fact that parents were in the middle age and healthy. Patient was treated with dorzolamide and timolum, dekstrose infusion, oxygen therapy and others. After all medication infant's condition was stabilized.

Testicular Feminization or Androgen Insensitivity Syndrome (AIS), in Iran

D. Farhud D.[1], **S. Zandvakili**[1], *M. Zarif Yeganeh[2], H. Sadighi[1];*
[1]Tehran Genetic Clinic (Dr.Farhud Genetic Clinic), Teharan, Iran, Islamic Republic of, [2]Researcher, Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Teharan, Iran, Islamic Republic of.

Background:The androgen insensitivity syndrome (AIS) or testicular feminization is a partial or complete inability of the cell respond to androgen. This syndrome is caused by inutility of androgen and so, testosterone converts into estrogen. The human androgen receptor (AR) is encoded by a gene located on the X chromosome. AIS occurs when the AR is impaired. This inexpressive to androgen hormone can damage or prevent masculinization of male genitalia in the developing status. AIS is divided in three categories, complete, partial and mild by intensity of external genital masculinization.
Methods:The specified screening was applied in 70 AIS patients and XY pattern was cytogenetically diagnosed and confirmed, out of 72000 families' medical records in Tehran Genetic Clinic. The essential basis to submit these patients to the Genetic Clinic from their gynecologist was primary amenorrhea. The other indicators are assessed such as: maternal and paternal age, parents consanguineous marriages, family history and clinical observation of the patients.
Results:The results specify that there was no association in maternal and paternal age. Marriage pattern of the parents has not shown any remarkable results in AIS cases. The clinical surveillance illustrated that amenorrhea has a high percentage in case study which may prove that it is the primary symptom of AIS patients.
Conclusion:The correlation of maternal and paternal age with AIS is not found. The parent's consanguineous marriage is high as a national culture in Iran. The frequency in clinical observation is reasonable and high percentage of this observation belongs to Amenorrhea. Therefore, amenorrhea is the most significant signs of AIS based on clinical assessments.

J11.22

Co-occurrence of supernumerary marker chromosome 22 and 17p13.3 microduplication in patient with developmental delay

A. R. Shorina[1,2], *A. B. Maslennikov[2], V. A. Makasheva[1], N. A. Skryabin[3], A. A. Kashevarova[3], I. N. Lebedev[3];*
[1]Novosibirsk Regional Children's Clinical Psychoneurological Dispensary, Novosibirsk, Russian Federation, [2]State Novosibirsk Regional Clinical Diagnostic Center, Novosibirsk, Russian Federation, [3]Institute of Medical Genetics, Tomsk, Russian Federation.

The delineation of karyotype-phenotype correlations in patients with chromosomal abnormalities is a central goal of clinical cytogenetics. However, the knowledge about structure of chromosomal aberrations strongly depends on the resolution level of molecular cytogenetic techniques. Here we report a 1.2 year old patient with severe developmental delay and a small acrocentric supernumerary marker chromosome 47,XY,+mar[13] according to conventional G-banding. Chromosomal microarray (60K, Agilent Technologies) revealed 22q11.1-q12.2 duplication (13,971 kb in size). Moreover, 733 kb interstinal 17p13.3 microduplication involving 11 genes (RPH3AL, LOC1000506388, C17ORF97, FAM101B, YPS53, FAM57A, GEMIN4, DBIL5P, GL004, RNMTL1, NXN) was also observed. The latter was mapped to the region of 17p13.3 microduplication syndrome. However the genes from critical region (YWHAE, PAFAH1B1, CRK) were not affected by CNV. The patient was born from the first pregnancy from healthy non-consanguinity parents. A boy presented a severe developmental delay with inability to hold up the head up to 7 months. He doesn't sit at the age of 1.2 years old. A clinical examination revealed microcephaly, downslanting palpebral fissures, epicanthus, hypertelorism, hypermetropy, astigmatism, divergent concomitant strabismus, small nose with saddle broad nasal bridge and flat tip, protruded low set ears, long smooth philtrum, short neck, hypertelorism of nipples. Early teething at the age of 4 month was noted. At the age of observation a boy has 10 teeth. Oval foramen of heart was also observed. Abdominal ultrasound revealed no pathology. Diffuse muscle hypotonia was noted. Our findings point out the significance of high-resolution array-based molecular karyotyping for patients with idiopathic developmental delay.

20q Duplication Syndrome: A case report

A. H. CEBI, *G. KARAGUZEL, S. SEYHAN, R. POLAT, H. ONDER, M. IKBAL;*
Karadeniz Technical Universiry, Trabzon, Turkey.

A 14 year old boy came to our clinic because of motor and intellectual disability. He had no prenatal history. His mother first took him to doctor when he was one and half year old because of walking problems. He had speech delay too. He had an operation of undescended testes and inguinal hernia. He has only left kidney. He has hyperthyroidism and glaucoma.His brain MRI and cardiac ecocardigraphy is normal. In his examination he looks like he is smiling. He has flapped-ears and exoftalmus. He doesn't have any other physical findings. First we made a chromosome analysis. Its result was 46,XY,der(20). The chromosome anlysis of his mother and his father were all normal. We decided to do an Array CGH with SNP Array-Illuminal HumanCytoSNP-12 BeadChip. Its result was there is a duplication of chr20:31.146.232-48 .340.036. Partial 20q duplication syndrome is rare. This report is one of the biggest isolated 20 q duplication.

J11.24

Case of Cri du Chat syndrome in Lithuanian health science university hospital

A. Vadisiute[1], *D. Serapinas[2,1];*
[1]Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Cri du Chat Syndrome (CdCS) or "cat-cry syndrome" is a rare genetic disorders resulting from a deletion of the short arm of chromosome 5 (5p-). Characteristic clinical manifestations of this syndrome are cat-like high-pitched cries, distinct facial dysmorphism, microcephaly and severe psychomotor and mental retardation. The size of the deletion ranges from the entire short arm to solely 5p15 and all include the CTNND2 gene. The prevalence is approximately 1 in 15,000 - 50,000 newborns and with females to male ratio of 4 : 3.
We report pacient, that was born at term (gestation age: 37 weeks) and was the first child of healthy, and unrelated parents. The family history was unremarkable. During pregnancy was diagnosed fetus hypotrophy and metabolic acidosis. After delivery, dextroposition of the aorta and a large subaortic ASD and VSD was detected by cardioechoscopy. When she was 6 months old, she had a heart defect corrective surgery and implanted cardiostimulators by reason of atrioventricular block. A girl was admitted for psychomotor retardation, also unable to sit and stand, incapable to chew and talk. Evident phenotypic changes: microcephaly, bilateral epicanthus, eye corners laterally slit down, long filter, triangle cranny mouth, narrow lips, high palate, micrognathia, hair on the neck, narrow feet and muscular hypotonia.
Cytogenetic analysis (FISH) revealed karyotype 46, XX, del (5) (p15) confirming diagnosis of Cri du Chat syndrome. This deletion was not find in girl parents, in fact this case occured as a de novo mutation. The reccurent risk for the parents was similar like in general population.

J11.25

C677T and A1298C mutations in methylenetetrahydrofolate reductase gene in patients with 21 trisomy and their mothers

S. Bucerzan[1], *R. A. Popp[2], C. Alkhzouz[3], A. Mocan[3], D. Micle[2], P. Grigorescu-Sido[1];*
[1]First Pediatric Clinic, Cluj-Napoca, Romania, [2]Department of Medical Genetics - University of Medicine and Pharmacy, Cluj-Napoca, Romania, [3]FIRST PEDIATRIC CLINIC, CLUJ-NAPOCA, Romania.

Introduction. Deficiency of methylenetetrahydrofolate reductase (MTHFR) causes a deficiency of the active metabolic form of folic acid, with important consequences, especially haematological (anemia, trombocytopenia) and hyperhomocysteinemia, a metabolic disorder which stimulates proliferation of smooth muscular cells, promoting early onset of atherogenesis, a risk factor for cardiac and cerebro-vascular disease. Folic acid deficiency is cited as promoting factor of chromosomal nondisjunction in gametogenesis, with increased risk for appearance of aneuploidy. The study aims to evaluate the prevalence of C677T and A1298C mutation in MTHFRgene in a group of children with 21 trisomy and in their mothers.
Patients and methods.The study group consisted of 73 patients with 21 trisomy and 67 mothers, who were registered in the Center of Genetic Pathology of First Paediatric Clinic Cluj in the period 2010-2014. Analysis of the two mutations was performed by PCR-RFLP technique.
Results. There were diagnosed 19 homozygotes (8 with C677T mutation and 11 with A1298C mutation), 16 composite heterozygotes and 31 heterozygotes (14 with C677T mutation and 17 with A1298C mutation). There were diagnosed 18 homozygous mothers (7 with C677T mutation and 11 with A1298C mutation), 15 composite heterozygotes and 28 heterozygotes (12 with C677T mutation and 16 with A1298C mutation).
Conclusions. Introduction of folic acid therapy in patients with 21 trisomy, homozygotes for C677T and A1298C mutations is beneficial in improvement of evolution of this patients, and treatment with folic acid in woman with homozygote or composite heterozygote genotype might reduce the risk of chromosomal nondisjunction in gametogenesis.

Rare genetic syndromes confirmed in adult dysmorphic patients - clinical and molecular characteristics in 10 Slovak patients.

D. Durovcikova[1], *R. Lohajova-Behulova*[1], *S. Machalova*[2], *J. Šimko*[3], *A. Gencik*[4]; *[1]Slovak Medical University, Bratislava, Slovakia, [2]Slovak Medical University, Dept. Med.Genet, Bratislava, Slovakia, [3]Gendiagnostica-Alfamedical, Bratislava, Slovakia, [4]Medgene, s.r.o, Bratislava, Slovakia.*

Genetic counseling and DNA diagnostic tests in adult outpatients in our genetic clinic have been performed for various monogenic diseases. Genetic testing in adult patients with unexplained dysmorphy spans the smallest proportion, because majority of them was clarified in childhood. The aim of this study was to obtain cause and number of the adult patients undergoing genetic testing. We analyse results of genetic testing in group of 12 adults with various kraniofacial, skeletal, ectodermal dysmorphic signs. Clinical diagnosis have been made in childhood according to occurence of the major signs in 7 cases. This study offers survey of 10 different rare genetic syndrome and provide selected clinical and molecular data in Slovak patients. Causal mutation detected in Marfan, Hypochodroplasia, Ostechondrosis, Osteogenesis imperfecta, Albrigt, Oculodentodigital, Stickler and Cowden syndrome. Expanding spectrum of rare genetic syndromes which were confirmed at the molecular level during the last few years is fulfilling Eu initiatives on the issue of rare diseases.

J11.27

Familial osteoporosis and interstitial duplication of chromosome 5

E. Tassano, *N. Di Iorgi, S. Marchese, F. Napoli, P. Fiorio, G. Gimelli, C. Cuoco; Istituto Giannina Gaslini, Genova, Italy.*

Osteoporosis is a systemic bone disease characterized by low bone mineral density and structural deterioration of bone tissue leading to an increased risk of fractures. Genetic factors have been recognized to play an important role in osteoporosis and a number of susceptibility genes have been identified and validated. Here, we describe an 11-year-old girl affected by severe osteoporosis with vertebral fracture and intellectual disability. Her father was affected by a severe form, too. Cytogenetic investigations revealed a dicentric chromosome 5, rearranged at the centromeric level, present also in her father. The two centromeres were both active, as demonstrated by immunological staining with CENP-C antibodies. Array-CGH of the proposita showed a large proximal duplication at 5p11q11.2 band and a small distal one at 5q11.2, while her father presented a unique duplication of 5p11q11.2 bands. The duplicated region on chromosome 5 contains ITGA1 (integrin alpha 1), an osteoporosis susceptibility gene, and FST (follistatin) gene. ITGA1 encodes integrin alpha 1 chain that binds to the beta chain to form a receptor involved in cell attachment and neurite outgrowth on laminin and collagen. Proper collagen-integrin interactions are important in fracture healing, which suggests that ITGA1 plays role in the regulation of mesenchymal stem cell and cartilage proliferation. FST encodes a monomeric glycoprotein that actively participates in the regulation of bone metabolism. Experiments performed in mice overexpressing follistatin showed a decreased quality of skeleton and susceptibility to bone fractures. In conclusion, interstitial 5p11q11.2duplication involving ITGA1 and FST could play a causative role in familial osteoporosis.

J11.28

The role of copy number variations (CNVs) in genetic mechanisms of 22q11.2 Deletion Syndrome

M. C. Molck, *M. Simioni, T. P. Vieira, I. C. Sgardioli, A. Santos, V. Gil-da-Silva-Lopes; Faculty of Medicine, University of Campinas, Campinas, Brazil.*

The 22q11 chromosomal region contains low copy repeats sequences that mediate non-allelic homologous recombination, which predisposes to CNVs at this locus. Hemizygous deletions result in the 22q11.2 deletion syndrome (22q11.2 DS) that presents a highly variable phenotype, including congenital heart diseases. Most of cases present a ~3 Mb typical deletion, spanning LCRs A-D, and a minority of cases present a ~1.5 Mb nested proximal deletion spanning LCR22-A to LCR22-B; but other atypical CNVs have been reported. We used high-resolution array genomic hybridization (aGH) technique (CytoScan HD chip, Affymetrix®) to map the breakpoints at 22q11.2 region and investigate CNVs in other genomic regions in a cohort of 28 subjects with congenital heart disease and 22q11.2 deletion, previously detected by FISH and/or MLPA. Twenty-seven patients showed the typical deletion at 22q11.2 and one patient showed the proximal deletion. The size of deletion at 22q11.2 region varied from 1.8 Mb to 3.3 Mb. The breakpoints in 22q11.2 proximal region were from 18.644.790 to 18.916.842 kb and from 20.716.903 to 21.915.509 kb in distal region (Hg 19). The genes in these two breakpoint regions are variably hemizygous depending on the location of the breakpoints. 22 CNVs ≥ 300 kb outside the 22q11.2 region were detected, including a deletion at 11q14.3 (2.9 Mb) and duplications at 5q11.1 (628 kb), 6p21.2 (668 kb), 7p11.2 (662 kb) and 16q23.3 (367 kb). These regions could be potential loci acting as genetic modifiers contributing to the phenotypic variability found in the 22q11.2 DS.

Financial support: FAPESP, CAPES and CNPq.

Dominant mutations in KAT6A cause intellectual disability with recognizable syndromic features.

E. Tham[1], *A. Lindstrand*[1], *A. Santani*[2], *H. Malmgren*[1], *A. Nesbitt*[2], *H. A. Dubbs*[3], *E. H. Zackai*[4], *M. J. Parker*[5], *F. Millan Zamora*[6], *K. Rosenbaum*[7], *G. N. Wilson*[8], *A. Nordgren*[1]; *[1]Karolinska Institutet, Stockholm, Sweden, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, United States, [3]The Children's Hospital of Philadelphia, Philadephia, PA, United States, [4]The Children's Hospital of Philadelphia, Philadelphia, PA, United States, [5]Sheffield Children's Hospital, Sheffield, United Kingdom, [6]GeneDx Laboratory, Gaithersburg, MD, United States, [7]Children's National Medical Center, Washington DC, DC, United States, [8]Texas Tech University Health Science Center, Lubbock, TX, United States.*

The histone lysine (K) acetyltransferase KAT6A is prone to translocational events involved in acute myelogenous leukemia. Through a multi center collaboration study, we here report six individuals from five unrelated families, with mutations in KAT6A/MOZ detected by whole exome sequencing.
All five different de novo heterozygous truncating mutations were located in the C-terminal transactivation domain of KAT6A: NM_001099412.1: c.3116_3117delCT, p.(Ser1039*); c.3830_3831insTT, p.(Arg1278Serfs*17); c.3879dupA, p.(Glu1294Argfs*19); c.4108G>T p.(Glu1370*) and c.4292dupT, p.(Leu1431Phefs*8). An additional subject with a 0.23 MB microdeletion including the entire KAT6A reading frame was identified with genome wide array comparative genomic hybridization. Finally by detailed clinical characterization we provide evidence that heterozygous mutations in KAT6A cause a distinct intellectual disability syndrome. The common phenotype includes hypotonia, intellectual disability, early feeding and oromotor difficulties, microcephaly and/or craniosynostosis and cardiac defects in combination with subtle facial features such as bitemporal narrowing, broad nasal tip, thin upper lip, posteriorly rotated or low-set ears, and microretrognathia. The identification of human subjects complements previous work from mice and zebrafish where knockouts of Kat6a/kat6a lead to developmental defects.

Discovery and genetic characterization of new neuropsychiatric syndromes from family-based studies in Utah.

G. J. Lyon[1], *J. O'Rawe*[1], *Y. Wu*[1], *H. Fang*[1], *L. Jimenez Barron*[1], *G. Narzisi*[1], *M. Schatz*[1], *K. Wang*[2], *M. He*[3]; *[1]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, United States, [2]University of Southern California, Los Angeles, CA, United States, [3]Marshfield Clinic, Marshfield, WI, United States.*

We conduct large-scale genomic studies of families in Utah, where there is a founder effect, large families, and good genealogical records, which enable well-powered genetic studies for rare diseases. We optimize exome and whole genome sequencing (WGS) to identify mutations that segregate with various syndromes, and we undertake comprehensive functional studies of identified mutations. We report the identification and characterization of many new genetic syndromes, including Ogden Syndrome, RBCK1 Syndrome, and most recently RykDax Syndrome. This latter syndrome presents with severe intellectual disability (ID) and very distinctive facial features. We show increased reliability of the biological inferences with an integrative WGS pipeline, including a new algorithm, Scalpel, developed for more accurate identification of indels. We find a 2 to 5-fold difference in the variants detected as being relevant for various disease models when using different sets of sequencing data and analysis pipelines, and we derive greater accuracy when more pipelines are used in conjunction with data encompassing a larger portion of the family. We have shown that 60X WGS depth of coverage from the Illumina HiSeq platform is needed to recover 95% of indels. We also developed SeqHBase, a big data-based toolset for analysing family-based sequencing data, and we demonstrated SeqHBase's high efficiency and scalability on several disorders, including with RykDax Syndrome, where we identified a maternally inherited missense variant in an X-chromosomal gene, TAF1. A "genotype-first" approach led us to other families with variants in TAF1 and a remarkably similar clinical presentation. More generally, we are setting standards for more accurate WGS, including for indel detection, in family-based studies.

J11.31

Clinical exome sequencing in Czech Kabuki-like syndrome patients

J. Paderova, *N. Ptakova, A. Holubova, M. Vlckova, R. Pourova, V. Krulisova, S. Vejvalkova, M. Havlovicova, A. Krepelova, M. Turnovec, M. Macek sr., M. Macek jr.;*
Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic.

Kabuki syndrome (KS) is a dominantly inherited multi-systemic disorder caused predominantly by de-novo mutations. Phenotypic features vary among KS patients and therefore it is difficult to diagnose this syndrome based on phenotype unequivocally. Currently, two disease genes have been associated with KS: *KMT2D* and *KDM6A*, but in 24-56 % of patients genetic basis of a Kabuki-like phenotype remains undetermined. In our previous study we examined KMT2D/KDM6A mutations in cohort of Czech patients referred for KS genetic testing. Seven "negative" patients were subjected to clinical exome sequencing (TruSightOne, Illumina, USA) in order to reveal pathogenic disease genes and variants responsible for Kabuki-like phenotype. In two male patients we found truncating mutations in EFTUD2 gene (linked to mandibulofacial dysostosis), in one of these patients in mocaics form, while another male patient had deleterious missense mutation in HUWE1 gene (X-linked mental retardation). Truncating mutation in KMT2C gene (previously linked to Kleefstra syndrome spectrum) was detected in female patient. KMT2C interacts with KDM6A and EHMT1 from this spectrum. In the remaining three patients potentially pathogenic missense and truncating variants in TGFBR2, KIF1A, RAI1, ILRAPL1, CDH15, SHANK3 and ZEB2 will be further assessed. We conclude that clinical exome analysis is a high yield method in Kabuki-like patients without mutations in KMT2D/KDM6A genes.

A girl with 2q36 chromosome deletion and phenotypic features of Waardenburg syndrome

I. M. Bradinova[1], *R. Vazharova*[2], *S. Andonova*[1], *E. Simeonov*[3], *A. Savov*[1];
[1]*National genetic laboratory, UHOG „Maichin dom", Sofia, Bulgaria,* [2]*Sofia University „St. Kliment Ohridski", Faculty of medicine, Sofia, Bulgaria,* [3]*University hospital „Alexandrovska", Sofia, Bulgaria.*

We report a 12 years old female patient with clinical presentation of MCA/MR syndrome including severe growth retardation, facial dysmorphism, microcephaly, limb anomalies, skin and hair pigmentation abnormalities, generalized hypertrichosis and mild mental retardation.

The child was born from a first pregnancy of young and healthy non-consanguineous parents with low birth weight (1600g), microcephaly and dysmorphic features noticed at birth. The karyotype of the patient was normal (46,XX). Because of the present severe growth retardation and microcephaly, right hand deformity, and generalized hypertrichosis with synophrys the initial clinical diagnosis was Cornelia de Lange syndrome.

The most prominent dysmorphic features at the age of 12 years included synophrys, hypertelorism and telecanthus, high nasal bridge, high arched palate together with generalized hypertrichosis and premature graying of the hair, skin hypopigmentation areas, and café au lait spots.

The performed array-CGH of the patient identified a heterozygous 6.759 Mb deletion of chromosome 2q36 (arr 2q36.1q36.3(222,508,616x2, 222,598,182-229,358,111x1, 229,409,228x2)) including 19 OMIM genes, with PAX3gene one of them.

Diseases associated with PAX3 gene include Waardenburg syndrome type 1 and 3. Waardenburg syndrome (WS) is autosomal dominant dysmorphic syndrome characterized by pigmentary abnormalities of the hair and eyes and congenital sensorineural hearing loss. WS is classified into 4 main phenotypes. WS type 1 is distinguished by the presence of dystopia canthorum. WS type 3 has dystopia canthorum and upper limb abnormalities, prominent nasal bridge and synophrys.

The detected 2q36 deletion explains the complex MCA/MR syndrome phenotype in our patient including symptoms of WS in association with other dysmorphic features.

Partial trisomy 13q and partial 3pdel in a patient with a novel clinical finding due to paternal reciprocal 3p;13q translocation

M. Martin de Saro[1], *Z. Compeand*[2], *K. Aguilar-Cuarto*[2], *L. Gonzalez-Huerta*[3], *S. Cuevas-Covarrubias*[4];
[1]*1Medical Genetic Department, Hospital Materno Infantil ISSEMyM, Mexico DF, Mexico,* [2]*Medical Genetic Department, Hospital Materno Infantil ISSEMyM, Toluca EdoMex, Mexico,* [3]*Hospital General de Mexico, Mexico DF, Mexico,* [4]*Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.*

Individuals with 3p deletion present a great clinical variability. Apparently, a 1.5 Mb terminal deletion, including CRBN and CNTN4 genes, is sufficient to cause this syndrome. Partial trisomy 13q is an uncommon chromosomal abnormality with a variable phenotypic expression but in most cases, patients have a phenotype resembling complete trisomy 13. The aim of the present study is to describe a novel case of 3pdel/13qdup of chromosome 13 in a Mexican patient with a novel clinical finding. A 9 months male was the fourth child of non-related, young and healthy parents. There was no family history of congenital malformations. The child was born after 35 weeks of uneventful pregnancy. At birth, he had hepatoesplenomegaly, colesthasis and facial dysmorphism. On physical examination, he had a weight of 3800 (<3th centile), length of 62cm (<3th centile), upslanting palpebral fissures with long eyelashes, anteverted nares, high narrow palate, heart murmur, umbilic hernia and bilateral inguinal hernia with right cryptorchidism. Echocardiogram reported cardiac insufficiency with hypertrophic cardiomyopathy and pulmonar hypertension, ultrasound showed normal liver and brain CT revealed cortical atrophy. Conventional karyotype reported 46, XY, add(3)(p26). Karyotype from de father was 46, XY, t(3;13). Microarray assay exhibited an approximately 2.6Mb loss at terminal 3p26.3 and a 27.7Mb gain of the long arm of terminal chromosome 13 at q31.1q34. The presented case suffered a chromosomal unbalance with a partial trisomic component 13q31.1-q34 and a monosomic component 3p26.3 from paternal origin. Although clinical spectrum is too high in this chromosomal aberration, this type of cardiomyopathy has not been previously reported.

ABSTRACT

Robinow syndrome (RS) is a rare genetic disorder characterized by limb shortening, genital hypoplasia, and craniofacial/orodental abnormalities. The syndrome follows both autosomal dominant and recessive patterns of inheritance with similar phenotypic presentation and overlapping features. Autosomal recessive Robinow syndrome (ARRS) is caused by mutation in the ROR2 gene. Here, we present the clinical, radiological and molecular findings of eleven Egyptian patients from seven unrelated consanguineous families with clinical features of ARRS. Mutation analyses of ROR2 gene identified five pathogenic mutations distributed all over the gene. The identified mutations included four novel (G326A, D166H, S677F and R528Q) and one previously reported (Y192D). Our results extend the number of ROR2 mutations identified so far, suggest a founder effect in the Egyptian population, and emphasize the important role of genetic testing in proper counseling and patients' management.

J11.35

RHYNS syndrome is an MKS3/TMEM67-related ciliopathy

L. Marsili[1,2], *V. Vega-Warner*[3], *E. Colao*[4], *N. Perrotti*[4,5], *A. Cagliotti*[6], *F. Sangiuolo*[1,2], *G. Novelli*[1,2], *E. A. Otto*[3], *F. Brancati*[2,7];
[1]*Department of Biomedicine and Prevention, Section of Genetics, School of Medicine, Tor Vergata University, Rome, Italy,* [2]*Medical Genetics Unit, Policlinico Tor Vergata University Hospital, Rome, Italy,* [3]*Department of Pediatrics and Communicable Diseases, University of Michigan, Ann Arbor, MI, United States,* [4]*Medical Genetics Unit, University Hospital "Policlinico Mater Domini", Magna Graecia University, Catanzaro, Italy,* [5]*Department of Human Health, University Magna Graecia, Catanzaro, Italy,* [6]*Nefrology Unit, University Hospital "Policlinico Mater Domini", Magna Graecia University, Catanzaro, Italy,* [7]*Department of Medical, Oral and Biotechnological Sciences, Gabriele D'Annunzio University, Chieti, Italy.*

RHYNS syndrome was defined as the association of Retinitis pigmentosa, HYpopituitarism, Nephronophthisis (NPHP), and mild Skeletal dysplasia. Few cases have been reported in the literature; yet, the underlying genetic bases are unknown. The occurrence in two brothers and the observation that only males are affected suggested either an X-linked or autosomal recessive inheritance. We revaluated a 38-year-old male patient presenting with retinitis pigmentosa leading to an extinguished electroretinogram by 11 years of age, NPHP since the age of 12 years, thyrotropin (TSH) and growth hormone (GH) deficiency, and mild skeletal anomalies including an abnormal pelvic configuration with irregular acetabular margins. He was one of the first patients described with this unusual pattern of association. Notably, there was no evidence of neurological involvement and he worked as a

computer technician. We used a panel of ciliopathy-related genes to unravel the molecular defect in this patient and identified biallelic mutations in the MKS3/TMEM67 gene. Mutations in MKS3/TMEM67 are associated to a vast range of ciliopathies encompassing Meckel syndrome (MKS) type 3, Joubert syndrome (JBTS) type 6, COACH syndrome, and NPHP with liver fibrosis (NPHP11). According to previously reported genotype-phenotype correlations, we identified one missense and one truncating mutation in MKS3/TMEM67, in a non-lethal phenotype. Our findings expand the clinical spectrum of MKS3/TMEM67-related disorders to include RHYNS syndrome.

J11.36
Mutations in *CENPF* cause apple peel intestinal atresia, microcephaly and ocular anomalies

S. Hanks[1], *S. Yost*[1], *E. Ruark*[1], *A. Zachariou*[1], *N. Rahman*[1,2];
[1]*Division of Genetics & Epidemiology, Institute of Cancer Research, Sutton, United Kingdom,* [2]*Cancer Genetics Unit, Royal Marsden Hospital, London, United Kingdom.*

Apple peel intestinal atresia describes a condition characterised by a shortened small intestine with a coiled configuration around its vascular supply that resembles an apple peel. It often occurs as an isolated anomaly, but the association of apple peel intestinal atresia with other features, including microcephaly and ocular defects, has been reported, and is sometimes referred to as Stromme syndrome (MIM243605). Using exome sequencing we identified biallelic protein truncating variants in *CENPF* in a patient with apple peel intestinal atresia, microcephaly and ocular anomalies. The mutations were confirmed by Sanger sequencing and each unaffected parent was shown to be a heterozygous *CENPF* truncating mutation carrier. Neither mutation was present in the ICR1000 UK population exome series, nor the ExAC database of >60,000 exomes. Further sequencing of individuals with the same phenotype identified three additional cases from two unrelated families who also carry *CENPF* truncating mutations.
CENPF encodes a protein that is required for kinetochore function and chromosome segregation in mitosis. It is also involved in the regulation of DNA synthesis and hence cell cycle progression. Our findings demonstrate that the association of apple peel intestinal atresia, microcephaly and eye anomalies is a distinct recessive genetic syndrome caused by inactivating mutations in *CENPF*. We also demonstrate that exome sequencing provides a good strategy to identify causative genes in individuals with combinations of rare, distinctive clinical features. This work was funded by the Wellcome Trust Grant 100210/Z/12/Z.

J11.37
Clinical delineation of Schinzel alopecia-synostosis syndrome, a newly recognized condition of unknown genetic cause

M. Castori[1], *M. Iascone*[2], *A. Schinzel*[3], *F. Brancati*[4,5];
[1]*Division of Medical Genetics, San Camillo-Forlanini Hospital, Rome, Italy,* [2]*Laboratory of Medical Genetics, Papa Giovanni XXIII Hospital, Bergamo, Italy,* [3]*Institute of Medical Genetics, University of Zurich, Zurich, Switzerland,* [4]*Department of Medical, Oral and Biotechnological Sciences, Gabriele D'Annunzio University of Chieti-Pescara, Chieti, Italy,* [5]*Medical Genetics Unit, Policlinico Tor Vergata University Hospital, Rome, Italy.*

In 1980, Schinzel described a hitherto unreported multiple malformation syndrome in a 17-year-old girl featuring congenital alopecia, multiple synostoses of the upper limbs, joint contractures, cutaneous IV-V toe syndactyly, costo-vertebral segmentation defects, short stature and intellectual disability. Scrutiny of early literature identified two additional sporadic cases with overlapping features. Additional similar patients were subsequently reported by van Gelderen (1982), Dumić et al. (2000) and Schell-Apacik et al. (2008). Here, we describe a 4-year-old sporadic girl with growth delay of prenatal onset, micro-trigonocephaly, congenital alopecia and an unusual pattern of malformations showing striking similarities with Schinzel's original patient. In our patient SNP-array excluded chromosomal rearrangements at a resolution of 75 Kb, while sequencing of candidate genes including *RNU4ATAC, PCNT, MBTPS2, GJA1, PVLR1* and *CKAPL2* ruled out causative mutations. We had the opportunity to follow-up Schinzel's patient at the age of 53. She presented with severe short stature (126 cm), intellectual disability and reduced visual acuity due to retinitis pigmentosa-like changes. For years, the patient walked with support, but subsequently needed the use of a wheelchair. In an attempt to define the clinical characteristics of this condition, we compared data from published individuals and outlined a recognizable malformation pattern shared by our patients and that reported by van Gelderen (1982), thus delineating a unrecognized, likely rare alopecia-synostosis syndrome. The patients presented by Dumić et al. (2000) and Schell-Apacik et al. (2008) seemed affected by distinct disorders. Further molecular investigations are warranted to unravel the genetic bases of this condition.

J11.38
A new case of 8q21.11 microdeletion syndrome in a Mexican patient narrows the potential minimal critical region including the ZFHX4 gene

S. Martinez, **M. Ibarra**, *J. Lugo, D. Campos, L. Garza;*
Facultad de Medicina Universidad Autonoma de Nuevo León, Monterrey, Mexico.

The 8q21.11 microdeletion syndrome (OMIM: #614230) has been reported by Palomares et al in a series of 8 patients who presented a similar phenotype characterized by intellectual disability and common facial dysmorphic features that remarkably include round face, ptosis, wide nasal bridge, underdeveloped alae, short philtrum, cupid's bow of the upper lip, and downturned corners of the mouth. All patients comprised an overlapping loss of a 539.6kb that involves 3 genes: (1) the ZFHX4 gene which codes a transcription factor expressed in the adult human brain, skeletal muscle, and liver, (2) LOC10019232378 a miRNA with unknown function and (3) MRPL9P1 a pseudogene.
We report the case of a 4 year old Mexican female patient evaluated after presenting progressive hypotonia and global developmental delay accompanied with minor dysmorphic features sharing many of the characteristics previously described by Palomares et al. Array-CGH analysis was performed using probes for copy number and SNP on the Affymetrix CytoScan HD Platform with a resolution of 30kb for deletions and 60kb for duplications. The data were analyzed using the February 2009 NCBI human genome build 37.1(hg19) reporting a formula [hg19]8q21.11q21.13(77,751,515-83-,516,216)x1 indicating a microdeletion of 5.8Mb on chromosome 8q21.11-8q21.13 confirmed through FISH analysis using the probe (RP11-834L7).
The patient shares a deleted region of 14.7kb when compared with the previous series of 8 patients. Interestingly, this smaller overlap region includes the ZFHX4 gene narrowing the previously proposed minimal critical region for the development of the characteristic phenotype of intellectual disability and facial dysmorphic features.

46,XX,dup(18)(q12.2q21.1) associated with encephalocele, periventricular nodular heterotopia, ostium secundum atrial septal defect and dysmorphisms: report of a case

M. Artigas Lopez[1], *C. Catalli*[1], *M. Moreno Igoa*[1], *B. Hernandez Charro*[1], *A. Bengoa Alonso*[1], *M. Yoldi Petri*[2];
[1]*Genetics Department. CHN, Pamplona, Spain,* [2]*Neuropediatrics. CHN, Pamplona, Spain.*

We present the case of a 16 months old child who came to attention to our clinical genetics unit for psychomotor retardation. Pregnancy was unremarkable until 31 weeks, when echography detected a parietal tumor, for which C-section was planned at 38+1 weeks. Born small for dates, the physical exam showed a 3x4 cm soft mass, covered by skin, on the parietal suture and a bone defect around the lesion. Craneal sonogram and MRI revealed an encephalocele with periventricular nodular heterotopia of the left ventricle, thinning of the corpus callosum and slight dilatation of ventricles bilaterally. No other malformations except for a ostium secundum atrial sept defect were present. She had surgery at 11 days, when the encephalocele was sucessfuly resected. Neurologic follow-up showed mild retardation of milestones. At 16 months she was not able to walk autonomously but no gross neurologic deficit was noted. Physical examination revealed short stature with normal head circumference and dysmorphisms: prominent forehead, thelecantus, short neck, slight malar hypoplasia, bilaterally short fingers with clinodactyly of the 5th and very short and proximally placed thumbs. Karyotype was performed and a 46,XX,dup(18)(q12.2q21.1) was detected. The duplication was characterized by array-CGH involving 17.6Mb and 68 genes. At 2 years of age the patient shows good evolution with no other medical complications. Similarities and differences with trisomy 18 and other segmental duplications of chromosome 18 are discussed.

Background: Recent advances in molecular biology tools have enabled the identification of genes involved in rare disorders in families with small pe-

digrees. A Lebanese consanguineous family with 3 affected children was previously reported as presenting a newly individualized syndrome with neonatal spontaneous fractures, developmental delay, prominent eyes, generalised hirsutism, gum hypertrophy, and hepato-splenomegaly. Liver dysfunction was also observed and led to the early death of these patients.
Methods: To elucidate the genetic basis of this rare disease, a combination of genotyping and exome sequencing was performed.
Results: A homozygous missense mutation (NM_015909: c.C409T; p.R137W) was identified in the Neuroblastoma Amplified Sequence NBAS gene. The latter was already linked to a short stature syndrome with facial dysmorphism, optic nerve atrophy and leucocytes anomaly [MIM 614800]. A clinical comparison between both entities is discussed.
Conclusion: Here we report a newly described phenotype secondary to a NBAS mutation identified by exome sequencing in a Lebanese consanguineous family. Our paper expands the spectrum of disease linked to NBAS mutations and highlights the importance of exome sequencing in the delineation of the molecular basis of rare diseases especially when the clinical presentation is unclear.

J11.41

A *de novo* heterozygous *PLXDC2* variant is associated with a cerebellum-oculo-facio-skeletal syndrome.

P. Prontera[1], *V. Ottaviani*[2], *I. Isidori*[3], *D. Rogaia*[1], *A. Mencarelli*[1], *P. De Nittis*[2], *L. Micale*[2], *G. Stangoni*[1], *G. Merla*[2];
[1]*Medical Genetic Unit, University and Hospital of Perugia, Perugia, Italy,* [2]*IRCCS Casa Sollievo della Sofferenza, Medical Genetics Unit, San Giovanni Rotondo (FG), Italy,* [3]*Neurology Unit, University and Hospital of Perugia, Perugia, Italy.*

The Plexin Domain Containing Protein 2 gene (*PLXDC2*), located on the chromosome 10p12.31, encodes for a 529-aminoacid transmembrane protein expressed at high level in midbrain-hindbrain and cerebellum, and other tissues such as lung buds, heart, and spinal cord. In mouse model, functional analysis demonstrated that Plxdc2 acts as a mitogen for neural progenitors and as a receptor for Pigment Epithelium Derived Factor (PEDF), mediating many of its biological activities. Plxdc2 knock-out mice showed no obvious phenotype, whereas misexpression leads to severe alteration of neurogenesis during CNS development.
To date, any mutation in *PLXDC2* gene has been identified in human inherited disease.
Here we described a 6-year-old male patient showing a complex pattern of neurological and physical defects, including microcephaly, cerebellar atrophy, cataract, bilateral clubfeet, profound intellectual disability, and thorax deformity.
A trio-exome analysis disclosed a de novo missense variant in the *PLXDC2* gene. The variant is predicted to be deleterious from different bioinformatics tools, was not found in database of control individuals, and it leads to substitution of an evolutionally highly conserved aminoacid residue.
While the development of cellular and animal models will be necessary to prove the causality, we here discuss the potential role of the *PLXDC2* variant and the associated clinical condition, also with the aim to identify the potential phenotypes towards which extends the analysis of *PLXDC2*.

Rubinstein-Taybi syndrome (RSTS, # 180849, # 613684) is a rare disorder characterised by cognitive impairment and congenital anomalies. Mutations in two homologous genes CREBBP and EP300 are responsible for ~55% and~8% of RSTS patients, respectively. CREBBP mutational spectrum includes point mutations (30-50%) and deletions (~10%). We report 14 novel CREBBP deletions identified by FISH and MLPA in a cohort of 171 RSTS patients. By FISH we detected five large deletions (from 480 kb to 1.35 Mb), one encompassing only CREBBP, whereas the others four extending beyond the gene at both the 5' and 3' ends. The patients displayed a phenotype often indiscernible from those carrying CREBBP point mutations, although a slightly more complex clinical presentation was observed. By MLPA we identified nine deletions (from 930 pb to 154 kb): two affect a single exon, the other seven remove one/ many CREBBP exon/s and a region including TRAP1 gene and a part of SLX4. Among these patients, the phenotype ranged across the spectrum found in point mutations carriers. All 14 deletions, were validated by aCGH, and their breakpoints precisely mapped.

G-banding study of peripheral blood cells in newborn infants with congenital malformations in north west of Iran

s. manaflouyan khajehmarjany, *S. Rahmani;*
medical genetic lab, Tabriz, Iran, Islamic Republic of.

Background: According to the world health organization, the rate of major malformations in newborn infants is about 3 million in each year. Chromosomal abnormalities are common and the most important causes of congenital anomalies. Conventional cytogenetic is one of the most important techniques to diagnosis of recurrent chromosomal anomalies. The aims of this study are determination of incidence and patterns of Chromosomal abnormalities in newborn infants with congenital defects.
Materials & Methods: This study was conducted during one-year period (2013-2014). The participants were recruited from medical genetic laboratory, Tabriz, East Azerbaijan Province, Iran. We analyzed 110 Peripheral Blood (PB) samples from 110 infants with congenital defects by G-banding.
Results: Among the 110 analyzed samples, 53 (48.18%) had normal karyotype. Chromosomal abnormalities were observed in 57 (51.82%) babies. Forty eight showed to have Down syndrome with observation as; 47, xy/xx +21 (89.58%), 46, xx/xy-i(21q) (8.33%), 46, xy+ t rob (13; 21)(q10; q10) (2.08%). Out of 9 remaining infants with Chromosomal abnormalities, one had mosaic karyotype as (46, xx/47, xx+13), 2 (47,xx+ 22 del q (13qter)), 2 (46, xy, 9q (del), 2 (47,xx+18), and 2 male infants with female karyotype.
Conclusion: According to this study in the north west of Iran, the rate of chromosomal abnormalities in infants with congenital defects is 48.18%. And the most common chromosomal abnormality is Down syndrome. These findings show that chromosomal abnormalities, particularly numerical of them are one of the most important causes of congenital anomalies in newborn infants. Therefore, conventional cytogenetic is an essential technique to consideration of newborns with congenital defects.

The expression analysis of HMGA2 gene in uterine leiomyoma

M. Abbasi[1], *R. Mirfakhraie*[2], *M. Amin-Beidokhti*[2], *S. Irani*[1], *F. Akbari-Asbagh*[3];
[1]*Islamic Azad University, Science and Research Branch, Tehran, Iran, Islamic Republic of,* [2]*Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of,* [3]*Mirza Koochak Khan Hospital, Tehran, Iran, Islamic Republic of.*

Background: Uterine leiomyomas, the most common gynecologic tumors in women, are attended scientifically due to their high prevalence, irrecoverable complications, and their high therapeutic burden. Genetic factors are among the factors playing an important role in the initiation and progression of these tumors. A subset of uterine leiomyomas, shows chromosomal rearrangements of the region 12q15, leading to an over-expression of the high-mobility group protein A2 gene (HMGA2). The purpose of this study was to assess the HMGA2 gene expression in samples of uterine myoma in Iranian patients.
Methods: The gene expression analysis was performed using quantitative RealTime PCR on 49 tissue samples including, 39 uterine leiomyomas and 10 normal uterine tissues as control. The relative quantification was assessed using REST software 2009.
Results: HMGA2 gene was significantly over-expressed in 89% of the uterine leiomyomas compared to normal tissue. However, the gene was not expressed in 11% of the leiomyomas.
Conclusion: HMGA2 gene over-expression plays an important role in the formation of the majority of tumors. Although it is not the only reason for the tumor development and the role of other genes should be concidered.

Association between HIF and p53 in Endometrial cancer

l. .. kafshdooz[1,2], *A. Dastranj,T. Kafshdooz4;;*
[1]*medical university, tabriz, Iran, Islamic Republic of,* [2]*Women's Reproductive Health Research Center, Tabriz, Iran, Islamic Republic of.*

Background: Tumor suppressor p53, which shows many similarities to HIF-1 in terms of protein control by degradation, is predominantly involved in adaptation of cells to genotoxic stresses. p53 is a well-characterized transcription factor that plays a crucial role in responses to DNA damage, aberrant cell cycle control, apoptosis, and senescence. More than 60 target genes induced by HIF. In this study, we aimed to investigate the association between HIF-1 1772 C/T polymorphisms and polymorphism at codon 72 of Tp53 in endometrial cancer.
Materials and Methods: 75 patients with endometrial carcinoma and 75 patients whose underwent hysterectomy for non tumoral indication selected for evaluation of HIF-1 1772 C/T polymorphisms and mutations in exon 4 of the p53 gene by PCR-RFLP and sequencing.
Result: For the 1772 C/T polymorphism, the analysis showed that the T allele and genotype TT were significantly associated with endometrial cancer risk. In recent study, The rate of homozygote genotype of pro/pro or Arg/Arg in high grade group was higher than in comparison with low grade one. In addition samples that were undigested in RFLP, showed mutation in exone 4.
Conclusions: Our results suggest that the C1772T polymorphism of the HIF-1a and polymorphism at codon 72 of Tp53 may be associated with endometrial cancers. This report describes no mutual relations between p53 and HIF-1.

hRgr overexpression in human T-cell malignancy

B. Islek[1], *Z. Karakas*[2], *T. Soysal*[3], *M. Sayıtoglu*[1], *R. Suzme*[1], *U. Ozbek*[1];
[1]*Research Institute for Experimental Medicine, Department of Genetics, Istanbul University, Istanbul, Turkey,* [2]*Istanbul Faculty of Medicine, Department of Pediatric Oncology and Hematology, Istanbul University, Istanbul, Turkey,* [3]*Cerrahpasa Medical Faculty, Internal Medical Sciences Division, Department of Hematology, Istanbul University, Istanbul, Turkey.*

Introduction: The expression of dtr-hRgr (diseased truncated human Ral GDS Related) protein produced by abnormal transcript of hRgr which is only observed in T-cell neoplasms, can induce cellular transformation through the activation of Ras and Ral GTPases. In this study, we purposed to determine eventual differences between hRgr and dtr-hRgr expression levels in subtypes of T cell malignancies initiatively. Thus we generate perspectives on inhibiting dtr-hRgr as a future treatment in T-cell ALL.
Materials and Methods: Peripheral blood samples were obtained from patients with T-ALL and B-ALL. Human T and B cell lines were used as controls. Total RNA was extracted from peripheral blood samples with using trizol methods. Gene specific oligonucleotides were used for the abnormal hRgr and human GAPDH in qRT-PCR. Relative fold changes were calculated using the 2-ΔΔCt method.
Results: qRT-PCR analysis was performed and overexpression of the abnormal hRgr transcript is only observed in T-ALL derived cell lines (Jurkat, CEM) and in human tissues with T-cell malignancies.
Conclusion: In with the aggressive treatment the prognosis for relapse in childhood T-cell ALL remains poor. In this study we indicate abnormal expression of dtr-hRgr in T-cell ALL. In ALL treatment, molecular tests are important for risk classification at initial diagnosis. dtr-hRgr may be a potential target for therapeutic approaches in future treatment in T-cell ALL.

Autophagy gene ATG16L1 in gastric cancer

F. Burada, *N. Florescu, I. Streata, R. Nicoli, M. Ioana, D. Gheonea;*
University of Medicine and Pharmacy from Craiova, Craiova, Romania.

Gastric cancer remains a major global health burden, being the third leading cause of cancer death in both sexes worldwide. Recent evidence indicates the involvement of autophagy ATG16L1 gene in Helicobacter pylori infection and gastric carcinogenesis. Our study aimed to analyze the expression profile of ATG16L1 gene in gastric adenocarcinoma and to assess the possible association of ATG16L1 T300A (rs2241880) polymorphism with the risk of gastric cancer. A total of 350 Romanian subjects (108 patients with gastric adenocarcinoma and 242 healthy controls) were genotyped by allelic discrimination TaqMan-PCR assay with specific probes. ATG16L1 mRNA level was evaluated by qRT-PCR in biopsied tumoral and peritumoral tissue obtained by upper endoscopy from 34 patients. All genotype frequencies were distributed in accordance with Hardy-Weinberg equilibrium. A statistically significant association was observed for both AG and GG genotype carriers and furthermore, in a dominant model for carriers of G allele. Stratified analysis showed that the G allele of the ATG16L1 T300A polymorphism confers a protective effect, especially against non-cardia and intestinal type of gastric adenocarcinoma in the Romanian population. We found a tendency of increased expression of ATG16L1 in tumor samples when compared with the normal tissue. In conclusion, ATG16L1 T300A polymorphism may influence susceptibility to gastric cancer, mainly for the non-cardia and intestinal type in Eastern Europe. Our current research can improve the understanding of the autophagy pathway in gastric carcinogenesis.

Frequency of co-polysomy of chromosome1p and 19q in oligoastrocytomas

A. C. Kuskucu[1], *Z. Demir*[1], *F. Ozkan*[2], *I. D. Ekici*[2], *S. O. Coskun*[3], *O. F. Bayrak*[1], *U. Ture*[4];
[1]*Dept.of Medical Genetics, Yeditepe University Medical School, Istanbul, Turkey,* [2]*Dept.of Pathology, Yeditepe University Medical School, Istanbul, Turkey,* [3]*Department of Genetics and Bioengineering, Yeditepe University Faculty of Engineering and Architecture, Istanbul, Turkey,* [4]*Dept.of Neurosurgery, Yeditepe University Medical School, Istanbul, Turkey.*

Gliomas are the most frequent primary brain tumor of adults. Gliomas with oligodendroglial component (oligodendrogliomas) are relatively rare and associated with longer survival than astrocytic gliomas (astrocytomas). Cellular and morphological distinction between oligodendroglioma and astrocytoma can be subjective with inter-observer variability. It is well established the impact of co-deletion of chromosomes 1p36 and 19q13 in oligodenrogliomas. There is also a high incidence of 1p and 19q deletion in oligoastrocytic glial tumors (oligoastrocytomas). Co-deletion of 1p/19q is associated with a positive prognosis and survival. These deletions occurred in 60-70% of oligodendrogliomas and they are less common astrocytomas (about10-20 %). Based on our literature search and best knowledge, the frequency and impact of polysomy status for given chromosomes have not been deeply investigated.
In this study we have evaluated the polysomy status of 1p/19q in 45 paraffin embedded tissue of oligoastrocytomas by using florescent in-situ hybridization (FISH). Tumors were 33 oligoastrocytoma (OAs) WHO Grade II, 11 oligoastrocytoma WHO Grade III, and 1 glioblastoma multiforme with oligodendroglial component (GBM-O). We found 12 co-polysomy of chromosome 1p/19q in our series (26,66 %). 8 were belong to OAs WHO grade II (24,24 %) and 4 were belong to OAs WHO grade III (36,4 %).
However previous studies suggested that co-polysomy of chromosome 1p/19q has worse prognosis in oligodendrogliomas, there is no detailed information for astrocytoma or oligoastrocytomas. All of our cases were newly diagnosed therefore we don't have long-term follow-up data.

Karyotypic diversity in a patient with chronic myeloid leukemia treated with tyrosine kinase inhibitors and development of secondary acute myeloid leukemia

M. S. Dencic Fekete[1], *J. Jovanovic*[1], *V. Đorđević*[1], *B. Todorić-Živanović*[2], *S. Davidović-Mrsić*[3], *I. Franić*[3], *A. Bogdanović*[1];
[1]*Clinic of hematology, Belgrade, Serbia,* [2]*Militar Medical Academy, Belgrade, Serbia,* [3]*Clinical center Rebro, Zagreb, Croatia.*

Case report: We present a patient with Philadelphia-positive (Ph+) chronic myeloid leukemia (CML) who developed a resistance to therapy with imatinib mesylate which coincided with the appearance of t(5;6;12) in the Ph+ cells. Despite karyotype evolution, the patient remained in a chronic phase of CML and mutation analysis of kinase domain was negative. She was switched to Nilotinib, and her response fluctuated during the time. With continuation of nilotinib and its escalation to 800mg, she achieved major cytogenetic response (MCR) at 18 months (10% of Ph+ clone with t(5;6;12)), and complete cytogenetic response (CCR) after 24 months. Her further follow up showed stable CCR and MR3 for another three years. During this period, a Philadelphia negative (Ph-) clone with +8 appeared and persisted one year. After its disappearance, the patient developed neutropenia, without signs of anemia and thrombocytopenia but with elevated transaminases. Immediate bone marrow evaluation revealed dysplastic changes and 6% of blasts. Karyotype analysis revealed poor chromosome morphology with monosomy in C-group. By interphase fluorescence in situ hybridization (iFISH), monosomy 7 was detected. At the same time, the patient was negative for Ph chromosome and BCR/ABL fusion by both cytogenetic and iFISH analyses and was still in MR3. In another 6 months, she developed acute myeloid leu-

kemia and shortly after induction therapy, died.
Conclusion: The present case suggests the importance of the morphologic and karyotype follow-up of patients on TKI therapy even after achieving CCR.

J12.07

Nested Methylation Specific PCR for MGMT promoter methylation test in prediction of radiotherapy and alkylating agents based chemotherapy of Ewing sarcoma tumor

N. Cucu[1,2], *D. Nedelcu*[3,2], *C. Arsene*[2], *R. Talmaci*[4,2], *L. Burlibasa*[1], *V. Tandea*[2], *S. Arghirescu*[3], *M. Puiu*[3];
[1]*Genetics Department, University of Bucharest, Bucuresti, Romania,* [2]*Epigenetics Laboratory for Advanced Biomarkers, Bucuresti, Romania,* [3]*University of Medicine &Pharmacy Victor Babes, Timisoara, Romania,* [4]*Hematology Department-Molecular Biology Laboratory, Fundeni Clinic- "Carol Davila" Medical and Pharmaceutical University, Bucuresti, Romania.*

Introduction: MGMT (O6-methyl-guanine-DNA methyltransferase) is a protein with a specific enzyme activity that is involved in DNA repair. MGMT enzyme repairs DNA alkylation damage, introduced by classical chemotherapy, and also the double strand braking points introduced during radiotherapy. Epigenetic inactivation by promoter methylation of the MGMT gene is very well established. This gene is epigenetically silenced in a variety of cancers, especially glioblastomas, colon cancer, non-small cell lung cancer, gastric carcinoma, head and neck squamous cell carcinoma and also in Ewing sarcoma tumors.
Materials and methods. Ewing sarcoma tumors (2 specimens) were collected from diagnosed patients. Methylation specific (MS) PCR and Methylation specific MLPA methods were used for estimation of the MGMT transcription state through its promoter methylation pattern. Neste MSPCR was used instead of classical MSPCR in order to increase the sensibility and specificity of the method.
Results: The nested MSPCR gave better and clear results as compared with classical and MSMLPA methods. Certain specific conditions for optimization are described.
The Nested MSPCR method proved its efficiency in characterizing the methylation pattern of MGMT gene. The clinical significance of this estimation is linked with the repair capacity of the MGMT enzyme of the tumour damage introduced by classical (alkylating) chemotherapy and radiotherapy. The resistance of Ewing sarcoma tumors was correlated with the MGMT activity and nonmethylated state of its coding gene promoter.

Diagnostic panel for testing of germline mutations associated with breast and/or ovarian cancer in Russian population.

I. S. Abramov[1], *C. A. Dzhumakova*[2], *A. S. Tyulyandina*[2], *S. M. Portnoy*[2], *L. N. Lyubchenko*[2], *T. N. Nasedkina*[1];
[1]*Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, Russian Federation,* [2]*N.N.Blokhin Russian Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Genetically based breast and / or ovarian cancer is one of the most common forms of family
malignant tumors. Germline mutations in breast cancer are found in 10%, in ovarian cancer in 15% of cases. The routine biochip diagnostic for founder mutations in Russian Federation (185delAG, 300T> G, 4153delA, 4158A> G, 5382insC in BRCA1, 6174delT in BRCA2, 1100delC in CHEK) is commonly used. Additionally, the association of other mutations in NBS1, BLM, KRAS, TP53, PALB2 gene with the higher risk of BC/OC familial cancer has been found in the Slavic population. Also, many researchers have described new clinically relevant mutations in genes BRCA1, BRCA2, CHEK2. To optimize the genetic testing an improved diagnostic panel has been established, including also the following mutations: 2073delA, 3819delGTAAA, 3875delGTCT (BRCA1), 470T> C, IVS2 + 1G> A (CHEK2), R72P, IVS6 + 62G / A (TP53), rs61764370 (KRAS), 172_175delTTGT (PALB2), Q548X (BLM) and 657del5 (NBS1). Analysis of DNA samples of BC/OC patients in has shown the importance of these genetic markers for the Russian population. In addition, searching for new mutations BRCA1/BRCA2 in patients with familial form of BC/OC cancer was performed using the 454 technology (Roche). BRCA1/BRCA2 coding regions were amplified using the BRCA MASTR v2.1 Assay (Multiplicom). Two rare pathogenic mutations (rs80357433, rs80357123) were found in patients with bilateral BC. c.4689C>G mutation (rs80357433) forms a premature stop codon in the BRCA1 gene. The mutations were confirmed by Sanger sequencing. Further investigations using NGS may help in searching of new pathogenic mutations in Russian population.

J12.09

Investigation of the melatonin effect on apoptosis and differentiation in breast cancer stem cells

K. Nadir, *H. Donmez, H. Acar;*
Selçuk University, Selçuklu Medical Faculty,The Department of Medical Genetics, Konya, Turkey.

Introduction: Cancer is still one of the major health problems. Even though there are significant developments on the anti-cancer treatment, but 5-year survival rates were not significantly improved. In literature, it has been discussed that the main failure of treatment was related to cancer stem cell (CSC) behaviours due to many challenges in the targeted therapies. Melatonin and like chemicals have been used for different diseases. Some studies showed that melatonin is affective on cancer in different ways. However, there is no data about the effect of melatonin on CSCs in the literature. In the present study, we aimed to investigate the effect of melatonin on apoptosis and differentiation in breast CSCs *in vitro*.
Materials and methods: After appropriate treatment time and dose (IC50) were determined by using MTT, MCF7 breast cancer and HEK293 control cells were treated with melatonin. The effects of melatonin on apoptosis, number of CSCs and differentiation were evaluated by flow-cytometry with Annexin-V, CD44+/CD24- markers and MTT, respectively. In order to confirm the FACS results, apoptotic pathway target *BAX* ve *BCL-2* and CSC marker genes (*SOX2*, *NANOG* and *OCT4*) were analysed by using qPCR.
Results and conclusion: Melatonin increases apoptosis and differentiation in the MCF7 CSCs, but it decreases both in control. This result indicates that the effect of melatonin needs to be studied on the other pathways in order to clarify the therapeutic effect *in vitro* and *in vivo* experiments.
This study was supported by TUBITAK project # 113S478
Key words: Breast cancer, cancer stem cell, melatonin, apoptosis, differentiation

„Evaluation of BIOMED-2 Molecular Gene Rearrangement Protocols for Clinicopathological Diagnosis of Hodgkin Lymphoma"

s. ghorbian[1], *I. Jahanzad*[2], *G. R. Javadi*[1], *E. Sakhinia*[3];
[1]*Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Iran, Tehran, Iran, Islamic Republic of,* [2]*Department of Pathology, Imam Khomeini Hospital Complex, Medical Sciences / University of Tehran, Tehran, Iran., Tehran, Iran, Islamic Republic of,* [3]*Department of Medical Genetics, School of Medicine, Tabriz University of Medical Sciences, Tabriz, Iran, Tabriz, Iran, Islamic Republic of.*

Analysis of molecular clonality was performed by applying BIOMED-2 protocols to evaluate immunoglobulin gene rearrangements patterns in Hodgkin's Lymphoma (HL) cases). We implemented a standard protocol in HL cases, which have been previously suggestion for clonality detection on formalin fixed, paraffin-embedded (FFPE) tissue of non-Hodgkin lymphoma (NHL) patients.
We investigated 50 consecutive FFPE specimens of HL cases, which consisted of 43 cases of cHL and 7 cases of nodular lymphocyte-predominant¬¬ Hodgkin's lymphoma (NLPHL). Positive CD30, CD20, CD15, CD3, LCA and Facsin markers and IGH, IGK, IGH D-J, and IGL monoclonality in cancerous cells were evaluated using immunophenotyping, BIOMED-2 protocols and Heteroduplex analysis method.
Overall, our finding showed 94% (47/50) clear rearrangements in HL cases; consisting of 74% (37/50) in IGH, 70% (35/50) in IGK, 42% (21/50) in IGH D-J and 44% (22/50) in IGL. IGH clonality detection has related to positive CD30, CD15 ($P<0.005$) as well as LCA and Facsin population cells ($P<0.005$). In addition, the relationship between IGK clonality and CD20, CD3-positive population cells ($P<0.005$) were seen as statistically significant.
Analysis of clonal gene rearrangements in IGH and IGK genes using BIOMED-2 protocols could be implemented as a valuable method for increasing sensitivity (94%) and accuracy of HL similarly to NHL.

J12.11

Clinicopathological and genetic characteristics of breast cancer in Bulgarian women

Z. Kamburova[1], *K. Kovacheva*[1], *S. Popovska*[1], *I. Ivanov*[1], *M. Simeonova*[1], *D. Dimitrov*[1], *I. Petrova*[1], *P. Angelova*[1], *T. Deliyski*[1], *R. Dodova*[2], *D. Dacheva*[2], *A. Mitkova*[2], *V. Mitev*[2], *R. Kaneva*[2];
[1]*Medical University of Pleven, Pleven, Bulgaria,* [2]*Medical University Sofia, Sofia, Bulgaria.*

One in 14 women in Bulgaria will develop breast cancer (BC) during her life (age 75). Despite the advantages in therapy worldwide, prophylactic measurements are the only certain way of handle with this disorder. One of the well-recognized management tool is genetic screening for the main BC susceptibility genes (BRCA1 and 2). There are more than 3000 distinct

mutations in both genes and alterations are two types - point mutations and large genomic rearrangements (LGR).
Each population has specific clinical, histopathological and genetic characteristics of BC. The aim of our study was to investigate them among Bulgarian women with BC.
The total number of patients included in the study (recorded in the Cancer Registry of University Hospital, Pleven) was 176 women with BC, with average age at diagnosis 57 years. On the basis of preliminary selected criteria, 80 women (with average age at diagnosis 50 years) were referred for genetic testing of BRCA1 and BRCA2.
All of them (100 %) were screened for deleterious point mutations - two in BRCA1 (C61G, 5382insC) and three in BRCA2 (6079del4, 9326insA, 9908insA) and 89% for LGR.
The results of our study were: 20 (11%) of women showed familial BC, 21(13%) of them - early onset BC, 20 (13%) had TNBC and only four of them (2%) had bilateral BC. We found only one point mutation among selected patients - 5382insC in BRCA1 in 2, 5% and did not find LGR.
The established data were similar to the reported data for other European populations.

J12.12
Detection of Immunoglobulin IGH Gene Rearrangements on Formalin-Fixed, Paraffin Embedded Tissue in Lymphoid Malignancies

G. moharrami, *E. Sakhinia;*
Tabriz University Of Medical Science, Tabriz, Iran, Islamic Republic of.

Human lymphomas are aggressive malignant diseases, which can be categorized based on their B and T cell lineage. B-cell lymphomas form around 90% of the total lymphoma cases, whilst the remnants of malignancies arise from the T cell branch. Lymphomas are mostly characterized as clonal proliferations of specific tumor cells. The detection of malignant lymphomas are extensively investigated by their morphological features, immunohistochemistry and flowcytometric immunophenotyping, but in some cases remain unknown. The BIOMED-2 protocols were used to determine the clonality of IGH gene rearrangements in patients with lymphoma. PCR amplification was performed on FFPE of 50 patients with B-cell lymphoma, which consisted of 11 cases with HLs, 25 cases of B-NHLs and 14 cases of B-LPD (lymphoproliferative disorders) which were diagnosed as unclassifiable lymphoma. The rate of positive clonality was detected in 96% (24/25) of B-NHLs, whereas in 4% (1/25) of cases clonality was showed in a polyclonal pattern. In B-HLs, 82% (9/11) of cases showed clonality and 18% (2/11) of the cases showed polyclonality. (The rate of positive clonality observed was 64.3% (9/14) of cases with B-LPD and in 35.7% (5/14) of cases clonality was not detected in any of immunoglobulin gene family (FR1 , FR2 ,FR3). In groups with DLBCL, clonality was detected in 95% (19/20) of the cases) This makes no sense. In patients diagnosed with FL and MALTs, 100% of cases showed clonality for complete IGH. Our study revealed that Euro Clonality BIOMED-2 protocols could be considered as a valuable and reliable method for clonality detection, especially in IGH analysis.

J12.13
upregulation of stanniocalcin1 gene expression in colorectal cancer

s. rezapour[1], **E. sakhinia**[1], *S. Hashemzadeh[1], M. Nemati[2], R. Dehghan[2];*
[1]Tabriz university of medical science, Tabriz, Iran, Islamic Republic of, [2]Tabriz university, Tabriz, Iran, Islamic Republic of.

Introduction: Identification of the genes involved in the carcinogenesis of the colorectal cancer could be useful for identifying of diagnosing biomarkers and improvement of treatment. Stanniocalcin1 is a glycoprotein hormone that is known to be involved in various biological function especially calcium hemostasis.Its upregulation has been shown with various cancers in several studies however its main role is not clear in cancer progression. In this study we assessed the expression of STC1 gene in colorectal cancer for the first time in Iran.
Material and methods: Tumor tissues and adjacent tissues were obtained from 48 colorectal carcinoma patients who undergone partial or total colectomy for CRC. The relative expression of STC1 was measured by using quantitative RT-PCR. GAPDH was used as a housekeeping gene. The Relative Expression Statistical Tool (REST) and SPSS software were applied for data analysis.
Results: Relative mRNA levels of STC1 were significantly higher in tumor tissues in comparison with margins (p value =0.025).
Conclusion: Our results showed that STC1 gene expression significantly increases in tumor tissues and therefore, it may be helpful as a molecular biomarker for early diagnosis of CRC.

J12.14
The EGFR mutational status screening in Romanian lung adenocarcinoma patients

P. APOSTOL[1], *F. Iordache[1], R. Motoc[1], M. Gongu[2], G. Cardos[1];*
[1]Personal Genetics, Medical Genetics Center, BUCHAREST, Romania, [2]OncoFort Hospital, BUCHAREST, Romania.

The personalized medicine (tyrosine-kinase inhibitors-TKI) represents an alternative to the advanced lung cancer patient's healthcare. Nowadays, the screening of the EGFR gene (which codifies a protein-kinase), has become a TKI-therapy selection tool. In non-small-cell lung carcinomas, the TKI-therapy response depends, additionally, on hystopatological subtype, the most suitable being adenocarcinoma (ADK).
The study aim was to analysis the EGFR mutational status in ADK patients which makes them susceptible for EGFR TKI-therapy.
DNA was extracted from formalin-fixed paraffin embedded tumor tissues (85 biopsies and 222 resections) from 307 Caucasians patients in different ADK stage (185M:122F, enrolled from December 2013-February 2015). EGFR mutations screening (exons 18-21) was performed by PCR reverse-hybridization (n=144) and ARMS-PCR (n=163).
EGFR mutations were detected in 50 (16,29%) patients (35 with primary and 15 with secondary tumors, mostly TTF-1 positive, tumor cell between 90% - 0,5%, sex distribution of 1M:1.39F, patients age 35-87 year old, average age at screening time-61,17±10,15). The most frequent mutations, which confer sensitivity to TKI therapy, were identified in exons 19 (62%) and 21 (24%). Less frequent were detected mutations in exon 18 (G719S) (6%), and the compound mutation p.E746_A750del/p.L858R (2%). The resistance mutation T790M (exon 20) was detected in 3 cases, in singlet (2%) or doublet condition (4%). The mutation T790M/EGFR-sensitive denotes acquired resistance post TKI-therapy (erlotinib), both high-stage ADK women having a progressive disease evolution.
Our results, in accordance with international data, showed that the EGFR mutational status detected by PCR-based method screening is a sensitive and helpful tool for the clinical decision in the ADK anti-EGFR personalized therapy.

J12.15
Discordance of HER2 status in primary breast carcinomas and distant metastatic sites

G. C. COZARU[1], *M. Aschie[2], A. F. Mitroi[1], G. I. Bălțătescu[1], C. Brinzan[1], I. Poinareanu[1];*
[1]Constanța County Emergency Hospital, CONSTANTA, Romania, [2]Medicine Faculty of „Ovidius" University, CONSTANTA, Romania.

Background: Assessment of human epidermal growth factor receptor 2 (HER2) status in patients with breast carcinoma (BC) is commonly performed using neoplastic tissue from the primary tumor. There are few data regarding the HER-2 status in the corresponding distant metastases. Several papers have shown that HER2 status may be different in metastatic lesions when compared with the primary tumor, and this discrepancy is more frequently found in distant metastases than in locoregional ones.
Methods: HER-2 status in 47 patients with a primary breast tumour (at different time of therapy stages) and at least one distant metastatic (bone, brain, lung, liver, or other) lesion was analysed by immunohistochemistry (IHC) and chromogenic in situ hybridization (CISH).
Results: The overall concordance rate for HER2 was 91.48%. Thirty-four cases were concordantly HER2-negative in primary BC and distal metastases, nine cases were HER2-positive in both primary and metastatic tumors, and 4 cases were discordantly HER2-positive in the primary BC and HER2-negative in the metastases.
Conclusion: Simultaneous determination of HER2 in BC and corresponding distant metastases is not mandatory, but may influence the therapeutic management. Discordance in HER2 status may be found not only between primary BC and its metastases, but also between consecutive relapses of the same tumor.

Hypermethylation of KISS1 and EDNRB promoters as predictors of disease progression in patients affected with sporadic colorectal cancer

r. mousavi[1], *E. Sakhinia[1], S. behrouzsharif[1], L. teimoori toolabi[2], S. Hashemzadeh[1], M.*

zadi heydar-abadi[1];
[1]tabriz university of medical science, tabriz, Iran, Islamic Republic of, [2]Pasteur Institute of Iran, tehran, Iran, Islamic Republic of.

Background & objective: The incidence of Colorectal Cancer (CRC) is increasing rapidly world-wide, especially among the ageing. This sentence makes no sense (The accumulation of genetic and epigenetic changes are primarily occur in CRC, here on, the methylation profiles are altering in promoter KISS1 and EDNRB genes). In many cancers, KISS1 and EDNRB act as metastasis suppressor and tumor suppressor genes, respectively. This study aimed to examine the promoter hypermethylation status of KISS1 and EDNRB genes for predicting CRC progression.
Materials & methods: Total DNA was extracted from 45 paired fresh CRC samples and adjacent normal tissue, and then treated by bisulfite. Finally, DNA methylation status of KISS1 and EDNRB genes were determined by using the Methylation-Sensitive High-Resolution Melting method (MS-HRM).
Results: Primary data in this study showed that there are statistically significant differences in the methylation status of KISS1 gene between CRC samples and adjacent normal tissue (p-value=0.03). However, we observed no significant association in promoter methylation of the EDNRB gene (p-value=0.1).
Conclusion: KISS1 promoter hypermethylation might be a candidate biomarker for predicting CRC progression. Furthermore, to determine the use of EDNRB promoter hypermethylation as a predictor, other studies with more samples are necessary.

J12.17
Molecular analysis of the expression of miR-221 in tumor and marginal tissues of breast cancer patients

A. Abak[1], *E. Sakhinia[1], E. Babaei[2], S. Amini[1];*
[1]Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, [2]Tabriz University, Tabriz, Iran, Islamic Republic of.

Identification of biomarkers is important not only for cancer diagnosis, prognosis and treatment, but also in providing new insights into cancer biology. The aim of this study was to evaluate the clinical significance of miR-221 in patients with breast cancer. The miR-221 has been demonstrated to function as an oncomiR in human cancers. miR-221 promotes epithelial-to-mesenchymal transition (EMT) and confers tamoxifen resistance in breast cancer. However, the effects and mechanisms by which miR-221 regulates breast cancer aggressiveness remain unclear. The real-time reverse transcription-polymerase chain reaction was used to examine miR-221 levels prospectively in 40 pairs of samples of breast tumor tissue and adjacent noncancerous tissue. In addition, the relationship between miR-221 levels and clinicopathological features was explored. The capability of miR-221 to function as a tumor marker was also examined. miR-221 expression levels showed significant changes overall. However, miR-221 was significantly upregulated in a group of breast tumor tissue samples compared with matched noncancerous tissue samples.
We consider that miR-221 act as promising biomarkers for breast cancer and it would offer a new way in molecular targeting cancer treatment. Therefore, miR-221 may contribute to the aggressive clinical behavior of basal-like breast cancers.

J12.18
Molecular analysis of the expression of microRNA-222 in tumor and marginal tissues of breast cancer patients

s. amini[1], *e. Sakhinia[1], e. Babaei[2], a. abak[1];*
[1]Tabriz University of Medical Science, Tabriz, Iran, Islamic Republic of, [2]Tabriz University, Tabriz, Iran, Islamic Republic of.

Breast cancer is a common malignancy and a leading cause of mortality due to cancer among woman. About 1.3 milion females develop breast cancer each year. microRNAs are small noncoding RNAs that regulate genes at post transcriptional level. Misexpression of miRNAs have been associated with tumorogenesis in various cancers including breast cancer . Emerging evidence has shown associations of microRNA-222 (miR-222) with crucial cell processes such as the epithelial-mesenchymal transition (EMT) and aberrant expression with tumorogenesis in many types of human malignancy. the aim of this study was to evaluate the clinical significance of miR-222 in patient with breast cancer. This study characterized the contribution of miR-222 to the breast cancer(BC) tumorogenesis. We evaluate the expression level of miR-222 in marginal and tumor tissue of 40 breast cancer patients using real time- PCR. miR-222 was significantly upregulated in tumor tissues compared with noncancerous tissue samples. Therefore, targeting miR-222 and its activators might be a promising therapeutic option to prevent malignant progression toward metastasis.

Complex translocation involving Philadelphia chromosome in a patient with chronic myeloid leukemia

M. Stoian[1,2], *C. Ionescu[1], R. Manolache[3], G. Mocanu[3], S. Dinu[1], P. P. Apostol[1], G. Cardos[1];*
[1]Personal Genetics-Medical Genetics Center, Bucharest, Romania, [2]Discipline of Medical Genetics, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania, [3]Coltea Hospital, Hematology Clinic, Bucharest, Romania.

The Philadelphia (Ph) chromosome is the cytogenetic marker in chronic myeloid leukemia (CML). However, about 5-10% of Ph positive patients with CML show variant translocations. We describe a patient with CML with a rare translocation between chromosomes 9, 10, 18 and 22. The patient is a 64 years old male diagnosed in 2004 with CML in blast phase. The patient had multiple hospitalizations and showed resistance to various therapies. In January 2014 we performed cytogenetic and molecular analysis in our laboratory. Molecular testing identified a molecular response of 62.69% of the BCR-ABL fusion transcript. Because of the patient's therapy resistance we performed molecular testing for the detection of mutations in the BCR-ABL1 transcript in the region corresponding to the BCR-ABL1 TK protein. The c.951C>A mutation was detected corresponding with the p.F317L phenotype associated with resistance to treatment with certain tyrosine kinase inhibitors. Conventional cytogenetic analysis at a 350 bands resolution initially revealed a 46,XY,t(9;10;22)(q34;q22;q11) karyotype in all the analyzed metaphases. To better characterize this translocation we performed a metaphase FISH analysis with BCR-ABL1 probes (MetaSystems). This revealed the involvement of the short arms of chromosome 18 in the complex translocation, as confirmed later by adding the centromeric probe for chromosome 18.
The formation mechanisms of these translocations, and their clinical significance is still unclear, and resistance to therapy of patients with these complex translocations remains to be studied.

Polymorphism of p53 Gene Codon 72 in Endometrial Cancer: Correlation with Tumor Grade and Histological Type

t. kafshdouze pourpolsangy, *a. dastranj tabrizi, l. kafshdooz;*
medical faculty, tabriz, Iran, Islamic Republic of.

Background: Endometrial cancer is the fourth most common cancer among women in developed countries. Patients with endometrial cancer may benefit from systemic chemotherapy alone or in combination with targeted therapies if the disease is clinically diagnosed prior to spread and metastasis to other organs. The aim of this study was to evaluate the prognostic role of p53 polymorphism and its correlation with tumor grade in human uterine endometrial carcinomas. Materials and Methods: A total of 75 patients with endometrial carcinomas were studied for possible mutations in exon 4 of the p53 gene using polymerase chain reaction and restricting fragment length polymorphism techniques and sequencing. Results: In recent study, The rate of homozygote genotype of pro/pro or Arg/Arg in high grade group was higher than in comparison with low grade one. In addition samples that were undigested in RFLP, showed mutation in exone 4. Conclusions: Our findings showed that high grade endometrial carcinomas are highly associated with TP53 polymorphisms in comparison with low grades.

Isochromosome14q ıs a non-random cytogenetic abnormalıty ın MDS

A. Ugur Bilgin[1], **T. Akin Duman**[2], *M. S. Yildirim[2], A. G. Zamani[2], S. Demirci[1];*
[1]NECMETTIN ERBAKAN UNIVERSITY MERAM MEDICAL FACULTY,DEPARTMENT OF HAEMATOLOGY, KONYA, Turkey, [2]NECMETTIN ERBAKAN UNIVERSITY MERAM MEDICAL FACULTY,DEPARTMENT OF GENETIC, KONYA, Turkey.

Myelodysplastic syndromes(MDS) are heterogenous group of clonal disorders characterized by dysplasia in one or more myeloid cell lineages, inefficient hematopoiesis, peripheral cytopenies and an increased risk of transformation to AML. MDS frequently occurs in adults, particularly the elderly. The annual incidence of MDS is about four cases per 100.000 people. Cytopenia(s), bone marrow morphology and cytogenetics are central to the diagnosis of myelodysplastic syndrome.
The presence of isolated gain of a chromosome is reported in 6-7% of human malignancies; the most common of which in myeloid neoplasms are chromosomes 8, 9, 13, and 21. Trisomy 14 (trisomy 14 or isochromosome 14) as the sole cytogenetic abnormality is rather uncommon and has been reported in myeloid disorders such as MDS, myeloproliferative disorders, atypical chronic myeloid leukemia and AML.
A 60-year-old female who had a history of chronic kidney disease with

amyloidosis had been hospitalizated for haemodialysis ten months ago. She was consulted to haematology for anemia and reduced white blood cells and neutrophil. The bone marrow biopsy was hypercellular and revealed eritroid dysplasia. Her bone marrow cytogenetic analyses was normal. The patient was diagnosed as MDS. Seven months later rebiopsy was performed. Bone marrow karyotype was as 46,XX,i(14)(q10) [4]/46,XX[8] and AML-MDS FISH panel was normal. Patient is stil being followed.
The clinicopathologic futures and prognostic importance of trisomy 14 has not been well described so that we report this case in order to contribute the literature.

Multidisciplinary Consultative Meetings for breast monitoring of femals who have a high risk of developping breast cancer in France : evaluation of strenghts and weaknesses, proposition of improvement

F. Gillmann, *C. Cordier, C. Maugard, C. Mathelin;*
Hopital Civil, Strasbourg, France.

The French National Cancer Institute published in its annual report of 2013 (Summary of 2013 oncogenetic activity - Consultations and laboratories, dec 2014) that there are more than 40.000 patients in France with a mutation implicate in hereditary predisposition of cancer, including more than 17.000 concerning BRCA gene.
Since its renewal mission in 2012, the French National Cancer Institute supports 17 projects to promote breast and ovarian monitoring for femals who have a high risk of developping breast cancer .
Four main missions are to be conducted: 1) develop an individualized monitoring of people hereditarily predisposed to cancer; 2) coordinate their breast and ovarian monitoring in regional or interregional level; 3) ensure and facilitate access to multidisciplinary skills, either within the institution (or institutions) holder of the project, or outside; 4) ensure resort activity and expertise for difficult cases.
We initiated a questionnaire to assess in France the faisability to the fourth mission. We sent a link to an online survey to french oncogeneticists thanks to a mailing list. The first part of the survey evaluates the expanded and modalities of implementation of the Multidisciplinary Consultative Meetings. The second part evaluates the interest of the development of these Multidisciplinary Consultative Meetings.
The aim of this article is to identify strenghts and weaknesses of these Multidisciplinary Consultative Meetings and to propose improvement.

J12.23

Study the genetic and epigenetic biomarkers in Iranian patients with colorectal cancer (CRC) in comparison with normal individuals

N. Bazazzadegan[1], *H. R. Khorram Khorshid*[1], *M. R. Zali*[2], *H. Asadzadeh Aghdaei*[3], *E. Nazem- alhosseini Mojarad*[2], *S. Savabkar*[2], *S. Shahrokh*[2], *M. Iranshahi*[2], *B. Hatami*[2], *L. Alizadeh*[2], *H. Abedi*[2], *P. Azimzadeh*[2], *F. Khorshidi*[2], *M. Y. Taleghani*[2];

Colorectal cancer (CRC) is the third most common cancer worldwide. CRC develops with progressive accumulation of genetic mutations. Stool DNA test as a non-invasive test, has high sensitivity and specificity for diagnosis of cancerous and pre-cancerous lesions and is associated with more acceptability of patient than invasive tests. Tumor shedding cells contain genetic markers which have significant role in CRC diagnosis. No single molecular marker has been recognized and validated for detection of all types of colorectal cancers. The aim of this survey is to study the genetic and epigenetic markers in colorectal cancer patients and comparison with control individuals to reach a multi-markers panel with reasonable sensitivity and specificity.
Colonoscopy is performed on patients with sporadic CRC and control individuals, after obtaining consent form and questionnaires. From all patients, stool, tumoral and normal tissue (or blood) and from all control, stool and blood are taken. Following DNA extraction from stool, tissue and blood, the samples are subjected for *Kras*, *BAT-26*, long DNA and *Vimentin* markers detection. Finally all markers (individually or in combination) are used to calculate the sensitivity and specificity of the test.
So far samples from 13 CRC and 48 control individuals have been collected. DNA from all tissue and blood samples were extracted and quantified. Long DNA detection was optimized in stool DNA. *BAT-26* detection is optimizing in blood and tissue DNA. Sample collection and optimization of other markers is underway.
Keywords: Colorectal cancer, molecular marker, Iran

CAT, *GPX1*, and *GSTP1* genetic polymorphisms and the risk of acute myeloid leukemia in Romanian patients

C. Banescu[1], *A. Trifa*[2], *V. Moldovan*[3], *I. Macarie*[3], *E. Benedek Lazar*[3], *F. Tripon*[3], *A. Crauciuc*[3], *C. Duicu*[3], *M. Dobreanu*[3];
[1]*Department of Genetics, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [2]*Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania, Cluj napoca, Romania,* [3]*University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.*

Reactive oxygen species (ROS) are associated with oxidative damage at the DNA level and thus may lead to genomic instability and to an increased the risk of developing malignant hemopathias.
Catalase (CAT)and glutathione peroxidase (GPX) are implicated in the defence mechanisms against oxidative stress.
Glutathione S-transferases (GST) enzymes, are responsible are by detoxification for the xenobotics' and thus protecting against oxidative damage produced by high levels of ROS.
The purpose of our study was the investigation the relationships between namely CAT C262T, GPX1 Pro198Leu as well as GSTP1 Ile105Val polymorphisms and the risk of acute myeloid leukemia (AML).
Genotyping of the mentioned polymorphisms were based on a multiplex polymerase-chain-reactions and restriction fragment length polymorphism (PCR-RFLP) methods in 100 AML patients and 200 healthy controls. We observed that variant genotypes of CAT C262T gene polymorphism were not associated with the risk of AML. Our findings showed that the variant homozygous genotypes of GPX1 Pro198Leu and GSTP1 Ile105Val polymorphisms were associated with an increased risk of developing AML ($p<0.0001$, $p=0.012$). The combined variant genotypes of all three investigated polymorphisms were analyzed in relation to FLT3 and
DNMT3A gene mutations. No significant associations between investigated polymorphisms and these parameters (p-value > 0.05)were found.
In conclusion, our data suggests that GPX1 Pro198Leu and GSTP1 Ile105Val variants seem to have an important role in development of AML.

der(19)t(1;19) in Childhood Acute Lymphoblastic Leukemia Patient

E. Pariltay[1], *E. Karaca*[1], *A. Aykut*[1], *B. Durmaz*[1], *B. Akinci*[2], *Z. Sivis*[2], *D. Karapinar*[2], *H. Akin*[1], *O. Cogulu*[1];
[1]*Ege University Faculty of Medicine Department of Medical Genetics, Izmir, Turkey,* [2]*Ege University Faculty of Medicine Department of Pediatric Hemetology, Izmir, Turkey.*

t(1;19)(q23;p13) comprises approximately 5% of the translocations observed in childhood and adult acute lymphoblastic leukaemias (ALLs). It occurs either balanced t(1;19) or unbalanced der(19)t(1;19) where the TCF3/PBX1 fusion protein is associated with pre-B cell immunophenotype in both situations. Here we present 4 years old girl who was referred because of weakness and bone pain. She had hepatosplenomegaly and ecchymosis lesions at lower limbs. After routine laboratory investigations and flow cytometry she was diagnosed as pre B ALL. Fluorescence in situ hybridization (FISH) analysis at diagnosis revealed mosaic pattern which included 35% of balanced t(1;19) and 16% of unbalanced der(19)t(1;19). Following ALLIC BFM 2002 treatment protocol control FISH analysis was revealed chromosomal constitution normal. However 21% of der(19)t(1;19) was detected before reinduction therapy. She is still receiving maintenance treatment which is planned to continue for 6 months. Literature search revealed that derivative chromosome 19 is more common than balanced t(1;19). In conclusion here we present a further pre B ALL patient which is characterised by an interesting shifted translocation pattern with good prognosis.

J12.26

EMT gene expression signature in colorectal cancer with liver metastatic or peritoneal carcinomatosis

V. P. Shubin, *Y. A. Shelygin, A. S. Tsukanov, A. A. Ponomarenko, E. G. Rybakov, O. A. Maynovskaya, O. I. Sushkov, S. I. Achkasov, N. I. Pospekhova;*
Ministry of Health / State Scientific Center of Coloproctology, Moscow, Russian Federation.

Aim
Colorectal cancer (CRC) has been considered a molecularly heterogeneous disease. Investigation of gene expression signature in CRC is an effective approach for prognosis of disease. The analysis of EMT (epithelial- mesenchymal transition) program classifies colon tumors on two molecular subtypes: epithelial and mesenchymal.
Methods

We investigated 38 patients with colon or rectal cancers T3-4N0-2cM1. The gene expression signature (5 genes) was studied to 8 tumor samples and its liver metastatic (MTS), as well 20 tumor samples and its peritoneal carcinomatosis nodules (PC) by RT-PCR.
Results
Samples were characterized as mesenchymal subtype if detected: high level of ZEB1, ZEB2, VIM, SFRP2 and low level of CDH1. Tumor of mesenchymal subtypes were found in: 1 of 18 and 8 of 20 samples with liver MTS and PC, respectively. However, its MTS node was not mesenchymal phenotypes, whereas all of eight PC nodules had been mesenchymal subtypes. Concordance epithelial phenotype between tumors and nodules were observed for 12 and 3 samples with MTS and PC, respectively. Finally, five of 18 MTS and 9 of 20 PC nodules were corresponded to mesenchymal subtypes.
Conclusion
Our data confirm the notion that the occurrence and development of liver MTS and PC are different by the pathogenetic mechanism.

Study of the correlation between p53 Arg72Pro and MDM4rs4245739 - Polymorphisms and Breast Cancer among Iranian-Azeri population

N. Pedram;
tabriz university of medical sciences, Tabriz, Iran, Islamic Republic of.

Abstract
Background: Breast cancer is a clinically heterogeneous and complex disorder and its transformation can occur in different shapes which may be manifested as identical clinicopathologic indices. MDM4 is a negative regulator of the p53 tumor suppression pathway. Different researchers have revealed that the rs4245739A>C polymorphism of MDM4 in 3-untranslated regions makes it a miR-191 target site which leads to lower MDM4 expression. On the other side, the importance of Arg72Pro polymorphism of p53 in breast cancer has been proven. The aim of this study was to therefore realize the correlation of these SNPs and the risk of breast cancer in East-Azerbaijan, Iran.
Methods: 199 healthy controls and 206 women with breast cancer from Eastern-Azerbaijan, Iran were included. Tetra-ARMS PCR was employed in order to detect alleles of both positions. SPSS for Windows (version 22.0, IBM SPSS Inc., USA) and the SHEsis online software was exerted for allele typing, genotyping and haplotype analysis.
Results: Different alleles of both MDM4 rs4245739 and p53 Arg72Pro had no significant frequency in cases when compared to the control (P>0.05). Also, genotypes of neither MDM4 rs4245739 nor p53 Arg72Pro were shown to increase or decrease breast cancer risk in patients in comparison to healthy women. Gene-gene interaction also could not significantly affect the risk of breast cancer.
Conclusion: Our ungoing study revealed that two genetic variants, MDM4 rs4245739 and p53 Arg72Pro polymorphisms failed to be associated, alone and in their combination, with the risk of breast cancer development in Iranian-Azeri Patients. However, additional well-designed studies on larger populations are required to validate this association

J12.28
Verification of influence of C1236T (rs1128503) polymorphism in the ABCB1 gene in chemotherapeutic response and clinical variability in the breast cancer

R. W. Vencatto, *C. M. Dutra;*
UNICAMP, Campinas, Brazil.

Introduction: Different polymorphisms in genes involved in the metabolism of drugs, has been evaluated and associated in the response to chemotherapy. Among the genes, *ABCB1*, with important function of efflux drug, has been studied. In the gene, the C1236T polymorphism (rs1128503) has been evaluated and presented intriguing results, including in the breast cancer. The objective of the present study was to associate the response to chemotherapy in patients with breast cancer and the clinical variability of the disease with the C1236T polymorphism in the *ABCB1*gene
Material and methods: The study enrolled 100 female patients with breast cancer. The clinical markers included were: race, use of oral contraceptive, breastfeeding, hormone replacement therapy, smoking, alcoholism, hypertension, diabetes mellitus, histological type, histological and nuclear grades, tumor classification by TNM, clinical stage, radiation therapy, hormone therapy, patient status, age, menarche, menopause, age at first live birth, height, weight, estrogen and progesterone receptors, and chemotherapy. **Results and discussion:** For genotypic analysis, the polymorphism was in Hardy-Weinberg equilibrium (p>0.05). In the present study, we found no association of the polymorphism analyzed with the clinical presentation of patients with breast cancer, except for race (Caucasian versus non-Caucasian) patients, however there was no positive oddsratio after the data correction. However, there was no association with response to chemotherapy used in patients followed in our center. In conclusion, in this study, the C1236T polymorphism was associated with patient's race, time to onset of menopause and the percentage of progesterone receptors in patients with breast cancer.

J12.29
Prognostic and predictive significance of the bcl -2/IgH translocation in malignant follicular lymphomas

M. NEAGU;
Nationale Institute of Pathology Victor Babes, Bucharest, Romania.

In Europe, follicular lymphomas constitute up to 30% of non-Hodgkin lymphomas.
Prognostic markers, identified by 2 different working groups, immunohistochemical (CD10, bcl 2 positivity) and molecular the bcl 2/IgH hybrid gene, the t(14;18)(q32:q21.
The aim of our study was to analized the cytogenetical aberrations in malignant follicular lymphomas, in order to identify the prognostic and predictive value of bcl2-2/IgH translocation in these malignancies.
Material and method:
We conducted a study on 79 patients with follicular lymphomas. The study was carried out on tissue samples selected from the "Victor Babes" National Institute of Pathology files. These samples were formalin-fixed paraffin embedded-tissues, routinely processed for histology.
The t(14;18) translocation, realized by the bcl 2/IgH rearrangement, supposedly occurs in almost all follicular lymphomas (FL) can be detected by FISH methods
We employed the PathVysion LSI IGH Spectrum Green/ LSI bcl2 Spectrum Orange (VYSIS) kit.
Results:
Asingnificant positive correlation was found between the IHC positivity for bcl 2 and the FISH detection of t (14;18) translocation (p=0,04).
Twenty two cases were selected for FISH analysis, five cases were excluded because of the processing artifacts , ten of the 17 cases without artifacts (58.8 %) presented t(14:18) translocation: two cases of FL grade 1-2, two cases of FL grade 1, six cases of FL grade 3.
In 66.6% of cases with t(14;18) translocation, the immunohistochemical reaction for bcl 2 protein was positive.
Bcl2 t(14;18) translocation plays an important role in the pathogenesis of follicular lymphoma, and is an important tool in the diagnosis and treatment.

J12.30
NTRK3 and SEPT9 promoter hypermethylation in patients with sporadic colorectal cancer can act as early diagnostic biomarkers

S. Behrouz Sharif, *E. Sakhinia, R. Mousavi, S. Hashemzadeh;*
Tabriz University of Medical Science, Tabriz, Iran, Islamic Republic of.

Background & objective: Colorectal cancer (CRC) is one of the most common malignancies and the third leading cause of cancer mortality worldwide. Timely detection of CRC in patients in the earlier stages of disease provides the highest rate of survival. Epigenetic alterations which play a significant role in tumorogenesis are prevalent among CRC patients and represent as the primary modifications of cancer cells, therefore, these alterations are thought to hold great promise as tumor biomarkers. It has been shown that NTRK3 and SEPT9 gene promoters are hypermethylated and can be used as biomarkers for early detection of CRC. In this study we analyzed promoter methylation status of these genes' in CRC patients.
Materials & methods: Genomic DNA was extracted from 45 CRC and paired adjacent normal tissues and undergone bisulfite conversion. Finally, the methylation status of NTRK3 and SEPT9 were defined with the Methylation-Specific High-Resolution Melting (MS-HRM) method.
Results: Our results showed that there are statistically significant differences in the methylation status of NTRK3 and especially SEPT9 between CRC and adjacent normal tissues (p-value=0.05 and 0.02 respectively).
Conclusion: SEPT9 promoter hypermethylation might play a role as a trusted biomarker for detection of CRC development; however, to validate the biomarker potential of NTRK3 there is a substantial need for further investigations.

J12.31

VEGF gene expression level in tumor and non tumor colorectal tissues

F. Mohammad Rezaei[1], *S. Hashemzadeh[1], L. Rostamizadeh[1], N. Pouladi[2], p. kheiroddin[1], M. Hossein Pour Feizi[3], E. Sakhinia[1];*

[1]Tabriz University of Medical Sciences, Tabriz, Iran, Islamic Republic of, [2]Azarbaijan Shahid Madani University, Tabriz, Iran, Islamic Republic of, [3]Tabriz University, Tabriz, Iran, Islamic Republic of.

Colorectal cancer (CRC) is one of the most lethal malignancies in the world. It is the third most common cancer and a leading cause of cancer-related death. There has been much interest in the development and use of molecular-based research aimed at identifying biomarkers for the diagnosis of the disease. Vascular endothelial growth factor (VEGF) has a crucial role in tumor angiogenesis and is found to be overexpressed and involved in the development and progression of CRC. Moreover, its over-expression is frequently considered as a marker of both, a poor prognosis and of an aggressive tumor phenotype. Thus, the aims of this study were to quantitatively examine the expression of VEGF in tumor and marginal tissue in CRC and to correlate their expression levels with clinico-pathological variables. Human colorectal cancer tissues (n=45) and non-tumor (marginal) tissues (n=45) which were all pathologically diagnosed, were obtained after surgery. After RNA extracting from frozen pieces for gene amplification, the expression of VEGF were assessed using Real-Time PCR subsequently after cDNA synthesis by polyA RT-PCR. VEGF expression was significantly raised in the tumor than in the non-tumor tissues ($P < 0.005$). And its expression was lower in patients with stage I than in patients with higher clinical stages. In conclusion, our data suggests that dysregulated VEGF gene expression is potentially involved in the carcinogenesis of CRC and the clinical outcome could be related to its over-expression in CRC patients. Hence, VEGF may has prognostic and therapeutic values in them.

Differential effects of radiotherapy on normal cell, cancer stem cells and cancer cells

S. Yilmaz Susluer[1], *T. Balci[1], S. Hoca[2], E. Tavlayan[2], C. Kayabasi[1], B. Ozmen Yelken[1], N. Olacak[2], Y. Anacak[2], M. Olukman[3], C. Gunduz[1], S. Kamer[2];*

[1]Ege University Medical Faculty Department of Medical Biology, Izmir, Turkey, [2]Ege University Medical Faculty Department of Radiation Oncology, Izmir, Turkey, [3]Ege University Medical Faculty Department of Pharmacology, Izmir, Turkey.

Radiotherapy is an important method for treatment of cancer. In radiation oncology preclinical models such as cell culture methods are necessary for cancer research. For this purpose, human head and neck stem cell line (HNSC), head and neck cell line (FADU), and as control group, epithelial cell line (WSS-1) have been studied. Dose ranges determined by using clonogenic assay, cell proliferation assay, DNA double break analysis, apoptosis analysis and cell cycle analysis. All cell lines were exposed to 0,2,4,6,8 and 10Gy and cell amount were variable for each. When evaluated the effectiveness of radiotherapy on HNSC and FADU, they were similar according to the clonogenic assay results, there was a significant relationship between dose and survival and 10% survival was close to 8Gy and there was a significant relationship between dose and survival (p= 2,16E-4) and 10% survival was close to 4 Gy on WSS-1. According to the apoptotic activity, for HNSC, apoptosis at 48 hours was induced compared to control between 2-10Gy, for FADU, at 72 hours, 4-10Gy and for WSS-1, between 24-72 hours at 8 and 10Gy. A significant increase was detected in the formation of γh2ax foci after DNA double strand breaks in HNSC and FADU at 48 hours, between 2-8 Gy, compared to control and there was no DNA double strand breaks in WSS-1. On the efect of cell cycle, in HNSC and FADU, arrested at G2/M between 2-10Gy and in WSS-1, arrested at S and G2/M between 24-72. hours. Radiotherapy shows differential effects on normal tissuse compare with cancer stem cells and cancer cells.TUBİTAK

KRAS, BRAF oncogene mutations and tissue spesific promoter hypermethylation of tumor supressor HIC-1, P16, DAPK1, SFRP2 and MGMT genes in colorectal cancer patients

B. Bagci[1], *M. Sari[2], K. Karadayi[3], M. Turan[3], O. Ozdemir[4], G. Bagci[5];*

[1]Department of Nutrition and Dietetics, Faculty of Health Sciences, Cumhuriyet University, Sivas, Turkey, [2]Department of Biology, Faculty of Science, Cumhuriyet University, Sivas, Turkey, [3]Department of General Surgery, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey, [4]Department of Medical Genetics, Faculty of Medicine, On Sekiz Mart University, Canakkale, Turkey, [5]Department of Medical Genetics, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey.

Aims: Within the context of this study, frequencies of oncogene KRAS and BRAF mutations, promoter hypermethylation profiles of tumor suppressor genes HIC1, SFRP2, P16, DAPK1 and MGMT and possible associations between hypermethylations of these genes and KRAS and BRAF mutations in colorectal patients were aimed to find out.

Methods: 93 colorectal cancer tissue and 14 normal colon mucosa were included in the study. Common twelve KRAS gene mutation were investigated with using reverse-hybridisation strip assay method. BRAF V600E mutations were investigated with using RFLP method.

Results: Hypermethylation status of tumor suppressor genes (SFRP2, DAPK1, MGMT, HIC1 and p16) were detected by using reverse-hybridisation strip assay method after bisulphite modification of DNA. In the patient group, KRAS and BRAF mutation frequency were determined as 54.84% (n=51) and 12.9% (n=12) respectively. Promoter hypermethylation frequencies of tumor suppressor genes SFRP2, DAPK1, MGMT, HIC1 and p16 were determined as 66.7%, 45.2%, 40.9%, 40.9%, 15.1% respectively. No statistically significant associations were found between KRAS gene mutation and tumor suppressor gene hypermethylation. Statistically significant associations were found between BRAF gene mutations and SFRP2 and p16 tumor suppressor gene hypermethylation ($p=0.005$ for SFRP2 and $p=0.016$ for p16). In terms of the tumor location, SFRP2 ($p = 0.017$) and MGMT ($p = 0.013$) genes have statistically significantly higher promoter hypermethylation in colon compared to the rectum.

Conclusions: KRAS mutations and SFRP2 tumor suppressor gene promoter hypermethylations play important role in colorectal cancer oncogenesis. BRAF V600E mutation was found to be associated with tumor suppressor gene hypermethylation.

J12.34

Increase of the risk of differentiated thyroid carcinoma in the Great Poland population by c.470T>C CHEK2 missense variant

S. Hryhorowicz[1,2], *M. Kaczmarek-Ryś[1], K. Ziemnicka[3], K. Górczak[4], J. Hoppe-Gołębiewska[1], M. Ruchała[3], R. Słomski[1,2];*

[1]Institute of Human Genetics Polish Academy of Sciences, Poznań, Poland, [2]Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland, [3]Department of Endocrinology, Metabolism and Internal Diseases, University of Medical Sciences, Poznań, Poland, [4]Department of Mathematical and Statistical Methods, University of Life Sciences, Poznań, Poland.

Differentiated thyroid carcinoma (DTC)originates from thyroid follicular epithelial cells and belongs to a group of slowly progressing tumors with a relatively good prognosis.However, recurrences and metastases are a serious problem in advanced stages.

The majority of DTC are sporadic but a few alleles increasing the cancer risk are known. One of them is the c.470T>C (p.I157T, rs17879961) missense substitution in the CHEK2 gene.

The aim of this study was to investigate whether this specific CHEK2 alteration, c.470T>C, predisposes the Great Poland (Wielkopolska) population to thyroid cancer.

602 differentiated thyroid carcinoma patients and 829 controls randomly selected from population were genotyped for the presence of the c.470C allele using pyrosequencing. Hardy-Weinberg Equilibrium (HWE) was tested for both groups by chi-square distribution and Fisher's exact test. The odds ratios (ORs), 95% confidence intervals (CIs), and p-values were calculated using the R software.

The results of genotyping showed the presence of the c.470C allele in 51 patients with a frequency of 4.49%, while in a controls in 42 with a frequency of 2.53%. We demonstrated that in the Great Poland population the c.470C CHEK2 variant increases the risk of developing differentiated thyroid cancer almost twice (OR=1.81, p=0.004). The risk of papillary thyroid carcinoma in female patients homozygous for the c.470C allele was shown to increase almost 13-fold (OR=12.81,p=0.019).<br Identification of c.470C CHEK2 gene variant ought to be taken into account by healthcare policymakers. Future well-designed and larger population studies are of great value in confirming these findings. Moreover, a combination of genetic factors together with environmental exposures should also be considered.

Introduction: Thyroid cancer is the most common endocrine malignancy. Medullary Thyroid Carcinoma (MTC) is one of the most aggressive thyroid tumors which occur in both hereditary (25%) and sporadic (75%) forms. Mutations of the RET proto-oncogene in MTC development have been well

demonstrated. The aim of the study was to investigate the mutational spectrum of exons 2, 3, 5, 8, and 10-19 of RET Proto-oncogene in MTC patients. Material and methods: this retrospective study has been started since 2001 in Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, and Tehran, Iran. 399 participants, including 233 patients (176sMTC, 40FMTC, 8MEN2A, 4MEN2B, 5pheochromocitoma), and 166 relatives were evaluated. Genomic DNA was extracted by the standard Salting Out/ProteinaseK method and Mutation detection was performed through direct DNA sequencing. Results: Totally, 102 mutations were identified in RET exons 10, 11, 13-16 and 18. Furthermore, 357 Single Nucleotide Polymorphism (SNP) were found in exons 2, 3, 13, 14, 15. Interestingly, G691S SNP and S904S SNP were 100% in linkage disequilibrium in 131 patients and 87 relatives (Table 1). The most common mutation in our population were C634Y and C634R (4%) whereas C618R, C618S, C620G, L887L mutations had rare allele frequency (0.3%).Discussion: Exon 11 and after that exon 10 were the most frequently mutated exons of RET proto-oncogene in MTC patients in Iranian population. We did not find any substantial mutation in non-main exons of RET. Therefor these exons may not be recommended for RET genetic screening test in MTC patients and their relatives.

Early detection of genome changes with I-FISH in patients with cellular atypia in urinary sediment

S. Davidović, *I. Franić Šimić, F. Mrsić;*
Clinical Unit of Cytogenetics and FISH Diagnostics of Hemato-oncological Disease, University Hospita, Zagreb, Croatia.

Urinary bladder carcinoma is one of the leading cancers in male population. With highly sensitive, specific and non-invasive techniques of molecular biology such as interphase FISH (I-FISH) it is possible to detect genome changes in urine sediment cells and therefore distinguish between malignant and benign atypical cells. The aim of the study was to detect and confirm the presence of genome changes in atypical urine sediment cells. The I-FISH technique identified numeric and structural changes (CEP3, CEP7, CEP17 and LSI9p21) in urine samples with confirmed atypical cells. The UroVysion test (FDA approved, CE) allowed us to detect various changes in the genome of one atypical cell simultaneously. 270 urine samples in which atypical cells were present were analyzed. A positive urine finding was confirmed in 113 patients (42%). In 24 patients (21%) both numeric and structural changes were present, while in 83 patients (74%) only numeric changes, and in 6 patients (5%) only structural changes were found. Conclusion: With the I-FISH technique it is possible to detect and monitor known genome changes in cells of urinary bladder cancer and in this way distinguish between benign and malignant atypical cells.

J12.37

Polymorphisms and allelic imbalance of the TP53 gene and sensitivity of gastric cancer patients to 5-FU chemotherapy.

A. Udilova, *T. Kchorobrich, M. Nemtsova, D. Zaletaev;*
I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.

TP53 is a tumor suppressor gene involved in multiple pathways including apoptosis, cellular transcriptional control, and cell cycle regulation. Single nucleotide polymorphism (SNP) at codon 72 of the TP53 gene has been associated with the risk of developing various neoplasms.
We examined Arg > Pro in codon 72 (rs1042522) and 16 bp insertion in intron 3 (rs17878362) in 80 gastric cancer patients after surgical treatment and chemotherapy with 5-fluorouracil. Determination of allelic imbalance of the locus 17p13 (TP53) in tumor samples from 80 gastric cancer patients was performed by microsatellite analysis.
We have found the Pro/Pro genotype to be associated with poor prognosis, development of local recurrence, carcinomatosis, appearance of distant metastases during the first 3 years after surgery and 5-FU treatment ($p = 0.031$). There is a statistically significant increase in disease-free survival in patients with Arg/Arg genotype, compared to the Pro/Pro ($p = 0.013$) and a statistically significant increase in disease-free survival with genotype Arg/Pro vs. Pro/Pro ($p = 0,015$). In the study of the 16 bp insertion (rs17878362) in the patients after surgical treatment and chemotherapy we found no significant differences.
We have shown that the frequency of allelic imbalance of the locus 17p13 (TP53) in patients with intestinal gastric cancer was significantly higher than in patients diffuse type ($p = 0.016$).
We suggest that TP53 polymorphism rs1042522 can serve as individual prognostic factors of adjuvant treatment effectiveness in patients with locally advanced gastric cancer.

J12.38

RAD51D Mutations in Breast and Ovarian Cancer Families from Northeast of Spain.

C. Velázquez Pérez[1], *E. Esteban Cardeñosa[1], M. Durán Domínguez[1], M. Tascón Torres[1], E. Lastra Aras[2], G. Marcos García[3], L. Hernández Sanz[1], N. Martínez Martín[1], M. Infante Sanz[1];*
[1]IBGM, Valladolid, Spain, [2]Complejo Hospitalario, Burgos, Spain, [3]Hospital Río Hortega, Valladolid, Spain.

The identification of new predisposing genes to hereditary breast and ovarian cancer is essential to enable decisions about the treatment and follow up of this syndrome. Homologous Repair (HR) genes deserve special attention for two reasons: mutations on them could confer increased risk to develop Hereditary Breast and Ovarian Cancer and justify the use of PARP inhibitors in order to improve treatment effectiveness. RAD51D is a key player in HR pathway. Several studies concluded that RAD51D is a moderate penetrance susceptibility gene for ovarian cancer.
Our aim is to determine the prevalence of germline mutations of RAD51D in a cohort of Spanish Breast and Ovarian Cancer (BOC) families without BRCA mutations.
The screening for germline variants RAD51D was performed in 94 BOC families by High Resolution Melting. Mutations identified were confirmed by direct DNA sequencing.
A new frameshift mutation, c.94delG, has been identified in ovarian cancer case. In addition, other changes previously described have been found: four missense variants (c.494G>A, c.629C>T, c.695G>A y c.698A>G) and one intronic.83-4T>C. Bioinformatics analysis of missense substitutions predicted c.629C>T to be deleterious.
Genetic testing of RAD51D should be considered in high risk BOC families as far as preclinical studies have shown that RAD51D-deficient cells respond to PARP inhibition. The compassionate use of PARP inhibitors in high grade serous ovarian cancer patients should also be considered.

J12.39

First study of Braf V600E mutation's status in thyroid carcinoma in Tunisian population

O. Trabelsi[1], *S. Charfi[2], A. Chakroun[3], S. Hugonin[4], T. Boudawara[2], A. Ghorbel[3], N. Bouayed[1], T. Rebai[1];*
[1]Faculty of medecine, Sfax, Tunisia, [2]Laboratory of anatomopathology H.Bourghiba hospital, Sfax, Tunisia, [3]ORL service H.Bourghiba hospital, Sfax, Tunisia, [4]Laboratory of histology tumoral biology Tenon hospital, Paris, France.

Introduction: Braf V600E mutation was associated with high risk clinicopathologic characteristics in patients with papillary thyroid carcinoma (PTC) in many populations. This molecular alteration may be a potential prognostic factor in PTC. In our study, we wanted to determinate the status of the Braf V600E mutation in thyroid carcinoma in Tunisian population.

Matriels and methods: Twenty four patients with primary thyroid carcinoma (11 follicular, 13 papillary) underwent surgery at H.Bourghiba Hospital in sfax, between january and december 2010. Real Time Polymerase Chain Reaction was used to detect Braf V600E mutation gene, exon 15 on chromosome 7q34, from paraffin embedded thyroid tumor specimens.

Results: Braf V600E mutation was detected in 53% of the PTC (7/13). Any mutation was found in 8/11 follicular thyroid carcinoma and DNA was non informative in three cases. In one case the mutation was detected in both the primary tumor and the nodule tissues.

Conclusion: Braf V600E mutation may be a common genetic alteration in the Tunisian population despite the low number of patients. Another study with large series including clinicopathologic characteristics is necessary to determine the impact of this molecular alteration in the prognostic of PTC in our population.

Application of whole-exome analysis to find molecular-genetic predictors of safe cancellation of targeted therapy in patients with chronic myeloid leukemia

S. A. Smirnikhina[1], *A. Lavrov[1,2], E. Adilgereeva[1], E. Chelysheva[3], O. Shukhov[3], A. Turkina[3], S. Kutsev[1,2];*
[1]Federal State Budgetary Institution "Research Centre for Medical Genetics", Moscow, Russian Federation, [2]State Budgetary Educational Institution of Higher Professional Education "Russian National Research Medical University named after N.I. Pirogov" of Ministry of Health of the Russian Federation, Moscow, Russian Federation, [3]Federal State Budgetary Institution "Hematological Research Centre" of Ministry of Health of the Russian Federation, Moscow, Russian Federation.

High efficacy of targeted therapy with tyrosine kinase inhibitors (TKI) led to major molecular response in more than 50% of chronic myeloid leukemia (CML) patients. After discontinuation of the therapy only 41% of CML patients keep molecular remission in the following 12 months. In order to identify genes with predictive significance for relapse-free survival after stopping targeted therapy in CML patients we performed exome sequencing using PGM Ion Torrent in DNA samples from 6 patients with stable long deep molecular remission (BCR-ABL less than 0.01%IS for 12 months) before discontinuing therapy. The patients were divided into groups with relapse (group 1, BCR-ABL more than 0.1%IS, n = 3) and without relapse (group 2, n = 3) after 24 months since therapy stopping. 371 unique common genetic variants were identified in the group 1, 366 unique common genetic variants - in the group 2. These variants were functionally annotated using Variant Effect Predictor. SIFT and PolyPhen scores were used for filtering of the potentially most meaningful variants: 12 in patients in group 1 and 18 in group 2. Among these selected variants we describe 4 genes related to cancer. In group 1 found variant in SPINT1 gene mutations in which are often associated with cancer. In the group 2 we found variants in the MAP2K3 gene, involved in carcinogenesis, WDR5, associated with leukemia, and CASC5, which expression is increased in a variety of tumor cells. Found exome variants are potential markers of persistent remission in CML patients after cancellation of TKI therapy.

J12.41
The prevalence of FLT3 internal tandem duplication in acute leukemia: A Tunisian experience

R. FRIKHA[1], *O. Kassar*[2], *M. Mdaffer*[2], *S. Daoud*[1], *N. Bouayed Abdelmoula*[1], *M. Elloumi*[2], *T. Rebai*[1];
[1]*Laboratory of Histology, Faculty of Medicine, Sfax, Tunisia,* [2]*Department of Hematology, Sfax, Tunisia.*

The fms-like tyrosine kinase 3 (FLT3) gene is a member of the class III receptor tyrosine kinase family which plays an important role in hematopoiesis. Targeting the FMS-like tyrosine kinase receptor-3 (FLT3) in acute leukemia is mainly important. Mutations in the fms-like tyrosine kinase 3 (FLT3) genes, primarily the FLT3-internal tandem duplication (FLT3-ITD) is well established prognostic marker especially in acute myeloid leukemia (AML).
The present study investigated the molecular screening and incidence of FLT3-ITD in acute leukemia patients from Tunisia.
Genomic DNA was extracted from EDTA-anticoagulant blood samples from a total of 35 patients suffering from acute leukemia. After DNA extraction, the polymerase chain reaction using specific primers was conducted to screen the FLT3-ITD.
In acute lymphoblastic leukemia (ALL), 9 cases are LAL-B and median age is 24 years. In acute myeloid leukemia (AML), there were younger patients; M4 subtype and a leukocytosis. Chromosome abnormalities were detected in 23% (2 patients with AML and 5 with ALL) and are correlated with worse prognosis (very high risk and relapse). At molecular lever, never FLT3-ITD was detected both in AML and ALL.
Our findings suggest that FLT3 ITD is uncommon in Tunisian acute leukemia and do not affect clinical outcome.

J12.42
Analysis of IDH mutation, EGFR/MDM2 amplification, and INA expression in clinical diffuse gliomas

N. Senhaji[1,2], *S.Louati, H.Hamdaoui, S.El badai, K.Mikou, A.Amarti, S.Bennis;*
[1]*University hospital Hassan II of Fez, Fez, Morocco,* [2]*Laboratory of bioactive molecules: structure and functions. Faculty of science and technology of Fez., Fez, Morocco.*

Introduction: The diagnosis of gliomas is mainly based on the 2007 WHO classification, which suffers from a lack of precision and reproducibility. Nowadays, the search for genetic alterations in gliomas shows a potential role in diagnosis, prognosis and response to treatment.
The purpose of this study is to evaluate the presence and the frequency of some genetic biomarkers in Moroccan diffuse glioma patients.
Materials and Methods: 99 tumor samples were used for this study. They were obtained from patients diagnosed with glioma at the University Hospital Hassan II of Fez between January 2010 and December 2013.
Immunohistochemistry was performed with the antibody directed against the internexin alpha (INA) which is used as a surrogate marker of 1p / 19q codeletion in oligodendroglial tumors.
We performed a RT-PCR to study *EGFR* and *MDM2* genes amplification in glioblastomas and sequencing techniques to detect mutations in *IDH* genes in diffuse gliomas.
Results: INA immunostaining was found in 80% of patients presenting an oligodendroglial tumor. We identified *IDH1* mutation in 43 cases while one *IDH2* mutation was detected in an anaplasic oligodendroglioma.
The detection of EGFR/*MDM2* amplification with RT-PCR techniques is still in process.
This study will focus on the presence and the frequency of these markers. These data should be compared with literature.
Conclusion: The new molecular technology has allowed better classification of gliomas based on the alteration of specific genes for each tumor subtype. These molecular markers are necessary for accurate and objective differentiation and consequently for a more targeted therapy.

J12.43
Role of polymorphic fibroblast growth factor receptor Gene and Breast Cancer Risk

M. -. Hosseini[1], *M. Hoshmand*[2];
[1]*Islami Azad University Branche Islamshahr, Tehran, Iran, Islamic Republic of,* [2]*Institiut of genetic and food, Tehran, Iran, Islamic Republic of.*

Genetic factors related to cancer have been extensively studied and several polymor- phisms have been associated to breast cancer. Breast cancer (BC) is one of the most common causes of death among women, and second in Iran. The objectives of this study were to determine the frequency of the fibroblast growth factor receptor (FGF- R) Gene polymorphism in patients with breast cancer. For the first time, we evaluated these polymorphisms and effects on the breast cancer risk association in an Iranian sporadic population-based case-control study of 126 breast cancer cases and 160 con- trols using a PCR-RFLP-based assay. Analyses of affected and controls show that homozygote genotype FGFR4 Gly/Gly has the highest frequency in patients and control groups (30.4 and 18.9%). Genotype FGFR4 Gly/Gly most risk factor were in our population: ArgGly /GlyGly, OR= 2.359, 95% CI= 0.208 - 4.621, p=0.001; Arg- Arg /ArgGly, OR=0.412, 95% CL=0.082 - 0.547, p=0.078 , ArgArg /GlyGly, OR = 0.076,95%CI=0.030-0.189,p=0.

J12.44
A Jordanian trainee's perspective on cancer genetics services

L. Abujamous;
LEEDS/KHCC, Leeds, United Kingdom.

5.5 billion of the world's 7.1 billion population live in developing countries. Most of these people do not have access to services that could provide genetic counselling and diagnostic tests for familial cancer risk. It is expected that, over time, services currently available in developed countries will become increasingly available elsewhere.
King Hussein Cancer Center (KHCC) in Jordan is one of the most specialised centres in the Middle East dedicated to the treatment of paediatric and adult cancer patients. However, there is no comprehensive cancer genetics counselling or testing service.
The KHCC vision and strategic plan includes improving access to education, training, and research in collaboration with international centres. Our aim is to provide and implement service provision for cancer patients. Genetic counselling service will help cancer patients to access for genetic testing in line with international standards.
I have clinical attachment in the Yorkshire Regional Genetics Service based in Leeds, under the supervision of Dr Julian Adlard and his team. The future level of demand in Jordan is likely to increase as more members of the public become aware. There are challenges to introducing wider germline genetic testing. However, we are working to develop a Next Generation Service for genetic testing 'in house' in the near future.

J12.45
AML1 gene amplification in two TEL/AML1 positive acute lymphoblastic leukaemia cases

A. G. Zamani[1], *M. Basdemirci*[1], **M. S. Yildirim**[1], *H. Tokgöz*[2], *U. Caliskan*[2];
[1]*Department of Medical Genetics, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey,* [2]*Department of Pediatric Hematology, Meram Medical Faculty, Necmettin Erbakan University, KONYA, Turkey.*

TEL/AML1 (ETV6/RUNX1) fusion resulting from the translocation t(12;21)(p13;q22) constitutes the most common chimeric fusion gene in initial childhood acute lymphoblastic leukemia (ALL) (19-27%) and has been associated with good prognosis. Three secondary aberrations in TEL/AML1 positive ALL have been suspected to negatively influence outcome: deletion of the second TEL allele, gain of the second AML1 allele and duplication of the derivative chromosome 21 (der(21)).
In newly diagnosed two patients with TEL/AML1 positive ALL, additional (a) TEL loss, (b)TEL gain, (c) AML1 amplification (copy number greater than four), (d) combined TEL loss and AML1 gain were detected by FISH analysis.
RUNX1 is a transcription factor and targets key regulators of the hemato-

poiesis process (M-CSF R, IL3, neutrophil elastase, MPO, granzyme B, TCRs, and B-Cell receptors. It is possible that the expression levels of RUNX1 could explain the clinical heterogeneity of t(12;21) ALL cases. Indeed, it has been suspected that a RUNX1 gene copy number of four is associated with good prognosis. By contrast, whereas the amplification of RUNX1 to a copy number greater than four, which has been estimated to be the case in 2% of all pediatric ALL , may be characteristic of a subtype of B-ALL associated with a poor prognosis. Our data and published results on TEL/AML1 positive ALL with AML1 amplification and impact on prognosis were evaluated.

J12.46
A new BRCA 2 frameshift mutation detected on premenoposal woman with recurrent non metastatic breast cancer

A. Ö. Kaymak[1], *B. Çavdarli*[2], *Ç. Sönmez*[1];
[1]*Ankara Oncology ETH, Ankara, Turkey,* [2]*Ankara Numune ETH, Ankara, Turkey.*

BRCA1 and BRCA2 genes are the most known tumor supressor genes associated with breast and ovarian cancer. Approximately 10% of breast and ovarian cancer patients have BRCA mutations (1,2). Genetic screening for patients with early onset breast canser (premenoposal or < age 50) and over cancer at any age, is increasingly rising in our country. Here we report a 41 year-old premenoposal woman who have had bilateral total mastectomy for invasive ductal carcinoma of right breast for 7 years ago and left breast for 2 years ago. DNA sequence analyses for BRCA 1 and 2 genes were performed for the patient having not any familial history. The analysis revealed a frameshift mutation on the sixth exon of BRCA 2 gene (c.506 ins A mutation). This new frameshift mutation is not reported on literature or any databases. The patient had genetic counseling and was advised to have family screening. The clinical impact of this mutation will become clear with the increase of the patients with the same mutation.

Autophagic effect of theranekron in gastric cancer cells

V. B. Yenigun, *A. A. Azzawri, N. Kocak, H. Acar;*
Department of Medical Genetics, Selcuk University, Medical School, Konya, Turkey.

Introduction: Gastric cancer is a common type that originates at the mucosa epithelia of the stomach and expands rapidly to the lining of the stomach. Theranekron is an alcoholic extract of the venom from Tarantula cubensis spider. Theranekron is a homeopathic remedy that is used as a pharmaceutical compound serving in veterinary medicine with outstanding success for its antiphlogistic, demarcative, necrotizing, and wound healing effects. Autophagy is a tightly regulated cell death mechanism involving the degradation of a cell's own components through the lysosomal machinery and activating the signal pathways during the distribution of the homeostasis. The aim of the present study was to evaluate the effects of theranekron in respect of autophagy in metastatic AGS and non-metastatic MKN-45 human gastric cell lines and control HEK-293 cells.
Materials and Methods: After appropriate treatment time and IC50 was determined, effect of theranekron on cell death was investigated using different concentrations of the drug. The autophagic effect of the drug was determined through the LC3-GFP translocation assay, qPCR technique for target genes, and also using rapamycin as a positive control.
Results: Theranekron decreased the cell viability in respect to increasing concentrations. Additionally, a significantly increased GFP accumulation was detected in the autophagosomes of the cells treated with theranekron compared to non-treated cells ($p<0,05$), indicating the presence of autophagy. The findings were confirmed by using qPCR.
Conclusions: Theranekron result in cell death and stimulate the autophagy process, but it is not specific for cancer cells since it represented similar results in control cells.

J12.48
Our experience of unaffected BRCA1/2 testing in the Peninsula

V. L. Hunt[1], *G. Corbett*[1], *H. Walsh*[2];
[1]*Peninula Clinical Genetics Service, Royal Devon and Exeter Hospital, Exeter, United Kingdom,* [2]*Cardiff University, Cardiff, United Kingdom.*

In June 2013 NICE updated their recommended guidelines for BRCA1/2 testing. These new guidelines recommend that genetic testing should be available to an individual with 'no personal history of breast or ovarian cancer if their combined BRCA1 and BRCA2 mutation carrier probability is 10% or more and an affected relative is unavailable for testing' (NICE 2013).
Following this change in recommendations our department created a guideline for offering testing to unaffected individuals. We currently offer unaffected testing to individuals (both men and women) with an affected first degree relative, where there are no living affected relatives available for testing. The Manchester scoring system is used to calculate carrier probability, with testing being offered in families with a score of 20 or above. Boadicea may also be used as tool to help calculate risk. In addition, at least one of the cancers must be confirmed, ideally the most significant. We agreed that these patients should be seen by a Genetic counsellor and a consultant before testing, with results being given face to face. All patients will also be discussed at our cancer meetings.
Using these criteria we would expect a 10% or greater pickup of pathogenic mutations. We present our findings from testing over the past 14 months. We also discuss some of the challenges we have faced so far.

J12.49
The impact of 3'-UTR variant binding site of KRAS gene with let-7 micro RNA on metastasis in head and neck cancer

H. Acar, *V. B. Yenigun, Z. B. Sarı, N. Kocak, V. B. Ucar;*
Department of Medical Genetics, Selcuk University, Medical School, Konya, Turkey.

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer in the world and accounts for 90% of malignant neoplasia of the upper respiratory system. MicroRNAs (miRNAs) are highly conserved, small noncoding RNA molecules aberrantly expressed in various pathologies including cancer, regulation of tumour and metastasis associated genes. KRAS is very important oncogene, which leads to the overexpression of ras protein, suppression of apoptosis, promoting the pathogenesis and development of tumours. Variant (rs61764370) of the let-7 miRNA complementary site of KRAS gene 3'-untranslated region (KRAS-LCS6) has been shown to disrupt the ability of miRNAs to target genes resulting in differential target mRNA and protein expression. In the literature, there is data about a correlation of the KRAS expression with miRNA let-7 expression level, and also KRAS mutation and metastasis in different cancers. Yet, it is unknown about the impact of variation of KRAS-LCS6 site on metastasis pathway in HNSCC. In this study, the role of variant complementary site LCS6 of the let-7 miRNA on metastasis was evaluated in head and neck cancer. Using proliferation, invasion, migration, cancer stem cell and quantitative real-time PCR assays, we compared the effect of the rs61764370 (KRAS G12V-LCS6 T>G) in HEp-2 and HEK-293 cell lines transfected with KRASG12V -LCS6(T) (wild type), KRASG12V-LCS6 (G) (mutant) plasmids and empty pLenti-CMV-GFP-2A-puro plasmid, and also un-transfected cells for each type.

IL-33 Dependent ADAMTS5 Expression In Glioblastoma Multiforme

A. SUNGUROGLU[1], *Y. YUKSELTEN*[2], *D. AKCORA*[3], *M. G. BAL*[2], *K. DEMIRCAN*[4], *H. C. UGUR*[5];
[1]*Ankara University, School of Medicine, Department of Medical Biology, ANKARA, Turkey,* [2]*Ankara University, School of Medicine,Department of Medical Biology, ANKARA, Turkey,* [3]*Mehmet Akif University, Faculty of Arts and Sciences, BURDUR, Turkey,* [4]*Turgut Ozal University, School of Medicine,Department of Medical Biology, ANKARA, Turkey,* [5]*Ankara University, School of Medicine,Department of Neurosurgery, ANKARA, Turkey.*

Glioblastoma multiforme (GBM) is still one of the most deadly and incurable form of cancer, indicating a need for understanding the biology of GBM. In the present study we assessed the relationship between IL-33 and ADAMTS5 in GBM tumorigenesis. For this purpose, ADAMTS5 protein was initially determined in samples from GBM and low-grade tumor tissues (LGTt) and in samples from healthy brain tissues by western blot. We found that ADAMTS5 protein was significantly increased in both GBM and LGTt compared to healthy brain tissues (5,56 fold). Then, we performed primary tumor cell cultures derived from both GBM and LGTt. On these primary tumor cells, GFAP staining was performed as a marker of glial cells and found that GBM primary cells (GPc) were %92 GFAP positive. To evaluate the relationship between IL-33 and ADAMTS5, both low-grade primary tumor (LGPt) cells and GPc were treated with 10 ng/ml and 30 ng /ml IL-33 for 48 hours. Exposure of these cells to IL-33 for 48h resulted in a dose dependent increase in ADAMTS5 protein. In detail, a 9,98 fold increase in ADAMTS5 protein was observed after 30ng /ml IL-33 treatment of GPc. Similar results were obtained in LGPt cells as a 4,68 fold increase in ADAMTS5 protein was obtained after 30 ng/ml IL-33 treatment. As a conclusion, IL-33 seems to increase the expression of ADAMTS5 protein in GBM. Targeting IL-33 and

ADAMTS5 may be considered as a treatment strategy to improve prognosis and survival in GBM.

SCREENING OF BRCA GENE MUTATIONS IN MALE BREAST CANCER PATIENTS.

I. Aurrekoetxea Rodríguez[1,2], *E. Sánchez Tapia*[1,2,3], *T. Martín Gómez*[3,4], *R. Vidal Tocino*[3,4], *J. Cruz Hernández*[2,3,4], *R. González Sarmiento*[1,2,3];
[1]*Molecular Medicine Unit. Department of Medicine. University of Salamanca., Salamanca, Spain,* [2]*Institute of Molecular and Cellular Biology of Cancer. University of Salamanca-CSIC, Salamanca, Spain,* [3]*Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain,* [4]*Department of Clinical Oncology, University Hospital of Salamanca., Salamanca, Spain.*

Male breast cancer is a disease that affects approximately one in 1,000 men. Several risk factors influence the occurrence of this disease: age of diagnosis, unhealthy lifestyle and different genetic factors, such as mutations in BRCA genes. Mutations in BRCA2 gene are more frequent (incidence between 4-40%) than in BRCA1 gene (incidence less than 10%).
Our aim was to analyze the presence of pathogenic mutations in BRCA genes in 34 men with breast cancer divided in two groups: 15 with family history of breast cancer and 19 without it, all from the western part of the Spanish Castilla y León Community.
The analysis of point mutations was performed by PCR, CSGE and Sanger sequencing in both BRCA1 and BRCA2 genes. When no cause-disease mutations were detected, a further analysis of genomic rearrangements was performed using a MLPA test. All mutations detected in our study were found in BRCA2 gene and in males with family history. We found a nonsense mutation (c.145G>T) in one patient and the same frameshift mutation (c.2808_2811delACAA) in three others. Besides, we found 18 polymorphisms in BRCA2 and 10 in BRCA1 in patients of both groups. We did not find pathogenic mutations in patients without a family history.
In conclusion, we show that mutations tend to appear in the BRCA2 gene in a minority of patients with family history, which may be indicative of the existence of other genes associated with male breast cancer still unknown and should help to modify inclusion criteria in screening programs.
Supported by PI13/01741 and Consejería de Sanidad-Junta de Castilla y León.

Splicing effect analysis of twenty BRCA1 and BRCA2 unclassified variants identified in breast/ovarian cancer patients from south Catalonia

M. Rodriguez-Balada[1], *B. Roig*[2], *J. Borràs*[1,3], *M. Melé*[1], *M. Salvat*[1], *J. Gumà*[1,3];
[1]*Cancer Genetic Counselling Unit, Institut d'Oncologia de la Catalunya Sud, Hospital Universitari Sant Joan de Reus, IISPV, REUS, Spain,* [2]*Oncology Research Group, IISPV, REUS, Spain,* [3]*Institut d'Oncologia de la Catalunya Sud, Hospital Universitari Sant Joan de Reus, IISPV, Universitat Rovira i Virgili, Reus, Spain.*

Introduction: Hereditary breast and ovarian cancer syndrome (HBOC) is mainly caused by pathogenic mutations in the *BRCA1* and *BRCA2* genes. The detection of unclassified variants (UVs) is one of the main difficulties in the diagnosis of this syndrome. The pathological characterization of these unclassified variants is an indispensable tool for providing effective genetic counselling and preventive actions for these families.
Materials and methods: To assess the abnormal splicing of twenty UVs identified in *BRCA1* and *BRCA2* genes in families from the South Catalonia region, a combination of several methods has been used, including *in silico* prediction tools to assess they putative effect and mRNA analysis. A comparison of the mRNA results and splicing prediction bioinformatic methods has also been performed.
Results: Four of the variants detected have been previously reported. Two variants of *BRCA1* gene (c.331+1G>A, c.5397-1G>A) and one of *BRCA2* gene (c.744+2T>A) showed an abnormal splicing pattern also predicted by the bioinformatic programs, and they had been previously reported. The rest of the UVs analyzed did not show an abnormal splicing effect at RNA level. Of these 17 UVs all were novel except c.9729+9A>C (*BRCA2)* that had been previously reported.
Conclusions: Consistent with previous reports, our study shows that the combination of several *in silico* methods yields highly accurate information, making it a reliable tool for selecting those variants for sequencing mRNA analysis.

Table 1. Bioinformatic Prediction Scores and In Vitro Splicing Results of BRCA1 and BRCA2 Unclassified Variants

Familial adenomatous polyposis: a regional audit of families and recommendations

R. Jewell, *C. Falconer, J. Adlard;*
Yorkshire Regional Genetics Service, Chapel Allerton Hospital, The Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.

We have recently audited our families with familial adenomatous polyposis (FAP) identified from positive diagnostic or predictive tests for pathogenic *APC* mutations performed by our laboratory over three decades. Our service does not currently have a formally maintained register of FAP families. Genetics patient records were obtained and reviewed. A total of 183 patients from 42 families were ascertained. Further data on demographics will be presented. Management was audited against national and international guidelines. The majority (94.0%) of patients had recorded pre-test counselling. There was no formal written consent for genetic testing documented for 31.7% of patients, however, this has improved in the most recent 5-year cohort (90.5% documented). Deficits were evident in recording of screening recommendations, although generally improving over time. Formal recording in the notes of upper gastrointestinal screening recommendations was particularly low (42.6%). Presentation of the audit results in the department has highlighted the benefit of documenting consent. Standard letters and leaflets have been updated to improve advice and documentation. The audit identified 30 families with at-risk first-degree relatives who were not recorded as having been seen in our service. Letters are being sent to patients to remind them who in the family is at risk and regarding the availability of genetic testing, if not already performed. The audit demonstrated better recording of practice over time, but also areas for further improvement using simple measures.

Lamin A levels in the metastasis potential of lung adenocarcinoma cells from pleural effusions

E. KASPI[1,2,3], *S. LAROUMAGNE*[3], *T. VANDEMOORTELE*[3], *S. PERRIN*[1], *A. ROBAGLIA-SCHLUPP*[1,2,3], *D. BRAUNSTEIN*[3], *J. MICALLEF*[2,3], *H. DUTAU*[3], *A. DE SANDRE-GIOVANNOLI*[1,2,3], *N. LEVY*[1,2,3], *P. CAU*[1,2,3], *P. ASTOUL*[2,3], *P. ROLL*[1,2,3];
[1]*INSERM UMR_S910, Marseille, France,* [2]*Aix-Marseille Université, Marseille, France,* [3]*AP-HM, Marseille, France.*

The type V intermediate filament lamins are the principal components of the nuclear matrix, including the nuclear lamina. Lamins are divided into A- and B-types. The alternative splicing of LMNA produces two major A-type lamins, lamin A and lamin C. A-type lamins have been suggested as biomarkers for cancer diagnosis, prognosis and/or follow-up. The aim of the present study was to investigate lamins in cancer cells from metastatic pleural effusions using immunofluorescence, western blotting and flow cytometry. In a sub-group of lung adenocarcinomas, we reported reduced expression of lamin A but not of lamin C that cannot be explained by miR-9-induced degradation of lamin A mRNA. Moreover, the reduction in lamin A expression

was correlated with the loss of epithelial membrane antigen (EMA)/MUC-1, an epithelial marker that is involved in the epithelial to mesenchymal transition (EMT). Finally, the decrease in lamin A expression was correlated with an increased number of lung adenocarcinoma metastatic sites, with a preferential localization in bone.
We also hypothesized that lamin A expression could be regulated by other mechanisms, such as SRSF1, a LMNA splicing factor, or MALAT-1, a long, non-coding nuclear RNA, which negatively controls miR-9 expression and is implicated in SRSF1 regulation. Both SRSF1 and MALAT-1 are known to be involved in metastasis development in lung cancer.
In conclusion, low lamin A but not lamin C expression in pleural metastatic cells could indicate the lung origin of pleural metastatic adenocarcinomas and could represent a pejorative marker associated with the EMT and metastatic potential.

Molecular classification of colorectal cancer with/without peritoneal carcinomatosis by gene expression signature

N. I. Pospekhova, *Y. A. Shelygin, S. I. Achkasov, O. I. Sushkov, S. A. Frolov, A. S. Tsukanov, V. P. Shubin;*
State Scientific Center of Coloproctology, Moscow, Russian Federation.

Aim. Colorectal cancer (CRC) is a heterogeneous disease. CRC with peritoneal carcinomatosis (PC) is most unfavorable prognosis group. Molecular classification of CRC (Sadanandam et al., 2013) defined five distinct molecular subtypes based on the preferentially expressed genes: stem-like, SFRP2; transit-amplifying, CFTR; goblet-like, MUC2 and TFF3; enterocyte, MUC2 without TFF3; inflammatory, RARRES3. CRC groups have differences in prognosis and vary in degree of response to chemotherapy.
Methods. We analyzed 27 tumors obtained from patients with PC and 45 stage I-III CRC, among last ones six samples were obtained from patients with Lynch syndrome (LS). Subtypes classification was validated by analyzing 6-gene expression signature by RT-PCR. KRAS /BRAF mutations were analyzed by sequencing.
Results. The various subtypes frequency in CRC with PC and stage I-III was: stem-like - 44.5% (12/27) and 15.6% (7/45); transit-amplifying - 37% (10/27) and 57.8% (26/45); goblet-like subtype - 3.7% (1/27) and 13.3% (6/45); enterocyte - 7.4% (2/27) and 4.4% (2/45); inflammatory - 7.4% (2/27) and 8.9% (4/45), respectively. LS-tumors were: 3 - inflammatory; 2 - goblet-like and 1 - transit-amplifying subtypes. KRAS/BRAF-mutations were detected in 70.4% CRC with PC (19/27) and 46.7% (21/45) in stage I-III CRC. Four from 5 BRAF-V600E mutations was found in stem-like subtype.
Conclusion. The prevalence stem-like subtype in CRC with PC and its association with BRAF-mutation confers aggressiveness, high metastatic potential and poor prognosis of this subtype. LS-tumors belonged to more favorable subtypes that confirm the markedly better prognosis for them. Molecular classification of CRC can serve for tumor subtype assessment suggesting specific treatment for each one.

Frequency of the CHEK*2 1100delC among breast cancer patients in Iran

L. rostamizadeh[1], *R. Bahavarnia*[2], *M. Asadi*[1], *V. Zafari*[1], *S. Hashemzadeh*[1];
[1]*Tabriz science medical university, Tabriz, Iran, Islamic Republic of,* [2]*Blood Transfusion organization of Tabriz, Tabriz, Iran, Islamic Republic of.*

Breast cancer is one of the most common cancers and the main cause of cancer-related deaths among women worldwide. The mutation in BRCA1 and BRCA2 genes are mainly involved in just 15% to 20% of all hereditary form of breast cancer but there is still a major proportion of hereditary breast cancer with no BRCA mutation detected. It has been proposed that a significant number of breast cancers are caused by defects in larger number of moderate or low penetrance genes. CHEK2 is a third high breast cancer susceptibility gene with low penetrance alleles that has been shown to best explain residual non-BRCA aggregation of breast cancer. CHEK2 acts as a tumor suppressor gene that directly regulates the functions of p53 and BRCA1 in response to DNA breakage which stopped cell proliferation and initiates DNA repair.
In this study we attempted to investigate the frequency of 1100delC mutation in CHEK2 gene in breast patient to improve screening strategy in Iran and provide genetic testing and counseling to family members of the patients.
Breast cancer (N=50) and control samples (N=50) which were all pathologically diagnosed, were screened for the 1100delC mutation by RFLP-PCR method. In all mutation-positive cases, results were confirmed by sequencing. None of our 100 samples who underwent genetic testing for 1100delC mutations had the *CHEK2**1100delC mutation. Our preliminary data suggest that screening for CHEK2*1100delC mutation in Iranian patients is not warranted.

Non-invasive early detection of colorectal cancer: Determination of methylation pattern of ALX4 gene promoter in plasma

H. Babaei, *n. Atapour, A. Salehi, R. Salehi;*
Isfahan university of medical sciences, Isfahan, Iran, Islamic Republic of.

Background: To develop a non-invasive screening method for colorectal cancer, we evaluated the methylation of ALX4 gene promoter in serum samples from patients with colorectal cancer (CRC) and equal number of healthy individuals. Materials and Methods: In serum samples from 25 patients with colorectal cancer and 25 healthy control subjects, isolated serum free-floating DNA was treated with sodium bisulfite and analyzed by methylation-specific polymerase chain reaction (MSP) with primers specific for methylated or unmethylated promoter CpG island sequences of the ALX4 gene. Results: Methylation of the ALX4 gene promoter was present in the serum DNA of patients with adenoma and colorectal cancer. A sensitivity of 68% and specificity of 88% were achieved in the detection of promoter methylation in colorectal neoplasia samples. The difference in methylation status of the ALX4 promoter between the patients with colorectal neoplasia and the control group was statistically highly significant ($P < 0.001$). Conclusions: The results indicate that this serum free DNA test of methylation of the ALX4 gene promoter is a sensitive and specific method. Therefore in combination with other useful markers it seems ALX4 has the potential of a clinically useful test for the early detection of colorectal cancer.
Key Words: Colorectal cancer, DNA methylation, Free-floating DNA, non-invasive colorectal cancer diagnosis

New epigenetic markers of minimal residual disease in pediatric acute myeloid leukemia identified by unbiased screening of differential methylation of the genomes

V. V. Rudenko[1,2], *V. S. Nemirovchenko*[3], *A. V. Popa*[3], *A. S. Tanas*[1,2,4], *S. A. Kazakova*[1], *E. B. Kuznetsova*[1,2], *D. V. Zaletaev*[1,2,4], *V. V. Strelnikov*[1,2,4];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*I.M.Sechenov First Moscow State Medical University, Moscow, Russian Federation,* [3]*N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation,* [4]*Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

Introduction: Malignant neoplasms are characterized by genetic heterogeneity. Still there is a class of molecular genetic changes which characterizes all malignant tumors, namely, abnormal DNA methylation. The aim of our investigation was to develop a system of molecular genetic markers of minimal residual disease (MRD) in pediatric acute myeloid leukemia (AML) based on abnormal methylation of certain genomic loci.
Materials and Methods: The study involves samples of biological material of the bone marrow from AML patients and donor bone marrow used for transplantation. Identification of aberrant methylation is carried out by an unbiased DNA differential methylation screening method developed within this study. Experimental design has been carried out with the «AIMS in silico» software package developed in our laboratory.
Results: We have identified 16 novel genomic loci abnormally methylated in pediatric AML (15 belonging to the promoter CpG islands and one belonging to an intergenic CpG island on 7p21.1). Two of the genes (RXRA and KHSRP) with abnormally methylated promoters encode proteins involved in the epigenetic regulation of gene expression. We propose a system of 13 DNA methylation markers (belonging to the promoter regions of EGFLAM, RXRA, MAFA, TMEM176A /TMEM176B, KHSRP, TMEM200B, ABCG4, GSG1L, CLDN7, CXCL14, DLK2, AIFM3 and SOX8) for determination of the MRD in pediatric AML.
Conclusion: We have developed a panel of molecular genetic markers and an original technique for the assessment of aberrant DNA methylation in AML in children.

Federation, [4]Bashkir state university, Ufa, Russian Federation.

Prostate cancer (PCa) is one of the most serious oncological diseases in men with an incidence higher than that of all other solid tumors. Currently, it is the second cause of cancer mortality worldwide. The aberrant expression of microRNAs (miRNAs), small non-coding RNAs that negatively regulate gene expression, is related to the development of several cancers, including PCa. Since miRNAs serve as phenotypic signatures of different cancers, they appear as potential diagnostic, prognostic and therapeutic tools.

To determine whether miRNA polymorphisms are associated with PC risk we examined 30 SNPs of 18 microRNAs biogenesis genes *(GPC1, FAM212B, DDX20, FAM57A, DROSHA, C5orf22, AGO1, AGO2, RAN, PIWIL1, DICER1, GEMIN4, DGCR8, MIR196A2, NSRP1, MIR27A, DDX5),* using the OpenArray genotyping technology, in PCa patients of Russians (N=141), Tatars (N=69) and Bashkirs (N=52) and matched controls (N=95, N=137, N=56, respectively) from Russia.

We evaluated the association between SNPs in the mentioned genes and PCa risk as well as clinical characteristics (PSA level, clinical and pathological stage) in men (266 patients who underwent a prostatectomy and orchectomy) using logistic regression.

We observed that in Russians rs563002 (*G/*G vs. *A/*G+*A/*A: OR=0.21, CI=0.08-0.53), rs1057035 in DICER1 (*G/*G vs. *A/*G+*A/*A: OR=0.35, CI=0.13-0.88), rs1640299 in DGCR8 (*T/*T vs. *T/*G+*G/*G: OR=0.49, CI=0.26-0.92) were associated with decreased PCa risk and rs1640299 in DGCR8 (*G/*G vs. *T/*G+*T/*T: OR=4.48, CI=1.42-15.77) was associated with increased PCa risk. In Bashkirs rs595055 in *AGO1* was associated with increased PCa risk*:* (*T/*T vs. *C/*T+*C/*C: OR=2.48, CI=0.98-6.32).

Diagnostic and prognostic value of IDH1 mutation in glioblastoma patients

B. Yalaev[1], **I. R. Minniakhmetov***[1], S. Safin[2], A. Sultanbaev[2], S. Musin[2], I. Gilyazova[1], E. Khusnutdinova[1];*

[1]Institute of Biochemistry and Genetics, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation.

Glioblastoma multiforme (GBM) is the most common and aggressive primary brain tumor in adults, with a poor prognosis because of its resistance to radiotherapy and chemotherapy. The GBM patient survival time of approximately 1 year necessitates the identification of novel molecular targets and more effective therapeutics. Mutations in the gene isocitrate dehydrogenase 1 (IDH1) are present in up to 86% of grade II and III gliomas and secondary glioblastoma, and could be used as a biomarker for this subset of gliomas.

The purpose of this study was to investigate the incidence of mutations in IDH1 and IDH2 genes in patients with glioblastoma multiforme from Vola-Ural region of Russia and establishing correlation mutations in these genes with the treatment and survival.

The studied groups included 15 patients with glioblastoma multiforme. Genomic DNA was extracted from tumor sample and peripheral blood leukocytes by standard phenol/chloroform method. Mutation status was studied by direct sequencing of IDH1 and IDH2 genes.

As a result of screening for mutations in the IDH1 gene mutation G395A was discovered in 5 of 15 patients with GBM, which leads to the substitution of adenine for guanine at position 395 (p.R132H). The frequency of this mutation in our study was 33%. Mutations in IDH2 gene were not found.

We confirmed that the survival rate of patients with IDH1 mutations 2-fold higher than those without mutation. In addition, patients with mutations in the IDH1gene had a favorable response to treatment with temozolomide, which indicates about the importance of screening for this mutation in GBM patients.

J12.61

Spectrum of EGFR mutations in Bulgarian patients with non-small cell lung carcinoma

S. Popovska*, T. Dineva, I. Boneva, M. Simeonova, K. Kovacheva, Z. Kamburova;*
Medical University of Pleven, Pleven, Bulgaria.

Mutations in epidermal growth factor receptor (EGFR) are considered as predictive biomarker for the clinical and radiographic responses to tyrosine kinase inhibitors (TKIs) in the treatment of non-small-cell lung cancer (NSCLC).

The most frequent activating mutations are inframe deletions in exon 19 and L858R in exon 21. These two mutations comprise about 85% of all EGFR mutations. Other EGFR mutations and multiple EGFR mutations in one tumor have not been comletely characterized in Bulgarian patients. In order to establish the spectrum of EGFR mutations in Bulgarian patients with NSCLC we investigated total of 294 tumors using qRT PCR techniques.

The morphology of all 294 cases included 51.7% adenocarcinomas, 23.5% squamous cell carcinomas, 1.3% adenosquamous and 22.8 % other types.

Activating mutations in EGFR were found in 9% (25) of patients. Among all mutations the most frequent were a deletion in exon 19 (52%), followed by mutation L858R in exon 21 (24%). In 1 male patient (4%) a compound EGFR mutation (S768I in exon 20 and G719X in exon 18) was found.

Evaluation of EGFR status is important because TKIs are effective in patients whose tumors harbor activating mutations in the tyrosine kinase domain of the gene. We found low frequency of compound EGFR mutations in our patients.

J12.62

Pathways associated with relapse and high risk in childhood acute lymphoblastic leukemia

Y. Erbilgin*[1], O. Hatirnaz Ng[1], B. Islek[1], S. Firtina[1], T. Celkan[2], S. Anak[3], Z. Karakas[3], N. Sarper[4], E. Zengin[4], E. Turkkan[5], D. Yalcin Atay[5], Y. Ng[6], M. Sayitoglu[1], U. Ozbek[1];*
[1]Institute for Experimental Medicine, Istanbul, Turkey, [2]Pediatric Hematology Oncology, Cerrahpasa Medical Faculty of Istanbul University, Istanbul, Turkey, [3]Department of Pediatric Hematology, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey, [4]Pediatric Hematology Division, Kocaeli Medical Faculty, Kocaeli University, Istanbul, Turkey, [5]Pediatric Hematology Division, Istanbul Okmeydani Education and Research Hospital, Istanbul, Turkey, [6]Faculty of Engineering, Bilgi University, Istanbul, Turkey.

Introduction: Relapsed acute lymphoblastic leukemia (ALL) is one of the leading causes of death among children with cancer and the prognosis for early relapse remains poor. To discover the underlying pathways that may play a role in resistance, we analyzed gene-expression profiles in 818 ALL samples.

Materials and Methods: We performed gene-expression profiles in 16 matched diagnosis/ early relapse childhood ALL pairs, flow-sorted normal B cell progenitor subpopulations and CD4+CD8+ T cell by using the Illumina HumanHT-12v4 ExpressionChip. To extend the data, genome-wide expression data was retrieved from eleven ALL datasets via the Gene Expression Omnibus (GEO). The dataset contained expression data for 618 diagnosed,168 relapsed ALL samples and nine healthy controls. Data analysis was carried out in the R environment.

Results: Matched diagnosis/early relapse ALL samples clustered closely together and limited gene showed significant differences that involved in cell cycle regulation and apoptosis. Probe sets -1343 total were identified significantly different at diagnose who had not shown relapse compared to diagnose samples that relapsed in the future. Interestingly, various transcription factors had been down regulated in relapse-diagnose samples. ALL subgroups also compared with their controls. Leukemia samples showed aberrant expression of transcription factors that involved with MAPK and cell lineage pathways.

Conclusions: We have identified potential genes and pathways at relapse and initial diagnose that may play a direct role in drug resistance and leukemia development in childhood ALL. Ongoing further validation of the functional role of some of these genes will contribute the enlightenment of leukemogenesis.

The study was supported by TUBITAK and IU-BAP Project Number:114S038, 11021

Copy number characteristics of the 10q26.3 chromosome region containing the MGMT gene in glioblastoma

E. Alekseeva*[1,2], A. Tanas[1,2,3], E. Prozorenko[4], A. Zaytsev[5], O. Kirsanova[5], V. Strelnikov[1,2,3], D. Zaletaev[1,2,3];*
[1]FSBI „Research Centre for Medical Genetics", Moscow, Russian Federation, [2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation, [3]Pirogov Russian National Research Medical University, Moscow, Russian Federation, [4]N.N. Blokhin Russian Research Center for Oncology, Moscow, Russian Federation, [5]P.A. Hertsen Moscow Oncology Research Institute, Moscow, Russian Federation.

Inactivation of the MGMT gene located at 10q26.3 predicts glioblastoma's sensitivity to alkylating agents. Methylation of the MGMT gene promoter is considered to be the key mechanism for this gene silencing and the marker of a favorable response to alkylating drugs. Deletion can present the alternative mechanism of MGMT gene inactivation. Previously we have been the first to conduct a targeted analysis of loss of heterozygosity (LOH) at 10q26.3 and have shown LOH at the MGMT region in 63.2% (74/117) glioblastoma samples. However LOH merely reflects allelic imbalance in the area without detailed information on the gene copy number. In order to assess copy number alterations at the 10q26.3 region in glioblastoma samples with identified LOH, we have developed a system for quantitative microsa-

tellite analysis (QuMA). QuMA is based on amplification of microsatellite loci that contain (CA)n repeats where the repeat itself is the target for hybridization by the fluorescently labeled probe. The reference pool contains primer pairs for six genomic regions located on different chromosomes in which copy number violations are not typical for glioblastoma. In 51.5% (34/66) of the samples only one copy of the tested locus was found (deletion), while in 48.5% (32/66) two copies were detected (acquired uniparental disomy, aUPD). Thus, we have shown that MGMT LOH in glioblastoma can reflect either a deletion or an aUPD. The deletion of MGMT gene requires detailed study as a potential marker of glioblastoma sensitivity to alkylating agents.

Background
~15% of ovarian cancer (OC) patients have germline BRCA mutations. Knowledge of mutation status increasingly impacts treatment e.g. eligibility for PARP inhibitors. It is also important for ongoing patient management and provides risk information for relatives. In most European countries including UK, OC patients have restricted access to BRCA testing, despite meeting testing eligibility.
Methods
We developed an 'oncogenetic' pathway in which consent for BRCA gene testing in OC patients was undertaken by cancer team members that had completed 30 minute online training. Clear, interpreted results were returned by Genetics together with an appointment for all individuals with mutations. Cascade testing to relatives was performed through Genetics.
Results
207 OC patients were offered testing in 18 months and all accepted. Average time to result was 4-6 weeks. The BRCA result impacted management of 133 patients. Mutations were identified in 33 patients (16%); only 16 had a family history of breast or ovarian cancer. All mutation-positive women were seen in Genetics and ~100 relatives have been referred for counselling and consideration of predictive testing. Patient and clinician feedback was extremely positive; >95% of patients found the pathway simple and effective.
Conclusions
The Oncogenetic model allows flexible, patient-centred, high-throughput gene testing for OC patients with considerable time and cost savings compared to traditional models, and higher mutation detection rates. It is now the standard pathway for BRCA testing in OC patients at the Royal Marsden hospital. This work was undertaken by the MCG programme (www.mcgprogramme.com) funded by the Wellcome Trust Grant 098518/Z/12/Z.

The differential gene expression in clear cell renal cell carcinoma and biomarker development.

N. V. Apanovich[1]*, S. V. Poyarkov[1], M. V. Peters[2], A. A. Korotaeva[1], A. S. Markova[2], B. S. Kamolov[2], I. V. Pronina[1], E. A. Braga[1], V. B. Matveev[2], A. V. Karpukhin[1];*
[1]Research Centre For Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation, [2]Cancer Research Centre, Russian Academy of Medical Sciences, Moscow, Russian Federation.

With the aim to receive additional information on mechanism of clear cell renal cell carcinoma (ccRCC) progression and development biomarkers we studied two groups of genes. The first was made up of genes with the most expression. By bioinformatic analysis of gene expression databases 200 genes were selected. After quantitative RT-PCR of ccRCC sample in comparison with normal renal tissue 21 genes with the most frequent increased expression were identified. The majority of these genes were direct targets of HIF1α. It was found an association of six gene decreased expression (CA9, NDUFA4L2, VWF, IGFBP3, EGLN3, BHLHE41) with overall survival (OS) and genes VWF, IGFBP3,STC2 with metastasis (p = 0,008 - 0,044). Among these genes were as novel, without established significance in ccRCC, as NDUFA4L2 (OR = 0,048; 95% CI: 0,005 - 0,444), so well known biomarkers, as CA9. The second group was formed of genes participate in angiogenesis (5 genes), PI4K-AKT-mTOR pathway (10 genes) and EGFR. Only VEGFR1 and VEGFA decreased expression were interconnected with both OS and metastasis (p = 0,009 - 0,023). Increased expression in significant association with OS was observed for SAA1 and three genes - CSF1R, Fn1 and C1QA tended to be increased. All these genes are associated with inflammatory response. The data give a possibility for proposition of consistent involvement HIF1A -> HIF2A -> NF-kB/STATs modules, which can lead to the development of metastasis and reduced OS. Thus, for the first time shown coordinated expression decreasing of number of regulated HIF1α genes in connection with OS and metastasis.

Allelic imbalance and epigenetic changes as size markers of field cancerization in non-small cell lung cancer

A. A. Shikeeva[1,2]*, T. V. Kekeeva[2,1], L. E. Zavalishina[1], Y. Y. Andreeva[1], D. V. Zaletaev[2], G. A. Frank[1];*
[1]Russian Medical Academy for Postgraduate Education, Moscow, Russian Federation, [2]Federal State Budgetary Institution «Research centre for medical genetics», Moscow, Russian Federation.

Non-small cell lung cancer (NSCLC) is characterized by multiple genetic alterations such as loss of heterozygosity (LOH), microsatellite instability (MSI), promoter hypermethylation and changes of miRNA expression. According to a field cancerization (FC) phenomenon the adjacent histologically normal tissue plays an important role in tumor progression by triggering the transformation process.
The aim of the study was the analysis of genetic alterations in tumor and adjacent tissue to determine the FC size and to reveal associations with clinico-morphological features of patients.
The study group included 135 patients with NSCLC. From each patient 4 FFPE samples were analyzed: tumor, adjacent normal lung tissue at 2, 5, 10 cm. LOH/MSI analysis was evaluated by PCR using 7 microsatellite loci. Promoter hypermethylation in genes *RASSF1A FHIT, DAPK1, CDH1, CD44, TIMP3, MGMT* was investigated by methyl-sensitive PCR. The expression levels of miRNAs let-7a, miR-155, miR-205 were measured by real-time PCR.
Our results demonstrated that LOH/MSI occurs only in tumor while promoter hypermethylation occurs also in adjacent tissue at 2, 5 cm, but not at 10 cm. The downregulation of let-7a, miR-155 in adjacent tissue is lower than in tumor. The levels of investigated miRNAs in adjacent tissue vary depending on tumor differentiation - in patients with differentiated tumors it is higher than in the group with poorly differentiated tumors.
We postulate that FC size in NSCLC is at least 5 cm from tumor and includes only epigenetic but not structural (LOH/MSI) alterations. The evaluation of epigenetic changes in adjacent tissue (e.g., surgical margins) can potentially be used for postsurgical prognosis.

IDH1/2 mutations and concurrent DNA methylation in meningiomas

I. Chatziandreou[1]*, P. Tsioli[1], R. Soldatos[1], A. Gioti[1], P. Korkolopoulou[1], V. Samaras[2], A. Zisakis[2], E. Patsouris[1], A. A. Saetta[1];*
[1]University of Athens, Athens, Greece, [2]Hellenic Red Cross Hospital, Athens, Greece.

Background. IDH mutations are linked to an altered methylome phenotype in gliomas, involving key genes participating in cell growth, development, cell cycle and metabolism. Our aim was to search for IDH1/2 mutations in correlation with promoter methylation for MGMT, APC, PTEN, RASSF1, DAPK1 and MLH1 genes in an effort to delineate their possible role in the pathogenesis of meningiomas.
Methods: 75 meningiomas were examined (grade I n=42, grade II n=26, grade III n=6). Methylation and mutation status were assessed by HRM, pyrosequencing/or Sanger sequencing.
Results. IDH1 mutations at codon 132 were observed in 5% of the cases, with only 1 case bearing the hot-spot mutation p.R132H. IDH2 mutations were recorded in three cases including two silent mutations, (p.D117V, p.R172R, p.L143L). A varying level of promoter methylation for APC, RASSF1A, MGMT, DAPK, hMLH1 was detected in 37%, 25%, 41%, 41%, 28% of the cases respectively. 75.5% of the samples showed methylation at one or more promoters, in 14%, 30%, 22%, 8% of the cases for one, two, three or four promoters respectively. All IDH1/2 mutant samples displayed concurrent methylation of two or three promoters. No statistical associations were elicited between methylation, mutations and grade.
Conclusion. This report is the first to analyse simultaneously the presence of IDH1/2 mutations along with methylation status of five promoters in a cohort of meningioma samples of different grades. A subgroup of meningiomas presented IDH1/2 mutations along with partial promoter methylation, suggesting a possible role in their pathogenesis.

Breast cancer in female Peutz-Jeghers syndrome patients:

risk assessment in a large patient cohort and surveillance recommendations

S. E. Korsse[1], *C. H. M. van Deurzen*[1], *H. M. Zonderland*[2], *I. Obdeijn*[1], *E. M. H. Mathus-Vliegen*[2], *E. Dekker*[2], *C. W. Looman*[1], *N. P. M. Ezendam*[3], *E. J. Kuipers*[1], *M. E. van Leerdam*[4], *C. M. Seynaeve*[1], *A. Wagner*[1];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Academic Medical Centre, Amsterdam, Netherlands,* [3]*Eindhoven Cancer Registry, Eindhoven, Netherlands,* [4]*National Cancer Institute, Amsterdam, Netherlands.*

Female Peutz-Jeghers syndrome (PJS) patients have a highly increased cancer risk, including breast cancer (BC). Risk estimates for BC in these patients vary, while information on clinical and histological characteristics is scarce. In the present study, we assessed the BC risk and clinicopathological features of BC in a large PJS cohort, and sought to formulate a present-day BC surveillance recommendation. Cases were identified from the Dutch PJS cohort. PJS was diagnosed according to international criteria. Clinical data were collected and radiological and histological data were reviewed. Cumulative BC risks were calculated by Kaplan-Meier analysis and relative risk by Poisson regression analysis. Of 145 PJS patients, 75 (52%) were female. Nine women from 8 families were diagnosed with BC at a median age of 50 years (range 34-61). Mammography allowed good visibility of all but one BC. The majority of
analysed BCs was of good or intermediate differentiation grade and all invasive tumours were hormone sensitive and Her2-negative. Cumulative BC risk was 62% (95% CI 31%-93%) at age 65, and relative risk was 6 (95% CI 3 to 13, p<0.001) compared to the age matched general population. BC risk for female PJS patients is highly increased, approaching that of BRCA-mutation carriers, while PJS-associated BCs seem to have a later onset and more favourable clinicopathological characteristics than BRCA-mutation carriers. We propose to start annual BC surveillance with mammography in female PJS patients as of 30 years, with additional MRI in patients with dense breast tissue. Prospective evaluation of this schedule is required to determine its effectiveness.

Association between single nucleotide polymorphisms in candidate genes or regions and ovarian cancer risk for woman in Bashkortostan

D. Prokofyeva[1], *E. Fauzetdinova*[1], *M. Bermisheva*[2], *A. Nurgalieva*[1], *E. Khusnutdinova*[1,2];
[1]*Department of Biology, Bashkir State University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Ufa, Russian Federation.*

A genome-wide association study recently identified an association between single-nucleotide polymorphisms rs3814113 at 9p22.2, rs8170 at *MERIT40* gene, rs2072590 at 2q31, rs2665390 at *TiPARP* gene, rs10088218 at 8q24, rs9303542 at *SKAP1* gene, rs2736108 and rs2736109 at *TERT* gene and risk of ovarian cancer.
We analyzed the association this polymorphisms and ovarian cancer risk in cases (n=227) and controls (n=373) from Bashkortostan. Single-nucleotide polymorphisms detection was performed by allelic discrimination *Taqman*.
We have identified an association polymorphism rs2072590 (2q31) with risk of ovarian cancer for women in the general population, OR = 1.5, 95% CI 1.0-2.1, p = 0.045. In different ethnic groups the patient and control genotype and allele frequencies were not significantly different. Polymorphism rs2072590 is localized in a domain containing homeobox genes required for the regulation of embryogenesis and organogenesis in the noncoding region between *HOXD3* and *HOXD1* genes. Both genes involved in tumorigenesis.
Also we identified an association polymorphism rs8170 in *MERIT40* gene with the risk of ovarian cancer in Russian, OR = 0.5, 95% CI 0.3-0.9, p = 0.03. MERIT40 is necessary for BRCA1 localization to DNA damage sites.
Our data indicate that rs2072590 and rs8170 polymorphisms are associated this ovarian cancer risk for woman in Bashkortostan.

Methylation profiling of Socs1 gene in colon neoplasms

A. Zarandi;
Department of Biology, Science and Research Branch, Islamic Azad Universit, tehran, Iran, Islamic Republic of.

Background: Suppressor of cytokine signaling 1 (*Socs1*) protein plays an essential role in inhibition of JAK-STAT pathway, which is important for differentiation, proliferation and apoptosis of cells involved in tumorogenesis. Hypermethylation of the promoter CpG islands in the *Socs1* gene is an epigenetic phenomenon associated with gene silencing that leads to inactivation of this tumor suppressor gene function in colorectal cancer (CRC).The aim of this study was to determine the methylation status of *Socs1* gene promoter in colorectal neoplasms.
Materials and Methods: We investigated the aberrant methylation status of *Socs1* gene in 37 polyp and 13 tumor biopsies obtained from participants (24 female and 26 male with age of 53±26) and 50 corresponding nonmalignant epithelium, by methylation specific PCR (MS-PCR). Tissue samples were collected during 2011 to 2013, after colonoscopy from participants. Informed consent was obtained from patients.
Results: Eighteen percent (8 of 50) of the studied biosies were found to have methylated CpG islands in *Socs1* gene promoter region.There was a significant association between promoter methylation and size of neoplasms. Frequency of promoter methylation was higher in smaller neoplasms under 10 mm in size. None of the nonmalignant epithelium samples were methylated in the promoter region.
Concussion: Detection of *Socs1* promoter methylation in colon neoplasms may provide an informative approach for early detection of CRC.

Phenotype of MUTYH mutation carriers: Surprise, surprise!

C. D. DeLozier[1,2,3];
[1]*Community Regional Medical Center, Fresno, CA, United States,* [2]*Saint Agnes Medical Center, Fresno, CA, United States,* [3]*University of California San Francisco-Fresno, Fresno, CA, United States.*

The autosomal recessively-inherited form of colorectal adenomatosis polyposis (FAP2) results from homozygous or compound heterozygous mutations in the MUTYH gene. MUTYH, the human homologue of the E.coli mutY gene, is involved in base excision repair and cellular response to oxidative DNA damage. Two founder mutations (c.536A>G and c.1187G>A) account for the majority of pathogenic mutations reported to date. Carriers of two mutated alleles, who generally have onset of „attenuated polyposis“ as young adults, have a high risk of colorectal cancer, as well as some increase in the incidence of duodenal, gastric, endometrial and breast cancers. Data regarding polyp and cancer risk in monoallelic mutation carriers are limited and conflicting, with some evidence for an increased incidence of colorectal and breast cancers. In addition, until the recent inclusion of MUTYH in multigene cancer-risk panels offered on a clinical basis, little was known of other mutations, hence the high rate of Variants of Unknown Significance (VUS) in clnical testing. Our experience with mutations and variants in the MUTYH gene (see selected cases in Table 1) suggests that cancer risk has been underestimated in monoallelic carriers, and that it may be appropriate to follow individuals with one or two MUTYH mutations as we do individuals with Lynch syndrome (Hereditary Non-Polyposis Colorectal Cancer, HNPCC).

Genomic Variations detected by MLPA in Brazilian patients with Colorectal Cancer

M. Rocha[1,2], *A. T. Dias*[2], *E. A. Zanardo*[2], *T. V. M. M. Costa*[2], *F. A. R. Madia*[2], *F. Balsamo*[1], *S. Borato*[1], *S. H. C. Horta*[1], *B. A. Bianco*[1], *D. M. Christofolini*[1], *C. P. Barbosa*[1], *J. Waisberg*[1], *L. D. Kulikowski*[1,2];
[1]*Centro de Reprodução Humana e Genética, Departamento de Saúde Coletiva - Faculdade de Medicina do ABC, Santo André, Brazil,* [2]*Laboratório de Citogenômica, Departamento de Patologia, Faculdade de Medicina da USP, São Paulo, Brazil.*

Colorectal cancer (CRC) is a health problem that is increasing in importance worldwide although its etiology is still poorly understood. Therefore we investigated copy number variation anomalies (CNVs) in genes related to colorectal cancer using MLPA technique (Multiplex ligation-dependent probe amplification) in 16 samples obtained from colorectal carcinoma. The total of 16 tissue samples were obtained by biopsy of 8 patients with CRC, being 8 neoplastic samples and 8 samples obtained from adjacent regions (10cm distant tumor tissue). The DNA was extracted using the QIAamp DNA Blood Midi Kit (QIAGEN, Valencia, California) and investigated by MLPA method (MRC-Holland®, Amsterdam, The Netherlands) with specific kits for the subtelomeric regions (P036 and P070). The results were analyzed using the software GeneMarker® (SoftGenetics, LLC, State College, PA - www.softgenetics.com).
Using MLPA technique we were able to identify several indels in many regions involving different genes. We detected genetic imbalances in 15 samples and observed a consistent pattern of distribution of genetic alterations (losses) in some genes as *KDM5A*(12p), *TNFRS18* (1p), *CTDP1* (18q),

*TRIML2(*4q*) IL17RA*(22q), *MTA1*(14q), *GAS8* (16q); and gains in *CHL1*(3p), *PSPC1*(13p*)*, *SOX12*(20p), *SYBL1*(Xq), *CDC16*(13q), *PDCD6*(5p), *RABL2B* (22q). Unexpected we observed genomic alterations in samples from adjacent regions of the tumor, suggesting that the adjacent regions are not the adequate to use as a control. MLPA emerges as an important tool to improve comprehension of genomic profile of CRC and also is a reliable and efficient method to measure aberrations in tumor genomes

Basal cell carcinoma (BCC) is the most common malignant neoplasm in humans; however, it has not been studied by international cancer consortiums. Most BCCs are caused by aberrant activation of the hedgehog pathway (SHH) by PTCH1 mutations. BCC's varying morphology and aggressiveness, as well as their response to SMO inhibitors, may be associated with the acquisition of secondary driver mutations.

To characterize the genomic landscape of BCC, we performed exome-sequencing of frozen material from 50 cases/matching germline samples and a validation cohort of 100 FFPEs. BCCs have ~88 SNVs/Mb; much higher than all other tumors, including melanoma. In all cases, primary drivers in PTCH1, SMO or TP53 were identified. As expected in tumors with high mutation rates, we observe secondary driver mutations in 55% of cases; remarkably, we detect additive activation of SHH downstream of SMO-GLI by MYCN (40% of cases), PPP6C (15%) and FBXW7 (6.5%) mutations. We experimentally determined that MYCN mutations promote N-Myc stabilization by impairing its ubiquitination by FBXW7. N-Myc stabilization, truncating FBXW7 mutations, and PPP6C p.R264C mutations found in our cohort are all known to stabilize AuroraA. We further show activation of the HIPPO pathway (30% of cases); we observe truncating mutations in PTPN14, involved in cytoplasmic sequestration of YAP1. Immunohistochemistry confirms the enrichment of nucleus-localized YAP1 in PTPN14-mutated tumors.

This study is the most comprehensive and integrative analysis of BCC to date. We provide new insights into mechanisms mediating resistance to SMO inhibitors via secondary oncogenic mutations and we report MYCN oncogenic point mutations for the first time.

Germline mutations in MMR genes among Russian patients with Lynch syndrome

A. S. Tsukanov, *Y. A. Shelygin, V. P. Shubin, I. Y. Sachkov, D. A. Semenov, S. I. Achkasov, V. N. Kashnikov, N. I. Pospekhova;*
Ministry of Health / State Scientific Center of Coloproctology, Moscow, Russian Federation.

Aim

Lynch syndrome is one of the most frequent inherited colorectal syndromes. The syndrome is caused by a mutation in one of the mismatch repair (MMR) genes: mainly MLH1, MSH2 and MSH6. The aim of this study was to study frequency and spectrum of germline mutations of MMR genes among Russian patients.

Methods

Microsatellite instability was studied in tumor samples of probands, which corresponded to next criteria: age ≤ 45 and/or family history of colorectal cancer. Five loci markers (NR21, NR24, NR27, BAT25 and BAT26) were analyzed by fragment analysis. Germline mutation in MLH1, MSH2 and MSH6 gene of patients with MSI-H (high level) were investigated by PCR, conformation-sensitive electrophoresis, Sanger sequencing and next generation sequencing.

Results

Microsatellite instability was found in 76 tumor samples. Of these 76 patients 24 (31.5%) had germline mutations in MMR genes. Fourteen germline mutations were found in MLH1, eight mutations - in MSH2 and two mutations - in MSH6. Eight of these mutations were nonsense, 6 - frameshift, 5 - splice sites and 5 - missense mutations.

Conlusion

Frequency of germline mutation in MLH1, MSH2 and MSH6 gene among present set of Russian patients is 58.33%, 33.33% and 8.33%, respectively.

BRCA 1/2 mutation carriers in Reunion Island

A. Costa[1], *F. Cartault*[2], *H. Randrianaivo*[3], **M. IRABE**[3], *E. Fourme*[4], *C. Ferdynus*[5], *M. Boukerrou*[6];
[1]*Service de gynécologie obstétrique , CHU Réunion, Réunion, Réunion,* [2]*Service de génétique, CHU Réunion, Saint Denis, Saint Denis, Réunion,* [3]*Unité de génétique Humaine, CHU Réunion, Saint Pierre, Saint Pierre, Réunion,* [4]*Institut Curie, Hôpital René Huguenin, Saint Cloud, France,* [5]*CHU Saint Denis, Saint Denis, Réunion,* [6]*Service de gynécologie obstétrique, CHU Réunion, Saint Pierre, Saint Pierre, Réunion.*

Introduction :

In Reunion Island, we have chosen to study the BRCA 1/2 mutation carriers, and thus to search for the presence of a founder mutation.

Methods :

This study is a retrospective, multicentric one, over 10 years, about 65 subjects, who are carrying a BRCA 1/2 mutation.

Their epidemiologic characteristics, as well as the all cancer and mutation characteristics, were analysed.

We have also compared the initial breast cancers of this population with the french national cohorte GENEPSO.

Results:

A specific mutation was found, the 2840C>A (exon 11) of the BRCA 2 gene, wich concerned 37 % of the Reunion's BRCA carriers. An usually BRAC 2 mutations number was also observed,

with 70 % of the subjects, against 35% of the GENEPSO cohorte.

Conclusion :

This particular BRCA mutations distribution is related to ethnic and cultural history of the Reunion Island, with a mixed population but compartmentalized in its sociodemographic functioning. Cancer's characteristics of this population appear to be usual, however this study shows the importance of hereditary risk factors cancer screening. It has to be based on a suggestive family history, but also on tumorous characteristics, like a triple negative profile before 50 years.

This study underlines the presence of a probable founder mutation, specific of Reunion Island.

We didn't found difference between Reunion or French BRCA mutation carriers, especially for the initial breast cancers, except younger age of occurence, less triple negative breast tumors, and a statistically significant high proportion of BRCA 2 gene mutations.

J12.76

NGS-assisted DNA-based digital PCR for a personalised approach to the detection and quantification of residual disease in CML patients

M. Alikian, *P. Ellery, M. Forbes, G. Gerrard, D. Kasperaviciute, A. Sosinsky, M. Mueller, A. Whale, J. Apperley, J. Huggett, L. Foroni;*
Imperial College London, London, United Kingdom.

Recent studies indicate that 40% of chronic myeloid leukaemia (CML) patients who achieve sustained undetectable BCR-ABL1 transcripts on tyrosine kinase inhibitor (TKI) therapy remain disease-free after drug discontinuation. In contrast, 60% experience return of detectable disease and have to re-start treatment, thus highlighting the need for an improved method of identifying patients with the lowest likelihood of relapse. Here we describe the validation of a personalised DNA-based digital PCR approach for quantifying very low levels of residual disease, which involves the rapid identification of BCR-ABL1 fusion junctions using targeted next generation sequencing coupled with the use of a digital PCR (dPCR) platform. BCR-ABL1 genomic breakpoints were successfully mapped in samples from 32 of 32 patients with early disease. Disease quantification by DNA-dPCR was performed using the Fluidigm BioMark platform on 46 follow-up samples from 6 of the 32 patients, including 36 samples that were in deep molecular remission (MR). Digital PCR detected persistent disease in 81% of MR samples, out-performing both RT-dPCR (25%) and DNA-based qPCR (19%). We conclude that dPCR for BCR-ABL1 DNA is the most sensitive available method of residual disease detection in CML and may prove useful in the management of TKI withdrawal.

Down regulation of *SnoN/SKIL* gene in T-cell Acute Lymphoblastic Leukemia

O. Hatirnaz Ng[1], *O. Taşar*[2], *Y. Y. Ng*[3], *C. Öztunç*[2], *Y. Erbilgin*[2], *M. Sayitoğlu*[2], *U. Özbek*[2];
[1]*Genetics, Istanbul University, Institute of Experimental Medicine, Department of Genetics, Istanbul, Turkey,* [2]*Istanbul University, Institute of Experimental Medicine, Department of Genetics, Istanbul, Turkey,* [3]*2. Istanbul Bilgi University, Faculty of Engineering, Department of Genetics and Bioengineering, Istanbul, Turkey.*

T-cell acute lymphoblastic leukemia (T-ALL), is a severe disease that occurs in the malignant transformation of T-cells in the thymus. Here we performed whole genome expression analysis in 31 T-ALL childhood patients. In addition to some well-known targets a new target has been identified in the patient group *SnoN/SKIL* gene, known as a regulator of TGF-β pathway, was down regulated when compared to thymocyte controls. Quantitative Real Time PCR and analysis of proteins by proximity ligation assay (PLA) also confirmed this down regulation in a larger patient group (n=72). In the thought of the reasons of this downregulation, we searched the possible miRNAs that target *SnoN/SKIL* gene via online databases. Among these miRNAs we select mir-223, which is also known to be deregulated in hematologic malignancies, and by Stemloop RT-PCR we found out that all the samples with low *SnoN/SKIL* expression show high mir-223 expression levels. When we block mir223 in Molt4 cell line, by anti-mir223 LNA *in vitro*, *SnoN/SKIL* expression was leveled up. In the same group when we checked the apoptosis levels by Annexin V flow cytometry assay we found out that when we block mir223, cells were lead to apoptosis almost 10 fold higher than untreated cells. Our study is still ongoing to validate the direct relation between *SnoN/SKIL* and mir223, but these preliminary results show that *SnoN/SKIL* gene, which is known to have dual role in different malignancies like being oncogene or tumor suppressor, might be acting as a tumor suppressor gene in T-ALL.

Strauss, Strasbourg, France,* [6]*Consultation d'oncogénétique, Hôpital Pasteur, Hospices civils, Colmar, France.*

Introduction: BRCA1 and BRCA2 germline mutations account for 5-10% of breast-ovarian cancer families. A large majority of these familial aggregation remain unexplained. Recent studies report a 4-16% mutations prevalence when investigating other genes but BRCA1/2. New candidates are emerging. To further elucidate the role of these candidate genes in breast-ovarian cancer susceptibility, we selected a cohort of BRCA1/2 negative index-cases to be tested with a 29-genes panel.
Patients and methods: 24 affected women with at least 3 first degree relatives diagnosed with breast/ovarian cancers were recruited in 4 familial clinics in Alsace province (France). A first capture panel of 29 genes was designed. Genomic DNA Library preparation was performed using the SureSelect XT™ (Agilent) and sequenced with the MiSeq® Sequencing System (Illumina). Primary analyses were performed via the MiSeq Reporter Software, secondary analyses via an in-house bioinformatic pipeline.
Results: Sequencing (2x150bp) generated 7Gb of data, with 95% of the bases ≥QV30. All coding regions and intron-exon jonctions were covered (mean depth of coverage 150X. Preliminary results revealed 2 deleterious mutations: 1 frameshift on PALB2, and 1 nonsense mutation on RAD51C. Variants of uncertain significance will be reported. Further analyses will be needed to classify these variants.
Conclusion: This preliminary analysis support the contribution of PALB2 and RAD51C in breast/ovarian cancer families. Inclusion of new patients is currently ongoing.
Collection of such data together with clinical records are of importance to contribute to collaborative efforts to offer proper guidelines for breast and ovarian cancer risk management of mutation carriers.

MicroRNA-330-3p functions as an oncogene in human esophageal cancer by targeting Programmed cell death 4

W. Kai, *H. meng, J. Li, Y. Bai;*
Third Military Medical University, Chongqing, China.

MicroRNAs comprise a family of small non-coding RNA molecules that have emerged as key post-transcriptional regulators of gene expression. Aberrant miRNA expression has been linked to various human tumors. This study was aimed to identify novel miRNAs involved in the carcinogenesis of esophageal squamous cell carcinoma (ESCC) and their potential functions. We performed miRNA microarray and found that miR-330-3p was highly expressed in ESCC tumor tissues. Ectopic expression of miR-330-3p significantly promoted ESCC cell proliferation, survival, migration, invasion in vitro and stimulated tumor formation in nude mice. Knockdown miR-330-3p expression leaded to the opposite effects. Further, we revealed that miR-330-3p could repress the expression of programmed cell death 4 (PDCD4) by targeting its 3' un-translated region (UTR) and expression of PDCD4 was inversely associated with miR-330-3p in ESCC tissues. In addition, silencing of PDCD4 significantly promoted cell growth, cell migration, invasion and inhibited cisplatin-induced apoptosis. In conclusion, our findings demonstrated that miR-330-3p might play an oncogenic role in the development of ESCC partially via suppression of PDCD4 expression.

Clonal hematopoiesis markers in Ph-negative myeloproliferative neoplasms (PH(-)MPN)

L. Polushkina, *I. Martynkevich, E. Petrova, L. Martynenko, M. Ivanova, N. Cybakova, E. Kleina, E. Shabanova, A. Zhernyakova, M. Fominykh, V. Shuvaev, K. Abdulkadyrov;*
Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation.

Inroduction: In 2013 several researchers have published data describing recurrent mutations - insertions and deletions - in 9th exon of CALR gene among patients with Ph(-) MPN which allow to consider these mutations as a new marker of clonal hematopoiesis like JAK2 and MPL mutations. The goal of our study was to determine frequency of JAK2, MPL, CALR mutations in MPN patients and to analyze overall survival (OS) in groups with different clonal markers and triple-negative.
Methods: In our work we used PCR-RFLP, high resolution melting and direct sequencing methods. Results: JAK2V617F mutation was determine in 74/76(97,3%) pts with polycythemia vera (PV), 26/63(41,27%) pts with essential thrombocythemia (ET) and 21/43(48,83%) pts with primary myelofibrosis (PMF). 2/76(2,7%) pts with PV have mutations in 12th exon of JAK2. 515 codon mutations of MPL were observed in 3/43(6,97%) cases of PMF and 3/63(4,76%) cases of ET. Frequency of CALR mutations among pts with PMF and ET was 20,63%(13/63) and 13,95% (6/43) respectively. There was no reliable differences in OS in groups of pts with JAK2(+), MPL(+), CALR(+) and without mutations (p=0.127), but it should be mentioned that 4 of 6 died pts have unfavorable karyotype (+7, +8, del (5),(q13,q39), complex). It was not take into account when determining OS. Interestingly, OS in CALR-mutated group was 100% while OS in MPL(+) and triple-negative group was 67% and 80% respectively.
Conclusion: Genetic testing of clonal markers is insufficient. Only complex genetic and cytogenetic analysis of tumor cells has crucial importance for diagnosis and prognosis of MPN.

J13.01

Effect of Sodium benzoate preservative on micronucleus induction, chromosome break and Ala40Thr Superoxide dismutase gene mutation in lymphocytes

M. Pongsavee;
Department of Medical Technology, Faculty of Allied Health Sciences, Thammasat University, Patumthani, Thailand.

Sodium benzoate is food preservative that inhibits microbial growth. The effect of sodium benzoate preservative on micronucleus induction, chromosome break and Ala40Thr Superoxide dismutase gene mutation in lymphocytes were studied. Sodium benzoate conc. 0.5, 1.0, 1.5 and 2.0 mg/ml were treated in lymphocyte cell line for 24 and 48 hrs. respectively. Micronucleus test, Standard chromosome culture technic, PCR and Automate sequencing technic were done for detect micronucleus, chromosome break and gene mutation. The results showed that at 24 and 48 hrs. incubation time, Sodium benzoate conc. 1.0, 1.5 and 2.0 mg/ml increased micronucleus formation when comparing with the control group ($P<0.05$). At 24 and 48 hrs. incubation time, Sodium benzoate conc. 2.0 mg/ml increased chromosome break when comparing with the control group ($P<0.05$). Sodium benzoate did not cause Ala40Thr in Superoxide dismutase gene. Sodium benzoate had the mutageneic and cytotoxic toxicity in lymphocytes caused by micronucleus formation and chromosome break.

J13.02

Balanced chromosomal rearrangements and their clinical significance

L. Angelova[1], *M. Hachmeriyan[1], D. Konstantinova[1], M. Stoyanova[1], M. Cvetkova[2], M. Georgieva[3], V. Iotova[4];*
[1]Laboratory in Medical Genetics, University Hospital „St. Marina", Varna, Bulgaria, [2]Laboratory in Medical Genetics, University Hospital, Varna, Bulgaria, [3]2nd Pediatric Clinic, University Hospital „St. Marina", Varna, Bulgaria, [4]1st Pediatric Clinic, University Hospital „St. Marina", Varna, Bulgaria.

The aim of the study is to present the correlation between the presence of chromosomal rearrangement (BCR) and the clinical impact on the carriers. During 2003 to 2014 2414 patient were investigated by conventional karyotyping. The retrospective study analyzed cases with BCR (reciprocal translocations, inversions and insertions) in relation to the original reason for referral, phenotype (any significant clinical findings) case type (prenatal, postnatal), sporadic/ familial inheritance. BCR were found in 44 out of 2414 (1,82%) studied diagnosed patients. These were 29 (65,9%) reciprocal translocations (one prenatal case with two translocations and one postnatal of complex tree way translocation included), 10 (22,7%) Robertsonian translocations and 5 (11,4%) inversions. A combination of numerical mosaicism and BCR was found in two different familial cases. The most common referral was reproductive problems: recurrent abortions in 21 (47,7%) and primary infertility in 5 (11,4%) followed by unbalanced offspring in 9 (20,4%). Abnormal phenotype with significant clinical findings (developmental delay/disability, behavioral abnormality, major psychosis, tuberous sclerosis, hypergonadotropic hypogonadism) was found in 6 (13,6%) of the studied patients. BCR were diagnoses mainly in patients with spontaneous pregnancy losses and primary infertility and in a less degree in families with unbalanced offspring or even phenotypes with some significant clinical findings. It is important to distinguish between truly balanced and those that appear balanced cytogenetically but are really unbalanced on molecular level . The concept of their difference is still arbitrary and subject to ongoing molecular investigations nowadays announced as "Saturation of the human genome with chromosomal breakpoints".

J13.03

The role of ROS in the context of chromosome aberrations induced by arecoline

Y. Li, *Z. Hung;*
Department of Biomedical Sciences, Chung-Shan Medical University, Taichung, Taiwan.

Backgrounds:Areca nuts are widely chewed in the southeast Asian. Arecoline is one of the major alkaloid in Areca nut. It has been evidenced arecoline-induced cytotoxicity in various mouse and human cell types, while the induced chromosome aberrations only in mouse cell lines but not in human cell lines. The arecoline-induced ROS (reactive oxygen species) was also identified in several human cell lines. It was known that the oxidative stress from the elevated ROS impairs cellular functions involving in cytotoxicity, cell cycle arrest, and DNA damage, etc. In this study, we would identify the role of ROS in the context of the arecoline-induced chromosome aberrations. Materials & Methods:The in vitro chromosome aberration assay was used to evaluate the extent of chromosome aberrations. The cell growth and cytotoxicity were assessed using MTT assay and PI staining. Apoptosis was analyzed using the Annexin-V/PI assay and TUNEL assay. The ROS was quantitated using DCFDA detector. Results:The result of cytotoxicity and chromosome aberrations (CAs) showed that CHO-K1 cells (Chinese hamster cell line) was more resistant to arecoline than S-G (human oral gingival epithelial cell line). The arecoline-induced CAs was dose dependent in both CHO-K1 and S-G cells. The curve of dose- CAs was slower in CHO-K1 than S-G cells. Surprisingly, we found that arecoline induced ROS in CHO-K1 cell, but no ROS in S-G cell. Conclusion:Based on these findings, we suggested that arecoline caused different toxic responses in different cell lines. The induced ROS attenuated the arecoline-induced cytotoxicity and CAs in CHO-K1 cells.

Modulation of the expression of antioxidant enzymes and proinflammatory cytokines by cerium oxide nanoparticles in vitro.

A. Popov[1], *N. Popova[2], I. Selezneva[3], V. Ivanov[4];*
[1]Queen Mary, University of London, School of Engineering & Materials Science, London, United Kingdom, [2]Institute of Theoretical and Experimental Biophysics Russian Academy of Sciences,, Pushchino, Russian Federation, [3]Institute of Theoretical and Experimental Biophysics Russian Academy of Sciences, Pushchino, Russian Federation, [4]Kurnakov Institute of General and Inorganic Chemistry Russian Academy of Sciences, Moscow, Russian Federation.

Action mechanisms of cerium oxide nanoparticles (nanoCeO$_2$) to the intracellular signaling pathways, including conditions of oxidative stress at present is not entirely clear. The mechanism of the antioxidant properties of nanoCeO$_2$ associated with the presence on the surface of cerium ions in different oxidation states (Ce3 + and Ce4 +). On the one hand, nanoCeO$_2$ can serve as free radical scavengers since they have mimetic activity as antioxidant enzyme activity, such as superoxide dismutase and catalase. On the other hand, there is evidence confirming the effect of nanoCeO$_2$ on intracellular signaling pathways.
We analyzed the expression levels of a wide range of target genes in human mesenchymal stem cells with combination of cerium dioxide nanoparticles (for 24 hours prior to irradiation at a dose of 10^{-7} M) and X-ray dose of 15 Gy by RT-PCR method. We showed that nanoCeO$_2$ synthesized by citrate method, can regulate the expression of some enzymes (MnSOD, CuSOD, catalase, IL-1, IL-6, TNF-a, iNOS), reducing the level of oxidative stress in the cell, thereby preventing the development of oxidative stress, induced by ionizing radiation.
These data allow us to propose the assumption that nanoCeO$_2$ can act not only as a scavenger of reactive oxygen species and to modulate the metabolic pathways functioning cells, causing the formation of a specific adaptive response.
The obtained data can serve as the basis for the development of new highly selective radioprotective for clinical radiotherapy.
The project was supported by grants from RFBR № 14-04-32199 mol_a and №14-44-03615 r_center_a

J13.05

Fetal anomaly and feto-placental discrepancy in karyotyping

A. Kondo[1,2], *S. Nambara[1], D. Nakaoku[1], M. Murakami[1], M. Morine[1], M. Sone[1], S. Izumi[2], K. Maeda[1];*
[1]Shikoku Medical Center for Children and Adults, Zentsuji, Japan, [2]Tokai University School of Medicine, Isehara, Japan.

[Background] It is well known that confined placental mosaicism (CPM) is related to fetal growth restriction since chorionic villus sampling (CVS) has been becoming common. At our hospital, we experienced 4 cases of CPM in a few years and one of them had a hepatic tumor which is related to mosaicism. In this study, we focused on the frequency of CPM in the group of fetuses with anomalies not only fetal growth restriction.
[Method] In Japan, CVS is not so common and select more amniocentesis still now, so we have done the karyotyping of neonates and placenta (with all three embryonic cell lineages) postnatally. We obtained the samples from neonates with anomalies such as dismorphologic features, growth restriction and other problems including fetal death.
[Results] In 55 cases since November 2013 to date, two cases were failed at culture because of severe infection. Only 1 case was diagnosed as CPM and that case was clinically diagnosed as fetal growth restriction. This is 0.26% of FGR cases and 0.18% of total, while Kalousek et al. reported the prevalence of CPM detected at term in FGR could be between 8% and 60%.
[Conclusion] Against our hypothesis, fewer cases were diagnosed as CPM in this study. It suggests there might be some difficult point in diagnosing CPM at term pregnancy or the actual frequency of CPM would be rather low. We would like to continue this study with larger numbers to clarify the mechanism and the clinical impact of CPM.

J13.06

In vitro and in vivo preliminary genotoxicity study of dipotassium-tri oxohydroxytetrafluorotriborate K2[B3O3F4OH]

M. Hadzic[1], *S. Haveric[1], A. Haveric[1], M. Mijanovic[2], B. Galic[3];*
[1]Institute for genetic engineering and biotechnology, Sarajevo, Bosnia and Herzegovina, [2]Department of Toxicology, Faculty of Medicine, University of Sarajevo, Sarajevo, Bosnia and Herzegovina, [3]Faculty of Science, University of Sarajevo, Sarajevo, Bosnia and Herzegovina.

Genotoxic effects of inorganic molecule dipotassium-trioxohydroxytetrafluorotriborate, K2[B3O3F4OH], recognized as a promising new therapeutic for the treatment of the epidermis changes, have been evaluated in this study. In vitro analysis included evaluation of genotoxic and cytotoxic potential of K2[B3O3F4OH] in concentrations of 0.01, 0.02, 0.05 and 0.06 mg/ml applying cytokinesis-block micronucleus cytome assay in human lymphocyte cultures of 4 volunteer peripheral blood donors. With the increase of K2[B3O3F4OH] concentration the frequency of micronuclei elevates as well but the differences are not significant. Also, there were no significant differences among the frequencies of nuclear buds and nucleoplasmic bridges in controls and treated cultures. NDI and NDCI values did not differ significantly, although the means of both values were slightly decreased in treated cultures in comparison to controls. In vivo genotoxic effects were analyzed on 4 mice of BALB/c strain per each group, applying reticulocytes micronucleus assay. K2[B3O3F4OH] in concentrations of 10, 20, 50 and 55 mg/kg have been administrated intraperitonealy to the animals. Significant decrease of reticulocytes ratio and increase of micronuclei frequencies against pre-

treatments have been found for both sampling periods of 48 and 72 hours only for the highest applied concentration of 55 mg/kg.

Translocation t(18;19)(p11.2;p13.1) and its Clinical Implications; Case report and Mechanism of Pathogenesis

A. Turkyilmaz, *H. Simsek, E. Mamadov, K. Delil, B. Geckinli, M. Soylemez, I. Guney, P. Ata;*
Marmara University Faculty of Medicine, Dept. of Medical Genetics, Istanbul, Turkey.

A 30-year-old married female with one healthy child admitted to the medical genetics outpatient clinic for evaluation of recurrent fetal loss. Chromosomal analysis revealed a t(18;19)(p11.2;p13.1) translocation. Patient's parents, husband, and healthy child were also tested for chromosomal abnormalities. Married couple had a healthy 9-year-old child and 4 successive miscarriages, all at 5-6 weeks of pregnancy. First three abortions were spontaneous; the last was therapeutically induced . Family history revealed a sister with a known recurrent fetal loss and an early death of a male child from epileptic seizures at 6 years of age. Chromosomal analysis for the patient's sister, parents, healthy child and husband revealed t(18;19)(p11.2;p13.1) at patient's sister and mother. Chromosomal analysis of the patient revealed the same translocation. Questions concerning the probability of a patient to have a successful pregnancy and the risk of having an affected child were raised. With genetic counseling, patient was advised to have PGD and subsequent IVF to prevent the possibility of having an affected child or a miscarriage. IMPA2 gene and is responsible for a production of childhood febrile seizures, corresponds to 18p11.2 locus, which has been translocated to patient's chromosome 19. Although patient's sister's diseased epileptic child had no karyotyping, it is assumed that he had a chromosome with missing IMPase gene (chromosome 18 with a missing p11.2 locus), which caused decrease in IMPase production. Because of this occurrence, it is possible that the patient is also at risk of giving birth to a child with febrile epileptic seizures and migth result in early death of the child.

J13.08
Cytogenetic findings associated with X chromosome in the Genetic laboratory of Varna over 12 year period

M. Hachmeriyan[1], *L. Angelova*[1], *M. Stoyanova*[1], *D. Konstantinova*[1], *M. Cvetkova*[1], *W. Mladenov*[1], *S. Ivanov*[2];
[1]*University Hospital „St. Marina", Varna, Bulgaria,* [2]*University Hospital, Varna, Bulgaria.*

The cytogenetic analysis is still useful for the establishment of diagnosis in genetic diseases and in Eastern Europe it is basically the initial genetic analysis. The aim of this study is to reveal heterogeneity of X chromosome pathology among tested patients from the region of Varna, Eastern Bulgaria.
Patients and Methods: Retrospective analysis in the Laboratory of Medical Genetics was performed to find out patients with X chromosome abnormalities for a period of 12 years (2003-2014). These were cytogenetically examined phenotypic females and males at the age of a newborn to 53 years with indications: females with Turner-like phenotype, infertility (sterility or recurrent spontaneous abortions), premature ovarian insufficiency (primary or secondary amenorrhea), and ambiguous genitalia (congenital adrenal hyperplasia included). Conventional karyotyping with G-banding cytogenetic testing was performed.
Results: Significant X chromosomal aberrations were found in 57 (9.86 %) of all 578 indicated patients. The most common finding was Turner syndrome confirmed diagnosis with classical monosomy X in 13 (22.8%) or mosaic variants of numerical and/or structural abnormal cell lines of any known type 12 (21.0%) patients. Abnormal karyotype was found in 16(28.0%) (mostly females and one male) patients with infertility; 6 (10.5%) of females with premature ovarian insufficiency (reciprocal translocations of X chromosome with an autosome), undifferentiated gender in 3 (5,3%), dysmorphism and mental retardation in 2 (3.5%). In 5 patients (8.9%) familial rearrangement was diagnosed.
Conclusion: Cytogenetic analysis is an important first step in the overall schedule for genetic investigation that is still invaluable in the diagnostic algorithm of some entities.

J13.09
Loss of the chromosome PAR2 region in a case with a satellited Yq chromosome and attention deficit disorder

B. Hernández-Charro, *M. Moreno-Igoa, A. Bengoa, A. Valiente, M. Artigas, M. Ramos-Arroyo;*
Complejo Hospitalario de Navarra, Pamplona, Spain.

The so-called satellited Y chromosomes (Yqs) are the product of a translocation of the short arm of an acrocentric, preferentially chromosome 15, and the long arm of the Y, and they are considered without clinical consequences. We present a case with attention deficit hyperactivity disorder (ADHD), carrier of a Yqs with a deletion in Yq12. We also speculate about the possible role of genes on sex chromosomes as possible risk factors for ADHD.
We present a 12-year-old boy, second child of a mother who underwent amniocentesis for advanced maternal age. Karyotype in cultured amniocytes and parental blood samples revealed the presence of a de novo Yqs in the fetus. Additional FISH studies showed the chromosome 15 origin of the Yq satellited material. Baby delivery was uneventful. After an apparently normal development, he presented learning difficulties and behavioral problems, compatible with ADHD. Arrays-CGH studies, performed at the age of 12, identified the presence of a maternally inherited 152Kb duplication on 12q24.32 and a 242Kb deletion in the PAR2 region on the X or Y chromosome: arr[hg18]12q24.32(128224063-128376460)x3,Xq28(154600946-15843418)x1,Yq12(57460146-57702618)x1. FISH studies using BAC probes that hybridize with SPRY3 and VAMP7, confirmed the deletion which was localized on chromosome Yq12. The presence of the deletion was ruled out in father by FISH analysis.
Deletion of SPRY3 and VAMP7 genes on Yq12 cannot be considered the cause of the ADHD phenotype, as these genes are genetically inactive in the Y chromosome in males. We cannot rule out, however, loss-of-function genetic or epigenetic defects in the copy of these genes on X chromosome

J13.10
De novo reciprocal translocations are associated with different chromosomes and clinical outcomes

T. Cora, *N. Kocak, H. Acar;*
Department of Medical Genetics, Selcuk University, Medical School, KONYA, Turkey.

Balanced chromosomal rearrangements are the most frequent genetic abnormalities in the population (0.3-0.5%) and a major concern in the couples with reproductive problems (2-8%). These problems are usually recurrent miscarriages, chromosomally abnormal offspring or in some cases with infertility. These translocations usually do not show any phenotypic effect in most carriers, but sometimes may cause abnormal phenotype. In this report, the clinical, cytogenetic and molecular cytogenetic evaluations were performed on 13 patients with de novo balanced reciprocal translocation. Eleven of 13 patients have normal phenotype and two cases have dysmorphic features. Seven of 11 patients applied to our department for fertility problems and the remaining 4 have recurrent miscarriages. All these cases were undertaken IVF-PGD programme, by giving the genetic counselling. The other two patients were clinically evaluated for syndromic cases. In these patients, the responsible gene(s) in breakpoint regions were planned to identify for abnormal phenotype.

J13.11
Fanconi anaemia, chromosome instability, DNA replication and fragile sites.

F. Pelliccia, *M. L. Genovesi, K. Maccaroni;*
University Sapienza of Rome, Rome, Italy.

Fanconi anaemia (FA) is an inherited DNA repair deficiency syndrome caused by biallelic mutations of 1 of the 15 FANC genes. FA cells feature a high frequency of broken and radial chromosomes and are highly sensitive to interstrand DNA crosslinks. Chromosomal aberrations are often associated with incomplete genome duplication following replicative stress. Common fragile sites (CFSs) are usually late replicating regions and it is now common opinion that their expression as chromosome gaps or breaks may be due to unreplicated DNA.
Purpose: To study, within two CFSs, FRA2G and FRA2H, the relationship between DNA replication timing and fragility in FA lymphoblasts mutated in the FANCA gene (FA-A) and in the same cells transfected with normal FANCA gene (FANCA).
Methods: FISH, using sequences mapping within our two CFRAs, on interphase nuclei obtained from FA-A, FANCA and control cells: each locus before replication appears as a single hybridization dot signal (S), while after replication duplicated dot signals (D) are visible. Five distinct temporal S-phase stages can be distinguished from the G1- and G2-nuclei by adding BrdU twenty minutes prior to cell harvest and analysing the BrdU-labelling patterns of the DNA replication.
Results: Respect to control cells, in FA-A and FANCA cells, the fragile sequences show a DNA replication stalling between the second and third stage of S phase. Moreover, while FA-A cells reach the last phase with only a 55% of duplicated loci, FANCA cells show a more regular trend reaching, as the control cells, the last phase of S with about 69% of replicated alleles.

J13.12

Persistence of hidden chromosome instability in peripheral blood lymphocytes of persons occupationally contacted with ionizing radiation

M. A. Pilinskaya, *S. S. Dibskiy, Y. B. Dibskaya, L. I. Shvaiko, V. A. Sushko;*
National Research Center of Radiation Medicine, Kijiv, Ukraine.

To research the possible contribution of radiation exposure into persistence of hidden chromosomal instability (HCI) in somatic human cells two groups of observation - occupational group (persons exposed to low doses of ionizing radiation during conversion of Chornobyl's „Shelter" into ecologically safe system) and unexposed matched control group were cytogenetically observed via joint use of two modifying tests - «G2-bleomycin sensitivity assay» and two-termed cultivation of peripheral blood lymphocytes. Under standard short-term (48 hours) cultivation background mean-group frequency of cytogenetic parameters in occupational group did not differ (P>0.01) as from the results of cytogenetic observation of unexposed group as from values typical for spontaneous chromosome mutagenesis in human peripheral blood lymphocytes. Under long-term (100 hours) cultivation mean background cytogenetic effect in occupational group increased (P <0.001) compared with that in first mitosis, whereas in unexposed group it decreased with time. Following testing bleomycin exposure principal differences between the groups in the manifestation and dynamics of cytogenetic effects were revealed. Despite the unidirectionality in dynamics of mean cytogenetic effect in both groups (decline in third mitosis) its mean value in occupational group exceeded (P <0.001) such in unexposed group under both terms of cultivation. Moreover, examined groups differed in interindividual peculiarities of HCI persistence which in occupational group confirmed the possibility not only preservation, but even accumulation of chromosome instability in successive cell's generations. Data received can be used to identify persons hypersensitive to mutagenic exposure of ionizing radiation in view of individual features of HCI expression and persistence.

Functional studies of BBS2 gene by minigene assay

M. Alvarez-Satta[1,2], *G. Pousada*[1,2], *S. Castro-Sánchez*[1,2], *D. Valverde*[1,2];
[1]*University of Vigo, Vigo, Spain,* [2]*Instituto de Investigación Biomédica de Vigo (IBIV), Vigo, Spain.*

Introduction: Bardet-Biedl syndrome (BBS, #209900) is a genetic rare disease belonging to the group of ciliopathies. Since the molecular basis underlying BBS is not fully understood and the real role of *BBS* variants has to be characterised, we aimed to analyse the functional implications of two *BBS2* mutations (p.Tyr89Cys and p.Arg275*) predicted to alter the normal splicing process after transcription. Remarkably, BBS2 protein is part of the BBSome-core complex, an important intermediate in the assembly of the mature BBSome, which is known to be involved in trafficking to ciliary membrane.

Materials and Methods: We performed mRNA expression studies by minigene assay using *pSPL3* vector and COS-7 cells for *in vitro* experiments. All minigene constructions and cDNA sequences were confirmed by direct sequencing.

Results: The two mutations analysed here were not observed to affect mRNA processing, as wildtype and mutated constructions produced the same pattern after agarose gel electrophoresis. Direct sequencing supported these negative results. Interestingly, we observed that nonsense-mediated decay did not work when p.Arg275* variant was transcribed, since we detected the band corresponding to the mutated transcript.

Conclusions: Although bioinformatic predictions are helpful to focus on molecular studies, biological experiments always have to confirm this data. Despite the negative results obtained here, we cannot discard any kind of alteration in BBS2 protein structure and/or function. Further studies will have to clarify the real role of these variants in DNA processing.

Comparison of human dermal fibroblasts (HDFs) growth rate in culture media supplemented with or without basic fibroblast growth factor (bFGF)

P. Ghasemi-Dehkordi[1], *N. Abdian*[1], *M. Hashemzadeh-Chaleshtori*[1], *M. Ganji-Arjenaki*[2], *A. Doosti*[3], *B. Amiri*[1];
[1]*Cellular and Molecular Research Center, Shahrekord University of Medical Sciences, Shahrekord, Iran, Islamic Republic of,* [2]*Clinical Biochemistry Research Center, Shahrekord University of Medical Sciences, Shahrekord, Iran, Islamic Republic of,* [3]*Biotechnology Research Center, Islamic Azad University, Shahrekord Branch, Shahrekord, Iran, Islamic Republic of.*

Basic fibroblast growth factor (bFGF) is a member of the FGF family secreted by different kinds of cells like HDFs and it is an important nutritional factor for cell growth and differentiation. The present study aims to investigate the HDFs growth rate in culture media supplemented either with or without bFGF. HDFs were isolated from human foreskin sample and were cultured in vitro in media containing bFGF and lack of this factor. The karyotyping was performed using G-banding to investigate the chromosomal abnormality of HDFs in both groups. The real-time Q-PCR was used to measure the expression level of p27kip1 and cyclin D1 genes normalized to internal control gene (GAPDH). HDFs cultured in media or without bFGF had normal karyotype and chromosomal abnormalities were not observed. The cell growth rates in both groups were normal with proliferated exponentially but the slope of growth curve in HDFs cultured in media containing bFGF was increased. Karyotyp test showed bFGF does not affect on cytogenetic stability of cells. The survey of p27kip1 and cyclin D1 genes by real-time Q-PCR showed the expression level of these genes were up-regulated when adding bFGF in culture media (p<0.05). This study demonstrates appropriate supplementation of culture media with growth factor like bFGF could enhance the proliferation and differentiation capacity of cells. Similarly, fibroblast growth factors did not induce any chromosomal abnormality in cells. Furthermore, cultured HDFs in bFGF supplemented media, the p27kip1 and cyclin D1 genes were up-regulated and suggesting an important role for bFGF in cell-cycle regulation and progression and fibroblast division stimulation.

J13.15

The frequency of spontaneous and radiation-induced cytogenetic damages in persons aged 12-100 years

O. O. Talan, *O. V. Shemetun, M. A. Pilinskaya;*
State Institution National Research Center for Radiation Medicine, Kyiv, Ukraine.

Using G-banding cytogenetics the frequencies of spontaneous and radiation-induced chromosome aberrations in peripheral blood lymphocytes of adolescents, middle-aged, elderly and centenarians were established. The gradual increase of mean-group spontaneous chromosome aberrations frequencies from adolescents to middle-aged and elderly (1.16±0.25, 2.01±0.34, 4.44±0.55 per 100 metaphases, respectively) and decline of spontaneous chromosome mutagenesis intensity in centenarians (2.78±0.55 per 100 metaphases) were found. The scatter of individual values of chromosome aberrations was within the limits of 0.67-1.74, 0.80-3.33, 2.2-6.25 and 1.00-5.76 per 100 cells in adolescents, middle-aged, elderly and centenarians, respectively. Accumulation of translocations and inversions with age in all groups was registered. Under X-radiation in vitro exposure in dose 250 mGy increase of chromosome injuries due to increase of chromosome type aberrations was determined in all groups. There wasn't detected significant difference between the mean-group frequencies of radiation-induced chromosome aberrations in adolescents, middle-aged and centenarians (6.16 ± 0.72, 5.64 ± 0.65, 7.01 ± 0.74 per 100 metaphases, respectively) while in elderly cytogenetic effects appeared higher than in other groups (11.35±0.97 per 100 metaphases). The maximal above-spontaneous level of cytogenetic radiogenic markers was determined in group aged 12-16 which indicates increased radiosensitivity during adolescence. The elevated frequency of chromatid type aberrations was detected in persons aged 60-70 indicating increased chromosome instability. In persons from different age groups chromosomes damaged accordingly to their relative length, especially in euchromatic regions (79.8% and 88.1% under spontaneous and radiation-induced mutagenesis, respectively). The most sensitive chromosome bends to X-irradiation in vitro in each observed age group were determined.

Detection of Down syndrome using 6 STR markers

M. Mackic-Djurovic[1], *S. Ibrulj*[1], *P. Projic*[2], *J. Cakar*[3], *D. Marjanovic*[3];
[1]*Center for Genetics, Sarajevo, Bosnia and Herzegovina,* [2]*Genos LTD, Zagreb, Croatia,* [3]*Institute for Genetic Engineering and Biotechnology, Sarajevo, Bosnia and Herzegovina.*

Introduction: Down syndrome (DS) is a congenital disorder resulting from abnormalities affecting chromosome 21. The goal of this study was to examine the effectiveness of 6 STR markers application (D21S1435, D21S11, D21S1270, D21S1411, D21S226 and IFNAR) in molecular genetics diagnostics of Down syndrome.

Materials and Methods: Testing was performed on 73 children, 45 boys and 28 girls, cytogenetically confirmed to have DS. DNA isolated from the buccal swab was used. STR markers, located on chromosome 21, were simultaneously amplified using quantitative fluorescence PCR (QF PCR).

Results: STR markers D21S1435, D21S11, D21S1270, D21S1411 and IFNAR have shown themselves to be good polymorphism markers in detection of trisomy 21 because they had almost identical number of samples with three

or two alleles (peak ratio of 2:1) on previosly mentioned marker. On the other hand, the D21S226 marker was uninformative for 19 samples as it showed only one allele.
Conclusions: However, the analysis of the other five STR markers have given positive information or the confirmation of trisomy 21.

J13.17
Modification of radiation-induced bystander effect in human peripheral blood lymphocytes in vitro

O. V. Shemetun, *O. O. Talan, M. A. Pilinskaya;*
State Institution National Research Center for Radiation Medicine, Kyiv, Ukraine.

Exposure of ionizing radiation accompanied by release from irradiated cells into surrounding medium cytokines and factors that promote the development of secondary oxidative stress and thus induce bystander effect in the unirradiated cells. The aim of the research was study the modification of bystander effect in human peripheral blood lymphocytes exposed to 1 Gy of X-rays via antioxidative vitamin complex (VC) containing water-soluble forms of tocopherol, ascorbic acid and retinol. GTG-banding metaphase chromosomes staining and developed by us "mixed human blood lymphocytes culture assay" consisted of cells differed on cytogenetic sex markers have been used. Mixed cultures received from 6 volunteers of different sexes have been treated by VC in concentration 40 μg/ml before the culturing. The level of chromosome aberrations in non-irradiated bystander cells cocultured with irradiated lymphocytes was 5.34 ± 0.49 per 100 metaphases and exceeded that in control cultures ($p<0.001$). Bystander effect in damaged chromosomes was presented mainly by chromatid breaks (3.97±0.42 per 100 metaphases). The frequency of chromosome types aberrations (deletions, translocations, inversions, dicentric and ring chromosomes) in bystander cells did not differed from control values ($p>0.05$). The modification of bystander effect by VC reduced the chromatid breaks frequency to a level (1.14±0.23 per 100 metaphases) which did not differ from such in control cultures (0.87±0.22 per 100 metaphases) ($p>0.05$). The data received testify about the protection of non-irradiated cells by antioxidative VC from the occurrence of secondary oxidative stress and elimination the development of radiation-induced bystander effect.

J13.18
Effect of spontaneous level of γH2AX foci on the level of cytogenetic damage in human cells

A. Belenko[1], *S. Vasilyev*[1,2], *A. Melnikov*[3], *I. Lebedev*[1,2];
[1]*Tomsk State University, Tomsk, Russian Federation,* [2]*Institute of Medical Genetics, Tomsk, Russian Federation,* [3]*Tomsk Cancer Research Institute, Tomsk, Russian Federation.*

Introduction: Spontaneous level of DNA damage and radiosensitivity of human cells are characterized by considerable interindividual variability. Mutagen-induced DNA double-strand breaks (DSBs), marked by γH2AX, in cells have traditionally been considered as dangerous pre-mutation damage. However, the nature of spontaneous γH2AX foci is not clear.
Purpose: To analyze the effect of spontaneous level of γH2AX foci on the spontaneous and radiation-induced level of cytogenetic damage in human cells.
Material and methods: Chromosome aberrations, micronuclei and γH2AX foci were assessed in lymphocytes of 54 healthy individuals and 11 patients with solid tumors, and extraembryonic fibroblasts of 18 human embryos.
Results: There was no direct correlation between spontaneous level of γH2AX foci and spontaneous frequency of centromere-negative micronuclei in both lymphocytes and extraembryonic fibroblasts. It suggests that not all spontaneous γH2AX foci, unlike the radiation-induced ones, correspond to DNA DSBs. Furthermore, after irradiation of lymphocytes from healthy individuals a negative correlation was found between spontaneous level of γH2AX foci and frequency of radiation-induced centromere-negative micronuclei (R=-0,37, p=0,025). Checking these results *in vivo* in the lymphocytes of cancer patients demonstrated that level of γH2AX foci before radiation therapy negatively correlated with the frequency of chromosome aberrations (mainly paired fragments) after the end of treatment (R=-0,73, p=0.024), reflecting the individual radiosensitivity.
Conclusion: Although the spontaneous level of γH2AX foci does not reflect the actual number of chromosomal abnormalities, it may be a marker of individual DNA DSBs repair capacity in human cells.
Study was supported by Grant of President №-14.122.13.6806, RFBR grant №14-04-31867.

J13.19
Insulin producing cells from murine Embryonic Stem Cells using Foxo1-siRNA and Gcg-siRNA

S. M. R. S. Enderami;
zanjan university of medical science, zanjan, Iran, Islamic Republic of.

Introduction: Embryonic stem cells (ESCs) are potential pluripotent cells derived from inner cell mass of embryonic blastocyst stage. So far, growth factors have been used for differentiation of ESCs to insulin producing cells . In the present study, in the absence of growth factors, siRNA was used to silence targeted genes.
Materials and Methods: In this study, embryoid bodies (EBs) were derived from murine ESCs. The EBs were then cultured in four groups; three test groups (containing culture medium with siRNA) and the control (the same culture medium used in test group without siRNA). After three weeks, differentiated cells were analyzed by using RT-PCR(expression of some pancreas-specific genes), immunocytochemistry (detection of insulin presence in cells) and ELISA (evaluation of the amount of secreted insulin to culture medium).
Results: The RT-PCR analysis of differentiated cells on three test groups showed expression of beta cell specific markers including insulin and Pdx1. The results of immunostaining showed that the insulin protein are expressed in differentiated cell of Foxo1 siRNA group and Foxo1/Gcg-siRNA group with different amounts and finally insulin secretion assay show that differentiated cells on Foxo1 siRNA group secreted more insulin in comparison with the other groups.
Discussion: Our data indicate that murine ESCs differentiate into insulin producing cell using siRNA ,without growth factors. Therefore, siRNA can be used as a novel approach for generating insulin producing cells from ESCs in vitro.

The profile analysis of 500 genes expression associated with immune system's function at the mentally retarded patient irradiated in utero due to the Chernobyl accident

L. S. Baleva, *E. N. Yakusheva, M. K. Tagirova, A. E. Sipyagina, N. M. Karahan, V. S. Sukhorukov;*
Research and Clinical Pediatrics Institute, Pirogov's Russian National Research Medical University, Moscow,, Russian Federation.

The main types of medico-biological consequences of radiation on human genome is genomic instability leading to malignant growths, intellectual backwardness, hereditary (chromosomal/gene) diseases in children from irradiated parents. The analysis of hospitalized diseases incidence showed a considerable share of intellectual retardation (IRD) in children irradiated in utero after the accident on the Chernobyl NPP. Data of IRD association with dismorfogenesis of brain and cerebral vessels is obtained (MRI-investigations).
The profile analysis of 500 genes expression associate with immune system's function which is carried out using the analyzer nCounter (Nanostring technologies, USA) showed statistically significant distinction ($p< 0.05$) to 10 genes expression (the raised expression - for genes IL1B, CXCL1, PTGS2, EGR2 and lowered - for IL17B, KIT, BATF3, CD83, CCL16, ATG12) at the mentally retarded patient irradiated in utero.
Children from a group of comparison have different immunopathological states. The further Bioinformatic analysis revealed changes of of genes expression functioning: IL1B, CCL16 participating in inflammatory reactions in nervous system, genes of EGR2, BATF3 - in regulation of a transcription of genes, genes of KIT, ATG12 - in regulation of process of apoptosis, IL17B gene - with nervous system functioning.
Changes in an expression of genes CXCL1, PTGS2, CD83 have association with oncogenic processes (according to scientific literature).
Our original research data concerning a characteristic of 10 genes profile in immune system's function will make a contribution in understanding of mechanisms of intellectual backwardness formation as a result of radiation pre-natal exposure and the radiation induced cancerogenesis.

J13.21
THE STUDY OF SODIUM LIGNOGUMATE AS MODIFICATOR OF RADIATION-INDUCED MUTAGENESIS

V. M. Shkarupa, *S. V. Klymenko, V. V. Talko;*
State Institution National Research Center for Radiation Medicine, Kyiv, Ukraine.

The objective of the study - complex cytogenetic analysis of sodium lignohumate (SLH) exposure under mutagenesis induced by γ-irradiation in Allium-test. Analysis of root meristem cells of Allium cepa L. seeds by usage of ana-telophase method had were carried out. The effects of SLH in concen-

tration of 100 mg/l on cytogenetic effects induced by γ-irradiation (Cs137) in doses of 5, 10 and 20 Gy was investigated. Polyfunctionality of SLH as potential antimutagen is ensured by the presence of not only antioxidant properties, but also a number of other mechanisms. Under SLH impact more effectively repair of chromosome damages in cells with one aberration took place, while in cells with a large number of chromosome injuries less efficient repair processes were registered. Stimulation of repair processes induced by SLH depended on the radiation dose. It was most effective under the dose of 5 Gy. With increasing of radiation dose up to 10 and 20 Gy this process deminished because it included other anti-mutagenic mechanisms: stimulation of repopulation and apoptosis, which are prevalent in the implementation of the final gene-protective effect. Differential antimutagenic activity of SLH in relation to various types of aberrations was revealed: the most effective reduction the frequency of short-lived markers of radiation mutagenesis (chromosome type aberrations) was detected; lower efficiency for long-term potential changes in the chromosomes, which then realized in chromatid type aberrations was showed. Thus, multiple mechanisms for implementing antimutagenic properties of SLH in γ-irradiation-induced mutagenesis in Allium-test were revealed. The data received permit to suppose that SLH can be use as therapeutic radioprotector.

J13.22
Post-replicative chromatin's role in formation of chromosomes and sex chromatin

A. Rafailov, *M. Rafailova;*
Department of Biology, Institute of Natural Sciences, M.K. Ammosov North-Eastern Federal University, Yakutsk, Russian Federation.

Distinctions between a pre-replicative and post-replicative chromatin remained imperceptible so far and didn't draw attention of researchers. However they were important for an explanation of fundamental structurally functional properties of a chromatin.
Replication of a threadlike chromatin doubles quantity of DNA in S period of an interphase. However, the quantity of the histone disks remains without change. Therefore, replication forms a new post-replicative form of a chromatin with double deficiency of histones (semihistonal chromatin or semichromatin). Spiralization and condensation are the main properties of a semichromatin. Semichromatin almost completely retained deficiency of histones and exposed to spiralization from interphase period G2 to a prometaphase, i.e. before merging of a nucleoplasm to cytoplasm. Free histones of cytoplasm compensate for the deficiency of histones of a semichromatin of chromosomes during an anaphase and a telophase. In such a way semichromatin of chromosomes turns in full on histones threadlike chromatin with a diameter of 11 nanometers.
All interphase nuclei contain chromatin bodies and nucleoreticulum. Nuclei of female cells have still sex chromatin. All of them represent the remains of a semichromatin of chromosomes which didn't manage to fill completely the missing histones and kept a spiralized form of a post-replicative chromatin. Preservation of the semichromatin parts of chromosomes in G1 period of an interphase can appear one of ways of long blocking of activity of seldom included genes. It is possible to explain with this property of a post-replicative chromatin the mechanism of blockade of genes of X chromosome in a sex chromatin.

Genotype-endophenotype correlation in patients with neurodevelopmental disorders and chromosomal microrearragements.

G. Di Rosa, *S. Guerrera, G. Munafò, A. Nicotera, F. Cucinotta, S. Rosina, M. Amorini, R. Siracusano, M. Lamberti, M. Bonsignore, A. Saporoso, A. Gagliano;*
Department of Pediatric, Gynecological, Microbiological and Biomedical Sciences, Unit of Infantile Neuropsychiatry, University Hospital of Messina, Messina, Italy.

Introduction: Rare CNV are frequently detected in patients with neurodevelopmental disorders, however, the relationship between pathogenic CNV and/or impaired dimensional neuropsychological traits need to be defined.
Material and Methods: We assessed a systematic analysis of the neuropsychological phenotype of 410 patients (56% M), age-range 24 months-18 years, affected by ID, ASDs, ADHD, communication disorders, tics and related-disorders attempted a correlation with CGH genotype.
Results: In 91 out of 410 patients (24.8%) 98 microrearrangements were detected by array-CGH among which 8 were disease-causing and 90 variants of uncertain significance, potentially pathogenic. Groups of patients with overlapping microrearrangements were identified and their neuropsychological profiles were systematically analysed (language, memory, attention, executive functions, visuo-spatial skills). Patients with chromosomal rearrangements showed more frequent facial and/or somatic dysmorphisms and major rate of comorbidities between ID with the other neurodevelopmental disorders. Chromosomal rearrangements associated with overlapping CGH included: 15q11.2 deletion comprising TUBGCP5, CYFIP1 and NIPA1-NIPA2 genes involved in neurogenesis, 15q11.2 duplication encompassing the autism susceptibility genes GABRA5 and GABRB3, 22q11.2 deletion and duplication affecting PRODH/DGCR6, TBX1, COMT and ZDHHC8 genes involved in neurotransmission and neurotoxicity, a gain-of-function Xp22.32 encompassing VCX3A and STS genes reported in patients with X-linked ichthyosis and ID.
Conclusions: Patients with somatic signs and lower cognitive levels associated to other neurodevelopmental disorders might be more likely to present CNV. The study of genotype-endophenotype relationship may support clinical diagnosis, prognosis and personalized rehabilitation programs.

J13.24
Mixoploidiy: A surviving case of 10-years-old with diploid-tetraploid with no mental retardation

J. Valdes-Miranda, *M. Rivera-Vega, R. Hernandez-Viquez, A. Perez-Cabrera, F. Garcia, P. Linares-Chavez, L. Gonzalez-Huerta, S. Cuevas-Covarrubias;*
Hospital General de Mexico, Mexico DF, Mexico.

Mixoploidy is the presence of a normal diploid cell population with 3 or more multiples of the haploid chromosome number. In 2n/4n mixoploidy the chromosome complement of the abnormal line is 92. The aim of the present study is to describe a case with mixoploidy. The proband, a 10-years-old male, was the second product of healthy, young and non-consanguineous parents with normal pregnancy. At birth, he weighed 1200 g and heighted 43 cm. Currently on physical examination, he showed a height of 103 cm (>3th percentile), weight of 17 kg (>3th percentile), head circumference of 48 cm (>3th percentile), normal IQ, pitched voice, microcephaly, brachycephaly, upper hairline anteriorly and posteriorly, ocular protrusion, downslanting palpebral fissures, hypertelorism, telecanthus, broad nasal bridge, dysplastic ear, low set ear, large philtrum, thick lips, wide mouth, dental malocclusion, hypoplastic mandible, small hands with brachydactyly and tips pointed, camptodactyly, coxa and geno varus, and pelvic limb shortening. At the age of 3-years-old, kariotype result in blood was mos 92, XXYY[35]/ 46,XY[65] and in fibroblasts mos 92, XXYY[42]/ 46,XY[58]. Currently, his kariotype in blood was mos 92, XXYY[73]/ 46,XY[27] and in fibroblasts mos 92, XXYY[71]/ 46,XY[29]; FISH analysis revealed nuc ish (DXZ1x2,DYZ3x2,D18Z1x4) [164]/ nuc ish (DXZ1x1,DYZ3x1,D18Z1x2)[39]. Genetic profile using 16 DNA markers showed only the presence of diploid complement. 2n4n mixoploidy seems to be due to a failure of cytokinesis after the first mitotic division of the zygote; other possibility is that a 2n zygote and a 4n zygote generate a chimera; in our case the former mechanism could be the cause of this mosaicism.

J13.25
An unusual association of a deletion on Xq21 in a Mosaic Turner female with mental retardation, seizures, facial and body asymmetry

N. Gharbi[1,2], *F. Abdelhedi*[1,2,3], *I. Ben Ayed*[1,2], *A. Lebbar*[3], *L. Maalej*[1,2], *M. Feki*[2], *L. Keskes*[2], *N. Belguith*[1,2], *H. Kamoun*[1,2], *J. M. Dupont*[3,4];
[1]*Medical genetic department – Hedi Chaker Hospital, Sfax, Tunisia,* [2]*Human molecular genetic laboratory - Medical school, Sfax, Tunisia,* [3]*Cytogentics laboratory, APHP, Cochin Hospital, Paris, France,* [4]*Paris Descartes University, Faculty of Medicine, Paris, France.*

Turner's syndrome affects about one in 2000 liveborn females. In about 50% of cases, karyotype analysis reveals the complete loss of one X chromosome, whereas the remaining patients display a multitude of chromosomal X abnormalities. Most people with Turner's syndrome have normal intelligence, however mental retardation was observed in patients with small ring X chromosome and terminal X deletions because of deletion of XIST or absence of skewed X inactivation, respectively.
We report the case of a twelve-year-old girl who was referred to our genetic clinic because of dysmorphic features, mental retardation and epilepsy. Craniofacial abnormalities included facial asymmetry, broad forehead, hypertelorism, bulbous nose, puffy cheeks and lower lip thick. The height was 104 cm (-4DS), and she had atrophy of the right hemicorpus, torso achromic lesions bands and absence of mammary development. Conventional cytogenetic analysis using G-bands revealed a 45,X/46,X,del(X)(q21.1) karyotype. Parental karyotypes were normal. Array-CGH refined the breakpoint location on Xq21.1, showed the absence of deletion of XIST and revealed the absence of other pathogenic copy number variations (CNVs). X-inactivation analysis with cytogenetic method will be considered.
Our observation is unique because facial and body asymmetry were never reported with mosaic Turner females. Usually large deletions are likely to be associated with complete skewed X inactivation when XIST is present so that the resulting phenotypes are relatively benign given the amount of

genetic material missing. The phenotype of our patient might be explained by inactivation of the normal X chromosome in cells with a deleted X.

J13.26
Digenic inheritance in Mexican patients with hereditary sensorineural hearing loss revealed through exome analysis

M. Martinez-Saucedo[1], *M. Gonzalez-Garay*[2], *M. Rivera-Vega*[1], *H. Urueta-Cuellar*[1], *L. Gonzalez-Huerta*[1], *S. Cuevas-Covarrubias*[3];
[1]*Hospital General de Mexico, Mexico DF, Mexico,* [2]*UTHSC at Houston, Institute of Molecular Medicine, Houston, TX, United States,* [3]*Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico DF, Mexico.*

Background: Hereditary neurosensorial hearing loss (NSHL) is a genetically heterogeneous disorder worldwide. GJB2 gene affections are a frequent cause of hereditary NSHL with a wide spectrum of clinical data that ranges from moderate to profound NSHL. Mexican population harbours a low frequency of GJB2 homozygous mutations in NSHL. In some cases, digenic inheritance is a cause of NSHL Objective: To describe two novel digenic mutations in the GJB2 gene and OTOA and MYO1C genes in patients with NSHL in a sample of Mexican patients. Materials and methods: Two families with prelingual NSHL were included in the study. Genomic DNA was extracted by conventional methods for exome analysis in affected patients. DNA sequencing analysis was performed to confirm exome findings. Results The digenic inheritance corresponded to GJB2 c.35delG in both families and OTOA p.E787X and MYO1C p.E831K in each family, respectively; both genes associated to NSHL. Parents were tested for these gene mutations and they had the heterozygous state that allowed to confirm the recessive inheritance pattern. These mutations were searching in 100 normal controls to discard a possible polymorphism. Conclusion: We describe two novel digenic varieties of homozygous mutations in patients with NSHL. All patients presented profound hypoacusia with no other anomalies. These data show the complexity in the genesis of NSHL and that the genetic defects are greater than expected in Mexican population.

Modification of plasmid antisense strand for in vivo transfection.

A. E. Khodova[1], *D. S. Polyakov*[2,3];
[1]*St.-Petersburg State University, Saint Petersburg, Russian Federation,* [2]*Federal State Budgetary Scientific Institution „Institute of Experimental Medicine", Saint Petersburg, Russian Federation,* [3]*North-Western State Medical University named after I.I Mechnikov, Saint-Petersburg, Russian Federation.*

Plasmid vectors are more preferable then viral ones since the former do not cause immune reaction, have relatively small size, and can be easily produced. Plasmid vectors do not integrate in chromosomes and are more stable. They might be used for treatment of monogenetic diseases, attribution new functions to cells, and various strategies for cancer therapy. However, nowadays plasmid vectors are not effective enough due to absence of stable bond with cell-penetrating peptide (CPP). The earlier solutions of the present problem were not successful enough. Non-covalently modified vectors are too large and chemical modifications affect the target genes. We suggest plasmid modification with biotin. By means of biotin-streptavidin interaction this plasmid might be strongly bound with CPP.
Prokaryote's transcription occurs only on the anti-sense strand of DNA and doesn't use the sense one. It allows the modification of the sense strand of plasmid to provide stable construction for gene therapy. Two types of plasmids were designed which contain green fluorescent protein gene downstream the eukaryotic promoter. In the first plasmid a part of thymine bases was replaced by biotinylated uracils on the sense strand of DNA. Similarly, in the second plasmid the anti-sense strand of DNA was modified.
The analysis of the biotinylated plasmid restriction fragments by immunoblotting confirms that both plasmids are biotinylated along the whole length. Peroxidase-labeled streptavidin was used for detection. The ability of the plasmids obtained for expression of green fluorescent protein was tested on the HEK 293 cell line. Expression of the target gene was observed only in the case of the sense strand modification.

Impaired DNA damage response to oxidative stress in Rubinstein-Taybi syndrome cells

C. Gervasini[1], *M. Thillon*[2], *I. Dutto*[2], *G. Passaniti*[2], *L. Larizza*[3], *E. Prosperi*[2];
[1]*Medical Genetics, Department of Health Sciences, University of Milano, Milano, Italy,* [2]*Institute of Molecular Genetics (IGM), CNR, Pavia, Italy,* [3]*IRCCS Istituto Auxologico Italiano, Milano, Italy.*

Rubinstein-Taybi syndrome (RSTS OMIM #180849, #613684), is a rare genetic disorder characterized by mental impairment, skeletal abnormalities, growth deficiency, and an increased risk of neoplasia. About 60% of RSTS patients carry a heterozygous mutation in CREBBP or EP300 genes encoding the homologous CBP and p300 acetyltransferase proteins that play a key role in DNA repair.
In order to investigate a possible altered DNA damage response (DDR) concurring to RSTS pathogenesis we analyzed lymphoblastoid cell lines (LCLs) derived from 5 patients carrying CREBBP (2 missense in KAT domain and a whole gene deletion) or EP300 (2 precocious frameshift) mutations to assess their ability to respond to different types of DNA damage.
All the analyzed RSTS cell lines showed i) signs of the presence of endogenous DNA Damage, as assessed by the appearance of phosphorylated histone H2AX, ii) increased sensitivity to oxidative potassium bromate-induced DNA damage and iii) significantly reduced ability to perform DNA incision after DNA damage, i.e. the first step of the base excision repair (BER) process carried out by a DNA glycosylase. The acetylation of DNA polymerase beta, DNA glycosylase OGG1, PCNA, histone H3 and also auto-acetylation of CBP and p300 are all reduced in RSTS cells, suggesting a correlation with BER deficiency.
All these findings support our rationale on impaired DDR, particularly at the level of BER, in RSTS cells, thus suggesting that full CBP/p300 activity is required for successful DNA damage removal and for maintainance of cell functions homeostasis.
Supported by „RTS una vita speciale" association.

J13.29
Beare-Stevenson and Crouzon syndromes: spectrum of the same disease. Identification of a novel mutation in the FGFR2 gene

R. Rivera-Vega, *V. Barcenas, J. Valdes-Miranda, L. Gonzalez-Huerta, S. Cuevas-Covarrubias;*
Hospital General de Mexico, Mexico DF, Mexico.

Beare-Stevenson syndrome (BSS,MIM 123709) is a syndrome characterized by craniofacial anomalies, craniosynostosis, ear defects, cutis gyrata, acanthosis nigricans, anogenital anomalies, skin tags, and prominent umbilical stump. Crouzonoid-like features are present in some cases whereas a few patients have a broad range of phenotypic features. Currently, a dozen of patients with FGFR2 gene mutations and BBS have been described; mutations p.Y375C and p.S372C. are the most characteristic point mutations in the FGFR2 gen and are present in 50-60% of patients with BBS. As not all patients have FGFR2 mutations, genetic heterogeneity has been proposed. The proband, a 21-years-old female, was the second product of healthy, young and non-consanguineous parents with normal pregnancy. At birth, she weighed 1500 g and heighted 39 cm. Currently on physical examination, she showed a height of 139 cm, weight of 41 kg, head circumference of 51 cm, borderline IQ, brachycephaly, sagittal suture and left coronal suture prominent, redundant skin in occipital region, low hairline posteriorly, ocular protrusion, upslanting palpebral fissures, hypertelorism, telecanthus, broad nasal bridge, broad and bulbous nose, short philtrum, thick lips, lip corners down, wide mouth, dental malocclusion, hypoplastic mandible, left geno valgus and left pelvic limb shortening. Genomic DNA analysis showed a novel p.F409I mutation within exon 9 of the FGFR2 gene. This mutation was not found in 100 normal controls or normal parents excluding a polymorphism. We describe a patient with mild clinical characteristics of Beare-Stevenson and Crouzon syndromes which enriches the spectrum of mutations in the FGFR gene and remarks the clinical variability overlapping of the symptoms of both diseases.

J14.01
Application of clinical exome sequencing in diagnostic setting

L. Pezzoli, *M. Sana, D. Marchetti, C. Lodrini, A. Lincesso, L. Perego, M. Iascone;*
AO Papa Giovanni XXIII, Bergamo, Italy.

High throughput sequencing has made possible the analysis of the human whole exome in clinical setting, raising technical, bioinformatics and interpretation challenges. We analyzed by clinical exome sequencing (CES) 130 patient-parents trios aged under 14 years, affected by cardiovascular, liver or neurologic disorders with suspected genetic causes. Our aim was the substitution of traditional gene-centered approach with a comprehensive analysis of all known disease genes.
Of the 130 patients, 61 (47%) carried at least one potentially causative mutation. Among them, 42 had an autosomal dominant disease of which 24 (57%) occurred de novo, 17 had autosomal recessive disease and two had X-linked disease. CES confirmed the clinical suspicion in 68% of cases, in 15% completely changed the initial clinical diagnosis and in 17% suggested a possible diagnosis.
Although the high detection rate observed, 53% of patients remained undia-

gnosed, of which 15% had positive family history and/or clinical presentations that strongly suggested a genetic basis.
We conclude that CES allows the rapid diagnosis of rare and heterogeneous genetic conditions in a unique and standardized laboratory workflow, but this type of analysis cannot be considered definitively negative because of the rapid improvement of genetic knowledge. Thus we suggest that a clinically optimized whole exome sequencing should be considered for clinical diagnosis of heterogeneous genetic conditions, focusing the analysis on known disease genes related to the patient's phenotype. By this approach, the report should be considered as a dynamic process, periodically revised on the basis of new clinical evidences or new research discoveries.

J14.02
Array Comparative Genomic Hybridization (array-CGH) for the genetic diagnosis of congenital heart defects

I. M. R. Hussein, *A. G. Chaudhary, R. Al Bader, H. Schulten, M. Al Quaiti, M. H. Al Qahtani; King Abdulaziz University, Jeddah, Saudi Arabia.*

Congenital heart defects (CHD) are the most common developmental anomalies and the leading non-infectious causes of mortality in newborns. The Microarray-based comparative genomic hybridization (Array -CGH) technique proved useful for the detection of submicroscopic chromosome rearrangements that could not be detected by conventional cytogenetic methods. **Objective**: The project aimed at the identification of inherited or/ novel genome variants causing syndromic or non- syndromic heart defects. **Subjects & Methods**: A total of 83 patients with CHD associated with developmental delay or other malformations were recruited in the study. We applied conventional cytogenetic methods such as G-banding and Fluorescent In-Situ Hybridization (FISH) techniques concomitant with high density array-CGH using 2X 400 oligo- microarray (Agilent). We could detect chromosome abnormalities in 11/83 (13%) cases using conventional cytogenetic techniques: Trisomy 18 (2), trisomy 13 (1), ring 18 (1), trisomy 9p (1), (del22q11.2) (3), (del7q11.23) (2), del 18(p11.32-p11.21) (1). Application of array-CGH technique confirmed the previous results and revealed pathogenic variants in another 10/33 samples (30%), besides large number of copy number variants (CNVs) were observed in all studied samples. **Conclusion**: the diagnostic yield of array-CGH technique is much higher than that observed using conventional cytogenetic techniques and proved to be useful for the clinical diagnosis of affected patients. The analysis of gene content in CNVs may be useful for detection of molecular pathways of cardiac development.
The project was funded by the KACST, King Abdulaziz University, (Grant No. P-L-11- 0556)

Evaluating the economic costs of clinical exome sequencing in a clinical genetics service laboratory

G. S. Sagoo[1], *M. Kroese*[1], *H. Martin*[2], *I. Delon*[2], *R. Armstrong*[3], *K. Brugger*[2], *F. Rodger*[3], *R. Littleboy*[3], *S. G. Mehta*[2], *S. Park*[3], *G. Woods*[2,3], *S. Holden*[2], *R. Sandford*[2,3], *E. Maher*[2,3], *S. Abbs*[2];
[1]*PHG Foundation, Cambridge, United Kingdom,* [2]*Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,* [3]*University of Cambridge, Cambridge, United Kingdom.*

In 2014, the regional clinical genetics laboratory at Cambridge University Hospitals, UK, introduced targeted clinical exome sequencing as a routine molecular diagnostic service. This offers potentially the best attributes of both the targeted gene panel and whole exome sequencing approaches. Initial tests were run on an Illumina HiSeq2500 but we then transferred the tests to a NextSeq500.
Here we report an economic analysis of this approach, detailing a cost consequences analysis from the perspective of the molecular genetics laboratory of prospectively testing approximately 900 patients chronologically referred for diagnostic testing over a period of 12 months. We compare: (a) costs associated with running the test on two different platforms, the Illumina HiSeq2500 and NextSeq500; and (b) differences in cost between this clinical exome sequencing approach and alternative conventional approaches which are available entailing Sanger sequencing and/or laboratory based NGS gene panel tests. The costs covered the diagnostic testing pathway and included laboratory work, machine costs, reagent costs, bioinformatics, confirmatory testing and result interpretation plus overheads as appropriate. Initial findings for the costs associated with a clinical exome sequencing approach suggest a potential average saving of between 15-25% per patient tested, compared with the cost of alternative available genetic tests.

J14.04
Bisulfite Sequencing Polymerase Chain Reaction for Analysis of the Promyelocytic Leukemia (PML) Promoter

k. karbalaie[1,2], *S. Vallian*[1], *L. Lachinani*[2], *S. Tanhaei*[2], *H. Baharvand*[3], *M. Nasr-Esfahani*[2];
[1]*Isfahan University, Isfahan, Iran, Islamic Republic of,* [2]*Royan Institute, Isfahan, Iran, Islamic Republic of,* [3]*Royan Institute, Tehran, Iran, Islamic Republic of.*

DNA methylation in vertebrates typically occurs at cytosine-phosphate-guanine sites (CpG sites). In these regions DNA methylation inhibits binding of active transcription factors and gene expression. In this study we have used two online software programs, MethPrimer and MSPPrimer, to conduct a search of the promyelocytic leukemia (PML) promoter, as a tumor suppressor protein, for the presence of CpG sites or CpG islands. MSPPrimer software predicted a large region to be the CpG island; MethPrimer software predicted a smaller region as the CpG island which was located inside the former. For bisulfite sequencing polymerase chain reaction (BSP) both softwares suggested primer pairs for a common region of the predicted CpG island. Bisulfite-treated DNA from NT2 cells was successfully amplified by the proposed primers. At BSP, in addition to the PCR buffer, we used an ammonium sulfate buffer (AMS) and general Taq polymerase to amplify bisulfite-treated DNA. Together, the results of this study showed that both softwares worked in parallel. Bisulfite-treated DNA was easily amplified with the AMS buffer and general Taq polymers.

The application of molecular genetic methods for diagnostic of idiopathic epilepsy in children

A. Abramov, *M. Belenikin, T. Kozhanova, N. Bruhanova, S. Zhylina, S. Aivasyan, T. Ananeva, T. Meshcheryakova, G. Mutovin;*
Scientific and Practical Center of children medical care, Moscow, Russian Federation.

Molecular genetic testing of SCN1A gene is mainly used for diagnosis of SCN1A-associated epilepsy. Mutations in SCN1A gene are the most common cause of generalized epilepsy with febrile seizures plus (GEFS+), severe myoclonic epilepsy of infancy (SMEI; Dravet syndrome) and rare cases of familial hemiplegic migraine. Selection of patients for genetic testing was carried out together with epileptologists among patients with idiopathic epilepsy (IE) observed in Medical Center. The five pathogenic mutations in SCN1A were determined in 45 patients: c.3022G>T, c.1144G>T, c.80G>C, c.3604C>T, c.1131A>C. The material from both parents was available for study in case of mutations detection c.80G>C and c.3604C>T. In the first family, mutation c.80G>C was detected in the mother without clinical features of epilepsy. There were no similar changes of SCN1A gene in the parents of patient with c.3604C>T. Unfortunately, genetic nature of GEFS+ and SMEI can not be confirmed only by sequencing SCN1A gene in many cases. As part of the research work, we developed panel, consisting of 34 genes, to examine of patients with IE. Total 90 patients with epilepsy were examined. The following number of mutations were found: SCN1A-7, SCN2A-6, SCN1B-3, SCN9A-4. Mutations in SCN1A, SCN1B, SCN2A, SCN9A genes were simultaneously detected in 2 patients. Clinically significant mutations in GRIN2A gene were determined in 2 children; mutations associated with Aicardi-Goutieres syndrome (RNASEH2A, RNASEH2B, TREX1) - in 7; mutation in SLC25A22 gene associated with early epileptic encephalopathy - in 3. There were no mutations in only 7 of all observed children, but 2 patients had deletion of SCN1A gene locus determined by chromosomal microarray analysis.

J14.06
The Investigation of pH Pump Based on Sodium-Bicarbonate Treatment for Acidosis Caused Disease

B. TÜRKGENÇ;
FATİH ÜNİVERSİTESİ, İSTANBUL, Turkey.

The blood pH should be maintained in very narrow limits for intracellular enzyme activities performed adequately and to protect the integrity of the cell membrane. Life-threatening blood pH is considered as the limits between 6.80 and 7.70. When the pH level falls below this value (pH <7.35) acidosis is occured. Acidosis, which occurs in the blood because of the excess of acidic materials is a severe illness. Acidosis could create mortality risks (eg, cardiovascular damage, kidney stones, hormonal problems, osteoporosis, etc.) for patients, unless the mortal risk factors could be eliminated by balancing biologically. To ensure this balance, bicarbonate (HCO_3), protein buffers of methionine and cystine, electrolite buffers of sodium and potassium materials are defined in the medical literature. Sodium bicarbonate is the body's most important buffer system. Due to this, bicarbonate has high concentration in the body and the hemoglobin is under the effect of this buffer. It is the most widely used in clinics and most effective acidosis stabilizer. In this study, the pH pump receptors will located in the abdominal area and

will perform measurements with chemical sensors. The amount of needed pH will be calculated by the software that integrated in the pH pump device. And the necessary sodium-bikarbonate will be pumped to the body, thus the pH level will be stabilized again and again. This project will be a precursor of medical literature and will lead to other studies. Also, In this project, we aim to increase the quality of life by producing the pH pump in order to diagnosed individuals against acidosis caused diseases.

J14.07
Application of a workflow classification of BRCA1 and BRCA2 sequence variants

X. Gabaldó Barrios, *M. Sarabia Meseguer, J. Alonso Romero, M. Marín Vera, G. Marín Zafra, P. Sánchez Henarejos, A. Sánchez Bermúdez, Á. Aliaga Baño, F. Ruiz Espejo; University Hospital Virgen de la Arrixaca, El Palmar (Murcia), Spain.*

Introduction. The likelihood of an unclassified variant result in BRCA1/2 is even higher for individuals from understudied populations.The IARC group has a clinical translation in which is provided a classification system in 5 levels. Not all variants are classified by this system,so we propose design a classification of all variants detected in our laboratory exploiting the information from the IARC system and literature.
Material and methods. Sequence variants classification criteria detected among 662 high-risk breast cancer families;Class 5(pathogenic):nonsense/frameshift variants or IARC level 5[1];Class 4(likely pathogenic):IARC level 4[1] or level 3S[2](splicing variants);Class 3(uncertain clinical effect):IARC level 3[1] or level 2S[2](splicing variants);Class 2(likely not pathogenic):IARC level 2[1] or level 1S[2](splicing variants) or variants described in Deffenbaugh[3] or Tavtigian[4] or using the recommended cut-off of 100:1 in favour of neutrality[5;6] or described in trans with a deleterious mutation and occur at a frequency≥1% in our population;Class 1(not pathogenic):IARC level 1[1],variants reported in control groups at an allele frequency≥1%.
Results. We classified 213 distinct variants:45 class 5 variants,1 class 4 variant, 59 class 3 variants,26 class 2 variants and 111 class 1 variants. Among families:106 families were class 5 variant carriers(16%),2 families were class 4 carriers(0.3%),59 families were class 3 carriers(8.9%) and 100% of families were class 2 or class 1 carriers.
Conclusions. A classification system for genetic variants with recommendations for action coupled to each class would help facilitate the communication between clinicians and laboratory.

A case report of suicide in a teenager with long-term use of fluoxetine associated with CYP2D6 polymorphism

S. Asriyants[1], *O. Veselkina*[2], *D. Sychev*[3], *Y. Obuhova*[2], *A. Polyakov*[4], *V. Klevno*[2];
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation,* [2]*The Bureau of Forensic Medicine of the Moscow region, Moscow region, Russian Federation,* [3]*Russian medical academy of postgraduate education, Moscow, Russian Federation,* [4]*Research Centre of Medical Genetics of the Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Background: CYP2D6 enzyme is responsible for the metabolism of antidepressants, including selective serotonin reuptake inhibitors, such as fluoxetine. Genetic variations in the highly polymorphic CYP2D6 gene may be associated with increased, reduced, or lost enzyme's activity, which can cause adverse drug reactions. Researchers discovered a link between fluoxetine use and suicidal behavior among teenagers.
Case presentation: A 17-years old teenager, a girl, has been taking fluoxetine for three months following neurologist's advice as a treatment for mood instability with a prevalence of depressed mood. The teenager committed suicide. After analyzing the girl's diary, the psychiatrist made a conclusion that the girl had been suffering from schizotypal personality disorder. Genotyping showed the presence of heterozygous CYP2D6*4 allele (c.1846G>A) and heterozygous CYP2D6*10 allele (c.100C>T), which may determine decrease in CYP2D6 activity. No other genetic variants (CYP2D6*3, CYP2D6*6, CYP2D6*9, CYP2D6*41) were found. Forensic chemistry research of bodily fluids pointed to presence of fluoxetine in blood and urine. Quantitative measurement of fluoxetine concentration in blood wasn't made because of insufficient volume of blood.
Conclusions: Fluoxetine use may cause toxic drug accumulation thus leading to worsening of suicidal thoughts if taken by teenagers with possible genetic determined insufficiency of CYP2D6 enzyme (poor metabolizer).

J15.02
A tale of genetic variation in the human SLC22A1 gene encoding OCT1 among type 2 diabetes mellitus population groups of West Bengal, India

D. Sur;
C.U., Kolkata, India.

The organic cation transporter 1, OCT 1 (also called SLC22A1-Solute Carrier Family 22 member 1), appears to play a role in the efficacy and disposition of variety of organic cation including drugs. Genetic polymorphisms in the drug
transporter have been increasingly recognized as a possible source of variation in drug disposition and response. Genetic variants in OCT1 have been identified largely in European, Asian (Japanese, Chinese and Korean) populations.
Interestingly, eight genetic variations were found in the human SLC22A1 gene, which encodes OCT 1, from 50 type 2 diabetes mellitus individuals (T2DM), in West Bengal population. The purpose of this study was to investigate genetic
variants of OCT1 in West Bengal populations. We detected the three previously reported non-synonymous variations, 480 G>C (L160F); 1022 C>T (P341L); 1222 A>G (M408V) and one synonymous variations 156 T>C (S52S) at a minor
allele frequencies (MAF) of 0.63, 0.20, 0.43 and 0.27 respectively. We also found four previously reported intronic variations: IVS1-43(T>G), IVS2 -99(C>T), IVS5 -61(G>A), IVS9 +43(C>T) with minor allele frequencies of 0.20, 0.17, 0.18, and 0.37 respectively.

Scientific justification the tactics of individual pharmacological correction in patients with Duchenne/Becker muscular dystrophy

V. C. Sacara[1], *S. Groppa*[2], *M. Duca*[3];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*State University of Medicine and Pharmacy "Nicolae Testemiţanu", Chisinau, Moldova, Republic of,* [3]*University of AS RM, Chisinau, Moldova, Republic of.*

Have been justified the hypothesis of modifying influence of the genes involved in methionine and folate cycle (MFC) as well as eNOS gene on the progression of myopathic process.
Materials and Methods: The study was carried out on the territory of Moldova, covering population living in all 39 districts of the Republic. The study period was 24 years, from 1991 to 2014. Epidemiological studies have been conducted: a retrospective cohort study and case-control study. For statistical analysis were used SPSS program and the MDR program.
Results: The prevalence of hereditary neuromuscular pathologies in RM was 23,5:100000 population. Have been identified 17 novel mutations in DMD patients (not described in LMD pages). Evaluation of genotypes association and risk of worsening of myopathy process has identified a statistically significant value for G66G allele of MTRRgene (OR=7.20,p=0.039) and heterozygous carrier status of A2756G mutations in MTRgene (OR=0.63,p=0.045) and carrier status of 4b allele of eNOS gene (OR=1.58,p=0.027). Polymorphic variants of genes involved in MFC and eNOS genes contribute to predisposition to the progression of myopathy process at the molecular level that can explain the nature of clinical polymorphism in development of disability. The genetic basis of susceptibility to progression of the myopathy process and early disability is evident synergy between FMC and eNOS genes.
Conclusions: FMC and eNOS genes are prognostically valuable markers in forecast of the age of stage of wheelchair dependency of DMD/B that substantiates the need for use in clinical practice of neurologists and geneticists for determining the groups at risk of progression of myopathy and personalized therapy of patients

Introduction:
Metformin is the most commonly prescribed drug in type 2 diabetes and showed to be associated with decreased risk of incidence of various types of cancer. Metformin is a substrate of organic cation transporters (Octs), especially Oct1, Oct3 (liver) and Oct2 (kidney), which determines the pharmacokinetics/dynamics of metformin and thus its action. There is a great variability in the clinical response to metformin e.g. glycaemic control, mainly due to genetic variances.
Methods:
Genotypes of intronic SNPs in Oct1, Oct2 and Oct3 were determined in the LURIC study a prospective cohort of 3316 male and female participants [mean age 62.6 (10.6) years] scheduled for coronary angiography between 1997 and 2000. We investigated whether intronic variants of Oct1, Oct2 and Oct3 were associated with all cause death and cardiovascular death in metformin users.
Results:
In a multivariate Cox regression analysis adjusted for classical cardiovascular risk factors, the intronic Oct1 SNP rs461473 genotypes were significantly associated with all-cause mortality (p=0.009) and cardiovascular mortality (p=0.0028). An additive Cox regression model showed a decrease in hazard ratio (HR) of 9.57 (95% confidence interval 1.75-52.42) for all cause death as well as of 20.81 (CI: 1.38-313.99) for cardiovascular death, respectively, for each present G allele.
Conclusions:
An intronic variant in Oct1 is associated with all cause and cardiovascular death in metformin users.

J15.05
CYP 2C9 polymorphisms distribution in anticoagulant treatment candidates

L. Pojskic[1], *S. Ackar*[2], *N. Lojo-Kadric*[1], *J. Ramic*[1], *K. Bajrovic*[1];
[1]*Institute for genetic engineering and biotechnology, Sarajevo, Bosnia and Herzegovina,* [2]*Department of Biology, Faculty of Science, University of Sarajevo, Sarajevo, Bosnia and Herzegovina.*

Individual variability in drug efficacy and drug safety is a major challenge in current clinical practice, drug development, and drug regulation. I.e. warfarin or coumarin is a typical drug example of how functional variants of genes affect drug metabolism which is shown in relation to Cytochrome P4502C9 polymorphisms. Cytochrome P4502C9 (CYP2C9) is largely responsible for terminating the anticoagulant effect of warfarin via hydroxylation of the pharmacologically more potent S-enantiomer to inactive metabolites. Mutations in the CYP2C9 gene result in the expression of three variants: CYP2C9*1, CYP2C9*2 and CYP2C9*3.
Main aim of this study was to evaluate the distribution of CYP2C9*1, CYP2C9*2 and CYP2C9*3 polymorphisms within patients who are candidates for anticoagulant (warfarin) treatment. Consequently, the potential side effects of the treatment could be evaluated.
We studied the random distribution of CYP2C9 polymorphisms in patients-candidates for anticoagulant treatment: first patient group was consisted of patients that had at least one thrombo-embolitic episode in their lifetime; second patient group was consisted of women that had recurrent spontaneous abortions (at least two). A control group gathered healthy volunteers who did not have any thrombo-embolitic episode or family history of thromboembolism. Cytochrome 2C9 polymorphisms were genotyped using ARMS PCR method.
Statistically significant over-representation of CYP2C9*2 genotypes were observed. Positive allelic CYP2C9*2(Cys144Arg) and genotype overrepresentation for CYP2C9*/CYP2C9*2 (P=0,0010) within secondary infertility-group. No statistically significant association for CYP2C9*3 variant with either investigated disorder was observed (p>0,05). Observation may imply that significant reductions in intrinsic clearance of a variety of 2C9 substrates could be a contributing risk-factor.

J15.06
Genetic polymorphism of enzymes in patients suffering from acetaminophen overdose

L. Jensen[1], *K. Dalhoff*[2], *C. Børsting*[1], *A. Buchard*[1], *N. Morling*[1];
[1]*Forensic Genetics, Copenhagen, Denmark,* [2]*Clinical Pharmacology, Copenhagen, Denmark.*

Introduction: Acetaminophen (APAP) is a mild, analgesic drug used extensively all over the world. APAP has only few side effects if used at therapeutic doses. However, APAP has a narrow therapeutic index. Even a minor overdose of APAP is associated with significant morbidity and mortality and is a major cause of acute liver failure in most western countries.
Genetic variability may predispose some individuals to be at higher risk of being APAP poisoned.
The aim of this study was to investigate if genetic polymorphisms in genes relevant for the metabolism of APAP are associated with the clinical outcome of an APAP overdose.
Methods: A total of 102 patients admitted after APAP overdoses were enrolled in the study. A total of 94 patients were considered to have intentional and eight patients unintentional APAP overdoses. Thirteen patients died or developed hepatic encephalopathy in relation to APAP overdose.
All patients and 50 healthy Danish controls were genotyped using the Sequenom iPLEX® ADME PGx Panel designed for the Sequenom MassARRAY®.
Results: The analysis of the patients showed that the mean dose of ingested APAP was 35.8 g (±29), and the mean ALT level was 5,333 IU/L (±4,775 IU/L). Analyses showed that patients heterozygous for the GSTP1 rs1138272 were overrepresented among patients who either died or developed hepatic encephalopathy/renal failure, with an odds ratio of 3.32 (95% CI. 1.09-10.22, p = 0.034).
Conclusion: The results suggest that rs1138272 may be associated with the clinical outcome of an APAP overdose.

J15.07
Machine learning algorithms based on genotype data predict subgroup of refractory Crohn's disease patients requiring biological therapy

U. Potocnik[1], *M. Mitrovic*[1], *K. Repnik*[1], *G. Stiglic*[2], *R. K. Weersma*[3];
[1]*University of Maribor, Faculty of Medicine, Maribor, Slovenia,* [2]*University of Maribor, Faculty of Health Sciences, Maribor, Slovenia,* [3]*University Medical Centre Groningen and University of Groningen, Groningen, Netherlands.*

Crohn's disease (CD) is in addition to ulcerative colitis (UC) one of the two main subtypes of inflammatory bowel disease (IBD). Refractory CD patients, who are not responding to standard therapy and/or are showing side effects during therapy, develop severe disease and fulfill criteria to be enrolled into treatment with TNF-alpha antagonists (infliximab and adalimumab). Aim of this study was to show that refractory CD is a sub-phenotype of CD patients with significantly different genetic architecture and to develop genotype profiles that could most efficiently identify and predict the refractory CD patients. Genotypes for 8.858 LD-pruned single nucleotide polymorphisms (SNPs) of 179 CD patients, including 92 refractory patients were obtained from a custom array Immunochip. Support Vector Machine learning algorithms were used for genotype profile modeling.
We have found that most efficient genotype profile distinguished refractory patients from other CD patients with the best-achieved AUC 0.64 and consisted of 59 discriminator SNPs. Inclusion of demographic data (smoking, age, sex) did not significantly improve the predictive model. In addition, discriminator SNPs were tested in a standard association test between CD and CD refractory patients and two SNPs, rs9592040 in DIAPH3/TDRD3 gene region and rs346818 in KIF1C/GPR172B gene region remained significantly associated after Bonferroni correction.Connectivity analysis (GRAIL) revealed, a total of 5 genes rs395561 (EFNA5), rs2690262 (UNCX), rs9720889 (SCXB), rs10992979 (BARX1), rs7127817 (NCAM1), with significant association to functional connectivity. Identification of patients that will not respond to standard therapy is important as these patients could be enrolled into biological therapy at early stages.

J15.08
Anti-TNF treatment response in Crohn's disease patients is associated with genetic polymorphisms and gene expression

K. Repnik[1,2], *S. Koder*[3], *U. Potočnik*[1,2];
[1]*Center for Human Molecular Genetics and Pharmacogenomics, Faculty of Medicine, University of Maribor, Maribor, Slovenia,* [2]*Laboratory for Biochemistry, Molecular Biology and Genomics, Faculty for Chemistry and Chemical Engineering, University of Maribor, Maribor, Slovenia,* [3]*University Clinical Center Maribor, Maribor, Slovenia.*

Anti-tumor necrosis factor (anti-TNF) agents are successful therapies in Crohn's disease (CD) however inadequate response occurs in up to 30% of patients treated. We have already identified strong association with anti-TNF response for ATG16L1 SNP rs10210302 and additional SNPs in 7 out of 31 tested CD associated genes. To improve predictive model of genetic markers for anti-TNF response we further investigate expression of 12 CD associated genes in well characterized cohort of 102 Slovenian CD patients treated with anti-TNF drug adalimumab (ADA) for which response was defined according to inflammatory bowel disease questionnaire (IBDQ) and C-reactive protein (CRP) 4, 12, 20 and 30 weeks after treatment, representing 570 RNA samples. In addition we tested if 22 SNPs previously associated with anti-TNF response in related autoimmune diseases (ankylosing spondylitis, rheumatoid arthritis, multiple sclerosis) could predict response in CD patients receiving ADA. We found strong association of SNP rs2275913

in IL17A gene with response to ADA in CD patients (p=0,006) where patients with GG genotype responded better compared to patients with AA genotype. Further we found strong associations between anti-TNF response and SNPs in genes MIF, TNFα, TNFRSF1A and CD14. We also found that expression of two selected CD associated genes, ATG16L1 and SLC22A5, correlates with response to ADA treatment, where expression of ATG16L1 and SLC22A5 genes was increased in responders compared to non-responders (p=0,014 and p=0,042, respectively). To predict response to anti-TNF therapy, SNPs as well as gene expression serve as promising markers for future personalized therapy.

Janus Kinase 2 V617F mutation as genetic biomarker used for diagnostic criteria of myeloproliferative neoplasms: comparison of two methods proposed for clinical approaches

D. Nedelcu[1,2], *N. Cucu*[2,3], *R. Talmaci*[4,2], *C. Arsene*[2], *L. Burlibasa*[3], *V. Tandea*[2], *S. Arghirescu*[1], *R. Ursu*[5], *M. Puiu*[1];
[1]*University of Medicine &Pharmacy Victor Babes, Timisoara, Romania,* [2]*Epigenetics Laboratory for Advanced Biomarkers, Bucuresti, Romania,* [3]*Genetics Department, University of Bucharest, Bucuresti, Romania,* [4]*Hemathology Department-Molecular Biology Laboratory, Fundeni Clinic, "Carol Davila" Medical and Pharmaceutical University, Bucuresti, Romania,* [5]*University of Medicine &Pharmacy Carol Davila, Bucuresti, Romania.*

Introduction: Janus kinase 2 (JAK2)V617F mutation is associated with myeloproliferative disorders. Its blood clonal level may be considered a diagnostic criteria of essential thrombocythemia, polycythemia vera, primary myelofibrosis and other disorders. The early detection of this mutation in suspected patients may provide important information regarding the prediction of the incidence of leukemic transformation and possible interventional schemes.
Materials and methods: We analyzed 30 DNA samples from patients with MPD diagnosis based on ARMS (amplification-refractory mutation system) -PCR method for Jak2V617F mutation detection. The i-densy (Japan Arkray 5600 system) based on automated digital HRM (High Resolution Melting Temperature) analysis using Q (quenching) Probes, that included direct blood DNA extraction, automated amplification and probe alignment, further specific amplicon analysis by melting temperature differentiation through rapid automated computerized data normalization and easily recording, as compared with ARMS-PCR approach involving time consuming DNA processing steps and finally an error prone electrophoretic estimation of mutant clone burden.
Results: HRM approach enabled a semiquantitative estimation of mutant clone burden which was not possible with ARMS method. Certain negative ARMS results turned in positive HRM results. Also ARMS method could not detect the benefic effect or inefficiency of treatment as HRM approach could do, by the variation of the mutant clone absorbance peak.
Conlcusions: HRM i-densy system proved a more sensible and semiquantitative measurement approach as compared with ARMS method based on easy sampling, automated DNA extraction, amplification and analysis steps and also on timing, repeatability and sensitivity in JAK2V617F mutation detection.

J15.10

Exploratory analysis of variants in HCN4 gene and in 3 SNPs of CYP3A4 gene for association with ivabradine reduction in heart rate.

L. Nunez[1], *M. G. Crespo-Leiro*[2], *N. Suarez-Fuentetaja*[1], *E. Barge-Caballero*[2], *G. M. Marrón-Liñares*[1], *M. Paniagua-Martín*[2], *R. Marzoa-Rivas*[2], *Z. Grille-Cancela*[2], *D. Martinez*[2], *J. Muñiz-Garcia*[1], *A. Castro-Beiras*[2], *M. Hermida-Prieto*[1];
[1]*Grupo de investigación en Cardiología. Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC). Spain., A Coruna, Spain,* [2]*Servicio de Cardiología. Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC). Spain., A Coruna, Spain.*

Objectives: Ivabradine, a selective bradycardic drug, inhibits the If. In patients with heart failure (HF), ivabradine reduce the risk of rehospitalization and mortality. The average heart rate (HR) reduction is 8-10 beats, but there is interindividual variability showed in clinical trials. The aim of the study is to identify variants associated with HR reduction produced by ivabradine in genes involved in the drug metabolism (CYP3A4) or related to the drug target (HCN4).
Methods: In an exploratory cohort (n=11), patients who started in ivabradine were genotyped and the HR reduction was studied.
Results: The mean HR reduction after the treatment was 18,10±12,26 bpm. The reduction of HR was ≥15bpm in 3 patients and >5 and <15bpm in 7 patients. Four synonymous variants, L12L, L520L, P852P, and P1200P, were detected in HCN4 gene (Frequency= 0.045, 0.045, and 0.681, respectively). Moreover, the CYP3A4*1F and CYP3A4*1B were found in one patient each and the CYP3A4*1G was presented in 3 patients.
Conclusions: This is the first study using an exploratory pharmacogenetic approach that try to explain the interindividual variability in ivabradine HR reduction. However, more research must be done to determine the role of variants in HCN4 and CYP3A4 genes in the response to ivabradine.
Funding Sources:
This study received financial support from the Sección de Insuficiencia Cardiaca y Trasplante of the Sociedad Española de Cardiología. Moreover, the present study is part of the research activities of the "Red de enfermedades cardiovasculares del Instituto de Salud Carlos III (RD12/0042)".

Association of obesity susceptibly gene variants with obesity and related traits in Tatars women

O. V. Kochetova, *G. Korytina, L. Akhmadishina, T. Viktorova;*
Institute of Biochemistry and Genetics Ufa scientific centre, Ufa, Russian Federation.

Genome-wide association studies have revealed gene variants associated with obesity and related traits (anthropometric, biochemical parameters); but have no investigations among Tatars, which differ in the distribution of alleles several genes from both the populations of Asia and Europe. We examined the associations of metabolic traits and obesity related locis with risk of obesity. 10 SNPs (SEC16 rs10913469, FTO rs9939609, rs7202116, rs9930506, MCR4 rs12970134, rs17782313, TMEM18 rs2860323, rs6548238, CRP rs1130864, LIPC rs1800588) were genotyped by TaqMan and by PCR and RFLP (restriction-fragment-length polymorphism). Genotyping was performed in 460 Tatars women aged 48.17±10.52 years.
The FTO rs9939609 variant was associated with obesity (OR 1.50, CI95% 1.06-2.12, P=0.021). Allele C TMEM18 rs2860323 was related to obesity (OR 2.22, CI95% 1.35-3.55, P=0.0011) and allele C TMEM18 rs6548238 was associated with obesity (OR 1.64, CI95% 1.12-2.40, P=0.013). SEC16B rs10913469 and MCR4 rs12970134 were associated with obesity (OR 3.23, CI95% 1.83-5.71, P<0.0001 and OR 3.81, CI95% 1.16-12.50, P=0.019, respectively). The CRP rs1130864 variant was associated with obesity (OR 1.54, CI95% 1.10-2.16, p=0.012).
The fasting serum insulin, OGTT, hs-CRP, serum triglyceride levels, HDL and LDL cholesterol assessed by general linear mode. Mean levels of fasting serum insulin and C-peptide were higher in TT genotypes versus CC/CT CRP rs1130864 (P=0.009 and P=0.006). Mean levels of glucose at 2 h and HOMA-IR were higher in TT versus CC/CT LIPC rs1800588 (P=0.006 and P=0.03). The rest clinical and biochemical parameters of metabolic disorders did not differ depending on the polymorphic loci genes.
The work was done under supporting Russian Humanitarian Scientific Fund №13-06-00101.

Genetic analysis of the rs2298881 polymorphism in the ERCC1 gene in Slovenia

D. Sever, *A. Roj, P. Ferk;*
Faculty of Medicine, University of Maribor, Maribor, Slovenia.

Background: The excision repair cross complementation group 1 (ERCC1) protein could be a risk factor for different cancer types and could influence patients' response to platinum-based cancer chemotherapy. The aim of the present study was to genotype the rs2298881 polymorphism in the ERCC1 gene in the general Slovenian population.
Patients and methods: In total, 88 healthy individuals were included in the study. Genomic DNA was extracted from whole-blood samples using QIAamp® DNA Blood Midi kit. Genotyping of the rs2298881 ERCC1 polymorphism was done using TaqMan® SNP Genotyping Assay C_16191190_10 and qPCR LightCycler 480 System II.
Results: The rs2298881 ERCC1 genotype frequencies in the general Slovenian population were 14.7% (13/88) and 85.3% (75/88) for AC and AA genotypes, respectively. No CC genotype was identified in our study sample.
Conclusions: In order to establish more effective strategies for prevention and treatment of cancer, the rs2298881 ERCC1 genotype distribution should be further investigated in cancer patients, especially those receiving platinum-based chemotherapy. According to the present as well as to some previous studies, the CC genotype might be characterized as the "risky genotype".

The contribution of the immune response genes polymorphisms to chronic obstructive pulmonary disease in Russia

G. Korytina, *L. Akhmadishina, O. Kochetova, T. Viktorova;*
Institute of Biochemistry and Genetics, Ufa, Russian Federation.

Chronic obstructive pulmonary disease (COPD) is a complex chronic inflammatory disease of the respiratory system affecting primarily distal respiratory pathways and lung parenchyma. This work was designed as a association study aimed at investigating the association of COPD with JAK1, JAK3, STAT1, STAT3, NFkB, TNFA, LTA, IL6, IL17A, ADIPOQ, ADIPOR1 in a Tatar population from Russia.
Methods: 15 SNPs (rs310216, rs3212780, rs12693591, rs2293152, rs28362491, rs1800629, rs909253, rs1800795, rs4711998, rs1974226, rs3748067, rs1501299, rs266729, rs12733285, rs7539542 were genotyped by TaqMan assays in a case-control study (511 COPD patients and 508 control). Logistic regression was used to detect the association of SNPs. Linear regression were performed to estimate the relationship between SNPs and lung function parameters and pack-years.
Results: The rs1974226 IL17A (P=0.005 OR=2.22), rs1800795 IL6 (P=0.0018 OR=0.66), rs310216 JAK1 (P=0.0002 OR =1.70), rs3212780 JAK3 (P=0.0019, OR=1.39), rs2293152 STAT3 (P=0.036 OR=1.71), rs28362491 NFkB (P=0.015 OR=0.69), rs1800629 TNFA (P=0.0007 OR= 1.78) were significantly associated with COPD in additive model. The relationship between the rs3212780 JAK3 (P=0.0002), rs310216 JAK1 (P=0.0003), rs1501299 ADIPOQ (P=0.036) and emphysema risk was found. Chronic bronchitis phenotype was significantly associated wish rs1800629 TNFA (P=0.0005), rs1974226 IL17A (P=0.0074), rs2293152 STAT3 (P=0.0044), rs266729 ADIPOQ (P=0.019). The rs310216 (JAK1) and rs12693591 (STAT1) were associated with decrease of FEV1% predicted. A gene by environment interaction was observed for rs12733285 ADIPOR1 and rs266729 ADIPOQ and the smoking status (Pinteract = 0.003 and Pinteract =0.03). The rs1974226 IL17A, rs310216 (JAK1), rs3212780 (JAK3), rs2293152 (STAT3), rs28362491 (NFkB) loci were significantly associated with pack-years in smokers.
Our study confirmed the key role of systemic inflammation in development of COPD.

J15.14

Association of tuberculosis forms with polymorphisms of VDR gene among new cases

A. AKHMETOVA, *U. Kozhamkulov, D. Yerezhepov, M. Zhabagin, A. Askapuli, S. Rakhimova, A. Abilmazhinova, A. Akilzhanova;*
CENTER FOR LIFE SCIENCES, NAZARBAYEV UNIVERSITY, ASTANA, Kazakhstan.

Introduction. Environmental and lifestyle risk factors, genetically controlled host and bacterial factors contribute to tuberculosis (TB) development. Various publications show possible association of genetic polymorphisms of VDR gene with development of multidrug-resistant (MDR) TB of Beijing genotype.
Aim: To evaluate host-pathogen interactions in TB by comparing clinical-genetic features of TB patients with M. tuberculosis infection type (sensitive TB, mono-resistant TB, poly-resistant TB, MDR-TB)
Materials and methods. 80 patients with new pulmonary TB cases from Almaty, Kyzylorda and Kostanay regions were included in this study. Sample genotyping was done using Applied Biosystems 7900HT with TaqMan probes - rs2228570, rs7975232, rs731236 and rs1544410 for SNP markers FokI, ApaI, TaqI and BsmI of VDR gene, respectively. Drug resistance of M. tuberculosis to rifampicin, isoniazid, ethambutol and streptomycin was detected by absolute concentration method. Obtained results were confirmed by DNA sequencing of genes responsible for resistance to isoniazid - katG, ahpC-oxyR and fabG-inhA; rifampicin - rpoB; ethambutol - embB; and streptomycin - rpsL.
Results. Association of GG genotype of FokI with development of mono-resistant TB - 55,6 %; AC, AA and CC genotypes of ApaI (57,1%), TaqI (71,4%) and BsmI (71,4%) with development of poly-resistant form of TB was found among 4 groups. However, the results were not statistically reliable showing p-value 0,45; 0,84; 0,55 and 0,44 respectively.
Conclusion. No association between polymorphisms of VDR gene and infection with different forms of TB was found in our study. In order to confirm obtained results sample size should be increased and additional methods (MIRU-VNTR, spoligotyping) should be carried out.

J15.15

Association of CTLA4 polymorphisms as genetic risk factor in kidney transplant rejection

A. Taleb[1], **M. Hasanzad[1]**, *S. M. H. Ghaderian[2], M. Nafar[3], M. Samzadeh[3], S. Ghayem Amani[1], M. Imani[1], M. Afshari[4];*
[1]Medical Genomics Research Center, Tehran Medical Sciences Branch, Islamic Azad University, Tehran, Iran, Islamic Republic of, [2]Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [3]Urology and Nephrology Research Center (UNRC), Shahid Labbafinejad Medical Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [4]Department of Community Medicine, Zabol University of Medical Sciences, Zabol, Iran, Islamic Republic of.

Background: The most effective and common treatment for end-stage renal disease is kidney transplantation. CTLA4 may be a suitable candidate gene for studying allograft rejection.The aim of our study was to understand whether we can consider these two SNPs of CTLA4 gene as a risk factor of transplant rejection in Iranian population.
Materials and Methods: 169 kidney transplant recipients who underwent transplantation before 2010 were included in this study. The patients were classified into two groups according to Acute Rejection (AR) episodes. The -318C/T and +49A/G polymorphisms in CTLA4 gene were determined by RFLP.
Results: In +49 A/G polymorphism frequency of AG genotype was the same in both patients with and without history of rejection. None of those groups had homozygote genotype. Therefore, this polymorphism had no association with allograft rejection.In -318C/T both CT and TT frequencies among patients whose transplantations had been rejected
were lower than patients with normal outcome. Although that was not statistically significant. Compared to CC genotype as reference, TT genotype, caused 29% increase in the odds of rejection. However, this association was not significant (OR=1.29, p=1). **Conclusion:** The results of our study suggest that rs231775 (+49A/G) and rs5742909 (-318C/T) CTLA4 gene polymorphisms are not linked to acute rejection in the Iranian population who underwent kidney transplantation. So these polymorphisms cannot be considered as risk factors of acute allograft rejection in Iranian renal transplantation recipients.

Investigation of CYP2C19 polymorphisms which effect clopidogrel resistance and development of stent thrombosis in stent implanted CAD patients

D. Kirac[1], *T. Avcilar[2], A. Erdem[3], K. Yesilcimen[3], I. Guney[2], K. Ulucan[4], A. Emre[3], S. Yazici[3], S. Terzi[3], C. Kaspar[5], T. Isbir[1];*
[1]Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey, [2]Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey, [3]Dr. Siyami Ersek Chest & Cardiovascular Surgery Training & Research Hospital, Department of Cardiology, Istanbul, Turkey, [4]Marmara University, Faculty of Dentistry, Department of Medical Biology and Genetics, Istanbul, Turkey, [5]Yeditepe University, Faculty of Medicine, Department of Biostatistics, Istanbul, Turkey.

Introduction: Stent implantation (ST) is one of the major treatment for individuals who have coronary artery disease (CAD. It is a devastating complication of coronary stent implantation. Clopidogrel is an antiplatelet prodrug used to treat or prevent atherothrombotic events after percutaneous coronary intervention (PCI). It decreases the incidence of coronary artery ST. Clopidogrel resistance can be due to a genetic variation in one of the cytochrome P450 hepatic enzymes, particularly CYP2C19. Patients with polymorphisms in this gene, have more adverse clinical events following PCI. Indeed, this gene has been independently shown to be associated with early ST. Therefore the aim of this study is to investigate the effect of CYP2C19 gene mutations to clopidogrel resistance and stent thrombosis in stent implanted CAD patients.
Material-Methods: 80 CAD patients who have PCI and receiving 75 mg/day clopidogrel were recruited to the study. They were divided into two groups. 40 patients who have stent thrombosis were recruited to the first group, others were recruited to the second group. After DNA was isolated from peripherial blood, CYP2C19 mutations were investigated with RT PCR. Results were evaluated statistically.
Results: 8 heterozygous and 1 homozygous CYP2C19*2 mutations and 1 heterozygous CYP2C19*3 mutations were found in the first group. CYP2C19*2 mutations were found statistically significant in the first group when they were compared with second group.
Conclusion: It is possible to recommend CAD patients for increasing the dosage of clopidogrel or using other efficient drugs for preventing stent thrombosis. Therefore genetic screening of CAD patients for CYP2C19 gene mutations will help the improvement of personilized therapy strategies.

J15.17

Cytokines genes in susceptibility to JIA in patients from Russia.

L. S. Nazarova[1], *K. V. Danilko[1], T. V. Viktorova[1,2], V. A. Malievsky[1];*
[1]Bashkir State Medical University, Ufa, Russian Federation, [2]Institute of Biochemistry and Genetics, Ufa, Russian Federation.

Background: Some single nucleotide polymorphisms (SNPs) within cytokines and their receptors genes have been reported to be associated with juvenile idiopathic arthritis (JIA) and other autoimmune diseases in different populations.
Objectives: The aim of the study was to test the hypothesis that the TNFA, LTA, IL1B, IL2-21, IL2RA, IL6, IL10, MIF SNPs could underlie susceptibility to JIA or its subtypes in patients from Russia.
Methods: The TNFA (rs1800629), LTA (rs909253), IL1B (rs16944), IL2-21 (rs6822844), IL2RA (rs2104286), IL6 (rs1800795), IL10 (rs1800872), MIF (rs755622) SNPs was studied in 254 children with JIA and 204 healthy individuals from Bashkortostan, Russia using PCR-RFLP method and real-time PCR.
Results: LTA allele G (p=0,024), TNFA-LTA haplotype G-G (p=0,0009), IL6 genotype CC and allele C (p=0,026, p=0,021, correspondingly), MIF genotype GG and allele G (p=0,026, p=0,033, correspondingly) were significantly higher in JIA patients than in controls. Analysis stratifying by ILAR subtype showed that MIF genotype GG and allele G (p=0,005, p=0,013, correspondingly) were significantly higher than in controls in patients with RF-negative polyarthritis; LTA allele G (p=0,019), TNFA-LTA haplotype G-G (p=0,0016), IL6 genotype CC and allele C (p=0,005, p=0,012, correspondingly), IL10 genotype CC and allele C (p=0,019, p=0,022, correspondingly) - in patients with persistent oligoarthritis; LTA genotype AG (p=0,018), TNFA-LTA haplotype G-G (p=0,018), IL1B genotype TT (p=0,038), MIF genotype GG and allele G (p=0,038, p=0,050, correspondingly) - in patients with enthesitis-related arthritis.
Conclusions: Our data demonstrate the association of the TNFA (rs1800629), LTA (rs909253), IL1B (rs16944), IL6 (rs1800795), IL10 (rs1800872), MIF (rs755622) polymorphic variants with increased risk of JIA and/or its subtypes in patients from Russia.

J15.18

VDR gene polymorphisms impact on anemia at 2 week of anti-HCV therapy: a possible mechanism for early RBV-induced anemia.

J. CUSATO, *S. ALLEGRA, L. BOGLIONE, A. DE NICOLO', G. CARITI, G. DI PERRI, A. D'AVOLIO;*
University of Turin, Department of Medical Sciences, Amedeo di Savoia Hospital, Turin, Italy.

Vitamin D receptors (VDR) bind calcitriol and modulate several physiological systems, through genomic and non genomic pathways. Calcitriol stimulates store-operated channels Ca2+ influx by translocation of the caveolar VDR to the plasma membrane. Intracellular Ca2+ levels in erythrocytes control biophysical properties and an increase in its concentration can deregulate membrane composition, cell volume, glycolytic enzymes regulation, redox state and cell clearance.
We evaluated the role of single nucleotide polymorphisms in ITPA, CYP27B1, CYP24A1 and VDR genes in the prediction of ribavirin-induced anemia, in HCV-1/2/3/4 patients at 2 and 4 weeks of treatment.
Two hundred and twenty five patients treated with ribavirin and pegylated-interferon-α were genotyped by real-time PCR.
BMI at baseline>30 Kg/m2 (p=0.013, OR:10.95, IC95%:1.66-74.21), ALT at baseline>37 IU/L (p=0.020, OR:0.26, IC95%:0.09-0.81) and VDR BsmI AA profile (p=0.003, OR:5.09, IC95%:1.72-15.05) were anemia predictive factors at 2 weeks of therapy. At week 4, ITPA rs6051702 AC/CC profile (p=0.001, OR:0.19, IC95%:0.07-0.51) was the only factor able to predict this side effect.
BsmI AA genotype is a predictive factor of 2 weeks anemia and it could be related to a VDR enhanced activity, thus an increased calcium influx, resulting in the deregulation of the Ca2+-dependent signaling, which can lead to erythrocytes hemolysis. This rapid mechanism could be responsible of the early anemia development.
These results indicate for the first time the strong, significant and independent role of VDR in the early development of ribavirin-induced anemia and confirm the ITPA function in the prediction of anemia at week 4.

J15.19

microRNA profiling recognizing CML phases` pathophysiology

D. Jurkovicova[1], *R. Lukackova*[2], *M. Magyerkova*[3], *L. Kulcsar*[3], *M. Krivjanska*[3], *V. Krivjansky*[3], *M. Chovanec*[4];
[1]*KRD Molecular Technologies Ltd., Bratislava, Slovakia,* [2]*Medirex a.s., Bratislava, Slovakia,* [3]*KRD Molecular Technologies, Bratislava, Slovakia,* [4]*Cancer Research Institute, Bratislava, Slovakia.*

Chronic myeloid leukemia (CML) is a myeloproliferative disorder of hematopoietic stem cells carrying the Philadelphia (Ph) chromosome and an oncogenic BCR-ABL1 fusion gene. Oncogene and tumor suppressor microRNAs (miRNAs) are important regulators of transcription in hematopoiesis. Their expression deregulations were described in association with pathogenesis of chronic myeloid leukemia (CML), although they are still not fully understood. Our study was performed to assess and validate selected group of miRNAs in peripheral blood of patients for early detection and confirmation of found differences between patients with clinically defined CML phases and patients with uncorfirmed diagnosis. On mononuclear cells isolated from peripheral blood of CML positive versus CML negative patients, miRNA microarray analysis was performed. Selected miRNAs were validated by qRT-PCR. Using microarrays we identified differential expression profiles of 46 upregulated and 24 downregulated miRNAs in suspect CML patients at diagnosis distinguishing CML positive patients and patients with uncorfirmed diagnosis. Significantly increased expression of miR-17, miR-18a, miR-19a, miR-20a, miR-21, miR-27a and miR-155 in CML positive compared to CML negative patients and healthy individuals was confirmed by real-time quantitative PCR.
This study confirms the involvement of miR-17, miR-18a, miR-19a, miR-20a, miR-21, miR-27a and miR-155 in CML pathogenesis and suggests their possible clinical utilization as biomarkers for early recognition and confirmation of CML diagnosis.
This work was supported by grant co-sponsored by sources of EU - European fond for regional development through operation program of Research and Development (project code ITMS 26240220074 / call code OPVaV-2011 /4.2/07-SORO)

TNF-α GENE POLYMORPHISMS AND JUVENILE IDIOPATHIC ARTHRITIS: INFLUENCE ON DISEASE OUTCOME AND THERAPEUTIC RESPONSE

A. Scardapane[1,2], **R. Ferrante**[1,3], *M. Nozzi*[1,2], *A. Savino*[1,2], *I. Antonucci*[1,3], *V. D'Adorante*[1,2], *M. Balsamo*[1,4], *L. Stuppia*[1,3], *F. Chiarelli*[1,2], *L. Breda*[1,2];
[1]*Università G. D'Annunzio, Chieti, Italy,* [2]*Paediatric Rheumatology Unit, Department of Paediatrics, "G. d'Annunzio" University, Chieti-Pescara, Italy,* [3]*Laboratory of Molecular Genetics, Department of Psychological, Humanities and Territorial Sciences, "G. d'Annunzio" University, Chieti-Pescara, Italy,* [4]*Psycometric Laboratory, Department of Psychological, Humanities and Territorial Sciences, "G. d'Annunzio" University, Chieti-Pescara, Italy.*

Objective: To investigate the genetic contribution of TNF-α gene polymorphisms on the disease course and therapeutic response in patients with juvenile idiopathic arthritis(JIA).
Methods: 74 Caucasian patients with JIA were recruited with a control group of 77 healthy children. DNA was extracted for analysis of TNF-α gene promoter polymorphisms at position -163, -244, -238, -376 and -308.
Results: No SNPs at position -163 we observed while were observed only SNPs at position -244 and -376 in the controls. No differences were observed in the prevalence of SNPs at -238 and -308 between JIA and controls. In JIA patients no significant differences were observed between the -238 and -308 G/A genotypes and different disease phenotypes. We observed a significant lower disease activity expressed in the carriers of -308 GG genotype with respect to GA and AAgenotypes after 6 (p=0.008 p=0.013 respectively) and 12 months of disease (p=0.02 p=0.08 respectively). Also the -238 GG genotypes showed a better disease course after12 months of disease. Moreover the -238/-308 GG genotypes presented the higher reduction of disease activity both after 6 (p<0.01vs GA and p<0.01 vs AA) and 12months from baseline (p<0.01vs GA and p<0.01 vs AA). After 12 months of biologic therapy, a significant higher disease activity was observed in patients with genotype -308AA respect to both GA (p=0.012) and GG (p=0.016).
Conclusions: JIA patients carrying the TNF-α -308 GA/AA and -238 GA genotypes are associated with a worse prognosis and with a lower response to anti-TNF-α drugs.

The effect of polymorphisms in DNA repair genes and carcinogen metabolizers on leukocyte telomere length

Z. Verde[1], *C. Santiago*[1], *L. Reinoso-Barbero*[1], *P. Resano*[2], *I. Sánchez-Hernández*[3], *J. M. Rodríguez González-Moro*[4], *F. Bandrés*[5], *F. Gómez-Gallego*[1];
[1]*Universidad Europea, Madrid, Villaviciosa de Odón, Spain,* [2]*Hospital de Guadalajara, Guadalajara, Spain,* [3]*Hospital Carlos III, Madrid, Spain,* [4]*Hospital Gregorio Marañón, Madrid, Spain,* [5]*Universidad Complutense, Madrid, Spain.*

Introduction: Smoking implies exposure to carcinogenic agents that causes DNA damage, which could be suspected to enhance telomere attrition. To protect and deal with DNA damage cells possess mechanisms that repair and neutralize harmful substances. In this study we evaluated the effect of genetic polymorphisms in DNA repair genes and carcinogen metabolizers on leukocyte telomere length (LTL) in a cohort of healthy smokers.
Material and Methods: LTL and six genetic polymorphisms in CYP1A1 (Ile462Val), XRCC1 (Arg399Gln), APEX1 (Asp148Glu), XRCC3 (Thr241Met)

and XPD (Asp312Asn; Lys751Gln) were analyzed in 145 healthy smokers in addition to smoking habits. Genetic markers were determined by RT-PCR in blood samples. A logistic regression analysis adjusted for age, smoking history and gender was performed.
Results: Analysis showed an association between XRCC1 399Gln allele and shorter telomere length (OR=5.03, 95% CI=1.08-23.36). There were not association between the rest of polymorphisms analyzed and shorter telomere length, APEX1 (Asp148Glu) (OR=7.39, 95% CI=0.92-59.43), XRCC3 (Thr241Met) (OR=1.93, 95% CI=0.38-9.69), XPD (Asp312Asn) (OR=1.53, 95% CI=0.50-4.69), XPD (Lys751Gln) (OR=1.2, 95% CI=0.38-3.77) and CYP1A1 (Ile462Val) (OR=1.96, 95% CI=0.77-4.91).
Conclusions: Our data provide evidence that XRCC1 399Gln allele appears to confer sensitivity to the effects of tobacco compounds on LTL. Continuous exposure to tobacco could overwhelm the DNA repair machinery, making the effect of the polymorphisms that reduce repair capacity more pronounced. Analyzing the function of smoking-induced DNA-repair genes and LTL is an important goal in order to identify therapeutic targets to treat smoking-induced diseases.

Design and implementation of novel multiplex PCR assay to genotype EGFR mutations in patients with non-small cell lung carcinoma.

B. Gautam[1], *V. H. W. Dissanayake*[2];
[1]*National Acedamy of Medical Science,(NAMS), Bir Hospital, kathmandu, Nepal,* [2]*Human Genetic Unit, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka.*

Introduction: Lung cancer is the leading cause of cancer death worldwide. Approximately 80% of lung cancers are grouped as Non Small Cell Lung carcinoma (NSCLC). Mutations in Epidermal Growth Factor Receptor gene (EGFR) have been associated with improved response to tyrosine kinase inhibitors in patients with NSCLC. Two most common mutations, exon 19 deletion (E746-A750del) and exon 21 L858R Single Nucleotide Polymorphism (SNP) account for almost 90% of all EGFR mutations.
Objective: The aim of this study is to design and implement a new PCR assay for the screening of the two most common therapy-related EGFR mutations.
Methods: A Multiplex allele specific PCR assay was designed to detect the most common exon 19 deletion (E746-A750del) and exon 21 L858R SNP. Allele specific tetra primes were designed. To validate the assay for clinical diagnostics DNA was extracted from Formalin Fixed Paraffin Embedded (FFPE) tumor sample using QIAamp DNA FFPE Tissue Kit,
Results: PCR reactions were carried out in a single tube after optimization of the PCR conditions such as primer concentration, annealing temperature, and MgCl2 concentration. The designed assay provided the predicted amplification pattern for both mutant and normal genotypes
Discussion: The allele specific multiplex PCR assay we designed is fast and easy to perform in routine diagnostic laboratory compared with other proposed method for detection of EGFR mutations in NSCLC. PCR reaction could be carried out in a single tube with inexpensive reagents using standard PCR techniques which can be easily implemented at any clinical laboratory. This assay is sensitive and cost effective for initial EGFR testing.

J15.23
HLA-B*57:01: the Direct-PCR as fast and low-cost technology for pharmacogenetic screening

C. Strafella[1], *M. Ragazzo*[1], *S. Zampatti*[2,3], *P. Borgiani*[1], *S. Gambardella*[3], *A. Pirazzoli*[4], *G. Novelli*[1], *E. Giardina*[1,2], *R. Cascella*[1];
[1]*University of Rome "Tor Vergata", Department of Biomedicine and Prevention, School of Medicine, Rome, Italy,* [2]*Molecular Genetics Laboratory UILDM, Santa Lucia Foundation, Rome, Italy, Rome, Italy,* [3]*Neuromed IRCCS, Pozzilli; Italy, Pozzilli, Italy,* [4]*ViiV Healthcare, Verona, Italy, Verona, Italy.*

The extensive knowledge of the interindividual variability of the human genome paved the path for the development of the personalized medicine, based on the employment of personal genomic signatures as predictive, diagnostic and pharmacogenetic biomarkers (PGBMs). One of the most successful applications of PGBMs into the clinical practice is the genetic screening for the HLA-B*57:01 allele, which is strongly associated with a high risk of Hypersensitivity Reaction (HSR) to Abacavir (an antiretroviral drug for HIV treatment). Given the clinical utility of HLA-B*57:01 screening in decreasing the incidence of drug HSR, the test became mandatory prior Abacavir administration. Taking into account the limits of the current typing methodologies, the aim of our work was the development and validation of a fast, easy to use and inexpensive molecular approach for the HLA-B*57:01 allele detection. In our assay the DNA extraction and amplification are combined in one single step and performed directly on the biological sample (Direct-PCR), without needing any extraction/purification and sequencing procedures. The Direct-PCR phase consists of the amplification of HLA-B*57 region and allows to discriminate HLA-B*57-negative patients (~90%), who are eligible for Abacavir therapy. The remaining HLA-B*57-positive individuals (~10%) are further typed by Nested PCR, in order to recognize HLA-B*57:01-positive patients (7%) and prevent the dangerous administration of Abacavir. Among the different advantages, the low-cost technology required for the Direct/Nested-PCR assay promotes the exportation of the HLA-B*57:01 pharmacogenetic test in Low and Middle Income Countries, where current genotyping methodologies are too expensive or not available.

Introduction: Despite significant advances over the last decade in our understanding of the basis of disease, the cause underpinning the majority of human disorders remains fully or partially unknown. Identification of molecular changes provides a unique opportunity to understand their role in health and disease, and in a clinical setting to apply that understanding to prevention, diagnosis, and treatment.
Materials and Methods: The advent of high-throughput genome wide sequencing has significantly altered how genetics is practised in the clinic. We have been applying clinical genome wide sequencing (GWS; encompassing both whole genome and whole exome) within our genomic medicine clinics at MCW and CHW for more than 4 years.
Results: With application of both whole genome and whole exome sequencing technology and development of advanced informatics solutions we have been able to successfully diagnose more than a third of our patients. This includes many who would not have received a diagnosis through the previous standard of care testing. The diagnostic success rate is significantly higher with whole genome sequencing compared to whole exome.
Conclusions: This talk will provide a discussion of issues relevant to clinical application of genomics. Topics will include the development of informatics tools, methodologies, and decision making processes. Vignettes based on findings from particular cases will be presented to demonstrate what we have learnt over this time as well as to highlight ongoing challenges and future tasks.

Human genome project opened a door to fast and accurate diagnosis of disorders. But sometimes molecular detection of diseases such as eye disorders is very challenging, because of involving numerous genes. For instance, there are more than 200 known genes causing retinopathy. Hunting the right gene in these complex disorders is like finding the needle in the haystack. Nevertheless, modern sequencing platforms known under collective name Next generation sequencing or NGS is a huge help to solve this problem. One of great benefits of NGS is to see a list all candidate genes including disease causing gene mutations. On the other hand, accuracy of NGS is extremely depending on frequency and length of reads. So, NGS platforms that produce and sequence longer length show fewer errors. However, sequencing of terminals is generally a weak point in all NGS platforms. We experienced due analysis numerous NGS data that results are sometimes not valid (at least in most cases) within repeat sequences or stretches of single bases. For instance, in a Retinitis Pigmentosa (RP) case we found a homozygous insertion of single C within repeated sequence CCCCCCC in the NR2E3 gene that

is known being responsible for Retinitis Pigmentosa type 37. But, Sanger sequencing was negative for reported insertion. However, to avoid similar pitfalls we suggest using two different NGS method such as Ion proton and High seq, which is in large scale samples very expensive.

Proteomic output of a whole chromosome aneuploidy: a systems biology study using fibroblasts from trisomy 21 discordant monozygotic twins

Y. Liu[1], *C. Borel*[2], *A. Letourneau*[2], *F. Santoni*[2], *S. Antonarakis*[2,3], *R. Aebersold*[1,3];
[1]Department of Biology, Institute of Molecular Systems Biology, ETH Zurich, Zurich, Switzerland, [2]Department of Genetic Medicine and Development, University of Geneva Medical School, and University Hospitals of Geneva, Geneva, Switzerland, [3]These laboratories contributed equally, Zurich and Geneva, Switzerland.

Introduction: Down's syndrome commonly results from total trisomy of chromosome 21 (T21). To study the dysregulated gene expression without the noise of genomic variability, we previously used fibroblasts from a pair of monozygotic twins discordant for T21 and revealed the transcriptomic dysregulation between twins is organized in chromosomal domains[1]. These findings lead us to further investigate the translational profiles due to the supernumerary T21 in fibroblasts.
Materials and Methods: We used SWATH-MS[2], a novel mass spectrometry technique providing unprecedented reproducibility and quantitative accuracy for proteomic analysis. The primary fetal skin fibroblasts collected from the T21 discordant twins and fibroblasts from 11 unrelated T21 and 11 control individuals were analyzed.
Results: We reproducibly quantified 3,548 unique proteins assigned by 32,753 peptides between the T21 and Normal twin (R=0.979 between bio-replicates). The protein-transcript quantitative correlation was ~0.40. The detectable 32 proteins encoded in chromosome 21 on average harbored a higher expression in T21, whereas globally only ~40% of the proteome showed higher expression in T21. Interestingly, 291 proteins (most are non-chr21 encoded) were significantly up-regulated in T21, while only 63 proteins were significantly down-regulated. Moreover, GO processes such as translational initiation and protein transport were significantly enhanced in T21 proteome (P<0.0001), indicating the translational regulation resulting from the extra chromosome is remarkably extensive.
Conclusions: We discovered prevalent proteomic consequences of T21 by SWATH-MS. Further investigations are ongoing to increase the proteome coverage and to understand the biological correlations between the transcriptome and proteome.

Unique identifiers downstream from the TATA Box in human genes and human DNA embedded viral genomes

L. B. Scheiber, Sr., *L. B. A. Scheiber II;*
Osteoporosis & Arthritis Center, Trenton, MI, United States.

The human genome consists of approximately 21,000 protein coding genes. We hypothesized there exists an organized means for transcription machinery to locate a specific gene. Transcription Binding Protein (TBP) is an initial transcription factor that binds to DNA to commence assembly of the transcription complex. TBP attaches to the DNA in the vicinity of the TATA box upstream from the transcription start site (TSS). Frequently there exists 25 nucleotides between the TATA box and the TSS. 25 nucleotides would be sufficient to uniquely identify 200,000 differing genes for 5 billion species. It is estimated 25% of human genes have a TATA box upstream from the TSS. We hypothesized there may be a unique numbering system associated with a subset of genes, and DNA may be divided into executable genes (locatable gene associated with a unique identifier) and follower genes (transcribed automatically following transcription of an executable gene). Eight human genes with a TATA box and four viral genomes which embed in human DNA are reported. The 25-nucleotide sequence downstream from the TATA box was converted to the numbering system a=0, g=1, c=2, t=3 as published in ESHG 2014 Abstract J16.03. NCBI BLAST analysis determined the complete TATA+25-nucleotide unique identifiers associated with the reported genes were not otherwise found intact in the human genome. More extensive study is forthcoming. The unique identifiers associated with embedded viral genomes may be utilized as inimitable targets for future anti-viral therapies.

mtMart - a new database for effective human mitogenomic data analysis

H. Hovhannisyan, *A. Yesayan, L. Yepiskoposyan;*
Institute of Molecular Biology, Yerevan, Armenia.

Human mitogenomic data is continuously accumulating while effective methods of massive information storage and management lag behind. Publicly available databases of human mtDNA are either not regularly updated or lack functional tools for appropriate data parsing. For instance, HvrBase++ and mtDB databases, launched in 2006 have not been updated since 2007. Conversely, the Phylotree and Mitomap databases though updated regularly, lack functional tools for data handling, reducing its efficacy.
Here, we introduce the mtMart - a novel manually curated database for complete human mitochondrial genomes that is intended to significantly facilitate effective management of large-scale mitogenomic data.
The database is designed applying the MySQL open-source relational database management system. Its functional features are implemented in PHP and JavaScript (jQuery) programming languages. Using NCBI API, the database retrieves the information on mitogenomes accession number, complete mtDNA sequence, and the publication where the molecule was first described, subsequently storing the data in internal memory. Afterwards, mtMart semi-automatically sends the sequence information to the Haplofind on-line application to assign haplogroups according to Phylotree 16, using the RSRS reference sequence. The data on population and geographic region is manually appended to the database, thus ensuring high quality of stored information. mtMart provides the users with customizable sorting, searching and downloading functions. Moreover, for population/geographic region and haplogroup data, mtMart automatically generates an Arlequin .arp input file with haplogroup frequency data.
Though the mtMart database is available through http://genebank.hol.es/genebank/, its development is still in progress.

J16.05

Identification of a new IGL gene fragment in human RFPL2 gene

A. Gubsky;
Odessa National I.I. Mechnikov University, Odessa, Ukraine.

There are a lot of orphons (duplications of Ig or TCR gene fragments containing V-, D- or C-segments) in human genome outside Ig and TCR loci. Some of them can be find in protein-coding genes. For example, IGLCOR22-1 orphon (length is 316 bp) is located in RFPL2 gene (in the 4th intron) and has 83 % identity with immunoglobulin lambda light chain C region (IGLC2) gene.
Here we report that 1947 bp RFPL2 gene fragment with IGLCOR22-1 orphon has 81 % (1585/1947) identity with immunoglobulin lambda light chain region containing IGLJ5 and IGLC5 genes. These data demonstrate: a) IGL gene fragment in RFPL2 gene is 6 times bigger than reported earlier and contain homologues of IGLJ5 and IGLC5 (not IGLC2); b) in the human genome there are duplications of J-segments of IGL (not only V- and C-segments); c) appearance of close structural analogs of recombination signal sequences (cRSS) in protein-coding genes can be explained not only random nucleotide combinations and repeats but also by duplications of Ig, TCR gene fragments.

J16.06

Bioinformatics analysis of mi-RNA motifs distribution in cytokine genes and their surroundings

E. P. Omelchuk, *E. V. Butenko, D. E. Romanov, E. A. Pshenichniy;*
Southern Federal University, Rostov-on-Don, Russian Federation.

Cytokine production is the one of the basic processes in immune response, inflammation and hemopoiesis. Understanding of cytokine genes regulation and in particular mi-RNA regulation could lead to effective and targeted therapies of many diseases.
Based on the findings that genome functioning is tightly connected with its structure, we have conducted the bioinformatics analysis of mature mi-RNA and pre-mi-RNA motifs distribution in 16 cytokine genes and their surroundings to discover common and specific patterns of mi-RNA localization.

Full sequences were obtained from NCBI data base using E-utilities API. Mi-RNA sequences were taken from the miRBase release 21. Motif search was carried out with MEME Suite program package. The results were filtered to yield only those matches with 85% identical nucleotides.
The entire set of DNA sequences 16 cytokine genes and their surroundings contained 6007 motifs of 19-23 nucleotides homologous to mature mi-RNA sequences and 873 motifs of 68-72 nucleotides homologous to pre-mi-RNA sequences. MiR-466, miR-5096, miR-619 and miR-1273 were prevalent motifs in studied DNA sequences. Prevalent motif type and the density of motifs distribution varied from gene to gene. These results can be discussed as a background to the search of new targets for diagnostics and therapy.
This study was supported by the federal assignment № 6.98.2014/ from Russian Ministry of Science and Education. Analytical work was carried out on the equipment a Center for collective use of Southern federal university „High Technology", grant #RFMEFI59414X0002.

Multiple myeloma (MM) is clonal B-cell malignancy characterized with progressive proliferation of malignant plasma cells and accumulation of monoclonal immunoglobulin (M-spike) in blood and urine. Pomalidomade is immunomodulatory agent which have potentially suppress myeloma cell progression, especially in drug resistant cases. As epigenetic modifications have important role in gene regulationand because of revealing role of DNMT1 overexpression in myeloma pathogenesis, in this study DNMT1, 3a and 3b genes expression of U266 myeloma cell line treated with pomalidomide have been evaluated. In this study after treatment of U266 cells with 1 µM pomalidomide for 16 and 48 hours, total RNA extraction and cDNA synthesis was performed. Gene expression of DNMT1, 3a and 3b has been evaluated using real time PCR technique. The result of this study show that pomalidomide can downregulates the expression of DNMT1, 3a and 3b in 48 hours of treatment as 0.49, 0.58 and 0.55, respectively as comparing with untreated control ($p<0.05$). Based on these results we conclude that pomalidomide has derired effect on epigenetic modification by downregulation of DNMTs genes expression and has been considered as an effective drug for inhibition of myeloma proliferation.

Detection of SHOX2 gene DNA methylation in bronchial lavage and blood plasma in the lung cancer patients

M. Konecny[1], *J. Markus*[1], *L. Dolesova*[1], *R. Kozlova*[1], *V. Repiska*[2], *H. Novosadova*[3], *I. Majer*[3];
[1]*St. Elizabeth Cancer Institute, Bratislava, Slovakia,* [2]*Faculty od Medicine, Comenius University, Bratislava, Slovakia,* [3]*University Hospital Ruzinov, Bratislava, Slovakia.*

Methylation of the cytosine residues within the CpG dinucleotides plays an important role in the fundamental cellular processes, human diseases and even cancer. The DNA methylation represents a very stable sign and therefore may be used as a valuable marker for cancer screening. Epigenetic cancer biomarkers are independent of classical morphology and thus show extensive potential to overcome the limitations of cytology. Several epigenetic cancer markers have been reported to be detectable in body fluids such as bronchial aspirate, sputum, plasma and serum.
Short stature homeobox gene 2 (SHOX2) encodes a homeo-domain transcription factor, which has been identified as a close homologue of the SHOX gene and both genes are involved in skeletogenesis and heart development. Methylation of SHOX2 gene has been shown to be present at high prevalence in carcinomas of lung, however may also be used to identify other tumour entities.
In the presented study, we have compared suitability of two types of material associated with lung cancer for the detection of SHOX2 methylation. Using the appropriate DNA purification and quantitative real-time PCR kits (Epigenomics), we have tested SHOX2 methylation in samples of bronchial lavage and blood plasma from the same patients. Mutual correlation of these results as well as correlation with the clinical outcome were assessed and are reported.

[1]*Hospital Juárez de México, Mexico City, Mexico,* [2]*Posgrado en Ciencias Genómicas, Universidad Autónoma de la Ciudad de México, D.F., México., Mexico City, Mexico.*

Introduction: Breast cancer (BC) involves hormonal and epigenetic risk factors. Hormone resistance, due to hyper-methylation of the ESR1 (ERa gene) promoter, may occurs. This epigenetic alteration, is known to be one of the mechanisms by which the expression of ERa is suppressed. The goal of the present study was to determine the methylation status of the promoter A CpG island of the cancer-related gene ESR1 in a mexican woman group. Materials and methods: CpG island of the ESR1 promoter A, was detected by semi-quantitative PCR. A total of 51 patients were included: 17 controls (non breast cancer women), 17 cases ERa positive (<50%) and 17 cases ERa positive (>50%). Results: There was no difference in the prevalence of the DNA methylation of ESR1 gene between the three studied groups. Our population shown a parametric distribution. Conclusions: Our preliminary findings suggested that aberrant methylation of ESR1 occurs frequently in mexican women. On the other hand, although the methylation status didn´t show a statistical difference among case and control groups, future studies in the studied population must include an extensive clinical parameters and the examination of the methylation of more genes are needed.

A large-sized genomic deletion at the DYSF locus deregulates Retinoic Acid-dependent CYP26B1 expression and causes Antley Bixler Syndrome

F. Puppo[1,2], *M. Chapoton*[1,2], *C. Pecheux*[3], *K. Nguyen*[1,2,3], *C. Vial*[4], *N. Levy*[1,2,3], *M. Bartoli*[1,2,3], *N. Philip*[1,2,3], *M. Krahn*[1,2,3];
[1]*AixMarseille University, GMGF, Marseille, France,* [2]*INSERM, UMR_S910, Marseille, France,* [3]*APHM, Hopital La Timone, Département de Génétique Médicale, Marseille, France,* [4]*Hôpital neurologique Pierre Wertheimer, Lyon, France.*

Antley Bixler Syndrome (ABS) constitutes a very rare developmental syndrome characterized by craniosynostosis and radiohumeral synostosis which is genetically determined by mutations in the cytochrome P450 oxidoreductase gene (POR), the Fibroblast Growth Factor Receptor 2 gene (FGFR2) or the cytochrome P450 gene CYP26B1. Interestingly, clinical manifestations together with the genes involved, pinpoint on the retinoic acid (RA) signalization pathway involvement. The CYP26B1gene, which maps on minus strand of chromosome 2, is located 444kb downstream of the DYSF gene. Syntheny and relative gene positions are highly conserved through evolution.
Based on the specific exploration of one patient presenting with combined clinical manifestations of ABS and Miyoshi myopathy (MM), we report that DYSF contains regulatory sequences controlling CYP26B1 expression that, when deleted, lead to ABS by a long distance position effect. Strikingly, activation of CYP26B1 expression by RA is greatly reduced in lymphoblasts from one patient carrying a large internal deletion at the DYSF locus as compared to controls. Thus, the genomic DYSF deletion in this case not only affects dysferlin protein function but also CYP26B1 gene expression explaining the clinical outcomes for this patient. Altogether, these data underline the importance of searching for DYSF locus microdeletions in ABS patients without mutations in classically linked genes. Even in high-throughput sequencing era, it is worth to look for rearrangements causing positional effects, in patients showing combined clinical signs.

J17.05

Histone demethylase KDM2B inhibited the chondrogenic differentiation potentials of stem cells from apical papilla

Z. Fan;
Beijing Key Laboratory of Tooth Regeneration and Function Reconstruction, Capital Medical University School of Stomatology, Beijing, China.

Objective: Mesenchymal stem cells (MSCs) are a reliable resource for tissue regeneration, but the molecular mechanism underlying directed differentiation remains unclear; this has restricted potential MSC applications. Histone methylation, controlled by histone methyltransferases and demethylases, may play a key role in MSCs differentiation. Previous studies determined that KDM2B can regulate the cell proliferation and osteo/dentinogenic differentiation of MSCs. It is not known whether KDM2B is involved in the other cell lineages differentiation of MSCs. Here we used the stem cells from

apical papilla (SCAPs) to study the role of KDM2B on the chondrogenic differentiation potentials in MSCs.
Methods: Gain- and loss-of-function assays were applied to investigate the role of KDM2B on the chondrogenic differentiation. Alcian Blue Staining and Quantitative Analysis were used to investigate the synthesis of proteoglycans by chondrocytes. Real-time RT-PCR was used to detect the expressions of chondrogenesis related genes.
Results: The Alcian Blue staining and Quantitative Analysis results revealed that overexpression of KDM2B decreased the proteoglycans production, and real-time RT-PCR results showed that the expressions of the chondrogenic differentiation markers, COL1, COL2 and SOX9 were inhibited by overexpression of KDM2B in SCAPs. On the contrary, depletion of KDM2B increased the proteoglycans production, and inhibited the expressions of COL1, COL2 and SOX9.
Conclusions: These results indicated that KDM2B is a negative regulator of chondrogenic differentiation in SCAPs and suggest that inhibition of KDM2B might improve MSC mediated cartilage regeneration.

Gene-gene interactions in smoking and non-smoking adolescents with asthma

B. T. Batozhargalova[1], *N. V. Petrova*[1], *E. E. Timkovskaya*[1], *T. A. Vasilyeva*[1], *Y. L. Mizernitskiy*[2], *R. A. Zinchenko*[1,2];
[1]*Federal State Budgetary Institution „Research Centre for Medical Genetics", Moscow, Russian Federation,* [2]*Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

Asthma is a common condition with complex etiology. Susceptibility to asthma is due to interaction of genetic and environmental factors.The impact of smoking on asthma risk was analyzed in adolescents from Aguinskiy Buryat district of Zabaykalskiy region (Western Siberia, Russian Federation). An association study by genotyping for 11 polymorphisms of 9 genes in patients with asthma (49 smokers and 55 non-smokers) and 75 healthy controls (75 smokers and 75 non-smokers). The average age is 14,5±0,90y. The structure of asthma genetic predisposition differs between smoking and non-smoking adolescents. Genotype TT (rs7216389; GSDMB) is a factor of an increased asthma risk in the both smokers (OR=8.2, 95%CI[3.6-18.8]; p<0,0001) and non-smokers (OR=3,26; 95%CI [1,6-6,8]; p=0,001). Asthma is associated with NOS3 (VNTR; p=0,03) and ADRB2 (Gln27Glu; p=0,03) genes in smoking patients, and with CHRNA5 (rs16969968; p=0,001), ADRB2 (Gln27Glu; p=0,01) and TH0I (STR; p=0,01) genes - in non-smokers. Analysis by multifactor dimentionality reduction (MDR) allowed to detect the more significant models of gene-gene interactions: GSDMB (rs7216389) x ADRB (Gln27Glu) x NOS3 (VNTR) x TH0I (STR) - for smokers; GSDMB (rs2305480) x GSDMB (rs7216389) x ADRB (Arg16Gly) x ADRB (Gln27Glu) x CHRNA5 (rs16969968) - for non-smokers. The most additional genetic attributive risk was 12.3% for the 4-locus genotype, GSDMB (rs7216389)*TT - ADRB (Gln27Glu)*CG - NOS2 (CCTTT)n*LL - TH0I (STR)*SS, in smoking asthma patients. Increased asthma risk genotypes revealed in non-smokers group were GSDMB (rs7216389*TT) -- CHRNA5 (rs16969968)*GG (OR=3,52; 95%CI [2,0-6,2], p<0,0001); GSDMB (rs7216389)*TT - ADRB (Arg16Gly)*AG - ADRB (Gln27Glu)*CC (OR=17,73; 95%CI [2,4-131,5]; p=0,0002) .

Aberrant methylation of Rap1Gap gene promoter in thyroid cancers

B. Faam[1,2];
[1]*Cellular and Molecular Research Center,Obesity Research Center, Research Institute for endocrine sciences Shahid Beheshti University of Me, Tehran, Iran, Islamic Republic of,* [2]*Cellular and Molecular Research Center, Faculty of Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran., Ahvaz, Iran, Islamic Republic of.*

Introduction: Thyroid carcinoma is the most common endocrine malignancy in worldwide. Hypermethylation of suppressor genes considered as the hallmark of cancers [1]. Rap1Gap as a suppresser gene is implicated in the regulation of oncogenic pathways in thyroid carcinoma [2]. The objective of this study was to examine the DNA methylation pattern of Rap1Gap gene in thyroid carcinoma.
Methods: we analyzed 95 thyroid tumor samples including normal thyroid (28 cases), benign nodules (29 cases), papillary thyroid cancer (PTC) (29 cases), follicular thyroid cancer (FTC) (6 cases) and Anaplastic thyroid cancer (ATC) (3 cases) from Erfan grand hospital, Tehran, Iran. Rap1Gap gene expression was assessed using SYBR Green Real-Time PCR. CpG24 Island within Rap1Gap promoter region was selected; DNA methylation pattern was examined using methylation specific PCR (MSP).
Results: this study showed that Rap1Gap was frequently lost or downregulated in various types of tumors, particularly in the most invasive and aggressive forms of thyroid cancer. Downregulation could be related to promotor hypermethylation. DNA methylation was identified in 21% of normal tissues, 86% of benign nodules, 90% of differentiated tumors (PTC, FTC) and 100% of undifferentiated tumors (ATC).
Conclusion: the result of this study demonstrates that Rap1Gap is likely to serve as an important tumor suppresser gene in thyroid cells and its loss during aberrant methylation contributes to tumor progression and invasion.

Sequential changes in 5-hydroxymethylcytosine patterns during DNA methylation reprogramming in human zygotes and cleavage-stage embryos

A. V. Tikhonov[1,2], *O. A. Efimova*[1,2], *A. A. Pendina*[1,2], *I. D. Fedorova*[2], *M. I. Krapivin*[1], *O. G. Chiryaeva*[2], *A. S. Koltsova*[1,2], *T. V. Kuznetzova*[1,2], *V. S. Baranov*[1,2];
[1]*St.Petersburg State University, St.Petersburg, Russian Federation,* [2]*D.O. Ott Research Institute of Obstetrics, Gynecology and Reproductology, St.Petersburg, Russian Federation.*

We have studied chromosome hydroxymethylation and methylation patterns in metaphase chromosomes from IVF-produced human triploid zygotes and cleavage-stage embryos. To obtain metaphase chromosomes, zygotes and embryos were treated with 0.1% colchicines, 0.9% sodium citrate and fixed with freshly prepared 3:1 methanol:acetic acid. Using indirect immunofluorescence, we have analyzed the localization of 5-hydroxymethylcytosine (5hmC) and its co-distribution with 5-methylcytosine (5mC) on the QFH-banded metaphase chromosomes.
In zygotes, 5hmC accumulates in both parental chromosome sets, but hydroxymethylation is more intensive in poorly methylated paternal set. In maternal set, chromosomes are highly methylated, but contain little 5hmC. Hydroxymethylation is highly region specific in both parental chromosome sets: hydroxymethylated loci correspond to R-bands, but not G-bands, and have well-defined borders, which coincide with the R/G-band boundaries. The centromeric regions and heterochromatin at 1q12, 9q12, 16q11.2 and Yq12 contain little 5mC and no 5hmC. We hypothesize that 5hmC may mark structural/functional genome 'units' corresponding to chromosome bands in the newly formed zygotic genome. Hydroxymethylation of R-bands in zygotes can be treated as a new characteristic distinguishing them from G-bands. At cleavages, chromosomes with asymmetrical hydroxymethylation of sister chromatids appear. They decrease in number during cleavages, whereas totally non-hydroxymethylated chromosomes become numerous.
Thus, in the zygotic genome, 5hmC is distributed selectively and its pattern is determined by both parental origin of chromosomes and type of chromosome bands - R, G or C. At cleavages, chromosome hydroxymethylation pattern is dynamically changed due to passive and non-selective overall loss of 5hmC, which coincides with that of 5mC.

Extracellular matrix proteins play significant role in tumor development. We evaluated methylation status for 12 laminin-encoding genes (*LAMA1, LAMA2, LAMA3A, LAMA3B, LAMA4, LAMA5, LAMB1, LAMB2, LAMB3, LAMC1, LAMC2, LAMC3*), 8 genes of integrins (*ITGA1, ITGA2, ITGA3, ITGA4, ITGA6, ITGA7, ITGA9, ITGB1*), 2 nidogen genes (*NID1,NID2*), 2 genes of the cadherin family (*CDH2,CDH3*), the dystroglycan gene *DAG1*, 9 matrix metalloproteinases-encoding genes (*MMP2, MMP14, MMP15, MMP16, MMP17, MMP21, MMP23B, MMP24, MMP28*) and the metalloproteinase inhibitor 3 gene *TIMP3* in 194 samples of breast cancer, 194 paired adjacent nonmalignant samples and 6 samples of normal mammary gland from autopsy.
Promoters of 15 genes, *LAMA1, LAMA2, LAMB1, ITGA1, ITGA4, ITGA7, ITGA9, NID1, NID2, CDH2, CDH3, MMP2, MMP23B, MMP24, MMP28* have demonstrated abnormal methylation in 1,5% to 38% samples of breast cancer and/or adjacent tissues.
Promoters of the *LAMA3A, LAMB2, LAMB3, LAMC2, MMP14, MMP21* genes

were constitutively methylated in breast tissues.
Extracellular matrix proteins genes abnormally methylated in breast cancer

Gene symbol	Methylation in breast cancer and/or adjacent nonmalignant samples (%)	Methylation in normal mammary gland from autopsy (%)
LAMA1	29,4 (50/170)	0
LAMA2	25,8 (48/186)	0

Exosome-associated miR-146a as a potential lupus nephritis biomarker in urine

J. Perez-Hernandez[1,2], *M. J. Forner*[2,3], *J. Redon*[2,3], *F. J. Chaves*[1,4], *R. Cortes*[1,2];
[1]*Genotyping and Genetic Diagnosis Unit, INCLIVA biomedical research institute, Valencia, Spain,* [2]*Cardiometabolic and Renal Unit, INCLIVA biomedical research institute, Valencia, Spain,* [3]*CIBER Physiopathology of Obesity and Nutrition (CIBEROBN), Institute of Health Carlos III, Madrid, Spain,* [4]*CIBER of Diabetes and Associated Metabolic Diseases (CIBERDEM), Institute of Health Carlos III, Barcelona, Spain.*

Introduction: Changes in urinary miRNAs have been reported in several renal diseases, having a strong potential to be biomarkers of renal injury. We investigated if miRNAs in urine are concentrated in exosomes and whether a glomerular disease as lupus nephritis (LN) modifies the distribution pattern.
Methods: We used urine of patients with systemic lupus erythematosus (SLE) (6 active, 10 inactive and 12 absence of LN) and healthy controls (n=12), quantifying miRNAs by RT-qPCR in cell-free urine (CFU), exosome-depleted supernatant (Sn) and exosome pellet (Exo). Selected miRNA were: ubiquitously detected in urine (miR-302d, miR-335*), kidney damage biomarker (miR-200c) and altered in glomeruli of LN (miR-146a). Vesicles were characterized by TEM, western blot and NanoSight.
Results: In active LN, all miRNAs were significantly higher in Exo compared to Sn, especially miR-146a (57-fold change, $p<0.01$). Furthermore, comparing miRNAs of each urinary fraction among pathological groups with controls, we observed that miRNAs of Exo in active LN were significantly increased, being miR-146a the most augmented (103-fold change, $p<0.001$). Inactive LN only showed a significant increase for miR-146a ($p<0.05$). Finally, urinary exosomal miRNA-146a had the highest diagnostic role of active LN compared to SLE without LN (AUC 0.960, $p<0.01$), and between active and inactive LN (AUC 0.867, $p<0.05$). Moreover, logistic regression was performed for exosomal miR-146a (OR 24.00, $p<0.05$).
Conclusions: This study confirms that urinary miRNAs are enriched in exosome-containing pellet. In the presence of active LN, the quantity of miRNAs was increased, especially in isolated exosomes. MiR-146a showed high diagnostic accuracy of active LN, underlining the importance of exosome-associated miRNAs as renal disease markers.

HIV (Human Immunodeficiency Virus) infection induces a state of immune activation associated with chronic inflammation. Chronic inflammation contributes to the pathogenesis of many chronic medical illnesses. Membrane-derived microparticles (MP), released from cell surface, are implicated in cell to cell communication. Recent data evidenced the presence of miRNAs in MP that could mediate exchange of biological information.
We hypothesized that MP produced by CD4 T lymphocytes, which are target cells for HIV infection, are vehicles for miRNAs and could transfer them in receiver cells to alter the expression of numerous genes, in particular those related to inflammation. The aim of the study is to demonstrate the role of miRNAs transfer by MP in pathophysiology during HIV infection.
We analyzed the expression of 375 miRNAs in CD4 T cells, in CD4 T cells-derived MP and in circulating MP from HIV-1 patients receiving highly active antiretroviral therapy, from never-treated (naive) HIV-1 patients and from seronegative age- and sex-matched control individuals. This analysis showed that several miRNAs significantly differentiated HIV-1 patients from uninfected individuals. We identified 2 overexpressed miRNAs in both CD4 T lymphocytes, in CD4 T cells-derived MP and in circulating MP from naive HIV-1 patients compared to controls, which are of interest because they were described as downregulators of NF-kB pathway.
This study provides an opportunity to better understand mechanisms of inflammation in HIV infection. MP, and miRNAs they contain, could then be considered as therapeutic targets and MP production could be regulated in new therapeutic strategies.
This work was supported by grants from ANRS (2011 and 2012).

Early Detection of Preeclampsia using Circulating small non coding RNA

L. Yoffe;
Tel Aviv University, Tel Aviv, Israel.

Preeclampsia is one of the most dangerous pregnancy complications, and the leading cause of maternal and perinatal mortality and morbidity; yet its cause remains unclear. Current theory of preeclampsia pathogenesis states that it begins with poor placentation in the first trimester of pregnancy. Thus, although clinical symptoms are late, early detection of preeclampsia can be feasible at the first trimester. Recent findings suggest that circulating small non-coding RNAs (ncRNAs) in the mother's blood may be effective markers for early diagnosis of preeclampsia, however as of yet such ncRNAs were identified only in late stages of the pregnancy and have not been implemented in clinical practice. Furthermore, mapping ncRNA expression at an early stage of the disease might shed light on the possible mechanisms involved in the disease etiology.
We have compared small ncRNAs in plasma of first trimester pregnant women with and without preeclampsia. To this end, we have performed small ncRNAs Next Generation Sequencing (NGS) of preeclampsia and control samples, and identified several transcripts significantly differentially expressed between the two sets. We further utilized the list of these transcripts and created a pipeline for supervised classification of preeclampsia versus control samples. The classification pipeline obtained high accuracy in preeclampsia samples prediction. Furthermore, applying the procedure on two different ethnic groups resulted in high accuracy values as well, which demonstrates our method's generalization capability.
Our findings lay the foundation for an early non-invasive diagnostic tool of preeclampsia based on circulating small ncRNAs, in order to lower the life-threatening risk for the mother and fetus.

Beckwith-Wiedemann and Russell-Silver syndromes: Evidence of multilocus methylation defects.

A. Touati[1], *D. H'mida Ben Brahim*[1], *S. Nouri*[2], *F. Chioukh*[3], *M. Haddaji Mastouri*[1], *S. Trabelsi*[1], *S. Hammami*[4], *S. Sassi*[1], *S. Mougou*[1], *M. Gribaa*[1], *N. Guedich*[4], *H. Sebouï*[2], *A. Nouri*[5], *K. Monastiri*[3], *A. Saad*[1];
[1]*Laboratory of Human Cytogenetics,Molecular Genetics and Reproductive Biology, Farhat HACHED University Hospital, Sousse, Tunisia,* [2]*Depatment of neonatology , Farhat HACHED University Hospital, Sousse, Tunisia,* [3]*Department of neonatology, Fattouma BOURGUIBA University Hospital, Monastir, Tunisia,* [4]*Department of pediatrics, Fattouma BOURGUIBA University Hospital, Monastir, Tunisia,* [5]*Department of pediatric surgery,Fattouma BOURGUIBA university hospital, Monastir, Tunisia.*

The imprinted 11p15 region is crucial for the control of foetal growth and loss of imprinting at this locus is implicated in two clinically opposite disorders: Beckwith Wiedemann syndrome (BWS) and Russell-Silver syndrome (RSS). In order to investigate multilocus methylation defects in a series of 33 patients referred for BWS and RSS, we studied the methylation status of 4 maternally (6q24, 7q32, 7p12 and 11p15) and 2 paternally (11p15 and 14q32) methylated loci.Seven out of 14 BWS patients harbored maternal ICR2 hypomethylation and one BWS patient had both ICR1 and ICR2 defects which indicated paternal 11p15.5 uniparental disomy. Among the 19 suspected RSS patients, the diagnosis was confirmed in only one patient with a typical RSS phenotype with severe Intrauterine growth retradation, facial dysmorphisms and psychomotor retardation, and who showed maternal 11p15.5 duplication. Multilocus methylation defects concerns 2 patients out of 33. The first patient referred for BWS carried both maternal ICR2 hypomethylation and 7q32 hypomethylation, thusboth BWS and RSS diagnosis. He presented a BWS phenotype with macrosomia, macroglossia, facial

dysmorphisms and hypothyroidism and no obvious RSS clinical features. The second patient referred for BWS with macrosomia, macroglossia and hypoglycemia, surprisingly carried 7p12 and 6q24 hypomethylation, thus combining RSS and transient neonatal diabetes mellitus diagnoses.Although our series of RSS and BWS patients had Loss of methylation at loci involved in other human diseases, they did not generally show evidence of other clinical disorders. This is consistent with a phenotypic (epi)dominance of the 11p15 region Loss of imprinting in our series of patients.

Attention deficit hyperactivity disorder (ADHD) is one of the most common childhood brain disorders and implying strong familial, genetic and environmental risk factors. Despite the prevalence of ADHD, molecular markers for the diagnosis of ADHD have not yet been identified. DNA methylation is an important epigenetic mechanism associated with silencing of genes in CpG islands. In this sense, the investigation of methylation profile in patients with ADHD could reveal important aspects of the disease.
We performed the Genome-wide methylation profile using DNA extracted from blood lymphocytes of 10 patients with ADHD (ages 08-15) with Illumina Infinium HumanMethylation450 BeadChip. Array data were pre-processed using GenomeStudio software and full analysis was performed using specific packages within the environment R. Ingenuity Pathway Analysis was used to identify canonical pathways of the genes that were enriched in the list of CpG loci with significantly different methylation in ADHD patients.
Our analyzes showed significantly methylated probes involved in several networks, including Glutamate Biosynthesis and Glutamate Degradation X pathway, pointing out the relevance of glutamate, which is closely associated to the Central Nervous System and could be modified by epigenetic factors.
Thus, profile the tissue-specific DNA methylation patterns will provide novel insights into pathogenic mechanisms of ADHD, as well as, help in future epigenetic therapies.

Association between G-2548A leptin gene polymorphism and age at menarche

S. Rostami, *L. Kohan;*
Department of Biology, Arsanjan Branch, Islamic Azad University, Arsanjan, Iran, Islamic Republic of.

Background: Early menarche is a risk factor for teenage depression, insulin resistance, and breast cancer in adulthood. Among the various social, economic, biological, and environmental factors implicated in the secular decline in age at menarche, There is growing evidence that childhood obesity is an important determinant of early menarche. Obese children have high leptin levels, and these may play a role in their earlier onset of puberty. Leptin is one of many proteins important to obesity that secreted by adipocytes in proportion to adipocyte tissue mass. Lep-2548G/A polymorphism in the promoter region of leptin gene, that has previously been shown to correlate with variations in serum leptin levels and degree of obesity. The aim of this study was to evaluate the impact of leptin G-2548A gene polymorphism on the age at menarche in a sample of the Iranian population.
Material and Methods: This study was done on 374 Iranian women from February 2012 to February 2013. The leptin genotypes were determined using PCR-RFLP method and age at menarche was obtained by questionnaires. Data analysis was performed by SPSS version 18.
Result: women carrying the AA genotype had a significantly younger age at menarche (12.47 years) than women with the AG (12.94 years) and GG (13.47 years) genotypes. Also, we found that the AA genotype frequency in women with age at menarche <13 years was higher than in women with age at menarche ≥13 years (OR:3.4, 95%CI:1.7-6.7, P:0.001).
Conclusion: The G-2548A leptin gene polymorphism has an important role in the onset of menarche.

Candidate genes sequence variants in patients with congenital heart defects

A. G. Fayez[1], *I. R. Hussein[1,2], N. N. Esmaeil[1], A. A. El Darsh[1], M. O. El Ruby[1];*
[1]National Research Centre, Dokki, Giza, Egypt, [2]Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Saudi Arabia.

Congenital heart disease (CHD) affects the structure and function of the heart and is the most common major malformations and the largest proportion of mortality caused by birth defects in pediatric age. The current work engaged in identifying genomic variants and its effects in genes linked to sporadic CHD cases. To achieve this aim, DNA was extracted and purified, then followed by standard sequencing immediately. We used the bioinformatics tools to predict the effects of an outcome variants and was selected which have high predictor value to be under the functional genetic variant evaluation. The results revealed that many reported and unreported genetic variations were founded in GATA4, TBX5, Nkx2.5 and HAND2 genes, most of these variations were founded in GATA4 and TBX5 genes that underwent the functional analysis.

Candidate gene analysis of permanent tooth agenesis

J. Machida[1], *T. Tatematsu[2], D. Goto[2], A. Shibata[2], S. Makino[1], K. Shimozato[2], Y. Tokita[3];*
[1]Toyota memorial hospital, Toyota, Aichi, Japan, [2]Aichi-Gakuin University, Nagoya, Japan, [3]Aichi Human Service Center, Kasugai, Japan.

Permanent tooth agenesis is a common human anomaly of complex etiology that affects approximately 7 %, based on population based study (OMIM: #106600, #604625). It may occur independently, or as one feature of a syndrome. The non-syndromic forms may be sporadic or familial with prevalence varying by tooth type. According to severity, selective tooth agenesis can be divided into hypodontia, and oligodontia. Hypodontia is generally defined as agenesis with absence of less than six teeth, and oligodontia is a condition in which six or more teeth are missing. Mutations in MSX1 and PAX9 are associated with specific forms of tooth agenesis. In the dental mesenchyme, MSX1 is detected in the dental epithelia during the tooth development, and PAX9 is expressed in the neural-crest-derived mesenchyme of the maxillary and mandibular arches. In addition, several lines of observation have indicated that mutations in isolated tooth agenesis were detected in AXIN2, EDA, and WNT10A. Here we report mutation analyses of four candidate genes (MSX1, PAX9, WNT10A, AXIN2) in 72 probands (32 hypodontia and 40 oligodontia) in Japanese. A mean number of missing teeth was 7.1. We identified 17 mutations. Together with our previous reports, we have identified seven mutations in MSX1, two in PAX9, six in AXIN2, and two in WNT10A. MSX1 and PAX9 mutations were identified in 32.2%, and 54.5% of cases, respectively. Our findings on the intra oral distribution of agenesis of permanent teeth in children may help us better understand the etiology of agenesis.

J18.04
Epidemiology of Prothrombin G20210A Polymorphism in the Southern Iran, 2014

M. Arabnejad[1], *A. Ebrahimi[2], M. Nasiri[1], M. Karimi[3], M. moghadam[3], A. Khalili[4];*
[1]Department of Biology, Arsanjan Branch, Islamic Azad University, Arsanjan, Iran, Islamic Republic of, [2]Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [3]Hematology Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [4]Department of Obstetrics and Gynecology, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of.

Background: There are many genetic and non-hereditary risk factors that are known to cause venous thromboembolic (VTE) disorders. One of these is the Prothrombin G20210A mutation. Moreover, the association of PT G20210A polymorphisms with cancer has been reported. The present study was designed to determine the frequency of PT G20210A polymorphism in Southern Iran.
Methods: 140 healthy women were selected from Namazi Hospital in Shiraz city. A total of 5 ml of peripheral blood was taken from individuals then Genomic DNA was extracted using BioRon blood DNA kit. The ARMS-PCR method was used for the detection of PT G20210A single nucleotide polymorphism in each subject.
Results: The prevalence of G/G, G/A, and A/A genotypes was found to be 97.9%, 2.1%, and 0%, respectively.
Conclusion: Results of the present study might be important in understanding the distribution of PT G20210A polymorphism in the Iran population. Minor allele frequency (MAF) in this population was 1.1%.

To compare prevalence of endometriosis associated common polymorphism in Shiraz endometriosis clinics patients with control groups

a. Z. A. S. khalili;
shiraz university of medical science, shiraz, Iran, Islamic Republic of.

Background:Endometriosis is a common gynecologic disorder defined as ectopic presence of endometrial tissue in extra-uterine sites. Higher stages of endometriosis are associated with infertility and higher risk of malignancy. Identification of responsible gene alterations and mutations can improve therapeutic approaches. In the present study we investigated association of ARID1A and eNOS polymorphisms with endometriosis and staging of the disease.
Materials and methods:100 women with laparoscopy confirmed diagnosis of endometriosis were included and compared with 100 non-endometriosis women as the control group, regarding eNOS and ARID1A polymorphisms.
Results:Significantly higher prevalence of non-CC genotype for ARID1A Gln920Ter polymorphism and non-GG genotype for G894T polymorphism of eNOS gene was detected in endometriosis group. There was no significant relationship between these polymorphisms and staging of endometriosis.
Conclusion and discussion:The results of this study suggest that mentioned polymorphisms of ARID1A and eNOS genes may play role is development of endometriosis rather than staging and progression of the disease.

GENETIC STUDY MEFV GENE OF PERIODIC DISEASE : ABOUT 12 PATIENTS MAROCAINS

h. sayel, *L. Bouguenouch, K. Belhassan, H. Hamdaoui, S. TRHANINT, F. MOUFID, I. elotmani, k. ouldim;*
CHU HASSAN II FES, FEZ, Morocco.

Familial Mediterranean Fever (FMF) , also called periodic disease is a hereditary inflammatory disease. It is of particular geographic and ethnic distribution. Indeed, it is mostly observed in populations from around the Mediterranean (Arabs, Sephardi Jews , Turks and Armenians) . It is a genetic disorder autosomal recessive , due to mutations in the MEFV gene on chromosome 16. More than two hundred variants have been described, but only twelve mutations (E148Q , M680I , M680L , T681I , I692del , M694I , M694V , M694del , K695R , V726A , A744S , R761H) are frequently associated with most cases of FMF.
12 patients were recruited to the Medical Genetics Unit of the University Hospital Hassan II FES , seven women and five men. Genomic DNA was extracted from peripheral blood using the standard protocol of „ salting out „ and the MEFV gene was investigated by PCR- sequencing specific research of the most common mutations in exon 10 .
Molecular analysis conducted in patients showed that one patient carried the M694I mutation in the homozygous state . Eleven patients did not have the desired mutations , with a very suggestive clinical disease and a good response to the test treatment, which does not exclude the presence of other not yet sought mutations in other exons. Thus, it would be interesting to look for other known MEFV gene mutations involved in this disease in order to provide adequate genetic counseling to all patients .

J18.07

Trends in the prenatal diagnostics of the Down syndrome in the Czech Republic: What is the association with the maternal age?

A. Sipek Jr[1,2], *V. Gregor*[2,3], *J. Horacek*[2,4], *O. Vencalek*[5], *A. Sipek*[2,3,6];
[1]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University, Prague, Czech Republic,* [2]*Department of Medical Genetics, Thomayer Hospital, Prague, Czech Republic,* [3]*Department of Medical Genetics, Pronatal Sanatorium, Prague, Czech Republic,* [4]*Gennet, Ltd., Prague, Czech Republic,* [5]*Department of Mathematical Analysis and Applications of Mathematics, Faculty of Science, Palacky University, Olomouc, Czech Republic,* [6]*Department of General Biology and Genetics, 3rd Faculty of Medicine, Charles University, Prague, Czech Republic.*

Introduction: Down syndrome is the most common autosomal aneuploidy syndrome. Total incidence (including prenatally and postnatally diagnosed cases) of the Down syndrome in the Czech Republic is increasing during the last two decades. The two mainly discussed causal factors are the improvement of the prenatal screening/diagnostics methods and the eminent increase of the average maternal age.
Methods: Retrospective population-based analysis of the prenatally diagnosed cases of the Down syndrome in the Czech Republic (1998 - 2011 time period). Total number of 2 110 cases were analyzed.
Results: The relative number of the prenatally diagnosed cases of the Down syndrome has increased from 10.82 per 10 000 (in 1998) to 20.24 per 10 000 (in 2011), while the incidence in births has decreased from 6.41 (in 1998) to 3.50 (in 2011, relative numbers per 10 000 are given). The average gestation week at the time of prenatal diagnosis of the Down syndrome has decreased from 19.98 (in 1998) to 15.55 (in 2011). In 1998 the majority of Down syndrome cases were diagnosed in 20-22th week of gestation, while in 2011 the diagnosis was made mainly in 12-13th week of gestation.
Conclusion: We have found significant changes in the prenatal diagnostics of the Down syndrome. While in 1998-2003 time period the Down syndrome was diagnosed early in elder women (women aged 35 years or over - who chose karyotyping because of advanced maternal age indication) we have not found this connection in the 2004-2011 time period. This change represents the increasing role of the first trimester prenatal screening in the Czech Republic.

DNA microarray for the diagnostics of monogenic hereditary disease in Yakuts.

M. Turdieva[1,2], *N. Maximova*[1];
[1]*North Eastern Federal University, Yakutsk, Russian Federation,* [2]*Yakut Science center of Siberian branch of Russian Academy of Medical Sciences, Yakutsk, Russian Federation.*

Yakut people belongs to the monogenic population with ethnicity specific form of pathology, around ten hereditary diseases with the frequency significantly more higher than in other populations in the world. The molecular genetics research showed the presence of major mutations specific and often found among people of Yakut origin. One of the major problems for now is to do a screening for the found mutations, diagnostics of the diseases and to organize preventive care.
In collaboration with colleagues from „Alcor Bio" Co Ltd., Saint Petersburg, Russia there was established a testing system based on DNA microarray for the diagnostics of five high frequency diseases among Yakuts. This method has a lot of advantages and the main one is a possibility to screen several mutations at once comparing to routine methods such as PCR and restriction. It makes the diagnostics simple, fast and money saving.
There were five diseases with point mutations chosen:
1. Enzymopathic methemoglobinemia (OMIM 250800, Pro269Leu mutation in DIA1 gene)
2. 3 M syndrome (OMIM 273750, 4582insT in Cul7 gene).
3. SOPH syndrome (OMIM 614800, G5741 A in NAG gene).
4. Nonsyndromic hearing loss 1A type (OMIM220290, IVS1+1G>A in GJB2 gene)
5. Tyrosinemia type1 (OMIM 276700 1090G>C mutation in FAH gene).
Since the microarray technology is well known and rapidly developing in the world, the results of specific research of Yakut population itself using these biochips rather than then biochip establishment will have the significance. Until now the setting up the methods and optimization of procedures is carring on.
The research is supported by Federal special purpose program 2014-2016 in Russia

Genome-wide association study of elite strength athlete status in Russians

E. S. Egorova[1], *D. S. Ischenko*[2], *N. A. Kulemin*[2], *A. A. Galeeva*[3], *E. S. Kostryukova*[2], *D. G. Alexeev*[2], *L. J. Gabdrakhmanova*[1,3], *A. K. Larin*[2], *E. V. Generozov*[2], *E. A. Ospanova*[2], *A. V. Pavlenko*[2], *V. M. Govorun*[2], *I. I. Ahmetov*[1,3];
[1]*Kazan State Medical University, Kazan, Russian Federation,* [2]*Research Institute for Physical-Chemical Medicine, Moscow, Russian Federation,* [3]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation.*

Humans vary in their ability to achieve success in strength sports. The aim of the study was to identify SNPs associated with strength athlete status in Russians using a GWAS approach. The study involved 483 Russian athletes (49 strength athletes, 103 endurance athletes and 331 athletes from other sports with strength component: 89 sprinters, 38 strength/speed athletes, 64 wrestlers, 42 rugby players, 98 rowers/kayakers/canoeers) and 173 controls. HumanOmni1-Quad BeadChips (Illumina Inc, USA) were used for genotyping of 1,140,419 SNPs in Russian athletes and controls. Initially, 43 SNPs associated with elite strength athlete status (when compared with controls) with P<10-5 were identified, but none of them reached genome-wide significance level. Adding three criteria, i) an increase of the frequency of effect allele with increase of the level of achievement of strength athletes; ii) significant differences in allelic frequencies between strength athletes and endurance athletes; iii) at least one replication of association between effect alleles and predisposition to other sports with strength component, resulted in remaining eight SNPs (SUCLA2 rs10397 A, MED4 rs7337521 A, GPC5 rs852918 A, GABRR1 rs282114 A, CACNG1 rs1799938 A, ARHGEF28 rs17664695 G, WAPAL rs4934207 G, MPRIP rs6502557 A alleles) with P va-

lue from 9.1x10-5 to 3.1x10-6. These SNPs are located in the genes involved in the regulation of ATP production (SUCLA2), transcription of DNA (MED4), cell division and growth (GPC5, ARHGEF28), neurotransmission (GABRR1), muscle contraction (CACNG1, MPRIP) and DNA repair (WAPAL). Our results suggest that many genetic variants may influence strength performance but additional replication studies are warranted.

J18.10
Genetic diversity of human populations in genes associated with immunity-dependant diseases

A. Cherednichenko[1], *E. Trifonova*[1,2], *K. Vagaitseva*[1,2], *A. Bocharova*[1], *V. Stepanov*[1,2];
[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*National Research Tomsk State University, Tomsk, Russian Federation.*

The aim of this investigation was to study the genetic diversity in genes associated with allergic and autoimmune diseases and with regulation level of cytokines and immunoglobulin E levels in North Eurasia. 26 population groups from Northern Eurasia were analyzed. 27 markers in 24 genes were selected to perform statistical analyses of data collected in our populations of Northern Eurasia as well as in 31 populations from HapMap, 1000 Genomes and HGDP projects. The frequencies of alleles and genotypes within the populations demonstrated wide variability. Strong Spearman correlations of allele frequencies with absolute longitude and year range of average temperatures were revealed for the majority of loci. Significant correlations between average expected heterozygosis in 27 loci and absolute latitude, temperature of the coldest month, range of average temperatures and average annual level of precipitations were showed. The estimation of population genetic relations by principal components analysis has revealed the clustering of populations according to their geographic location. Participation of investigated genes in Jak-STAT signaling pathway, in interaction between cytokines and their receptors, in differentiation of lymphocytes by Th1/Th2-pathway have been identified using DAVID on-line recourse. Thus, the obtained data indicate that genetic diversity in genes associated with immunity-dependant diseases was probably shaped by adaptation to new environment during human dispersal in North Eurasia.

Analysis of the Y-chromosome in the Volga-Ural region populations from Russia

N. V. Trofimova[1], *S. S. Litvinov*[2], *R. I. Khusainova*[1,2], *V. L. Akhmetova*[2], *I. M. Khidiyatova*[1,2], *R. Villems*[3], *E. K. Khusnutdinova*[1,2];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa Scientific Center of the Russian Academy of Sciences, Ufa, Russian Federation,* [3]*Estonian Biocentre, Tartu, Estonia.*

We analyzed a sample of the Volga-Ural region, including 462 individuals from 8 populations: Udmurts, Komi, Mordvinians, Mari, Besermyans, Chuvashes, Tatars, Bashkirs. We have shown that the major proportion of Y-chromosome haplogroups in the studied populations accounted for the four branches (R1b-M269, R1a-M198, N1c1-Tat and N1c2-P43), which together make up from 51% to 100% of the patrilineal genetic diversity in the studied region.

We have shown that West Asian and Central Asian Y-chromosome haplogroup R1a-Z2125 in the Volga-Ural region occurs with the greatest frequency in Bashkirs (31%), which is the dominant subgroup of haplogroup R1a-M198 in this population despite the fact that in other populations Eastern European R1a-M558 and R1a-M458 are the dominant lines. This fact indicates that different haplogroup R1a-M198 lines in the populations of the Volga-Ural region have different sources.

The Eastern European influence in the population can be also seen in Tatars from Tuimasinsky district of Bashlortostan in which typical for Central Europe haplogroup R1b-M405 is the predominant line of the haplogroup R1b-M343. According to the PCA analysis based on the Y-chromosome haplogroups distribution, Bashkirs show the greatest separation from other populations of the region. The reason is the presence with the high frequency of Asian lineages in their gene pool.

J18.12
Statistical analysis for parentage test and mutation rate determination in Thai database

T. Rinthachai, *B. Rerkamnuaychoke;*
Human Genetics Laboratory, Department of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

Introduction: The analysis of DNA results for parentage test is expressed based on a mathematical as the combined paternity index (CPI) calculation. In case of mismatches between the father or/and mother and the child alleles, there is a chance of mutation in some loci.

Materials and Methods: Using DNA typing to determine the relationship between parents and child from 1,011 unrelated families. The DNA samples were amplified using commercial kits for 9 and 15 STR loci to establish kinship analysis of trio case from 324 families and then duo cases between fathers-child and mothers-child in 305 and 382 families, respectively.

Results: In trio cases the CPI of 376 values were 420.07 to 359,558,681.35. In duo cases of father - child, the CPI of 423 values were 228.71 to 38,900,000,000 and mother - child of 543 values were 70.45 to 1,730,000,000. In 1,377 parent/child allelic transfers, 35 isolated STR mismatches were observed. The increase or decrease of short tandem repeats (n=34) and a single base change (n=1) were detected. The mutation rate was 0 to 5.17 x 10^{-3} per locus per gamete per generation.

Conclusion: This report proposed a model for analysis of the variations in the distribution for CPI value in parentage test. The minimal value of CPI may be use to determine the cut off for the relationship criteria. In addition, the mutation rate may help for more reliable in calculation of CPI in mismatched case.

J18.13
The molecular spectrum of α- globin gene mutations in suspected of alpha-thalassemia carriers in south of Iran

M. Hamid[1], *G. Shariati*[2], *H. Galehdari*[2], *A. Saberi*[2], *M. Mohammadi –Anaei*[2];
[1]*Pasteur Institute of Iran, Tehran, Iran, Islamic Republic of,* [2]*Narges Medical Genetics & PND Laboratory, Ahvaz, Iran, Islamic Republic of.*

In this study, 895 individuals with low hematological values, normal Hb A2 who were not affected with β- thalassemia or iron deficiency, were investigated for the presence of α- thalassemia mutations. α-thalassemia mutations were characterized by gap polymerase chain reaction (gap-PCR), MLPA, and sequencing for both α genes. The most common deletion was -α(3.7) with a frequency of 57.9% and 12.1% for -α3.7 /αα and -α3.7/-α3.7 respectively, followed by α CD19(-G) α/αα (2.6%), αpoly A6α/αα (2.3%), -α4.2 /αα (1.91%), --Med/ αα (1.7%), α IVS donor site α/αα (1.2%),--20.5/ αα (0.8%), α Constant springα/αα (0.7%), αpoly A4α/αα (0.3%) and, etc. The results of this study will be useful for genetic counseling and the prevention of HbH disease in Khouzestan Province, Iran

Analyze of SNP rs9939609 in FTO gene of obese males in Iraqi population

M. N. Al-Darraji;
University of Al-Anbar, Al-Anbar, Iraq.

Abstract

The present study conducted on 120 and 50 obese and healthy males respectively, their age ranged from 20-50 years. The patients were divided into 3 groups based on Body Mass Index (BMI) and Central Obesity (CO); it has noticed that there is a significant relation between both indexes. DNA from blood of obese and healthy was isolated and SNPrs9939609 was then amplified by PCR using appropriate primers, genotype was identified using *Sac*I. Parameters TG, TC, HDL, LDL, VLDL and FTO enzyme level have been investigated. The results showed that there are significant differences P≤0.05 for AA genotype with all parameters whereas TA genotype showed significant differences with most of parameters in revers to TT genotype which has showed no significant differences with most of parameters. The percentage of AA, TA, TT alleles were 27.72%, 49.86%, 22.42% respectively, also an elevated of TT genotype was observed in healthy compare with obese. On the other hand the percentage of T and A allele frequency were 52.65% and 47.35% respectively.an elevated in serum FTO enzyme was observed in obese.

Conclusion: the presence of A risk allele in the Iraqi population is the cause in the incidence of obesity which reflected its impact on the BMI and CO through the turbulence in lipid profile and FTO enzymes value.

Table 1: Effect of SNP rs9939609 genotypes on investigated parameters

UGT1A1*16 and UGT1A1*28 alleles in 17 consanguineous Tunisian families from SIDI BOUZID and GAFSA

N. B. ABDELMOULA[1], *P. Lohse*[2];
[1]*Medical University, Sfax, Tunisia,* [2]*Department of Clinical Chemistry, Munich, Germany.*

We report a study of 17 Tunisian families with suspicion of Crigler-Najjar syndrome type I (CNS1). Molecular analysis was carried out using PCR and direct sequencing of the TATA box and exon 3 of UGT1A1 gene and then the remaining four exons of the gene. The 17 families were exclusively native of Sidi Bouzid and Gafsa, from specific delegations of these two towns: Bir El Hafey, Meknassy, Regueb, Sidi Bouzid, Gafsa and Mdhilla. 16 among 17 index cases were homozygous for the c.1070A>G mutation (UGT1A1*16) and for the TA insertion in the TATA box of the UGT1A1 gene promoter, resulting in TA7/TA7 genotype (2 UGT1A1*28 alleles or 2 A(TA7)TAA alleles or 7/7 homozygous genotype) or TA8/TA8 genotype particularly for some patients from Gafsa. Mutations were located on the same chromosome, as the analysis of the index patient reveals. 15 parents and related families members were heterozygous carriers of the TA insertion and the linked c.1070A>G mutation. Only 2 partners from Gafsa had TA7/TA8 genotype [(TA)7,8] with a child who was 8/8 homozygous.
These results indicated that CNS1 in Tunisia seems be associated with two founder effect related to the UGT1A1*16 (Q357R) mutation linked to TA7 (UGT1A1*28) or to TA8 alleles within two regions of the Western Centre. Consanguineous marriages, had limited the diffusion of these mutations for some times. But, at present, Tunisian's sanitary authorities have to set up a national strategy to offer genetic counselling and molecular preconceptional and prenatal diagnosis to prevent specially CNS1 new cases.

Genome-wide association study reveals seven genetic markers associated with maximal oxygen consumption rate in elite Russian endurance athletes

I. I. Ahmetov[1], *D. S. Ischenko*[2], *N. A. Kulemin*[2], *D. V. Popov*[3], *A. A. Galeeva*[1], *E. S. Kostryukova*[2], *D. G. Alexeev*[2], *E. S. Egorova*[4], *L. J. Gabdrakhmanova*[1], *A. K. Larin*[2], *E. V. Generozov*[2], *E. A. Ospanova*[2], *A. V. Pavlenko*[2], *E. B. Akimov*[5], *O. L. Vinogradova*[3], *V. M. Govorun*[2];
[1]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation,* [2]*Research Institute of Physico-Chemical Medicine, Moscow, Russian Federation,* [3]*Institute for Biomedical Problems of the Russian Academy of Sciences, Moscow, Russian Federation,* [4]*Kazan State Medical University, Kazan, Russian Federation,* [5]*Centre for Sports Innovation Technologies and National Teams, Moscow, Russian Federation.*

The aim of the study was to identify SNPs associated with elite endurance performance (maximal oxygen consumption rate, VO2max) and endurance athlete status in Russians using a GWAS approach, genotype-phenotype and case-control designs. The study involved 542 international-level athletes (103 long distance athletes, 120 middle distance athletes, 319 power athletes) and 173 controls. VO2max was measured in 71 endurance (41 males and 30 females; 26 long distance and 45 middle distance) athletes. HumanOmni1-Quad BeadChips (Illumina Inc, USA) were used for genotyping of 1,140,419 SNPs in Russian athletes and controls. No genome-wide significant results were observed. However, when we used the criteria that any SNP should be independently associated with VO2max in male and female athletes separately (with P<10-3 adjusted for sex), and the frequency of the endurance-related allele should be over-represented in endurance athletes in comparison with controls and power athletes, we identified seven alleles (ZNF429 rs1984771 G, FMNL2 rs12693407 G, ACOXL rs13027870 G, NFIA-AS2 rs1572312 C, ITPR1 rs2131458 A, GALM rs3821023 A, NATD1 rs732928 G) with suggestive significance in the determination of endurance performance. These SNPs are located in the genes involved in the regulation of lipid (ACOXL) and carbohydrate (GALM) metabolism, erythropoiesis (NFIA-AS2), morphogenesis and cytokinesis (FMNL2), intracellular Ca2+ signaling (ITPR1) and other processes (ZNF429, NATD1). Our results suggest that many genetic variants of small effect size may influence human physical performance.

Gene expression profile at different age periods among residents of Bashkortostan

V. V. Erdman[1], *T. Nasibullin*[1], *I. Tuktarova*[1], *I. Shaibakov*[2], *D. Karimov*[1], *O. Mustafina*[1];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Republican Clinical Hospital no. 2, Ufa, Russian Federation.*

Functional activity of transcriptome is decrease with age generally. This leads to age-related changes of organs and tissues. The aim of the present study was to evaluate the role of expression level of some genes for different age stages, in particular for senile age and age of longevity. For this purpose was performed gene expression analysis in groups of senile (75-89 years old) and long-lived (90-100 years old) persons in comparison with middle-age persons (25-39 years old). Total RNA was isolated from peripheral blood leukocytes of 60 healthy subjects, man and women, residents of Bashkortostan Republic, Russia. Quantitative real-time PCR was performed using RT2 SYBR Green/Fluorescein qPCR Master Mix and RT2 qPCR primers for IL6, JAK3, STAT5, TNFA, LAMA2, ACE, TEAD and COL13A1 genes. It was found tendencies to increase the expression level of mRNA gene IL6 in senile group compared to middle-age persons (2.14-fold). Among long-lived persons reduced the expression level of TNFA (3.28-fold) and LAMA2 (5.87-fold) genes. Transcription activity of LAMA2 gene in group of long-lived persons in 10.6 fold lower compared to the senile group (p=0.05). These data suggest a positive role of IL6 cytokine for senile age and negative character of TNFA and LAMA2 genes in the reaching of longevity. So, aged persons had altered cytokines and LAMA2 genes expression profile.

High proportion of W1282X mutation in Karachai CF patients

N. V. Petrova[1], *E. E. Timkovskaya*[1], *T. A. Vasilyeva*[1], *N. Y. Kashirskaya*[1], *E. I. Kondratyeva*[1], *N. I. Kapranov*[1], *S. G. Gavrilina*[1], *R. A. Zinchenko*[1,2], *E. K. Ginter*[1,3];
[1]*Federal State Budgetary Institution „Research Centre for Medical Genetics", Moscow, Russian Federation,* [2]*Pirogov Russian National Research Medical University, Moscow, Russian Federation,* [3]*Russian Medical Academy of postgraduate education, Moscow, Russian Federation.*

Cystic fibrosis (CF; OMIM #219700) is a common autosomal recessive disease. The spectrum and frequency of CFTR mutations significantly vary in different populations and ethnic groups. The Karachai - Turkic-speaking people of the North Caucasus (the indigenous ethnic group of the Republic of Karachay-Cherkessia (Russia), constituting about 40% of the Republic population (194 thousand)), live compactly in 4 districts, of which three were included in the genetic-epidemiological study. The cystic fibrosis prevalence was 1:2878 children in Ust-Jegutinsk, 1:2875 children - in Karachaevsk, 1:4630 children - in Malokarachaevskiy district.
Molecular genetic analysis for 29 CFTR mutations (shared up to 75-80% of mutant alleles in Russian population) was performed in 9 unrelated Karachai CF patients. A high proportion of W1282X mutation was revealed (16 of 18 mutant alleles, 89%): seven patients - homozygous for W1282X mutation, two - compound heterozygous (second allele has been not identified yet).
In 105 healthy Karachai the analysis of the 13 CFTR mutations (CFTRdele2,3(21kb), F508del, I507del, 1677delTA, 2184insA, 2143delT, 2183AA>G, 2184delA, 394delTT, 3821delT, L138ins; E92K; W1282X) identified one 1677delTA mutation carrier and one W1282X mutation carrier.
Thus, neither among the CF patients nor among the healthy Karachai the most common CFTR mutation (F508del) was detected. The most frequent mutation among CF patients was W1282X. Its frequency in healthy Karachai was about 0,005. Until now, the origin and spread of W1282X mutation was associated with the settlement of the Ashkenazi Jews. Further investigation of linked DNA markers could clear up the origin of W1282X mutation in Karachai.
The research was partially supported by grants RFFR 14-04-00525; 15-04-01859.

Ammosov North-Eastern Federal University, Yakutsk, Sakha Republic, Russian Federation,* [6]*Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation,* [7]*Aktash Regional Hospital, Aktash, Altai Republic, Russian Federation.*

Mutations in gene GJB2 (MIM 121011, 13q11-q12) which encodes gap junction protein connexin-26 (Cx26) are one of the main causes of nonsyndromic deafness. Pathogenic contribution and mutational spectrum of GJB2 are known to depend on population ethnic origin. The main objective of this study is a comparative estimation of the GJB2 pathogenic contribution to deafness in populations of two South Siberian regions (the Altai Republic, the Tyva Republic). The results were obtained on 364 ethnically matched patients (93 Altaians, 192 Tuvinians, 40 Russians, 13 Kazakh, and 26 pa-

tients of mixed ethnicity) with congenital or early onset hearing loss. The GJB2 (Cx26) pathogenic contribution to hearing impairment was defined as proportion of so called Cx26-positive patients with two homozygous or compound heterozygous recessive (or one dominant) GJB2 mutations. Mutation screening of GJB2 was performed by Sanger sequencing of GJB2 protein-coding region (exon 2), exon-intron 1 region and flanking sequences that revealed full set of GJB2 pathogenic mutations and polymorphisms in examined patients. We found similar proportion of Cx26-positive patients among Altaians (15.1%) and Tuvinians (18.8%) belonging to two indigenous peoples of South Siberia that substantially lower than in Russians (47.5%) living in studied regions. Equal GJB2 contribution in deafness (23.1%) was found in Kazakh and in group of patients of mixed ethnicity. Three GJB2 mutations c.235delC, p.W172C, and IVS1+1G>A are common in Altaians and Tuvinians, while mutation c.35delG is predominant in Russian and Kazakh patients. Study was supported by the State research project VI.58.1.1 and the RFBR grants #15-04-04860_a, #14-04-90010_Bel_a.

In terms of physiology and metabolism, power and endurance are located at the opposite extremes of a muscle performance continuum. The aim of the study was therefore to identify the difference in genomic profiles between endurance and power athletes by using a GWAS approach. The study involved 542 Russian athletes (319 power athletes, 223 endurance athletes) and 173 controls. HumanOmni1-Quad BeadChips (Illumina Inc, USA) were used for genotyping of 1,140,419 SNPs in all cohorts. In addition, endurance performance (expressed as a maximal oxygen consumption rate, VO2max) was measured in 71 endurance athletes. At the first stage, by comparing genetic profiles of two groups of elite athletes only (171 elite power and 56 elite endurance athletes), we identified 13 SNPs with suggestive significance (P values from 10-5 to 10-6). We then compared allelic frequencies of discovered SNPs between each group of athletes and controls and performed regression analysis to reveal association with VO2max of endurance athletes. These analyses resulted in remaining 3 SNPs (effect alleles: CLSTN2 rs2194938 C, FOCAD rs17759424 C, TPK1 rs10275875 G) associated with power athlete status and 5 SNPs (CLSTN2 rs2194938 A, TPK1 rs10275875 A, ITPR1 rs1038639 A, NALCN-AS1 rs4772341 A, SPOCK1 rs1051854 A) with endurance athletes status (based on case-control study and correlation with VO2max). These SNPs are located in the genes involved in the regulation of neuronal excitability (CLSTN2, NALCN-AS1), cell growth (FOCAD), vitamin B1 metabolism (TPK1), muscle contraction (ITPR1) and protein metabolism (SPOCK1).

Between seas and steppes: the genetic legacy of ancient Greeks and medieval Mongols in population of Crimea peninsula

A. Agdzhoyan[1,2], *E. Lukianova*[1], *L. Atramentova*[3], *E. Balanovska*[2], *R. Villems*[4], *O. Balanovsky*[1,2];
[1]*The Vavilov Institute of General Genetics (VIGG), Moscow, Russian Federation,* [2]*Federal State Budgetary Institution «Research Centre For Medical Genetics» (FSBI "RCMG"), Moscow, Russian Federation,* [3]*V.N. Karazin Kharkiv National University, Kharkiv, Ukraine,* [4]*Estonian Biocentre, Tartu, Estonia.*

Since prehistoric times, the Crimea was an area of intensive migrations. The (incomplete) list of populations migrated there includes Scyphians, ancient Greeks, Romans, Hunns, Gots, Tatars, and Russians. We collected 400 DNA samples from unrelated male volunteers representing two main indigenous populations in Crimea: Crimean Tatars (Steppe, Mountain, and Coastal subethnic groups) and Crimean Greeks (Urum and Romei sub-ethnic groups).
We analyzed Crimean populations by Y-chromosomal markers, full mitochondrial genomes and genome-wide autosomal markers. The results provided by all three genetic systems virtually coincided. We revealed three main features in Crimean gene pools. First, Mountain and Coastal Crimean Tatars and both Crimean Greeks populations are characterized by genetic component predominant in East Mediterranean peoples, especially in Greeks and Turks. Second, Steppe Crimean Tatars carry the contrasting genetic component, which is typical for Turkic populations from Eurasian steppe. Third, all indigenous Crimean populations do not show notable genetic similarity with their closest geographical neighbors - Ukrainians and Russians. We conclude, that present day gene pool of indigenous Crimean populations reflects the distant echo of marine Greek colonization in antique epoch and steppe expansion of Mongol civilization in medieval epoch.
The work was supported by RFBR grants 13-06-00670, 14-06-31331 and by Presidium of RAS Programme.

J18.22
THE Y-CHROMOSOMAL PORTRAIT OF THE INDIGENOUS POPULATIONS FROM THE RUSSIAN FAR EAST

Y. Bogunov[1], *A. Bogunova*[2], *O. Maltseva*[3], *E. Balanovska*[4], *O. Balanovsky*[1];
[1]*The Vavilov Institute of General Genetics (VIGG), Moscow, Russian Federation,* [2]*Amur State University of Humanities and Pedagogy, Komsomolsk-on-Amur, Russian Federation,* [3]*Institute of Archeology and Ethnography of the Siberian Branch of the RAS, Novosibirsk, Russian Federation,* [4]*Federal State Budgetary Institution «Research Centre For Medical Genetics» (FSBI "RCMG"), Moscow, Russian Federation.*

Populations from the Russian Far East (Amur river basin) have a particular importance for reconstructing the ancient human migrations in Eurasia because the gene pool in this region is supposed to be well preserved since the Neolithic. Using wide panel of Y-chromosomal SNPs we characterized two Manchu-Tungus-speaking ethnic groups - Nanais (N=226) and Ulchis (N=57).
The Nanais (census size about 10,000 persons) have complex population structure. The haplogroups N1c1-M178, C-M130, and C3c-M48 accounts for more than 80% of their gene pool, this feature brings the Nanais together with the Eastern Siberian populations. The less frequent haplogroups O3-M122, O3a2-M201, O1a-M120 indicate gene flow from East Asia. Haplogroups G2a-P15, J2-M172, I-M170, I2a-P37, R1a1-M198 and Q-M242 occur with a frequency of less than 1%.
The Ulchi (about 3,000 persons) dwell the Lower Amur district in Russia. The haplogroup C (C-M130, C3c-M48) comprises 54% of their gene pool; the haplogroup O (O-P186, O1a-M120, O2-P31, O3-M122) accounts for 17%. The rest of the gene pool is formed by I-M170, I2a-P37, J1(xJ1e)-M267, N1c-LLY22, N1c1-M178, and Q-M242 haplogroups.
The surprising peculiarity of the studied populations is the accumulation of haplogroups I-M170* and I2a-P37 which are often though to be European-specific lineages since Mesolithic epoch.
The multidimensional scaling plot revealed a significant genetic similarity of the Nanais and the Ulchis with the Oroch and the Mongols. At the same time the studied Nanai population from Russia is genetically distant from the Nanais sampled in China.

Prostate cancer (PCa) is the second most commonly diagnosed cancer among men and also the sixth leading cause of cancer related mortality. Still, genetic factors contributing to PCa susceptibility remain largely unknown. Even though a multitude of evidence supports the involvement of regulatory mechanisms based on activity of microRNAs in prostate carcinogenesis, to date, genetic variants in microRNA genes have been evaluated as potential PCa susceptibility loci in only few populations, none of European origin. Therefore, the aim of this study was to evaluate potential association of rs3746444 in hsa-miR-499 and rs11614913 in hsa-miR-196a2 with PCa risk and progression. The study population included 354 PCa patients and 354 patients with benign prostatic hyperplasia (BPH) from whom blood samples were obtained, as well as 311 healthy controls derived from general population who provided buccal swabs. Genotyping of rs3746444 and rs11614913 was performed by PCR-RFLP and HRMA, respectively. The results did not support the association of analyzed genetic variants with PCa risk. Also, these genetic variant were not found to be associated with the standard prognostic parameters of PCa progression (serum PSA level at diagnosis, Gleason score and clinical stage according to TNM classification system). Nevertheless, rs3746444 minor allele G was shown to be associated with the lower risk of PCa progression (according to D'Amico criteria) under recessive genetic model.

[1]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation,* [2]*Research Institute of Physico-Chemical Medicine, Moscow, Russian Federation,* [3]*Institute for Biomedical Problems of the Russian Academy of Sciences, Moscow, Russian Federation,* [4]*Kazan State Medical University, Kazan, Russian Federation,* [5]*Centre for Sports Innovation Technologies and National Teams, Moscow, Russian Federation.*

Endurance athlete status is a complex phenotype subject to the influence of both environmental and genetic factors. The aim of the study was to identify SNPs associated with elite endurance athlete status in Russians using a multi-stage GWAS approach (HumanOmni1-Quad BeadChips). The study involved 223 endurance athletes, 67 elite power (sprinters and speed/strength athletes) athletes and 173 controls. VO2max (major indicator of aerobic capacity) was measured in 71 endurance (41 males and 30 females; 26 long distance and 45 middle distance) athletes. Initially, we performed GWAS in 4 subgroups (all and elite long distance athletes, all and elite middle distance athletes) of endurance athletes and controls, and found replications of associations with endurance athlete status in all subgroups for 93 SNPs with P<10-4, but none of them reached genome-wide significance level. Adding three criteria, i) an increase of the frequency of effect allele with increase of the level of achievement of endurance athletes; ii) significant differences in allelic frequencies between 56 elite endurance athletes and 67 elite power athletes (second case-control study); iii) positive correlation of the effect allele with high values of aerobic capacity, resulted in remaining five SNPs (effect alleles: CAMK1D rs11257754 A, CPQ rs6468527 A, GRM3 rs724225 G, SGMS1 rs884880 A, L3MBTL4 rs17483463 A) associated with elite endurance athlete status. These SNPs are located in the genes involved in the regulation of carbohydrate metabolism (CAMK1D), synthesis of thyroxine (CPQ), glutamatergic neurotransmission (GRM3), sphingomyelin and diacylglycerol metabolism (SGMS1) and chromatin modification (L3MBTL4).

FREQUENCY OF ALL FORMS CONGENITAL MALFORMATIONS OF NEWBORNS BY BASED ON GENETIC REGISTER „UMIT» AND EUROPEAN INTERNATIONAL REGISTER EUROCAT

D. Zhanatayeva, *Nagimtayeva A., Abildinova G.;*
National Research centre of maternal and childhood, Astana, Kazakhstan.

According to the International Centre for EUROCAT, which unites more than 20 countries of the European Economic Community, the cumulative incidence of PPS varies widely - from 10.3 to 32.3 per 1,000 live births. This may be due to the peculiar environmental conditions surveyed regions, the difference in accounting methods congenital malformations, quality and principles of diagnosis, the difference in years of research. The study group was isolated malformations to be counted according to the list of the International Registry of congenital malformations (21 nosology), and analyzed in comparison with the data of our register. The overall frequency of these birth defects was 10.6 per 1,000 live births, which corresponds to the average values of the International Registry. The results of the research in our database, in comparison with the data EUROCAT more common Downs syndrome, multiple congenital malformations, congenital heart disease and malformations such as hydrocephalus, diaphragmatic hernia, Spina bifida. When comparing the frequency of congenital malformations in our case with those in the EUROCAT was found that the prevalence of a number of malformations of the central nervous system (anencephaly, encephalocele) and microtia, renal agenesis and bladder exstrophy 2-3 times lower. These types of birth defects, anophthalmia and microphthalmia as are found in our region is 3 times less than on the data recorded by the European register.

Genome-wide association study of elite power athlete status

D. S. Ischenko[1], *A. A. Galeeva*[2], *N. A. Kulemin*[1], *E. S. Kostryukova*[1], *D. G. Alexeev*[1], *E. S. Egorova*[3], *L. J. Gabdrakhmanova*[2], *A. K. Larin*[1], *E. V. Generozov*[1], *E. A. Ospanova*[1], *A. V. Pavlenko*[1], *V. M. Govorun*[1], *I. I. Ahmetov*[2];

[1]*Research Institute of Physico-Chemical Medicine, Moscow, Russian Federation,* [2]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation,* [3]*Kazan State Medical University, Kazan, Russian Federation.*

The aim of the study was to identify SNPs associated with elite power athlete status in Russians using a GWAS approach (HumanOmni1-Quad BeadChips). The study involved 176 power (89 sprinters, 38 speed/strength athletes and 49 strength athletes; 102 elite and 74 sub-elite) athletes, group of athletes with speed/strength component (n=204; 64 wrestlers, 42 rugby players, 98 rowers/kayakers/canoeers), 223 endurance athletes and 173 controls. Initially, we performed seven analyses using GWAS data (elite power athletes vs. controls, all sprinters vs. controls, elite sprinters vs. controls, all speed/strength athletes vs. controls, elite speed/strength athletes vs. controls, all strength athletes vs. controls, elite strength athletes vs. controls) and found 68 SNPs which were associated with power athlete status (with P value from 0.001 to 1.345e-05) and replicated in all three subgroups of power athletes (regardless of their level of achievement). The comparison of allelic frequencies of these SNPs between the large cohort of power athletes (n=380; i.e. power athletes plus group of athletes with speed/strength component) and endurance athletes (as a second control group) resulted in remaining eight SNPs (PPARGC1B rs10060424 C, NRG1 rs17721043 A, ZNF423 rs11865138 C, RC3H1 rs767053 G, IP6K3 rs6942022 C, HSD17B14 rs7247312 G, CALCR rs17734766 G, COTL1 rs7458 T) associated with power athlete status. These SNPs are located in the genes involved in the regulation of muscle fiber composition and carbohydrate/lipid metabolism (PPARGC1B), growth and development (NRG1, ZNF423), mRNA deadenylation and degradation (RC3H1), metabolism of inositol hexakisphosphate (IP6K3), metabolism of steroids (HSD17B14), calcium homeostasis (CALCR) and actin cytoskeleton (COTL1).

The mutation spectrum of the MEFV gene of the Southern Russia population

O. V. Lyangasova, *M. A. Amelina, E. V. Mashkina, T. P. Shkurat;*
Southern Federal University, Rostov-on-Don, Russian Federation.

Familial Mediterranean fever (FMF) is typical for populations living around the Mediterranean basin, it is also affects the Southern Russia population. Different clinical course may be caused by different mutations. Recent study reports the mutation spectrum of the FMF gene (MEFV) in the Southern Russia population.

Blood samples were collected from a cohort of 105 FMF patiens (52 male, 53 female; age: 4 to 88 years), inhabiting in the South region of Russia. The sequencing of the exon 10 in MEFV gene was performed by using a sequencer ABI PRISM 3500.

The six mutations were investigated in the exon 10 in MEFV gene in 67 patients: *M694V* - 58,3%, *V726A* - 19,1%, *M680I* - 14,8%, *R761H* - 6%, *A744S* - 0,9%, *K695R* - 0,9%.

Results of genotype analysis are shown in Table.

Genotype		Patients	%
Compound heterozygote	*M680I© / M694V*	11	16,42%
	M694V / V726A	10	14,93%
	M680I / V726A	3	4,48%
	M680I / R761H	1	1,49%
	M694V / K695R	1	1,49%
	M694V / R761H	1	1,49%
	V726A / R761H	1	1,49%
	Total	28	41,79% ± 9,32
Homozygote	*M694V / M694V*	15	22,39%
	V726A / V726A	2	2,99%
	R761H / R761H	2	2,99%
	M680I / M680I	1	1,49%
	Total	20	29,85% ± 10,23
Heterozygote	*M694V / N*	14	20,90%
	V726A / N	4	5,97%
	A744S / N	1	1,49%
	Total	19	28,36% ± 10,34
Total:		67	100%

This results can be discussed as a background to the search of new diagnostics and population research.

This research was supported by the Ministry of Education and Science of Russian Federation, grant #1878. Analytical work was carried out on the equipment a Center for collective use of Southern federal university “High Technology”, grant #RFMEFI59414X0002.

The genetic basis of the relationship between reproduction and longevity : a study on common variants of three genes in steroid hormone metabolism (CYP17, HSD17B1, COMT).

D. Scarabino[1], *F. Pelliccia*[2], *A. Pinto*[3], *R. Corbo*[4];

[1]*Istitute of Cell Biology and Neurobiology CNR, Monterotondo (Rome), Italy,* [2]*IDepartment of Biology and Biotechnology La Sapienza University, Rome, Italy,* [3]*Experimental Medicine Department, Food Science and Human Nutrition Research Unit, La Sapienza University, Rome, Italy,* [4]*Department of Biology and Biotechnology, La Sapienza University,CNR Institute of Molecular Biology and Pathology,, Rome, Italy.*

Evolutionary theories of aging predict an antagonistic relationship between

fertility and lifespan in humans, but the genetic basis of this phenomenon is not clear. The variation of three genes in steroid hormone metabolism, CYP17 (rs743572), HSD17B1 (rs 605059) and COMT (rs4680), was examined to elucidate the genetic basis of the relationship between fertility and lifespan. A sample of 277 individuals (mean age, 82.9 years) was recruited in 2000. Based on mortality data collected in 2009, the sample was divided into two groups of subjects surviving to over 90 years (long-lived) or not (controls). Fertility data (number of children) were collected in the same sample. CYP17 and COMT gene variation did not influence either lifespan or fertility. The HSD17B1AA genotype was found to be significantly associated (p=0.0085) with longevity only in females (estimated odds ratio = 3.77). As the HSD17B1AA genotype was also associated with a higher number of children (5.3±2.1) than the other genotypes (p= 0.006), we may infer that HSD17B1 genotypes could exert a positive pleiotropic action on longevity and fertility. We then searched the literature for genes studied in relation to both reproduction and aging. A review of the studies showed a pleiotropic action for six out of sixteen genes and revealed that genes may exert positive, or negative, or antagonistic pleiotropic actions. These actions may be modified by environmental factors such as changing reproductive behaviors, which seem to be able to mitigate or to enhance the gene phenotypic effects.

General Regression Model: a powerful "model free" association test for both qualitative and quantitative traits allowing to determine the underlying genetic model of transmission

M. DIZIER[1], E. Gloaguen[2], C. Julier[2], **F. MATHIEU**[2,3]*;*
[1]INSERM UMR-946, PARIS, France, [2]INSERM UMR-S958, PARIS, France, [3]UniversitéParis Diderot, Paris, France.

Genome-wide association studies (GWAS) are usually assessed using regression models, assuming additive mode of transmission. This choice leads to a significant loss of power in case of departure from additivity. We propose a General Regression Model (GRM) allowing detection of association without making hypothesis of the mode of transmission. Additionally, GRM permits the simultaneous estimation of the underlying genetic model. We compared the power of GRM to additive and other classical regression association tests under a large panel of genetic models.

Powers were estimated by simulation of a 2000 cases and 2000 controls sample for qualitative traits and a sample of 5000 cases for quantitative traits. Four association tests (GRM, additive, recessive or dominant tests) were applied to all replicates. The genetic underlying mode of transmission was then tested using GRM.

For both qualitative and quantitative trait, we showed that GRM powers to detect association was similar or greater to that of the additive test. In the case of recessive inheritance, gain of power up to 66% for qualitative and to 93% for quantitative traits respectively. The correct underlying model was determined in most cases.

GRM test appears powerful to detect association, as much as or even more than the classically used additive test, especially in case of recessive inheritance. This test is easily applied to GWAS and may be used to analyze or re-analyze new or existing GWAS datasets to identify new susceptibility loci involved in complex diseases.

Applying the GenoChip genotyping array for tracing Indo-European expansion

M. Chukhryaeva[1,2]*, E. Lukyanova[1], L. Quintana-Murci[3], D. Comas[4], E. Balanovska[2], O. Balanovsky[1,2];*
[1]Vavilov Institute of General Genetics,Russian Academy of Sciences, Moscow, Russian Federation, [2]Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation, [3]Institut Pasteur, Unit of Human Evolutionary Genetics, Paris, France, [4]Institut de Biologia Evolutiva,Departament de Ciences de la Salut i de la Vida, Universitat Pompeu Fabra, Barcelona, Spain.

At present, the Indo-European (IE) languages form the most widespread language family. However, there is no consensus on the IE homeland, early migrations of IE speakers, and how they influenced the gene pool. We compared genetic composition of 7 pairs of geographically adjacent groups, one of which belongs to the Indo-European language family, and the other is non-Indo-European (Table). Altogether, 300 samples were genotyped with the GenoChip array which includes 130,000 autosomal, 3,000 mitochondrial, and 13,000 Y-chromosomal SNPs.

Table. The studied population pairs

The Indo-European population	**Non Indo-European population (comparison group)**
Russian	Mordvinians, Karelia
Ukrainians	Nogai and Crimean Tatars
Armenians	Georgians
Ossetians	Kabardians
Tajiks and Pamir peoples	Turkmen, Uzbeks
Lithuanians	Estonians
French and Spaniards	Basques

We ran the Principal Component (PC) analysis, compared genetic and lexico-statistical similarities, and looked for SNPs found in IE populations more frequently than in their non-IE counterparts.

PC plot shows that genetic relatedness of populations depends not only on their geographical proximity, but also on their linguistic affiliation. Though separating into European and Asian clusters follows geography, in the Asian cluster IE Pomiri and Tajiks populations formed separate cluster from Turkic-speakers, and in the European cluster IE populations are more genetically similar to each other than all European populations as a geographic group. It is notable, that in Western Europe IE Spanish and French individuals group together and differ from the non-IE Basque – the trend is opposite to that expected from geography alone.

This study was supported by the Genographic 2.0 and RFBR (grant 13-04-01711).

FREGAT: an R library for Family REGional Association Tests

N. M. Belonogova, *G. R. Svishcheva, T. I. Axenovich;*
Institute of Cytology & Genetics SD RAS, Novosibirsk, Russian Federation.

Rapid progress in whole-exome and whole-genome sequencing technologies provides new opportunities for detecting rare variants that control complex traits. In this context, region-based association analysis is a more powerful tool for gene mapping than testing of individual genetic variants. Several approaches to regional association analysis have been developed recently and are increasingly used. However, there is still a lack of handy and powerful software tools for regional association analysis, especially for family data.

Here we present a new and effective tool for family-based regional association analysis. It offers several known high-performance regional association tests: famBT (burden test on family data based on collapsing genetic variants), FFBSKAT (fast family-based sequence kernel association test), FFBSKAT optimal, and famFLM (functional data analysis approach based on functional linear models on family data). For all these tests, the statistical properties and run-time performance have been extensively studied in recent years. High statistical power was shown under realistic simulation models, while the fast computation performance enables analysis of a whole exome within a reasonable time even on a single PC.

All tests allow for covariates and non-additive models, parallel or sequential calculation modes and run time estimation. They also offer extensive lists of specific analysis options with optimal default values. This makes FREGAT a simple, flexible, fast and effective tool for regional association analysis in related samples. The FREGAT package, along with its manual, is available for free download at http://mga.bionet.nsc.ru/soft/FREGAT/.

This work was supported by RFBR Grants No. 14-04-00126-a and No. 13-04-00272-a.

Rare coding variants and the risk of congenital anorectal malformations: an exome chip association study

C. H. W. Wijers[1], H. Reutter[2,3], J. Goeman[1], S. H. Vermeulen[1], T. Galesloot[1], E. Jenetzky[4], L. F. M. Zanden van der[1], L. A. L. M. Kiemeney[1], A. Hoischen[1], I. Blaauw de[1], M. M. Garcia-Barcelo[5,6], H. G. Brunner[1], N. Roeleveld[1], **I. A. L. M. Rooij van**[1]*;*
[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Institute of Human Genetics, University of Bonn, Bonn, Germany, [3]Department of Neonatology, Children's Hospital, University of Bonn, Bonn, Germany, [4]Division of Clinical Epidemiology and Aging Research, German Cancer Research Centre, Heidelberg, Germany, [5]Department of Surgery, Li Ka Shing Faculty of Medicine of the University of Hong Kong, Hong Kong, China, [6]Centre for Reproduction, Development and Growth, Li Ka Shing Faculty of Medicine of the University of Hong Kong, Hong Kong, China.

Introduction: Anorectal malformations (ARM) are rare congenital malformations and knowledge on their etiology is scarce. Previous genetic studies mainly focused on candidate genes, but did not yield substantial evidence. Hypothesis-generating approaches seem valuable for new knowledge.

Material and methods: We performed genotyping of 598 Caucasian ARM cases and 1,931 Caucasian population-based controls using the Illumina Human Exome BeadChip, which contains ~250K rare coding variants. Patients were derived from the AGORA biobank in the Netherlands and the German CURE-Net, while controls came from the Dutch Nijmegen Biomedical Study. Single variant and gene-based analyses were performed. Statistically significant single variant results ($p<1.13*10^{-6}$) were technically validated and re-

plicated in additional Caucasian and Han Chinese patients and controls with targeted sequencing, using the molecular inversion probe technique.
Results: In total, 241,177 markers passed all quality control steps. Variants with MAF>0.4% were tested (adjusted by genomic control) and 55 variants reached statistical significance in an allelic model. However, only three variants in the *CLCN1*, *LRBA*, and *ZNF423* genes could be validated and none were replicated. The gene-based analyses yielded 86 statistically significant genes, but did not lead to new insights as conditional analyses showed that gene-based signals were mainly driven by one variant per
gene, mostly already found in the single variant analyses.
Conclusions: We found no evidence for strong associations between ARM and rare coding variants captured by the HumanExome BeadChip. Future studies need large sample sizes to identify common and rare variants with small to moderate effects, while stratifying on phenotypically homogenous groups of ARM patients.

Detection of mitochondrial haplogroups variability of small population living in 9th century based on analysis of ancient DNA

L. Šebest[1], *M. Baldovič*[1], *& Kádasi*[1,2], *C. Bognár*[1], *K. Kyselicová*[3];
[1]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [2]*Institute of Molecular Physiology and genetics, Slovak Academy of Sciences, Bratislava, Slovakia,* [3]*Department of Anthropology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia.*

Introduction: Ancient DNA (aDNA) represents all types of DNA that can be recovered from archaeological and palaeontological material or museum specimens. Information from aDNA is very useful in phylogenetics, paleoanthropology or genealogy. The isolation and analysis of aDNA is accompanied by two major problems: low quality and quantity of aDNA and the risk of contamination with modern DNA. Therefore, several strict laboratory and methodological criteria must be followed. The aim of this study is to isolate and analyze aDNA from human remains of the small Avar-Slavic population living in 9th century and to determine mitochondrial haplogroups in order to estimate the ratio of haplogroups typical for these two ethnicities.
Material and methods: The 50 samples of human teeth and bones were used for the isolation of aDNA in this experiment. The samples were excavated from Avar-Slavic burial site located near Cífer-Pác (Slovakia). Isolation of aDNA were performed in recommended conditions. Mitochondrial haplogroups were determined by sequencing of the HVRI of mtDNA followed by analysis of polymorphisms in this region.
Results: Despite the fact that the graves of mentioned burial place contained Avar artefacts and some remains showed mongoloid cranial features, majority of detected mitochondrial haplogroups belong to the common lineages of the Slavic populations and only presence of haplogroup U7 (typical for region of Near East) indicate the Avar origin.
Conclusion: Our results suggest that the assimilation between Avars and other neighbour ethnicities was too extensive in 9th century and, therefore the presence of haplogroups characteristic for Avars is very rare.

J18.34
Long-range modulation of PAG1 expression by 8q21 allergy risk variants

C. T. Vicente, *S. L. Edwards, K. M. Hillman, S. Kaufmann, H. Mitchell, L. Bain, D. M. Glubb, J. D. French, M. A. R. Ferreira;*
QIMR Berghofer Medical Research Institute, Brisbane, Australia.

The gene(s) whose expression is regulated by allergy risk variants is unknown for many loci identified through genome-wide association studies. Addressing this knowledge gap might point to new therapeutic targets for allergic disease. The aim of this study was to identify the target gene(s) and the functional variant(s) underlying the association between rs7009110 on chromosome 8q21 and allergies. Eight genes are located within 1 Mb of rs7009110. Multivariate association analysis of publicly available exon expression levels from lymphoblastoid cell lines (LCLs) identified a significant association between rs7009110 and the expression of a single gene: *PAG1* (P=0.0017), 732 kb away. Analysis of histone modifications and DNase I hypersensitive sites in LCLs identified four putative regulatory elements (PREs) in the region. Chromosome conformation capture confirmed that two PREs interacted with the *PAG1* promoter, one in allele-specific fashion. To determine if these PREs were functional, LCLs were transfected with *PAG1* promoter-driven luciferase reporter constructs. PRE3 acted as a transcriptional enhancer for *PAG1* exclusively when it carried the rs2370615:C allergy predisposing allele, a variant in complete linkage disequilibrium with rs7009110. As such, rs2370615, which overlaps RelA and Oct-2 transcription factor (TF) binding in LCLs and is predicted to disrupt the motif of five Forkhead TFs, represents the putative functional variant in this locus. Our studies suggest that the risk-associated allele of rs2370615 predisposes to allergic disease by increasing *PAG1* expression which may promote B-cell activation and have a pro-inflammatory effect. Inhibition of *PAG1* expression or function may have therapeutic potential for allergic diseases.

J18.35
Heritability of the mental phenomena: evidence from a Lithuanian twin study

L. Kalasūnienė[1], *A. Goštautas*[2], *L. Šalomskienė*[3];
[1]*Behavioral Medicine Institute, Lithuanian University of Health Sciences, Palanga, Lithuania,* [2]*Department of Theoretical Psychology, Vytautas Magnus University, Kaunas, Lithuania,* [3]*Institute of Biological Systems and Genetic Research, Lithuanian University of Health Sciences, Kaunas, Lithuania.*

The problem of inheritance of the mental phenomena has not yet been solved until now. A classical method, investigation of twins, is often used to find relative contributions from genetics and the environment to quantitative traits. The aim of this study was to investigate a possible influence of heredity on cognitive functions (by applying the Raven test) and personality traits (according to the Eysenck's theory) in twins. In total, 139 pairs of same-sex twins were investigated at the Scientific Twin Center, Lithuanian University of Health Sciences. The zygosity of the twin pairs was confirmed through genotyping with 15 molecular DNA markers. The difference in the total number of incorrect solutions between monozygotic (MZ) and dizygotic (DZ) twin pairs younger than 15 years was not significant; however, in the group older than 15 years, this difference was found to be significant. Based on the total number of incorrect solutions, the concordance in the MZ twins was greater than in the DZ twins. The same tendency was found with cumulative EPQ scores on the extraversion scale. The correlation of the evaluations of cognitive functions was stronger between adult MZ twins than between the DZ ones, confirming 90% genetic similarity of MZ twins. The twin study proved that heredity by 48% influenced cognitive functions. Among the studied personality traits (psychoticism, extraversion, and neuroticism), only extraversion demonstrated a higher concordance between MZ than between DZ twins. The twin study proved that heredity by 51% influenced the extraversion trait.

Mutations in the GJB2 (Cx26) gene are known as a major cause of congenital hearing loss. More than 150 pathogenic mutations were identified in the GJB2 gene, and mutation spectrum and frequency vary considerably among different ethnic groups. Until now, the spectrum and frequency of mutations in the GJB2 gene were not fully described in Yakutia (the Sakha Republic) located in Eastern Siberia. The complete resequencing of promoter and coding protein-regions of the GJB2 gene was performed for the first time in 393 patients with congenital hearing impairment and in 187 normal hearing individuals living in Yakutia. In total sample (n=580) we revealed 13 allelic variants of GJB2 gene, and 8 from these were recessive mutations. We found 21 different GJB2-genotypes among 393 patients, and 10 of them were with two recessive mutations. The contribution of GJB2 gene mutations in hearing loss in the population of Yakutia (45.55%) is the highest among all previously studied regions in Asia. Three mutations: c.-23+1G>A, c.35delG, c.109G>A are the most frequent among deaf patients in Yakutia. The most common mutation for Yakut patients was c.-23+1G>A (94.2% of all mutant chromosomes), and for Russian patients - c.35delG (73.1% of all mutant chromosomes). The prevalence of congenital hearing loss caused by two recessive mutations in GJB2 gene was estimated as 2.00±0.14 per 10000 population of the Sakha Republic (Yakutia). Study was supported by the RFBR

The role of trade-off-like and conditional genetic effects in connections between aging, health decline and longevity

S. Ukraintseva, *K. Arbeev, L. Arbeeva, A. Kulminski, D. Wu, A. Yashin;*
Duke University, Durham, NC, United States.

Investigating trade-off-like and conditional effects of genes is critically important for understanding complex genetic connections between aging, health decline and longevity, and for public health. Here we discuss biological mechanisms of the trade-off-like and conditional genetic effects on health related phenotypes, using results of our ongoing research and review of published studies. We emphasize importance of better understanding such effects for success of both aging research and disease prevention. This includes situations when increased risk of a major disease due to genetic factor can be compatible with longevity and/or slower aging. Accumulating evidence suggests that such situations are common and may compromise well-intended prevention strategies that target general population rather than an individual.This research was in part supported by the NIA/NIH grants R01AG046860, P01AG043352.

Significance of thrombophilic markers in Sickle cell disease

A. K. AL Wahaibi[1], *S. S. Alkindi*[2], *A. Pathare*[2], *S. Al Zadjali*[2], *S. M. Al riyami*[1];
[1]*Oman Medical Specialty Board, Muscat, Oman,* [2]*Sultan Qaboos University Hosital, Muscat, Oman.*

Background: SCD is highly prevalent in the Sultanate of Oman. The gene in its heterozygous state is present in 6% of the indigenous Omani population. One of the complications of SCD is a thrombophilic state. Intermittant painful crisis often activate the haemostatic system with consumption and reduction of several haemostatic proteins.
Aim: To study the haemostatic alterations in SCD patients during clinical and sub clinical thrombotic manifestations.
Methods: We investigated 71 cases of SCD patients in steady state or following an episode of venous thrombosis. Plasma levels Antithrombin III,[AT] Protein S and C, Activated protein C resistance, and genetic screening of Factor V Leiden, [FVL] MTHFR mutation(C677T) and CBS mutation(844ins68) was performed in 37 patients.
Results: We observed a significant reduction in Protein S and C in 18(48.6%)and 16(43.2%) cases respectively. Ten patients(27%) showed a reduction of both Protein S and C levels. No patient showed AT deficiency or FVL. MTHFR C677T mutation was seen in 16(43.2%) cases, whereas the CBS 844ins68bp was seen in 12(32.4%) cases in heterozygous state. CBS mutation was significantly correlated with low Protein S levels, whereas the MTHFR mutation alone was not correlated with any other thrombophilic marker studied.
Discussion: This small study demonstrates variable alterations in several haemostatic markers of thrombophilia studied. However, in almost all cases, as AT levels were normal, it is likely to reflect an underlying cause rather than effect as one would have expected a reduction in the AT levels in case of consumption.

J18.39
In search of the holy grail in biogeography: From DNA to home village in less than 30 seconds.

E. Elhaik;
University of Sheffield, Sheffield, United Kingdom.

The search for a method that utilizes biological information to predict humans' place of origin has occupied scientists for millennia. Over the past four decades, scientists have employed genetic data to address this question with limited success. Biogeographical algorithms using next-generation sequencing data achieved an accuracy of 700 km in Europe but were inaccurate elsewhere. Here we develop the Geographic Population Structure (GPS) algorithm and demonstrate its accuracy with three datasets using 40,000-130,000 SNPs to improve this accuracy. GPS placed 83% of worldwide-individuals in their country of origin. Applied to over 200 Sardinians villagers, GPS places a quarter of them in their villages and most of the remaining within 50km of their villages. The accuracy and power of GPS to infer the biogeography of worldwide-individuals down to their country or, in some cases, village, of origin, underscore the promise of admixture-based methods for biogeography and has ramifications for genetic ancestry testing. Applications for ancient DNA will be discussed.

The „clan-based" mutation rate of the Y-chromosome estimated from high-throughput sequencing data.

M. Zhabagin[1,2], *Z. Sabitov*[3], *A. Agdzhoyan*[2], *M. Chukhryaeva*[2], *V. Zaporozhchenko*[4], *G. Highnam*[5], *Z. Zhumadilov*[1], *C. Tyler-Smith*[6], *E. Balanovska*[4], *O. Balanovsky*[2];
[1]*Center for Life Sciences, Astana, Kazakhstan,* [2]*Vavilov Institute of General Genetics, Russian Academy of Sciences, Moscow, Russian Federation,* [3]*Gumilov Eurasian National University, Astana, Kazakhstan,* [4]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [5]*Gene by Gene, Ltd., Houston, TX, United States,* [6]*The Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, United Kingdom.*

Within last three years the high-throughput sequencing technologies yield large datasets on Y-chromosomal variation in humans. Reliable estimation of the base-substitution rate is crucial for applying these data for dating population events. To estimate the mutation rate different approaches were used: human-chimpanzee comparisons (the evolutionary approach), analysis of the deep-rooting pedigree (the genealogical approach), adjusting the autosomal mutation rates, and using archeological dates of founding migrations (the calibration approach). We applied the independent "clan-based" approach using the historical dates of life of the tribe-clan founder and number of mutations accumulated among the clan members to count the mutation rate.
We genotyped 367 representatives of the Kazakh tribe Argyn by 45 SNP and 17-STR Y-chromosomal markers and found haplogroup G1-M285 with frequency 68%. The Argyn includes around 500,000 members claiming their ancestry from Karakhoja who is historical person lived 600 years ago. We applied the BigY technology (FamilyTreeDNA, Ltd) to sequence ~11 Mb of the Y-chromosomes of representatives of the 9 clans.
The reconstructed genetic tree of these Y-chromosomes perfectly fits the genealogical tree. This finding indicates the biological reality of the genealogy thus allowing calculate the Y-chromosomal mutation rate. The SNP substitution rate was 0.78×10^-9 per bp per year, falling within the range of published rates. The STR mutation rate was 0.0022 per locus per generation, very close to the so-called genealogical rate.
This study received primary support from the RSF (grant 14-14-00827), Nazarbayev University, and Wellcome Trust (grant 098051).

Brief report on setting up the first Huntington's Disease Center in Romania

R. Moldovan[1], *V. Tibre*[2], *D. Cosman*[2], *R. Popp*[2], *V. Pop*[2];
[1]*Babes-Bolyai University, Cluj Napoca, Romania,* [2]*Iuliu Hatieganu University of Medicine and Pharmacy, Cluj Napoca, Romania.*

In Romania, the diagnosis, care and support of patients with Huntington Disease (HD) and their families is often problematic given the absence of integrated services and multidisciplinary teams of specialists. At the moment, there is no standard practice for HD: patients and families are most often unaware of their options and commonly so do professionals who come into contact with them. By setting up an HD center we aimed to bring together a multidisciplinary team able to provide a platform for professionals and HD families that will facilitate (1) assessing and diagnosing HD; (2) providing information, social and emotional support; (3) offering genetic counselling; (4) overseeing management of symptoms; (5) giving information about research and the opportunity to take part in various research projects in HD. The establishment of this center will facilitate the transfer of know-how in our country in terms of international guidelines for the assessment, diagnosis, counseling and care. Our presentation is aimed at showing the process of setting up an HD center in Romania. We will first introduce the context our team had to take into account when setting up this center and then present some of the strengths and challenges we encountered. We will detail our most representative outcomes so far as well as our plans for the near future.

Ehlers Danlos Syndrome National Diagnostic Service and EDS-UK, working together.

M. Bartlett[1], *L. Bloom*[2], **J. Bowen**[3], *C. Cummings*[1], *J. Morrison*[2], *J. Tocher*[3];
[1]*Ehlers Danlos Syndrome National Diagnostic Service, London, United Kingdom,* [2]*Ehlers Danlos Support UK, London, United Kingdom,* [3]*Ehlers Danlos Syndrome National Diagnostic Service, Sheffield, United Kingdom.*

Since the Ehlers Danlos Syndrome (EDS) National Diagnostic Service was set up in 2009 we have valued our contact with the support group and charity, EDS-UK. The last six years have seen a number of changes for both of us and through this we have managed to form strong links enabling us to work closely on a number of projects.

Perhaps fortuitously, the EDS National Diagnostic Service for rare and atypical types of EDS, was set up at a time when EDS-UK were being asked to do more for members with the rare types of EDS. With our collaboration EDS-UK have now run their second patient day for patients and families with Classical, Vascular and Kyphoscoliotic EDS.
Our frustration at the amount of literature which refers to EDS as one condition led to our recent project to produce tailored information leaflets. These leaflets have now been reviewed by EDS-UK members. Here we present these new leaflets which will be available from EDS-UK for professionals and families to learn more about the different types of EDS.

Antenatal haemoglobinopathy screening; Iron deficiency and the alpha thalassaemias - A case study.

B. C. Player[1], *C. Kirwan*[1], *P. Palmer*[2];
[1]*University Hospital of Wales, Cardiff, United Kingdom,* [2]*Cardiff Sickle Cell & Thalassaemia Centre, Cardiff, United Kingdom.*

Introduction
As part of the service offered by the Cardiff Sickle Cell & Thalassaemia Centre and the All Wales Medical Genetics Service, haemoglobinopathy screening is offered to all women presenting at the Antenatal Clinic with family origins outside of the UK. A case is presented which illustrates the testing and counselling pathways that are activated when iron deficiency is identified in this context.
Iron deficiency in pregnancy in a woman originally from outside the UK
Mrs A accepted haemoglobinopathy screening at the antenatal clinic. She and her husband were originally from Oman. Screening identified the presence of iron deficiency.
Iron deficiency interferes with the ability to diagnose thalassaemias haematologically. A co-existing thalassaemia (most likely alpha) could therefore not be excluded without further testing.
Due to the complexities of testing for alpha thalassaemias, and also the high prevalence of certain genotypes in some populations, testing was next offered to the father of the pregnancy.
Testing identified the father, Mr B, as a possible thalassaemia carrier with the presence of Haemoglobin H inclusions. Further molecular testing was carried out to exclude the possibility of Haemoglobin Barts hydrops fetalis or Haemoglobin H disease in the pregnancy.
Initial testing ruled out the common forms of alpha zero thalassaemia. Mr B was subsequently identified as a carrier of homozygous alpha plus thalassaemia and Mrs A as a carrier of heterozygous alpha plus thalassaemia. It was therefore possible to counsel the couple that there was no discernible risk of a significant thalassaemia disorder in the pregnancy.

Genetic risk communication and autosomal dominant polycystic kidney disease: we need to talk

S. T. Carter[1], *M. Davies*[2], *A. Clarke*[1];
[1]*Institute of Medical Genetics, Cardiff University, Cardiff, United Kingdom,* [2]*University Hospital of Wales, Cardiff, United Kingdom.*

Introduction: Individuals affected by autosomal dominant polycystic kidney disease (ADPKD) are underrepresented in genetic counselling literature. Little is known about how individuals communicate the genetic risk of this condition to their relatives. We believe this is one of the first studies designed to explore the accounts of individuals diagnosed with ADPKD to understand: how communication to at risk relatives takes place, the factors influencing this process and if support is desired to facilitate family communication.
Materials and Methods: Data were collected via questionnaire (n =16), semi-structured interviews (n = 9) and retrospective medical records review (n = 9) then subsequently analysed using thematic analysis.
Results: Participants indicated several unmet needs, the most significant of which was a lack of information. Retrospective accounts showed that they recalled little to no information about ADPKD being shared with them by medical professionals at the time of diagnosis or at subsequent follow-up appointments. The results also suggested that despite current literature proposing the benefits of early intervention to reduce or slow kidney damage, the majority of participants were not aware of this information.
Conclusion: The study emphasises how misunderstandings and lack of information about ADPKD can influence genetic risk discussion within the family. Awareness of patient accounts may enhance the services designed to educate and support individuals with this condition as well as informing medical personnel who provide care to this population.

The Italian National Centre for Rare Diseases, at the IstitutoSuperiore di Sanità, provides the Italian External Quality Assessment (IEQA) in genetic testing since 2001. Currently, IEQA covers three molecular genetic tests: Cystic Fibrosis (CF), Beta Thalassemia (BT), Fragile X-Syndrome both full (FXf) and pre-screening (FXp) schemes.
Since 2009 the activity has been regulated by governmental document and participation is open both to public and commercial Italian laboratories. The goal of IEQA is to ensure a good laboratories practice.
Participants received four validated DNA samples with mock demographic and mock clinical indications. We ask laboratories to analyse samples and to report data using their routine protocols. Assessors review raw data and reports, sent by laboratories, taking into account genotyping, interpretation and reporting, according to marking criteria. A category of poor performance was defined.
In 2014 round the number of participants was 71: 59, 13, 12, and 6 laboratories participated for CF, BT, FXf and FXp respectively.
Results showed complete and correct data in 86%, 92%, 92%, 100% of CF, BT, FXf and FXpanalysis respectively. ten poor performing laboratories have been registered: 8 in CF, 1 in BT and 1 in FXf.
Critical errors occurred in both genotyping and interpretation in 6 and 2 laboratories respectively in CF scheme and only in genotyping in 1 laboratory in BT and in XF schemes respectively.
Assessors focused on the interpretation of results and we can show an improvement compared with previous round. This work will show in detail all Xth round results.

Obstetrician or midwife: who should offer pregnant couples the choice between invasive and non-invasive prenatal testing (NIPT)?

E. Mattemaker[1], *S. R. Riedijk*[1], *K. E. M. Diderich*[1], *M. G. Polak*[2], *S. L. van der Steen*[1], *E. Smith*[3], *M. F. Knapen*[1], *A. T. J. I. Go*[1], *D. R. M. Van Opstal*[1], *R. J. Galjaard*[1];
[1]*Erasmus Medical Center, Rotterdam, Netherlands,* [2]*Erasmus University Rotterdam, Rotterdam, Netherlands,* [3]*Bovenmaas Ultrasound Clinic, Capelle aan den IJssel, Netherlands.*

Introduction: In the Netherlands, pregnant couples at increased risk of trisomies 21, 13 and 18 may choose between invasive prenatal diagnosis (PND) and non-invasive prenatal testing (NIPT). Pre-test counseling, essential for informed decision-making, is currently reserved to obstetricians at academic hospitals. Presumably, in the near future all pregnant couples will be offered access to NIPT, leading to an increase in the demand for pre-test counselors. Our study aims to investigate whether midwives may perform pre-test counseling as adequately as academic obstetricians.
Methods: Ten midwives from a regional first tier practice will receive a tailor-made training aimed at learning to offer pre-test counseling for NIPT and PND. Couples at an increased risk of common aneuploidies will subsequently receive pretest counseling by a midwife and fill in an online questionnaire. The same questionnaire was administered to a group of couples counselled by an academic obstetrician. Data from both groups will be compared in order to assess whether pregnant couples counselled by midwives make equally informed decisions and whether choices, motivation and psychological distress differ from pregnant couples counselled by obstetricians.
Results: The training we develop comprises both theoretical knowledge and counselling skills. Our poster will present the development and content of this training.
Discussion: This study will reveal whether midwives have comparable skills and counseling results for NIPT counseling as compared to obstetricians. If so, the training we developed may be used for this purpose. If not, empirical evidence will support why the pre-test counseling license should remain with academic obstetricians.

J19.07

Genetic diagnostics from the perspective of next generation genetic sequencing of the human genome

M. L. Mihajlovic, 1993.[1], *L. Mihajlovic*[2], *N. Mihajlovic*[2];
[1]Faculty of Biology, Belgrade, Serbia, [2]Association for help to person with hereditary disorders, Nis, Serbia.

The fundamental and the only purpose of genetic counseling is genetic diagnostics. This means associating certain illnesses with certain genetic mutations. This has been the main purpose of genetic methods ever since they have been used in diagnostics, no matter how big the mutations are, such as changes in the number or structure of chromosomes, monogenic illnesses or microarray diagnostics. However in all of these event, the genetic test focuses on answering one specific question.
However with the appearance of next generation genetic sequencing (WGS-whole genome sequencing, WES-whole exome sequencing) we have gained the ability to directly associate certain genetic variations with certain often complex diseases sometimes even without earlier targeting of a specific gene. A good example is personal genetic sequencing which allows an individual to figure out if he carries the risk of developing certain illnesses. Nevertheless there are countless genetic variations from harmful ones to harmless ones. Due to this fact if WGS WES are going to become the diagnostic methods of the future it is essential that we target specific genetic variation which are the cause of dieses . Nevertheless like every other scientific method, WGS and WES and even genetic diagnostics as whole, can be manipulated and misused. This is why we would like to point out certain problems that may occur and the solutions to these problems, also we would like to help out future genetic counselors.

Lynch syndrome support day: A review

P. Dasani, *J. Hoffman;*
West Midlands Clinical Genetics Service, birmingham, United Kingdom.

The West Midlands Clinical Genetics Service held a support and information morning for families affected with Lynch syndrome in May 2014. This support day was was organised in the West Midlands and attended by over a 100 participants, these included partners and family members.
The day provided an opportunity for individuals and families to share experiences with one another and with us. We review the feedback received for this day including lessons learnt for a future support day. We hope this review will also be a good starting point for any other centres who wish to organise a Lynch syndrome support day locally.

Psychiatric genetic counselling: Addressing the needs of the UK population

R. E. Spencer-Tansley[1], *J. C. Austin*[2], *E. R. van Teijlingen*[3], *K. A. McGhee*[1];
[1]Translational Genetics Group, Bournemouth University, Bournemouth, United Kingdom, [2]Departments of Medical Genetics and Psychiatry, University of British Columbia, Vancouver, BC, Canada, [3]Faculty of Health and Social Sciences, Bournemouth University, Bournemouth, United Kingdom.

Introduction: Although not routinely offered for psychiatric disorders in the UK, there is growing awareness that psychiatric genetic counselling (PGC) may serve as an important tool in bridging the current gap between psychiatric genetic information and clinical application. In addition to conventional outcomes of traditional genetic counselling - including increasing aetiological understanding and provision of recurrence risks - PGC has positive psychotherapeutic outcomes through reducing feelings of shame, stigma and guilt associated with mental illness. This ultimately facilitates adaptation to the mental illness and reduces emotional burden, improving psychiatric outcomes. However there is a lack of awareness and misconceptions existing amongst the general public about the purpose of genetic counselling, and research has shown this can influence uptake and outcomes of genetic counselling sessions. Thus a potential gap exists in the future delivery of PGC services.
Method: Quantitative methods will be employed to explore a) current understanding about aetiology of mental illness b) perceptions of genetic risk c) perceptions of and attitudes towards genetic counselling and PGC, amongst UK individuals with psychiatric illness and their relatives. This will indicate i) whether PGC may be useful to this population; and ii) whether there is hypothetical interest in receiving PGC.
Results: This study will collect empirical data to assess and inform the future application of PGC to the UK.
Conclusion: This research will provide empirical evidence of whether the UK public want and would benefit from PGC. This will help inform policy makers on how to integrate this service into the current healthcare system.

J19.10

Are women making an informed choice regarding non-invasive prenatal testing for aneuploidy?

C. Lewis[1], *M. Hill*[1,2], *H. Skirton*[3], *L. S. Chitty*[1,2];
[1]Genetics and Genomic Medicine, UCL Institute of Child Health and Great Ormond Street Hospital for Children NHS Foundation Trust, London, UK, London, United Kingdom, [2]North East Thames Regional Genetics Service, Great Ormond Street Hospital for Children NHS Foundation Trust, London, UK, London, United Kingdom, [3]Faculty of Health, Education and Society, Plymouth University, Plymouth, United Kingdom.

Non-invasive prenatal testing (NIPT) for aneuploidy is currently being evaluated for use within the NHS. Previous research has highlighted concerns around routinisation of testing because of the ease with which the test can be conducted. We adapted a measure of informed choice, originally developed for use with women being offered Down syndrome screening, specifically for use with NIPT. The measure includes questions to assess knowledge, attitude, deliberation and test uptake, delivered in a questionnaire format. An informed choice is one in which there is good knowledge, deliberation, a positive attitude and NIPT uptake, or a negative attitude and NIPT is declined. The responses are calculated to provide a yes/no answer. The measure is being distributed to women recruited across seven antenatal clinics in England taking part in a study to evaluate NIPT in the NHS (www.rapid.nhs.uk). The sample includes women with a high (1:2-1:150) or intermediate (1:151-1:1000) DSS risk. Currently, 521 questionnaires have been completed. Our results indicate that the vast majority (89%) of women are making an informed choice around NIPT. Of the 11% who were judged to have made an uninformed choice, 54% had not deliberated, 44% had insufficient knowledge, and 17% had a negative attitude. Ethnicity was found to be a significant predictor of informed choice. The high rate of informed choice is likely to reflect the importance placed on the provision of pre-test counselling in this study. It will be vital to ensure this is maintained once NIPT is offered in routine clinical practice.

Exploring the understanding of anticipation in Myotonic Dystrophy type 1 patients and families: A pilot study

E. R. Lamb[1,2], *C. Sampson*[3], *M. Rogers*[1];
[1]All Wales Medical Genetics Service, University Hospital of Wales, Cardiff, United Kingdom, [2]Cardiff University, School of Medicine, Cardiff, United Kingdom, [3]Marie Curie Palliative Care Research Centre, Cardiff University, Cardiff, United Kingdom.

Myotonic Dystrophy Type 1 (DM1) is a dominantly inherited muscle condition predominantly characterised by muscle weakness and the phenomenon of anticipation, whereby there is increased severity of symptoms and earlier age of onset in successive generations. Anticipation is variable, highly unpredictable and may result in the birth of children severely affected with congenital myotonic dystrophy. This adds complexity to genetic counselling which may be further complicated as some patients with DM1 also have mild learning difficulties. The aim of this study was to explore communication between health professionals and patients with DM1, the understanding of Anticipation and how this may affect decisions about reproductive options. Using qualitative research methods, five interviews were conducted and analysed with six participants who had previous genetic counselling regarding anticipation with a genetics health professional. In addition thematic analysis was used to analyse clinical letters. This study confirmed important factors within understanding such as the importance of the clinician relationship and understanding from personal experience. This study also showed that though Anticipation as a concept appears well understood in this small group, patients did not understand the terminology. In addition other concepts such as chance are largely misunderstood in patients with learning difficulties. Therefore this study identifies important areas for further research into DM1 patient understanding of genetic concepts, particularly focusing on how this may affect reproductive decisions, on a much larger scale. In addition this study highlights that there is a significant lack of research within the genetic counselling of individuals with learning difficulties. Grant References: FfWG & YLCE

J20.01

Postmortem disclosure of genetic information to family members: active or passive?

S. N. Boers[1], *J. J. M. Van Delden*[1], *N. V. Knoers*[2], **A. L. Bredenoord**[1];
[1]University Medical Center Utrecht, Julius Center, Utrecht, Netherlands, [2]University Medical Center Utrecht, Dept of Medical Genetics, Utrecht, Netherlands.

The emergence of next-generation DNA sequencing (NGS) techniques creates new moral dilemmas, among which the question whether and to whom genetic information should be returned. Whereas consensus now exists that at least some subsets of genetic information should be disclosed

to patients, communication of genetic information to family members because of hereditary risk is less consensual. This issue becomes especially salient after the patient has died, and permission to inform relatives cannot be asked anymore.
In this paper we first identify and explain the arguments in favor of and against disclosure of genetic information to a deceased patient's relatives. The principles of beneficence, the duty to warn and the familial nature of genetic information could provide justification for postmortem disclosure. Furthermore, disclosure may have the favorable side effect of fostering a relative's positive autonomy. Postmortem disclosure could however be in conflict with the deceased's privacy. Moreover, communication of genetic information could disregard the deceased's wishes or have harmful consequences for relatives and violate a relative's interest in not knowing. Finally, postmortem disclosure may not always be feasible. When balancing these different types of arguments we conclude that there are strong justifications for postmortem disclosure. Potential objections are manifold but none of them supplies compelling fundamental reasons against postmortem disclosure. There are however important competing values that need to be taken into account. Therefore we propose a passive postmortem disclosure policy offering relatives access to genetic information if certain conditions are met.

J20.02
The sustainability of new modes of research participant recruitment

P. Miqueu[1], *H. C. Howard*[2];
[1]*KU Leuven, Leuven, Belgium,* [2]*Uppsala University, Uppsala, Sweden.*

The need for participants in biomedical research, including clinical trials and genetics studies, pushes organizations to actively promote and engage the public and patients in research. In order to overcome the current difficulties of participant recruitment, web registries and platforms are being developed to collect personal health data, and to match potential research volunteers with researchers. As a pioneer in the field, the research advocacy organization Genetic Alliance launched, in 2013, the initiative Reg4ALL (Registries for ALL). Because website, blogs and social media channels are essential to keep the momentum of public engagement, we analysed the activity of the main communication channels of promotion of Reg4ALL. We found that whereas the communication effort was substantial for the launch in April 2013 and during the following 6 months, communication has decreased dramatically since December 2013. This raises the question of how active or sustainable this initiative is? And, what does it mean for the research data that have already been collected? More pragmatically, what return of investment, if any, individuals who have uploaded their data may expect from the initiative? The case of Reg4ALL raises general questions on the responsibility of research-oriented platform providers regarding the benefits claimed for their users and on patient and public engagement in research.
This research is supported through an Erasmus Mundus scholarship from the European Commission and in part by the Swedish Foundation for Humanities and Social Sciences.

ABSTRACTS 6th INTERNATIONAL WORKSHOP ON THE HISTORY OF HUMAN GENETICS

Medical genetics in Mexico: the Origins of Cytogenetics and the Health Care System

A. Barahona
National University of Mexico, UNAM, Evolutionary Biology, Mexico, Mexico

In this paper, I explore the origins of medical cytogenetic knowledge and practices in the 1960s and 1970s in Mexico, focusing on the work of the group headed by Salvador Armendares, who spent two years in Oxford, England, with human genetics expert Alan C. Stevenson. Upon Armendares' return from England in 1966, the first Unit for Research in Human Genetics was created at a medical setting, the Instituto Mexicano del Seguro Social, (Mexican Institute of Social Security). Soon after its creation, another Mexican physician began to work with Armendares in the implementation of cytogenetics. Some of the research projects showed the embeddedness of these researchers in both public health policy and medical care, as they tackled the effects of malnutrition on chromosome structure, child mortality, chromosome aberrations and Down syndrome. Armendares and colleagues had trained at different foreign academic institutions at many different times, and contributed to transforming hospital medical practice into a medical research discipline. By posing malnutrition, one of the main concerns of Mexican post-revolutionary governments, as both medical and genetic problem, the unit contributed to positioning cytogenetic as a medical practice and a medical research domain. I will focus on the set of institutions, physicians, practices and ideas that began to reshape medical genetics to show the major roles played by both the clinic and post-revolution public health policies in the origins of medical genetics in Mexico within a global movement to delivering the benefits of scientific knowledge to the general population.

Marcus Pembrey recalls the catalyst for the establishment of the International Federation of Human Genetic Societies

K. Birmingham
University of Bristol, School of Social and Community Medicine, Bristol, United Kingdom

Marcus Pembrey, past President of the European Society of Human Genetics [ESHG] (1994-1995) and Emeritus Professor of Paediatric Genetics at University College London's Institute of Child Health was interviewed in 2013 concerning aspects of his work with the Avon Longitudinal Study of Parents and Children (ALSPAC). He was ALSPAC's Director of Genetics (1989-2005) and was instrumental in incorporating genetics into the initial design of this internationally acclaimed birth cohort. During this time he worked closely with ALSPAC's Ethics and Law Committee advising on the ethical issues involved when collecting genetic material from a population sample of mothers and children.
In describing his background before his involvement with ALSPAC, Professor Pembrey comments on how his ethical values evolved by discussion of real cases at the "famous Tuesday morning meetings" at Great Ormond Street Hospital, attended by many future eminent geneticists. He also describes working with Ségolène Aymé (ESHG President 1996-1997), when he was Chair of the ESHG's Public and Professional Policy Committee (1994-1998) when European policies were developed and harmonised.
He refers to an informal breakfast meeting of European and American geneticists in 1996 when his incensed American colleagues became aware of a guidelines "ambush"; without their knowledge the World Health Organisation had commissioned the writing of global ethical guidelines from Dorothy Wertz and Kåre Berg. Within 30 minutes of this disclosure, the establishment of the International Federation of Human Genetic Societies had been approved and subsequently this federation brought out their own international guidelines.

Pontecorvo's Legacy

Paula Blair
College of Social sciences, University of Glasgow, United Kingdom

Establishing Glasgow as a major centre for Genetic research is largely a consequence of the vision and enthusiasm of one man, Guido Pontecorvo (1907-1999). Ponte, as he preferred to be known, was born and educated in Pisa, and was forced to leave Italy in 1938 which allowed him to settle in Scotland. After a period of internment on the Isle of Man during the second world war, Ponte returned to Scotland and was soon appointed a lecturer in Genetics at the University of Glasgow's Zoology Department. By 1950 Ponte had established the new Department of Genetics in the Anatomy laboratories of the Anderson College building. He became a Reader in 1952, before his appointment to the new Chair of Genetics (1955-1968).
Ponte is often described as *one of the founding fathers of modern genetics*. He was one of the leading figures of his day in the study of cell genetics. He was the founder of the genetics of *Aspergillus nidulans*, a relative of *Penicillium*, and originated genetic studies in many other fungi. He was also one of the first researchers to demonstrate the divisibility of the gene by recombination.
Under his leadership the Department of Genetics thrived, becoming one of the major research centres of its day, not only allowing James Renwick and others to produce the first human gene maps, but, as the departmental visitors book reveals, also attracting key researchers from far and wide to disseminate and discuss their ideas.

Unravelling the complexity of HLA: genesis and success of the International Histocompatibility Workshops

M. Capocci
Sapienza University of Rome, Unit of History of Medicine, Dept. of Medical-Surgical Sciences and Biotechnologies, Rome (Italy)

The Human Leukocyte Antigen supergene was included in the first list of 64 genes assigned to each human chromosome at the first Human Gene Mapping workshop in 1973. Despite its complexity, the genetic control of histocompatibility was the focus of a wide effort. Following the discovery of HLA in 1958 (by Dausset, Payne and Van Rood), in the mid-1960s, a few International Histocompatibility Workshops (IHWs) contributed to set methods and standards in the field of immunogenetics and tissue-typing. These workshops were the result of a close collaboration between groups working in Europe and United States, as well as between different scientific communities. Well before the Human Genome Project, Geneticists and physicians laid the basis for one early example of "distributed big science" in biomedical disciplines. The results of the workshops were groundbreaking: the existence of one genetic system controlling histocompatibility was shown by means of a strictly genetic approach (mostly based on linkage disequilibrium analysis) that helped the interpretation of serological data, and a quick translation of the theoretical results was possible, so that HLA tissue typing was rapidly standardized and introduced for transplantation purposes. The paper will discuss the international dimension of the HLA endeavor, highlighting the conceptual and theoretical innovations introduced within the IHWs, as well as some institutional aspects of the international development of HLA research.

The Use of Oral History to Explore the Establishment of Genetic Counselling in the GDR during the 1970s and 1980s

S. Doetz
Charité-Universitätsmedizin Berlin, Institute for History of Medicine, Berlin, Germany

I frequently use interviews with contemporary witnesses - in addition to documents of participating institutions and historic publications - as the basis for my research project on "Establishing genetic counselling in the GDR in the area of conflict between science, politics and public". Most of interviewees had worked as human geneticists at the time; others had engaged with the subject from a different perspective, for example by dealing with medical ethics. Since the political situation in the GDR was complicated, a lot of background information does not emerge in official documents. Hence oral history offers the possibility to reconstruct processes of decision-making, unveil structures of communication and discern controversial opinions. In addition, it provides access to the conditions of everyday life and the working world. Taking into account the methods of Gabriele Rosenthal and Alexander von Plato, I am currently conducting open, narrative interviews. They provide interviewees with the possibility to present the subject quite autonomously. So, the interviewee's own prioritisation and emphasis become evident, as well as any avoidance of special topics. In my talk I would like to present my experiences with this approach and address the issue of how to analyse these interviews. Furthermore I include ethical and legal aspects regarding the archiving of interviews and their use as sources for publications.

The Oral History Initiative at the National Human Genome Research Institute (NHGRI)

C. Donohue
National Human Genome Research Institute, History and Archives, Bethesda, USA

As part of the archival and scholarly initiative launched by Eric Green, National Human Genome Institute (NHGRI) Director, I have been conducting oral histories (videotaped and transcribed) of key NHGRI staff and leaders in the genomics research community for nearly three years. To date, twenty oral histories have been conducted with several dozen more planned over

the next five years. These oral histories will be made part of a substantial textual and video archive which will be made public in the next two years, with significant plans being made for a documentary focusing on DNA sequencing technology development using these oral histories. These oral histories will also be edited into educational segments on topics such as personalized medicine, the scientific career, comparative genomics, 'mapping the genome', genomics and ancestry and genomics and 'race' and ethnicity. My presentation will focus on the approach and conceptualization of the questions for these oral histories and a discussion of the origins of the program and the perhaps less obvious models from which it draws- Alan Macfarlane's oral histories conducted at Cambridge, United Kingdom, which have now become YouTube staples. I will also discuss the legal/ethical issues associated with producing oral histories using United States Government time and resources as well as the challenges of interviewing not only genomic researchers but also scientific program administrators, whom I believe have a unique view of the progress of genomic science. Of particular interest to this audience as well will be a summation of a series of insights gained from the oral histories about European and British efforts in mapping and sequencing, from the origins of the Human Genome Project to more recent times.

Glasgow Contributions to the Human Gene Mapping Project, 1959-1987

M. Ferguson-Smith
Cambridge University, Veterinary Medicine, Cambridge, United Kingdom

The classic approaches to human gene mapping using genetic linkage in human pedigrees (Renwick) and nondisjunction and deletion in patients with chromosomal aberrations (MAF-S) were established in 1959-61 in Pontecorvo's Department. The genetic markers yielded several genetic linkages before Renwick left for UCL in 1968. The cytogenetics lab mapped a stature gene and others associated with the Turner phenotype to Xp, and TGF and XG were mapped in XX males with X-Y illegitimate recombination to just outside the pseudoautosomal boundary, leading to the discovery of SRY 24 years later. ACP1 to chromosome 2p was the first human gene to be mapped by deletion mapping. Others followed from the lab including the loci for ABO, AK1, HP, ADA, GALT, GOTS, XG, HPAFP, TS1, and HY. Heterozygosity at many other loci excluded them from the deleted regions enabling the construction of an exclusion map. A physical map of both the pairing and non-pairing regions of the Y was made using Southern blotting and DNA markers isolated from a Y chromosome library. The first reports of the successful localisation of single copy genes by isotopic in situ hybridisation came from the cytogenetics lab in 1980, specifically the regional localisation of the alpha- and beta-globin genes, followed by kappa light chain genes to 2p. Much of the Glasgow contribution to the human mapping project derived from a cytogenetic approach based on nondisjunction and deletions associated with chromosomal syndromes.

The Enduring Puzzle of Leber's Hereditary Optic Neuropathy

J. Friedman
University of Alberta, History and Classics, Edmonton, Canada

Leber's disease, currently known as Leber's hereditary optic neuropathy (LHON), is now understood to be caused by mutations in mitochondria, intracellular organelles which produce cellular energy, and is inherited maternally according to a non-Mendelian pattern of inheritance. The illness was first described in 1871 by the German ophthalmologist Theodor Leber. Although the clinical aspects of the disease were generally well-accepted, its pattern of heredity proved to be an enduring puzzle. As the Australian medical geneticist David Wallace wrote in 1970: "A cursory examination of an affected family gives one the impression of a sex-linked inheritance; closer study suggests cytoplasmic inheritance; still more detailed analysis leads to confusion." This paper traces the development of the controversial theories surrounding the inheritance of LHON until the discovery of its causative mutation in 1988 by the American geneticist Douglas Wallace. This work would not have been possible without the sequencing, in 1981, of the first part of the human genome—that of mitochondria—by Fred Sanger's research group at the Medical Research Council Laboratory of Molecular Biology in Cambridge, U.K. Yet Wallace also initially faced resistance in publishing his research linking a hereditary eye disease to a mitochondrial mutation. Unlike the case of myotonic dystrophy, where Lionel Penrose was able to successfully explain away its unusual pattern of inheritance, the international and interdisciplinary community of LHON researchers failed for decades to successfully reconcile clinical findings with contemporary theories of human inheritance. The solution to the puzzle was an unexpected one.

A critical triangulation: the combination of archival sources and oral histories in the investigation of contemporary genetics

M. Garcia-Sancho
University of Edinburgh, Science, Technology and Innovation Studies, Edinburgh, United Kingdom

In this presentation, I will address how the availability of new archival sources is shaping the research strategies of historians working on late-twentieth century genetics. The recent release of Codebreakers (1) and other collections documenting human genome mapping and sequencing initiatives is leading historical research to be less dependent on oral histories, given the accessibility of archival records. Some scholars may defend that these new records make interviewing dispensable and replaceable by (allegedly) less limited historical evidence. I will challenge this interpretation by arguing that the best way to exploit the new archives is in combination with oral histories. Building on my previous work on the history of biomolecular sequencing (2), I will show that the availability of archival evidence shapes the way in which oral histories are used rather than the decision of using them or not. When centralized archives are not available, projects tend to start with oral histories which lead to other interviews and personal collections still in the hands of scientists. The newly available archives enable historians to conduct oral histories after the records have been examined, this leading to more incisive questions and the selection of additional less well-known interviewees. By reporting early results of my ongoing research on the UK Human Genome Mapping Project, I will show the potential of this critical triangulation between archival and oral sources.

Interviews with Human and Medical Geneticists

P. Harper

Between 2003 and 2014 a series of 100 recorded interviews has been made by the author with older human and medical geneticists. Most of those interviewed have been from the UK or continental Europe, but the range of countries is world-wide and the fields of work varied across genetics. Currently 95 edited transcripts are accessible in full on the www.genmedhist.org/interviews website; others are still being processed; it is hoped to add audio clips, currently available on the website only for a small number of interviews. The interview transcripts provide a detailed, though not systematic picture of developments in human genetics as this has evolved during the past 60 years, notably early human cytogenetics and human molecular genetics. They also illustrate the growth of clinical genetics services over this period. Although many of the earliest founders of the field are no longer living, the interviews provide valuable details about them since they were often the teachers and mentors of those interviewed. At a personal level the interviews give vivid portraits of the individuals involved and of their colleagues, as well as the difficulties they often had to overcome in developing their lives and work. European Society of Human Genetics is now developing a new series of recorded interviews across Europe to cover the younger generation of workers.

The Thrill of Mapping: Bridging the Gap in Postwar Human Genetics

A. Hogan
Creighton University, History, 225 Humanities, Omaha, USA

Historians have largely examined cytogenetics and molecular biology in separate contributions. However, as the historical analysis of genetics has begun to shift towards a focus on the late-20th century, this distinction has become increasingly impractical. This paper examines the collaborative use of cytogenetic and molecular analysis by research groups as they sought to more accurately localize various disorders in the human genome, including Prader-Willi and Fragile X syndromes. During the 1970s and 80s, a number of approaches for mapping genes were developed, which integrated long-standing cytogenetic with new molecular approaches for examining the human chromosomes. I explore how attempts to better understand the genetic basis, and improve the diagnosis, of multiple genetic disorders brought together cytogenetic and molecular techniques, leading to the development of the hybrid field of molecular cytogenetics. New techniques and approaches offered exciting opportunities to bridge the gap between microscopically visible chromosomal abnormalities and molecular level nucleotide sequences, and in the process led to increased collaboration among cytogeneticists and molecular biologists. In addition to the potential clinical value of gene localization projects, I argue that many researchers were drawn into new professional alignments by the sense of thrill associated with human

gene mapping. Throughout the 1970s and 80s, Victor McKusick, Frank Ruddle, and others regularly pointed to the excitement and satisfaction associated with exploring unknown territories and identifying new genetic loci. I demonstrate how the promise and thrill of human gene mapping played a central role in bringing research communities and approaches together during the postwar era.

The History of Human Gene Mapping: remembering the times of PCR and discovery of the MECP2 gene mutation behind Rett syndrome at UCLA and translation of genetic competences to primary and secondary care

E. Houwink
VUmc/MUMC, Clinical genetics, Family medicine, Maastricht, Netherlands

On April 14, 2003 the National Human Genome Research Institute (NHGRI), the Department of Energy (DOE) and their partners in the International Human Genome Sequencing Consortium announced the successful completion of the Human Genome Project. How did it all begin for me? When I started my career in genetics, I was still a medical student, who wished to go to the USA (1998-2001), row and for one worked at the Department of human genetics, Gonda building at UCLA, a beautiful building, hyper modern. Together with colleagues we able to use the most advanced techniques (nt PCR for one and software on our distinctive Apple computers) in this building. These were exciting times. From all over the world parents and colleague medical specialists sent blood samples on dry ice to look for the gene which could somehow explain the phenotype in different gradations of Rett syndrome. Rett syndrome is a rare disease usually found in girls, who deteriorate around 1 or 2 years of age, loose their speech and can't walk anymore. They are sometimes called "silent angels". This is really where I found my passion for genetics and its possible implementation in patient care and discovered genetics should have a more fundamental place in medical curriculum, primary and secondary care and educational programs. December 20th 2013 I received my PhD (Cum laude) on "Training in genetics and genomics for primary care workers and have moved on to two new projects on pharmacogenetics in primary care and dissemination genetics education across 6 different countries Europe wide. Even though my career is still in the early phase, I would love to share my passion for genetics from a perspective as a general practitioner (FMD) who started her career right before the Human Genome Project was completed and human gene mapping and its implications for the clinic for the near future.

Narrating 'Geneticization': Living your genome in shifting scientific paradigms

D. Mahr, C. Rehmann-Sutter
University of Luebeck, Institute for medical history and science studies, Luebeck, Germany

The chronic inflammatory bowel diseases (CIBDs) were historically a paradigmatic case of psychosomatic diseases. Now they have become more genetically explainable. What does this mean for those affected? How is this 'geneticization' of CIBDs reflected in the life histories of patients and their families? In what way can their stories contribute to a better historical understanding of shifts within the biomedical explanations of diseases in the 21st century? In our project 'The lived genome and chronic inflammatory bowel diseases' we have conducted narrative interviews with above 50 affected persons (mainly long-term patients and their families) and analyzed their narratives in relation to the changes in the explanatory models. The goal of our contribution to the 'Sixth International Workshop on History of Human Genetics' is to explore the extent to which a more symmetrical image can be drawn between the historical narratives of healthcare professionals, medical historians and those narratives of people who witnessed the paradigm changes in biomedicine first-hand – or more literally with their own bodies.

"The London/Baltimore link has been severed": Human Linkage Mapping and the Early Computerization of Genetics

M. McGovern
University of Cambridge, Dept. of History and Philosophy of Science, Cambridge, United Kingdom

Almost two decades before the Human Genome Project was conceived, a lively research program using computers to map human genes was well underway. However, limited access to computing technology and its attendant expertise created a politicized economy of information sharing that led to the project's demise. From 1958 to 1971, the American cardiologist Victor A. McKusick and British geneticist James H. Renwick maintained a transatlantic collaboration on human genetic linkage analysis. Renwick utilized IBM mainframe computers available through McKusick at Johns Hopkins to calculate recombination fractions from large families with Mendelian disorders using likelihood methods. This practice formed a substantial link between the wartime development of blood group genetics in the UK and the postwar American research-funding boom. While the collaboration began due to UK manufacturing protectionism that prevented access to cutting-edge computing technology at the time, McKusick's institution building efforts expanded the project by enrolling a network of informal investigators keen to exploit the new technology. However, as the sole arbiter of mainframe information processing, Renwick provoked anxiety amongst his collaborators. He insisted on intricate and sensitive methods that required other investigators to provide raw data to be compiled into large data sets for processing. Although they wanted to explore potential linkages within their cohort with greater certainty, Renwick allowed focus on mapping and the establishment of a data centre to take precedence, which led to conflicts. Through this narrative, I argue that collection and computation of data became competing priorities in the development of human genetics.

Human Gene Mapping: The Mass Media Iconography of Human Genome Project in the Most Popular Greek Newspapers

C. Morfakis
National and Kapodistrian University of Athens, Dept. of Philosophy and History of Science, Galatsi – Athens, Greece

The media serve as intermediate between science and the public, framing social reality for their readers and shaping the public consciousness about science-related events. In this context, images, such as genetic map, which are used by the media, play an important role in the public communications of science. They facilitate the understanding of an, often obscure, techno scientific discourse and experimental methodologies. While the scientists are at work or their scientific triumph, they visualize microcosm by making it visible, analyze our biological structure and generally our cause through a rhetorical and ideological use of their positive or negative images of a scientific fact. For journalists, images are part of a journalist's routine used for the purposes of popularizing, concretizing and dramatizing issues, in brief for making issues both newsworthy and interesting for the relevant audiences. The Human Genome Project is one of the most important scientific events which has been covered by the media and the public attention which has received has helped to change the relationship between science and society. The purpose of this announcement is to present a review of the results of a case study that focuses on the media images of Human Genome Project in the most popular Greek newspapers and how their use has affect science communication. Specifically, we examine a series of selected photographs, sketches and drawings that surrounded / accompanied the publications which, have contributed to the development of a specific public image for Human Genome Project.

James Renwick: The First Human Genetic Maps

Kevin O'Dell
School of Life Sciences, University of Glasgow, United Kingdom

James (Jim) Harrison Renwick was a Titular Professor of Genetics at the University from 1967-1968. He joined the Department of Genetics in 1959 as a Research Fellow and was appointed to Senior Lecturer in 1960 and a Reader in 1966. He made a fundamental contribution to modern genetics, in particular to the development of human gene mapping that paved the way for the Human Genome Project.

James Renwick was educated at Sedburgh School winning a Harkness Scholarship to the University of St Andrews in 1943 where he studied medicine. In 1953, after National Service a Medical Research Council grant in Human Genetics allowed Renwick to undertake a PhD in the Galton Laboratory of University College London, studying under Lionel Sharples Penrose and John Burdon Sanderson Haldane (PhD 1956). Then, in 1958-59 Renwick worked under Victor McKusick at the Johns Hopkins Hospital Department of Human Genetics and on his return to the UK he took up a post as Research Fellow in Guido Pontecorvo's Department of Genetics at the University of Glasgow where he worked until 1968.

For a period of nearly 20 years up to the early 1970s, Renwick pioneered the use of genetic markers to map disease genes on human chromosomes, seeing this field develop from its infancy at a time when there was virtually no information on mapping human genes to a major international scientific endeavour. His Independent obituarist notes that, "His work linking the ABO blood groups and the nail-patella syndrome was seminal and is still cited as a classic in human linkage analysis" and he was behind the first generalised computer program for calculating LODs (Logarithm of Odds) for large human pedigrees.

Reflections on Ethical and Theoretical Aspects of Oral History of Human Genetics in Germany

H. Petermann
WWU Muenster, Institute for Ethics, History and Theory of Medicine, Muenster, Germany

"The stories and insights of the leaders and pioneers can help to explore the history of human genetics."
Oral History has established in history within the last years to gain more information about the history and evolution of fields that had been set up in the 20th century. Human genetics is one of those.

- The **German legal regulations** for archives in general do not allow using personal files before the person is at least ten years deceased. Therefore interviews with contemporary witnesses can give supplementary information, but also insights that have not been written down. Those have to be comparable in structure and should regard the personal and scientific situation, but also the relations to other scientists and special experiences. Oral history is supplementary to biographical files and has the same benefits and problems like autobiographical publications.
- Using Oral History as a tool for research, **ethical issues** like human dignity and personal rights must be considered. The interview partner has to be informed and must agree, but also authorise the transcription. One should careful handle and balance this information. Also one should be aware of juridical aspects.
- **Theoretical aspects** might refer to the "tacit dimension of science" (M. Polanyi), because the interviews can give insight to those aspects that were passed on only by acting or the spoken word and are not written down. This might be a first approach to a theory of oral history.

At all, oral history is a useful tool for contemporary aspects.

Changing the Point of View: the History of Human Genetics as an Applied Science in the Federal Republic of Germany from 1945 to 1975

H. Petermann
WWU Muenster, Institute for Ethics, History and Theory of Medicine, Muenster, Germany

"Human Genetics is both a fundamental and an applied science", so stated F. Vogel and A. Motulsky.
In the history of human genetics there was less focus on the aspect as an applied science as clinical genetics. The first approach was on the meaning of the term, the first tasks in medical genetics, the influence of human genetics on legislation and the specialisation in the Federal Republic of Germany.

- For the first time the term 'Human Genetics' was used in the 1940s. Until then f.e. "Erblichkeitslehre" characterized this field. The matter of the handbooks was the same like in English ones in the first and in further publications.
- The field of activities was focussing in the beginning on paternity tests and genetic counselling. The problems in the beginning were lack of appropriate premises, but also the unsolved question of reward.
- The increasing knowledge in human genetics had no influence on legislation in the first decades after 1945. For the first time it was important in changing the abortion law at the beginning of the 1970s.
- The Wissenschaftsrat (German Science Council) said in 1960 that a chair for Genetics is necessary at every medical faculty. This was the stimulus for the professionalization of human genetics. Furthermore it can be stated that there was a personal continuity relating to the time before 1945.

It can be concluded, in spite of the German history before 1945, human genetics was characterised by continuity focussing on it as an applied science.

A Brief History of Uncertainty in Genomic Medicine

R. Pyeritz
University of Pennsylvania, Pereleman School of Medicine, Philadelphia, USA

From antiquity, scholars have opined about the dealing with uncertainty in medicine. The field of statistics was stimulated in the 17th and 18th centuries by the need to quantify the level of uncertainty based on empiric data. The iterative nature of studying uncertainty proved an important stimulus to collect, archive and analyze more data so as to improve the power of statistical and probability estimates. In more recent times, Renée Fox formalized the recognition of uncertainty as a persistent, yet changing, attribute of medical science, research and practice and emphasized that rising expectations of the benefits of medical research were paralleled by a lowered tolerance for uncertainty. As first studied by Lippman-Hand and Fraser, in genetic counselling a patient's perception of facts can be more important to decision-making than what the facts actually are. Barton Childs was struck by the dichotomy of the biologist/geneticist depending on uncertainty to generate hypotheses versus the physician/medical geneticist needing to tolerate and even embrace uncertainty and ambiguity. Today, geneticists and genomicists face an undeniable irony: as analysis of the genome reaches a natural limit, i.e., one nucleotide change out of 6.4 billion, our ability to interpret its meaning can be severely challenged. Investigations will reduce uncertainty in genomic medicine. However, given a host of factors, such as epigenetics, gene interactions with the microbiome and with other aspects of the environment, and chance, the answer to whether uncertainty can be eliminated persists. As we increasingly know more, we are increasingly aware of what we do not know.

The First Human Genetic Map 1936

A. Rushton
Hunterdon Medical Center, Dept. of Pediatrics, Flemington, N.J., USA

The rediscovery of Mendel's law of heredity in 1900 fueled breeding studies of plants and animals which demonstrated the independent segregation of genetic characters during meiosis. The co-segregation of grouped characters suggested to T.H. Morgan that this behavior paralleled the behavior of chromosomes during meiotic segregation. Rare cross-over events implied a model in which the frequency of such recombination events was correlated with the physical location of genetic elements on specific chromosomes. Human genetic studies did not progress because there were many human chromosomes in each human cell and the likelihood of detecting co-segregation of two characters was minimal. The genes for different blood groups appeared to segregate independently and offered an opportunity to assess potential linkage with characters such as eye and hair color, or diseases such as hemophilia and Friedrich's ataxia. However, research groups in the US and the UK found no evidence of human genetic linkage before 1935. Julia Bell and J.B.S. Haldane from the Galton Laboratory in London then studied the segregation of two characters known to be associated with the X chromosome: hemophilia and colorblindness. Their pedigree analysis published in 1936 demonstrated close linkage of the two loci. Haldane then expanded the work to involve several other genetic characters associated with the X chromosome. Recombination frequencies were used to construct a genetic map of the human X chromosome with five defined loci. The concepts developed in this work provided the basis for linkage studies in the decades ahead until the advent of DNA technology.

Project Documenting the Development of Medical Genetics in Czechoslovakia after 1945

M. V. Simunek
Prague, Czech Republic

The main aim of the presentation is the recent project on the history of medical genetics in Czechoslovakia (Bohemia, Moravia, Slovakia). It started developing in the early 1960s, when especially the reception of the then latest discoveries made at the time official doctrine of Lysenkoism obsolete. A number of institutions, mostly related with paediatrician care, were created which focused on genetic counselling and prenatal care (Prague, Brno), on basic research in the area of immunogenetics (Prague), and, somewhat later, also cytogenetics (Prague), which was originally covered by endocrinology. Faculties of medicine in Prague and Brno and the Czechoslovak Academy of Sciences played a key role in this process. The project should: i. to map the development of medical genetics by recording authentic testimonies, which can cover the generations reaching now their 80s and 70s, ii. to establish an independent documentary collection, which gathers materials and images which would otherwise be irretrievably lost. The collection covers also the earlier history starting with 1900 and includes currently approximately 400 items (books) incl. offprints and some rare issues. The material thus collected should serve i. as a starting point for a study of the turbulent history of medical genetics in Bohemia, Moravia, and Slovakia in the twentieth century, and ii. as an accessible source for comparison with the development of medical genetics elsewhere, especially in CEE countries. Another important part of the project is the preparation of a monograph and edition of interviews concerning the history of medical genetics in Bohemia and Moravia.

Collecting Genomics at the Wellcome Library

V. Sloyan
Wellcome Trust, London, United Kingdom

Since 2011 the Wellcome Library has been developing its archival holdings relating to the field of genomics. The Library now holds a widespread collection of archives from notable figures and lesser known individuals, which together provide a comprehensive record of the development of genomics in Britain in the latter half of the twentieth century. These archives were acquired through a documentation strategy-based approach, which aims to capture

the networks and collaboration behind record creation, rather than just the outputs of key individuals taken in isolation. For instance, the John Sulston archive is complemented by the archives of his close collaborators Alan Coulson and Richard Durbin, whilst the wider context of Sulston's work can be understood by exploring the archives of Carol Churcher and Michael Ashburner. The poster will showcase the Wellcome Library's genomic archive collections and explain how the collecting strategy was implemented.

You're all history! Recording the voices of modern genetics

Tansey, Tilli M.
Queen Mary University of London, School of History, London, United Kingdom

The History of Modern Biomedicine Research Group studies the recent history of medical sciences principally by employing oral history methodology (http://www.histmodbiomed.org) . Research is focussed in five key thematic areas, one of which is clinical genetics. Of particular note is the Witness Seminar approach. These are meetings to which a group of people are invited to discuss particular debates, discoveries or developments to which they were witnesses. These meetings are recorded and edited, and the resultant volumes made freely available on the group's website. This lecture will describe some of the highlights of genetics meetings already held and discuss some of the problems and also the potentials of this type of oral history.
This work is funded by the Wellcome Trust.

Mapping the gene mapping workshops

T. M. Tansey, E. M. Jones
Queen Mary University of London, School of History, London, United Kingdom

The History of Modern Biomedicine Research Group convenes oral history 'Witness Seminars' with key actors in contemporary biomedical areas, which are edited for publication (www.histmodbiomed.org). In 2014, a seminar was held on Human Gene Mapping Workshops, chaired by Professor Peter Harper, principally involving UK-based scientists. Discussions ranged from the first meeting in Yale, in 1973, when the distinctive 'hands-on' format and the committee reporting structure evolved, to the 1991 meeting in London, which, with significant advances in informatics, provided the organisers with new computing challenges. Topics included the foundation of the workshops; influence of somatic cell genetics; role of non-human gene mapping; advent of DNA-based techniques; culture of collaboration in the gene mapping community; clinical applications, and the origins of the Human Genome Project and advent of sequencing technologies. Extracts from the Witness Seminar and photographs of the contributors will be presented.
This work is supported by the Wellcome Trust, and we thank Professor Peter Harper for his assistance.

Witnesses to medical genetics

T. M. Tansey, E. M. Jones
Queen Mary University of London, School of History, London, United Kingdom

Medical genetics is a core research area for the History of Modern Biomedicine Research Group (www.histmodbiomed.org). Witness Seminars have been held and published on a wide range of topics including genetic testing, clinical genetics, cancer genetics, molecular genetics and the Human Gene Mapping Workshops. This poster will present text and photographs from several of these meetings, to illustrate the Witness Seminar approach to recording the history of modern genetics.
This work is supported by the Wellcome Trust, and we thank Professor Peter Harper for his assistance.

Critical inquiry into rare disease research in Finland – Finnish Disease Heritage in a broader historical context

A. M. Tupasela
University of Copenhagen, Department of Public Health, Copenhagen, Denmark

The study of rare disease began in Finland during the early 1960s. During the subsequent decades, paediatricians and clinical geneticists developed the term of Finnish Disease Heritage(FDH), which is a group of over 30, typically recessive, rare diseases which are overrepresented in the Finnish population. Initially described in 1973 the term has become an important organizing principle around which genetic counselling and research in Finland has been organized. The purpose of this presentation is to present some insight into the process of studying and interviewing Finnish researchers who have been involved in the study of rare diseases in Finland. Focusing on the historical development of the notion of FDH I will seek to ponder some of the challenges one encounters in contextualizing the development of clinical genetics in Finland into broader theoretical and historical contexts. The work of respecting the time and effort provided by informants combined with the need to conduct critical inquiry poses a number of ethical challenges. Drawing on a paper I have written, the presentation will draw on experiences of interviewing Finnish researchers on their role in the development of FDH and its subsequent significance to Finnish clinical genetics.

Neonatal Screening: a Historical-comparative Perspective

C. van El
VU University Medical Center, Clinical Genetics, Amsterdam, Netherlands

After the first regional initiatives to screen newborns for PKU in the United Kingdom and United States in the 1960s, several European countries set up screening programmes. Though the number of disorders screened for gradually increased, European countries differed in their choices for specific screening strategies and the number of disorders screened for: from 1 to 29 (Loeber et al., 2012). For instance, in case of Congenital Hypothyroidism, the Netherlands followed Canada and several US states in the strategy used to detect both primary and central forms of CH, while most European countries concentrated on the primary forms. The Netherlands was one of the earlier countries to introduce screening for Congenital Adrenal Hyperplasia (2000). The reasons for this variety may range from health care priorities and budgets to practical considerations, organisational constraints or, perhaps, chance. Pollitt (2006) has suggested that the differences may be related to the professional background of individuals involved in policy-making. For the US the influence of patient organisations and commercial parties has been mentioned (Paul & Brosco, 2013). For the Netherlands we did not find evidence that these latter forces have played a major role. In our (poster) presentation we will highlight our research on the expansion of the Dutch neonatal screening programme after its beginning in 1974 (Loeber & Van El 2014). In addition we present an initiative to stimulate historical-comparative research on the rationale for the different choices that have been made regarding the expansion of neonatal screening in Europe.
