KEYWORDS: *Enterococcus faecalis*, enzyme inhibition, thymidylate synthase, X-ray crystallography screening, phthalimide scaffold, antibacterial.
ABSTRACT

Infections caused by Enterococcus faecalis (Ef) represent nowadays a relevant health problem. We selected Thymidylate synthase (TS) from this organism as a potential specific target for antibacterial therapy. We have previously demonstrated that species-specific inhibition of the protein can be achieved despite the relatively high structural similarity among bacterial TSs and human TS. We had previously obtained the EfTS crystal structure of the protein in complex with the metabolite 5-formyl-tetrahydrofolate (5-FTHF) suggesting the protein role as metabolite reservoir; however, protein–inhibitors complexes were still missing. In the present work we identified some inhibitors bearing the phthalimidic core from our in-house library and we performed crystallographic screening towards EfTS. We obtained two X-ray crystallographic structures: the first with a weak phthalimidic inhibitor bound in one subunit and 5-hydroxymethylene-6-hydrofolic acid (5-HMHF) in the other subunit; a second X-ray structure complex with methotrexate. The structural information achieved confirm the role of EfTS as an enzyme involved in the folate pool system and provide a structural basis for structure-based drug design.
1. Introduction

Enterococci can be found in soil, food and water and make up a significant portion of the normal gut flora of humans and animals. As for other bacteria of the gut flora, enterococci can also cause infectious diseases. Typical enterococcal infections occur in immunosuppressed patients and in hospitalized patients suffering from a wide spectrum of severe illnesses. Enterococci nowadays rank second to third in frequency among bacteria isolated from hospitalized patients. They can be often isolated from urinary tract infections, intra-abdominal and pelvic infections, bacteremias, wounds, tissue infections and endocarditis as part of a polymicrobial flora. Enterococcus faecalis (Ef) and Enterococcus faecium are the most prevalent species cultured from humans and they are present in more than 90% of clinical isolates. Enterococcus faecalis accounts for 80-90% of clinical strains, while Enterococcus faecium for only 5-10%. Some strains of E. faecalis and many of E. faecium are resistant to multiple antimicrobials [1]. The identification of new antibiotics targeting Enterococci infections is challenging since no specific antibacterial agents are known so far. This encourages the starting of active drug discovery programs. Molecules targeting the Enterococci folate pathway represent a source of potential and specific drugs able to inhibit the bacterial folate pathway without altering, in principle, the mammalian cells. In our antibacterial discovery programs we have identified some lead compounds bearing a phthalimide moiety targeting bacterial Lactobacillus casei (Lc) and Escherichia coli (Ec) thymidylate synthase (TS) and able to discriminate between the bacterial and the host (human) protein. This selectivity led to the discovery of antibacterial agents with a low toxicity [2–10]. TS (EC: 2.1.1.45) catalyzes the reductive methylation of 2′-deoxyuridine-5′-monophosphate (dUMP) to 2′-deoxythymidine-5′-monophosphate (dTMP), assisted by the cofactor N5,N10-methylene tetrahydrofolate (MTHF)
TS is the only synthetic source of dTMP in human cells, thus it represents a major target for the design of chemotherapeutic agents [13]. The well-known anticancer agents, 5-fluorouracil (the prodrug of 5-fluoro-2'-deoxyuridine monophosphate), methotrexate (MTX) and raltitrexed (Figure 1), are classical TS inhibitors belonging to the antimetabolite class. In our previous work, compound α156 (Figure 1) had been proposed as an antibacterial lead able to face vancomycin-resistant infections caused by gram positive bacteria such as *Staphylococcus aureus*. This molecule also inhibited the *Enterococcus faecalis* clinical isolates and showed a low toxicity towards human cells [7]. In a parallel work we had identified a library of phthalimidic derivatives, 4-methylisoindoline-1,3-dione N-derivatives (I, Figure 1) and 4-(aminomethyl)-2-methylisoindoline-1,3-dione derivatives substituted at the amino position (II, Figure 1), that presented inhibitory activity against bacterial TS enzymes. These phthalimidic derivatives inhibited also *Enterococcus faecalis* TS (EfTS), with the best inhibitors showing *K*_i in the range of 2-8 µM. These compounds exhibited a competitive behavior with respect to the folate cofactor and a significant selectivity towards bacterial TS [8]. EfTS X-ray crystal structure of the native protein had been obtained [14]. According to structural analysis, the protein crystallized in a ternary complex where a folate substrate analogue, 5-formyl-tetrahydrofolate (5-FTHF), originating from the bacterial metabolites pool, co-crystallized with the enzyme. Thus, we can conclude that EfTS could be considered a reservoir for folate substrates in the bacteria folate dependent metabolism. Although no structural information about EfTS-inhibitors complexes are available yet, we could suppose that the target druggability is influenced by the presence of the folate metabolites inside the bacterial cell and that higher affinity inhibitors are necessary to displace 5-FTHF. Aiming to obtain X-ray crystallographic structures to gain additional information on EfTS target druggability and to carry out further structure-based drug
design studies, we analyzed our in-house library based on a N-substituted phthalimide scaffold bearing a flexible chain linked to the nitrogen in position 2. In details, 56 compounds (Chart 1 and 2) were tested against E/Ts, Ec/Ts and human TS (hTS). In the present work, X-ray crystallographic screenings were carried out and one X-ray crystallography complex with a protein inhibitor, (S)-12, was obtained. In addition, we solved the X-ray crystal structure of E/Ts in complex with methotrexate (MTX), a known folate analogue. These studies represent an important starting point for a structure-based drug design aimed at identifying new antibacterial agents against Enterococcus faecalis infections.

2. Results and discussion

2.1. Library Selection and Compound Synthesis

With the aim of exploring the chemical space of the phthalimide core, a library of 56 compounds (Charts 1 and 2) was selected from our in-house libraries (for details see experimental section), previously synthesized as intermediates for the preparation of compounds with different pharmacological activities [15–33]. These compounds underwent in vitro screening towards E/Ts, hTS and Ec/Ts. All the molecules of the new library show an N-substituted phthalimide ring (III, Figure 1). The majority of the compounds have an aromatic ring in the side-chain linked to position 2 of the phthalimide moiety. In our previously published library the aromatic moiety in the side-chain was directly linked to the nitrogen in position 2 (I, Figure 1), whereas in the present work almost all the compounds have a spacer between the phthalimide core and the aromatic system of the side-chain, thus being more flexible. Few compounds (27–31, 34, 56) have a non-aromatic side-chain with a lower steric hindrance. This novel
phthalimide library includes several chiral compounds (1–8, 12, 13, 17, 21, 27–34, 40–43, 50, 51, 56) and for some of them we explored the biological profile of both the racemic mixture and the single enantiomers.

2.2. Chemistry

Only synthetic procedures followed to obtain compounds not previously characterized in literature are described in this paper. The synthesis of the racemic mixture and of the enantiomers of compound 8 is shown in Scheme 1. Ester (RS)-60 was obtained following Williamson reaction of (RS)-bromopropanoate, (RS)-58 with 2,6-dimethylphenol, while (R)- and (S)-61 were obtained by Mitsunobu reaction [34,35] of 2,6-dimethylphenol with (S)- or (R)-methyl lactate [(S)- or (R)-59], respectively. After esters reduction, the obtained alcohols 61 were submitted to Mitsunobu reaction with phthalimide to give the desired compounds. Compound 13 was obtained through hydrolysis of compound 12 (Scheme 2). The synthesis of compounds (S)-17, (S)- and (R)-33 is depicted in Scheme 3. (S)- and (R)-33 were obtained by protecting (S)- and (R)-2-amino-2-phenylethanol, respectively, with phthalic anhydride. Iodination of compound (S)-33 yielded compound (S)-17. Compounds 20 and 22 were synthesized as reported in Scheme 4. Cyano derivative 18 was converted into the corresponding trimethyltintetrazole derivative 62 by reaction with azido-trimethyltin. The treatment of compound 62 with gaseous HCl gave tetrazole derivative 22, which was alkylated with methyl iodide to give compound 20. Compound 24 was obtained by reacting 2-(methoxycarbonyl)benzoic acid with p-toluidine in presence of EEDQ as previously described (Scheme 5) [36]. The nitration of (R)-63, followed by reduction of the nitro group gave (R)-7 and, successively, (R)-43 (Scheme 6), as reported in the literature [26, 37, 38]. Compounds 25 and 55 were prepared by protecting 4-phenylbutan-1-amine with phthalimide or tetrachlorophthalimide, respectively (Scheme 7). The synthesis of
compound 52 is reported in Scheme 8. 3-Aminopropanol was protected with phthalic anhydride to give compound 64, which was submitted to Mitsunobu reaction with 1-naphthol. Compound 65 (Scheme 9) was synthesized by the reaction of 3-aminopropanol with tetrachlorophthalic anhydride and converted into compound 53. The synthesis of compound 54 is depicted in Scheme 10. Williamson reaction on 3-bromopropanol with thiophenol gave compound 67 which was converted into the thioether 55. Finally, the synthesis of (R)-1 was obtained via a Mitsunobu reaction starting from (S)-68 (Scheme 11).

2.3. Biological evaluation of the compounds library

The selected 56 compounds were tested against E/T5S and hTS enzymes in order to evaluate the inhibitory activity towards TS and the specificity towards the bacterial enzyme (Table S1, Figure 2, Table S1, see Supplementary Material). The percentage of inhibition (I%) at 100 µM are reported as heat-map plot in Figure 2 in which different color codes are based on the inhibition range of the compounds. Moreover, the inhibitory activity towards Escherichia coli TS (EcTS) was assessed, aiming to explore a larger biological activity profile. Several compounds of the library are chiral, thus they were tested as racemic mixture and/or as homochiral. Thirteen compounds (4, 7, 11, 18, 20, 23, 35, 39, 40, 45, 47, 52 and 54) show inhibitory activity towards E/T5S (I% = 20-60 % at 100 µM). Compounds 18, (R)-40 and 54, with Ki of 25, 13 and 24 µM, respectively, turned out to be the best inhibitors of the library. Moreover, they were species-specific inhibitors of E/T5S, since they were inactive at 100 µM towards hTS. Few compounds (RS)-1, (R)-7, (R)-8, 9, 14, 16, 24, 25 were able to decrease the EcTS activity by 35-48 % at 100 µM and represent the most potent EcTS inhibitors of this set of compounds. In our previous paper [8], we studied the inhibitory activity towards E/T5S of
more rigid phthalimide derivatives (6A, 8A, 12A, Figure 1). The phthalimide moiety had been directly connected to substituted aromatic or heteroaromatic rings in position 2. Compound 6A, 8A and 12A showed a significant E/TS inhibitory activity, with compound 12A being the most active (Kᵢ = 2.0 ± 0.35 μM). In the present study, we evaluated the activity of more flexible molecules. The spacer between the phthalimide moiety and the aromatic side chain was from 2 to 10 carbons long (Figure 1, III). In most cases, an ether or a thioether spacer was used. If we compare the overall inhibitory activity of the previously published library with that of the present library, we can state that more rigid compounds are preferable with respect of flexible molecules, for E/TS binding.

2.4. X-ray crystal structures of E/TS in complex with (S)-12 and with MTX

X-ray crystallographic studies were carried out on structurally different N-substituted phthalimides. Overall, the present library showed medium to low affinity towards E/TS. All the compounds showing a percentage of inhibition towards E/TS of 10%-60% were selected for the crystallographic screening. From the screened crystals, we obtained usable diffraction data only for E/TS complexes with (R)-2, (S)-12 and 14. Unfortunately, the Fourier difference maps for (R)-2 and 14 complexes showed only blurred features corresponding to the bound inhibitor into the active site that prevented model building. In addition, we also obtained a dataset for E/TS bound by MTX (Kᵢ = 13 μM) that has been used for comparison. Eventually, only the electron density for the (S)-12 inhibitor bound to E/TS was complete and confidently interpreted (PDB: 4O7U) and compared with that of E/TS-MTX complex (PDB: 5J7W). MTX has a Kᵢ equal to that of the best phthalimidic inhibitor of the series, compound (R)-40. The two independent E/TS dimers present in the crystal asymmetric unit of the E/TS-(S)-12 complex (Figure 3A) display
subunit heterogeneity: one subunit is empty and in the ‘open’ conformation [14], while the other one hosts the exogenous ligand and is in a ‘closed’ conformation (Figure 3B). The ‘open’ conformation is characterized by the loop 92-102 being open and mostly disordered and by the short helix 103-109 and the first two turns of helix 111-130 being completely unfolded. In the ‘closed’ conformation the secondary structure elements described above are fully ordered with the loop closer to the active site cavity (see Figure 3B). Further heterogeneity is present in the ‘closed’ subunits as they bind two different molecules into their active sites. We observed a mixture of two different complexes: 5-hydroxymethylene-6-hydrofolic acid (5-HMHF) is found in one dimer (Figure 4A), while the other dimer hosts the S-enantiomer of compound (RS)-12 used for co-crystallization (Figure 4B). Subunit heterogeneity and half-site reactivity is commonly found in TS enzymes [39-41]. The electron density present in the active site of the B subunit led to identify the folate analogue as 5-hydroxymethylene-6-hydrofolate molecule (5-HMHF), thus different from the 5-formyltetrahydrofolate (5-FTHF) already published [14]. The active site cavity of the B subunit shows electron density above noise, which is consistent with the planar structure of the pteridine moiety and in contrast with the puckered pyrazine ring of tetrahydrofolate found in our previous crystal structure of Ef/TS (14) (Figure 4A). The remaining parts of the molecule establish interactions similar to those of 5-FTHF. We have previously shown that Ef/TS obtained from our preparations contains bound metabolites from the folate pathway, such as 5-formyl-tetrahydrofolate (5-FTHF; PDB: 3UW1) [14]. 5-HMHF is a product of the conversion of 5-FTHF by bacterial enzymes (e.g. 5,10-methenyl-tetrahydrofolate synthetase enzyme). In fact, 5-HMHF was discovered for the first time bound to 5,10-methenyl-tetrahydrofolate synthetase from Mycoplasma pneumoniae (PDB 1U3G) [42]. Analyzing the binding mode of (S)-12, we can suggest that this compound displaces 5-HMHF (or other folate
structural analogues), at least partially, from \(E fT S\) active site. This finding provides structural evidence of the competitive inhibition pattern of compound \((S)-12\) with respect to MTHF. The orientation of compound \((S)-12\) into \(E fT S\) active site is similar to that of 5-FTHF and 5-HMHF (Figure 4A-B). Compound \((S)-12\) establishes interactions with the hydrophobic residues surrounding the active site (Ile80, Trp81, Trp84, Leu194, Cys197, Leu223, Phe227, Tyr260 and Ile313). Only one hydrogen bond between the carbonyl group of compound \((S)-12\) and a water molecule is formed. The phthalimide core of compound \((S)-12\) places itself in the same position occupied by the pteridine moiety of the 5-HMHF and the \(para\)-substituted aromatic chain replaces the PABA moiety of 5-HMHF. The phthalimide core is wrapped in a lipophilic binding site and interacts with Leu194, Trp84 and Trp81, typical residues involved in the cofactor binding. The aromatic side chain has contact distance from the side chains of Glu59 (3.4 Å), Trp84 (3.1 Å) and Phe227 (3.4 Å), while the acetoxy substituent in \(para\) position of the phenyl ring is at 3.7 Å from Leu223. In addition, the acetoxy group is located within 6.0 - 7.0 Å from several carbonyl groups of the main chain and from the backbone chains of Lys49 and Lys310.

The absence of direct H-bonds and the prevalence of lipophilic interactions explain the low affinity of the compound for \(E fT S\). Compound \((S)-12\) was the only compound of the series providing a crystal structure of its complex with \(E fT S\) despite \((S)-12\) is a weak inhibitor (10% at 100 µM). This occurs frequently when hits screenings are performed to identify X-ray crystal structures needed to start a structure-based drug design [43]. The puzzling aspect of our \(E fT S\) is that, despite the addition of the dUMP to the crystallization medium, the substrate has never been found bound to the active site. A structural comparison between our enzyme and other bacterial TS that form ternary complexes with dUMP and folate analogues (e.g. PDB: 1NCE) [41, 44] highlighted that 5-HMHF and \((S)-12\) are bound closer to \(E fT S\) catalytic Cys197

10
where usually dUMP binds, if compared to the folate analogues. However, a slight rearrangement of the cofactor could be expected to allow space for dUMP binding. Probably, the sulfate anions used at high concentration for crystallization compete for the same site where the phosphate group of dUMP binds [14]. Indeed, a sulfate anion is bound in the active site cavity at the same site in all subunits. This site corresponds to the binding site of the dUMP phosphate group in 1NCE as well as other E. coli TS complexes with dUMP and the inhibitors F9 (PDB: 4LRR) [10] or BGC 945 (PDB: 4ISK) [45, 46]. In our previous paper [8] the crystallographic complexes of LcTS with phthalimidic compounds (I in Figure 1) have been obtained. Due to the structural similarity between LcTS and EfTS, we can compare the complexes of LcTS-inhibitors already published [8] with the complex EfTS-(S)-12. The compounds of the previously published library presented a phthalimide core directly linked to the side chain, thus they cannot assume a folded conformation and they show a binding mode different to that of compound (S)-12. Moreover, the presence of dUMP in LcTS complexes suggested that dUMP induces a different orientation of the phthalimide core into TS active site and contributes to stabilize the protein-ligand complex interaction. On the other hand, the compounds of the present paper have spacers between the phthalimide core and the aromatic moiety, therefore only a folded conformation is possible for binding into EfTS active site; the obtained results suggest that this decreases the inhibition activity and complex stability. The structure determination of EfTS complexes with rigid inhibitors (e.g. 6A, 8A and 12A) could further clarify the potential of phthalimide derivatives as tool for the EfTS inhibition. The structure of EfTS-MTX shows the same subunit heterogeneity observed for the EfTS-(S)-12 complex with two subunits (A and B) in “open” conformation and two in “closed” conformation with the MTX inhibitor bound. At variance with the previous structure, no 5-HMHF is found, possibly suggesting that MTX has replaced the
folate derivative in both subunits. The pose and the electron density of MTX bound to *Ef*TS is reported in Figure 5A and compared with the *Ef*TS-(S)-12 in Figure 5B. (S)-12 and MTX assume essentially the same pose in the *Ef*TS active site and make similar interactions. The glutamic acid moiety terminal portion of MTX, that is missing in (S)-12, does not interact with the cavity, the closest approach being that of the vicinal carboxylate group of MTX lying at 3.4 Å and 4.0 Å from the side chains of Phe227 and Lys48, respectively. It is noteworthy that, as for the (S)-12 *Ef*TS structure, dUMP is not bound into the active site of the *Ef*TS-MTX complex and the binding site of dUMP phosphate is occupied by a sulfate anion in both crystal structures. Comparison of the *Ef*TS-(S)-12 and MTX structures with the closed form of human TS with bound raltitrexed (PDB: 1HVY) suggests a possible way to increase specificity and affinity of inhibitors towards the bacterial enzyme. The only relevant difference between human TS and *Ef*TS cavity consists in the presence of Glu88 that is replaced by Ala111 in the human enzyme. The side chain of Glu88 is located at about 7.0 Å from the dimethyl benzene ring of (S)-12 and from the PABA ring of MTX. The design and synthesis of (S)-12 derivatives where the benzene ring bears meta substituents able to form H-bonds with the side chain of Glu88 could lead to an increased affinity towards *Ef*TS together with specificity.

3. Conclusions

Aiming to obtain novel specific inhibitors of *Ef*TS enzyme, we combined an *in vitro* target-based screening approach with X-ray crystallographic studies. The most interesting compounds (18, (R)-40 and 54) showed *K* \(_i\) of 13-25 µM, with compound (R)-40 being the most potent and selective towards *Ef*TS with respect to the human enzyme. X-ray crystallographic studies were carried out on structurally different phthalimides. The X-ray crystal structure of *Ef*TS in complex
with a low affinity inhibitor, (S)-12, was determined and refined. In this structure EfTS behaves as half-site enzyme. According to the crystallographic structure, compound (S)-12 binds into the active site with an orientation analogue to that of folate metabolites, thus suggesting a competitive behavior with respect to the folate co-substrate. One subunit binds a folate metabolite (5-HMHF), suggesting that high affinity ligands are needed to fully displace the substrates in both the subunits. We can conclude that target druggability is affected by the presence of folate analogues bound into one EfTS subunit. Moreover, we solved the X-ray crystal structure of EfTS in complex with MTX ($K_i = 13 \mu M$) in which the folate metabolites, such as 5-HMHF, are not bound. This confirms the ability of high affinity ligands to displace the metabolites from the binding site. The present study discloses the EfTS druggability and represents an interesting starting point for a target-based drug design aimed at developing more potent EfTS inhibitors and antibacterial drugs.

4. Experimental section

4.1. Chemistry. The synthesis of compounds 1, 4, 10, 21, 23 [19], 2, 12, 42, 50 [21, 22], 3, 6, 41 [23, 24], 5, 27–32, 56 [25], 9, 11, 14–16, 26, 35, 44–49, 65 [27], 18 [29], 19 [47], 34 [30], 36–40, 51 [18], 63 [31, 32] has been already published in literature. For compound 7, only the (R)-enantiomer, not previously reported, has been herein described, while (RS)-7 is described in the literature [26]. Compounds 22, 24, 25, 52, 55 had been previously described in the literature (as referenced...
below) but not fully characterized and/or synthesized following different procedures. All chemicals were purchased from Sigma-Aldrich or Lancaster in the commercially available highest quality. Solvents were reagent grade unless otherwise indicated. Yields refer to purified products and were not optimized (Table S4, see Supplementary Material). The structures of the compounds were confirmed by routine spectrometric analyses. Only spectra for compounds not previously described are given. Melting points (mp) were determined on a Gallenkamp melting point apparatus in open glass capillary tubes and are uncorrected (Table S4, see Supplementary Material). The infrared spectra were recorded on a Perkin-Elmer SpectrumOne FT spectrophotometer and band positions are given in reciprocal centimetres (cm⁻¹). ^1H NMR and ^13C NMR spectra were recorded on a Varian VX Mercury spectrometer operating at 300 and 75 MHz for ^1H and ^13C, respectively, using CDCl₃ and DMSO-d₆ as solvents. Chemical shifts are reported in parts per million (ppm) relative to solvent resonance: CDCl₃, δ 7.26 (^1H NMR) and δ 77.3 (^13C NMR); DMSO-d₆, δ 2.48 (^1H NMR). J values are given in Hz (NMR Spectra for compounds 2, 3, 5, 6, 9, 11, 12, 14, 16, 18, 36-42, 44-50 are available in the Supplementary Material). Gas chromatography (GC)/mass spectroscopy (MS) was performed on a Hewlett-Packard 6890–5973 MSD at low resolution. Liquid chromatography (LC)/mass spectroscopy (MS) was performed on a spectrometer Agilent 1100 series LC-MSD Trap System VL. The molecular ion was designed as “M⁻⁺”. Elemental analyses were performed on an Eurovector Euro EA 3000 analyzer and the data for C, H, N were within ± 0.4 of theoretical values (Table S3, see Supplementary Material). Optical rotations were measured on a Perkin Elmer (Norwalk, CT) Mod 341 spectropolarimeter; concentrations are expressed in g/100 mL, and the cell length was 1 dm, thus [α]D₂¹ values are given in units of 10⁻¹-deg.⁻cm²-g⁻¹. Chromatographic separations
were performed on silica gel columns by flash chromatography (Kieselgel 60, 0.040–0.063 mm, Merck, Darmstadt, Germany) as previously described [48, 49].

4.1.1. (R)-2-[1-Methyl-2-(1-naphthyloxy)ethyl]-1H-isindole-1,3(2H)-dione (R)-1. Prepared as reported below for (RS)-8 starting from (S)-68 and phthalimide. Yield: 57%; mp 79–81 °C (EtOAc/hexane); [α]D = –38 (c 1, CHCl₃). Spectroscopic and spectrometric data were in agreement with those found in the literature for the racemate [19]. Anal. Calcd for C₂₁H₁₇NO₃ %: C, 76.12; H 5.17; N 4.23. Found: C, 75.85; H 5.16; N 4.31.

(R)-2-[2-(2,6-Dimethyl-4-nitrophenoxy)-1-methylethyl]-1H-isindole-1,3(2H)-dione (R)-7. 0.65 g (2.1 mmol) of (R)-63 were dissolved in 5 mL of trifluoroacetic acid at room temperature. Then, 0.22 g (2.5 mmol) of sodium nitrate were added to the solution in small portions during the period of 60 min. The mixture was stirred overnight, then diluted with 15 mL of diethyl ether and 3 mL of brine. The aqueous phase was extracted with Et₂O for three times. The organic layers, washed with 20% NaOH aqueous solution, were dried over anhydrous Na₂SO₄ to give 0.65 g (85%) of an orange foam which was recrystallized from Et₂O/petroleum ether to give orange crystals: mp 105–106 °C (Et₂O/petroleum ether); [α]D = –30 (c 2, CHCl₃). ¹H NMR (CDCl₃): δ 1.55 (d, J = 7.2 Hz, 3H, CH₃CH), 2.26 (s, 6H, CH₃), 3.96 (dd, J = 9.3, 5.5 Hz, CHCH), 4.48 (t, J = 9.3 Hz, 1H, CH), 4.80–4.95 (m, 1H, CH), 7.70–7.76 (m, 2H, ArH₅,6), 7.82–8.00 (m, 4H, ArOCH₃, ArH₄,7). Other spectroscopic data were in agreement with those reported in the literature for the racemate [26]. Anal. calcd for C₁₉H₁₈N₂O₅ %: C, 64.40; H 5.12; N 7.91. Found: C, 64.45; H 5.16; N 7.95.

(RS)-2-[2-(2,6-Dimethylphenoxy)propyl]-1H-isindole-1,3(2H)-dione (RS)-8. To a stirred solution of (RS)-61 (1.97 g, 10.9 mmol), phthalimide (2.40 g, 16.3 mmol) and
triphenylphosphine (4.28 g, 16.3 mmol) in dry THF (100 mL), under N$_2$ atmosphere, a solution of diisopropylazodicarboxylate (DIAD) (3.30 g, 16.3 mmol) in dry THF (50 ml) was added dropwise. The mixture was stirred at room temperature for 24 h. The solvent was then evaporated under reduced pressure, Et$_2$O was added and the precipitate formed was filtered off. The filtrate was evaporated in vacuo and the residue was purified by flash chromatography (eluent EtOAc/petroleum ether 2:8) to give 3.24 g of a white solid (96%) which was recrystallized from EtOAc: mp 90–91 °C; IR (KBr): 1772, 1717 (C=O) cm$^{-1}$; $^1$H NMR (CDCl$_3$): $\delta$ 1.19 (d, $J = 6.0$ Hz, 3H, $\text{CH}_3$), 2.22 (s, 6H, $\text{CH}_3\text{Ar}$), 3.85 (dd, $J = 13.5$, 6.3 Hz, 1H, CH), 4.07 (dd, $J = 13.6$, 7.0 Hz, 1H, CHH), 4.52 (sextet, $J = 6.3$ Hz, 1H, CH), 6.82–7.0 (m,3H, Ar), 7.68–7.78 (m, 2H, Ar), 7.82–7.90 (m, 2H, Ar); $^{13}$C NMR (CDCl$_3$):$\delta$ 17.3 (2C), 18.2 (1C), 43.4 (1C), 74.2 (1C), 123.5 (2C), 123.7 (1C), 129.2 (2C), 131.4 (2C), 132.2 (2C), 134.2 (2C), 153.1 (1C), 168.5 (2C); GC/MS (70 eV) $m/z$ (%) 309 (M$^+$, 16), 188 (100). Anal. calcd for C$_{19}$H$_{19}$NO$_3$: C, 72.71; H 6.26; N 4.46. Found: C, 72.85; H 6.19; N 4.51.

(R)-2-[2-(2,6-Dimethylphenoxy)propyl]-1H-isindole-1,3(2H)-dione (R)-8. Prepared as reported above for (RS)-8 starting from (R)-61. Yield: 87%; white crystals: mp 69–70 °C (EtOAc); $[\alpha]_{20}^D = -81$ (c 2, CHCl$_3$). Spectroscopic data were in agreement with the racemate. Anal. calcd for C$_{19}$H$_{19}$NO$_3$: C, 73.77; H 6.19; N 4.53. Found: C, 73.82; H 6.24; N 4.57.

(S)-2-[2-(2,6-Dimethylphenoxy)propyl]-1H-isindole-1,3(2H)-dione (S)-8. Prepared as reported above for (RS)-8 starting from (S)-61. Yield: 80%; white crystals: mp 70–71 °C (EtOAc); $[\alpha]_{20}^D = +79$ (c 2, CHCl$_3$). Spectroscopic data were in agreement with the racemate. Anal calcd for C$_{19}$H$_{19}$NO$_3$: C, 73.77; H 6.19; N 4.53. Found: C, 73.59; H 6.18; N 4.57.
2-[1-(4-Hydroxy-2,6-dimethylphenoxy)propan-2-yl]-1H-isoindole-1,3(2H)-dione (RS)-13. A solution of (RS)-12 (0.82 g, 2.23 mmol) in THF (6 mL) and 10% HCl solution (5 mL) was stirred in an ice-bath for 3 h. Then the mixture was stirred at room temperature for 48 h. The solvent was evaporated under vacuum and extracted with EtOAc. The organic layer was dried (Na₂SO₄) to give a slightly yellowish solid which was recrystallized from EtOAc/petroleum ether to give 0.43 g (59%) of slightly yellowish crystals: mp 178–179 °C; IR (KBr): 3412 (OH), 1770, 1699 (C=O); ¹H NMR (CDCl₃): δ 1.53 (d, J = 6.9 Hz, 3H, CH₃), 2.12 (s, 6H, CH₃Ar), 3.84 (dd, J = 9.2, 5.6 Hz, 1H, CH₂CH), 4.29 (t, J = 9.2 Hz, 1H, CH₂CH), 4.58 (br s, 1H, OH), 4.76–4.92 (m, 1H, CH), 6.41 (s, 2H, Ar), 7.65–7.74 (m, 2H, Ar), 7.78–7.90 (m, 2H, Ar); ¹³C NMR (CDCl₃): δ 15.4 (1C), 16.5 (2C), 47.4 (1C), 72.2 (1C), 115.2 (2C), 123.4 (2C), 132.1 (2C), 132.2 (2C), 134.2 (2C), 149.3 (1C), 151.5 (1C), 168.7 (2C); GC/MS (70 eV) m/z (%) 325 (M⁺, 5), 188 (100). Anal. Anal. calcd for C₁₉H₁₉NO₄.0.20H₂O %: C, 69.37; H 5.94; N 4.26. Found: C, 69.59; H 5.84; N 4.37.

(S)-2-(2-Iodo-1-phenylethyl)-1H-isooindole-1,3(2H)-dione (S)-17. Into a stirred ice-cooled solution of (S)-33 (1.74 g, 6.5 mmol) in dry toluene (30 mL) under N₂ atmosphere, HI was bubbled until saturation occurred. The mixture was stirred at −5 °C for 1 h and at room temperature for 48 h. The solvent was then evaporated under vacuum and the residue, taken up with EtOAc, was washed with 6 N NaOH, 2 N HCl, and brine. The organic layer was dried (Na₂SO₄) and concentrated under vacuum to give 1.7 g (70%) of a slightly yellowish solid which was recrystallized from MeOH to give (S)-17 as white crystals: mp 123–124 °C; [α]²⁰_D = −16 (c 2, CHCl₃); IR (KBr): 1780, 1707 (C=O); ¹H NMR (CDCl₃): δ 3.83 (dd, 1H, J = 10.5, 5.2 Hz, CHH), 4.53 (t, 1H, J = 10.8 Hz, CH), 5.56 (q, 1H, J = 5.2 Hz, CHH), 7.28–7.38 (m, 3H, Ar), 7.50–7.58 (m, 2H, Ar), 7.68–7.76 (m, 2H, Ar), 7.82–7.88 (m, 2H, Ar); ¹³C NMR (CDCl₃): δ 4.8
(1C), 57.8 (1C), 123.8 (2C), 128.1 (2C), 128.9 (2C), 129.2 (1C), 131.8 (2C), 134.5 (1C), 138.1 (2C), 168.1 (2C); GC/MS (70 eV) m/z (%): 377 (M+, <1), 250 (100). Anal. calcd for C_{16}H_{12}NO_2 I %: C, 50.95; H 3.21; N 3.71. Found: C, 51.15; H 3.25; N 3.79.

2-{(2’-(1-Methyl-1H-tetrazol-5-yl)biphenyl-4-yl)methyl}-1H-isooindole-1,3(2H)-dione 20. Potassium carbonate (65.2 g, 0.47 mmol) was added to a solution of 22 (0.15 g, 0.39 mmol) in 10 mL of acetone. The mixture was stirred at room temperature for 30 min, and then methyl iodide (0.11 g, 0.77 mmol) was added. The reaction mixture was refluxed for 2h. After cooling, the reaction mixture was filtered and evaporated. The residue was extracted with EtOAc and washed twice with H_2O. After drying (Na_2SO_4), the organic phase was evaporated to afford a crude solid which was purified by crystallization from CHCl_3/hexane affording 83 mg (54 %) of white crystals: mp 210–211 °C; IR (KBr): 1766, 1705 (C=O); 1H NMR (CDCl_3): δ 4.22 (s, 3H, CH_3), 4.82 (s, 2H, CH_2), 7.04–7.16 (m, 2H, Ar), 7.28–7.38 (m, 2H, Ar), 7.40–7.90 (m, 8H, Ar); 13C NMR (CDCl_3): δ 33.8 (1C), 41.3 (2C), 122.6 (1C), 123.6 (2C), 123.7 (1C), 128.2 (1C), 128.4 (2C), 129.1 (1C), 130.6 (2C), 131.7 (1C), 132.0 (1C), 134.3 (2C), 135.3 (1C), 136.6 (1C), 138.7 (1C), 141.5 (1C), 168.3 (2C); GC/MS (70 eV) m/z (%): 395 (M+, 34), 394 (100). Anal. calcd for C_{23}H_{17}N_5O_2 %: C, 69.86; H 4.33; N 17.71. Found: C, 69.47; H 4.37; N 17.43.

2-{(2’-(1H-Tetrazol-5-yl)biphenyl-4-yl)methyl}-1H-isooindole-1,3(2H)-dione 22. A suspension of compound 62 (0.60 g, 1.1 mmol) in a mixture of toluene (8 mL) and THF (2 mL) was stirred in an ice bath. Gaseous HCl was then added to give a clear solution followed by precipitation of the desired product. The precipitate was filtered, and the filtrate was washed with toluene to give a white solid (0.40 g, 96 %): mp: >250 °C; IR (KBr): 3458 (NH), 1767, 1714 (C=O), 1463, 1252 (N-N=N) cm^{-1}; 1H NMR (DMSO-d_6): δ 4.72 (s, 2H, CH_2), 7.04 (d, J = 8.2 Hz, 2H, Ar), 7.23 (d,
J = 8.2 Hz, 2H, Ar), 7.46–7.70 (m, 4H, Ar), 7.78–7.96 (m, 4H, Ar), 16.4 (1H, NH); LC/MS m/z 380 [M⁺ – 1]. Other spectroscopic data were in agreement with the literature [50]. Anal. – Anal. calcd for C_{22}H_{15}N_{5}O_{2}·0.50H₂O %: C, 67.68; H 4.13; N 17.94. Found: C, 67.73; H 4.03; N 17.70.

2-(4-Methylphenyl)-1H-isoindole-1,3(2H)-dione 24. EEDQ (1.48 g, 6 mmol), p-toluidine (0.59 g, 5.5 mmol) and Et₃N (1.04 mL, 7.5 mmol) were successively added to a stirring solution of 2-(methoxycarbonyl)benzoic acid (1.0 g, 5 mmol) in CHCl₃ (160 mL). The reaction mixture was heated under reflux for 6 h. The solvent was removed under reduced pressure and the residue, taken up with EtOAc, was washed three times with 2 N HCl, twice with 2 N NaOH, and then dried over anhydrous Na₂SO₄. The organic phase was evaporated to afford a crude solid which was purified by crystallization from CHCl₃/hexane to give 0.90 g (67 %) of 24 as beige crystals: mp 205–206 °C; IR (KBr): 1747, 1716 (C=O); ¹H NMR (CDCl₃): δ 2.41 (s, 3H, CH₃), 7.31 (s, 4H, Ar), 7.74–7.82 (m, 2H, Ar), 7.92–7.99 (m, 2H, Ar); GC/MS (70 eV) m/z (%) 237 (M⁺, 100).

Other spectroscopic data were in agreement with the literature [51]. Anal. – Anal. calcd for C_{15}H_{11}NO₂·0.20H₂O %: C, 74.80; H 4.77; N 5.82. Found: C, 75.06; H 5.08; N 6.00.

2-(4-Phenylbutyl)-1H-isoindole-1,3(2H)-dione 25. Prepared as reported for compound 55 starting from 4-phenylbutan-1-amine and phthalic anhydride. Yield: 62 %; white solid: mp 84–85 °C. Spectroscopic data were in agreement with the literature [52].

(R)-2-(2-Hydroxy-1-phenylethyl)-1H-isoindole-1,3(2H)-dione (R)-33. Prepared as reported above for compound 64 starting from (R)-phenylglycinol and phthalic anhydride. Yield: 88 %; white crystals: [α]^{20}_D = + 41 (c 2, CHCl₃); IR (neat): 3464 (OH), 1772, 1710 (C=O); ¹H NMR (CDCl₃): δ 2.64 (br s, 1H, OH), 4.21 (dd, J = 11.6, 5.0 Hz, 1H, CHH), 4.65 (dd, J = 11.6, 9.3 Hz, 1H, CHH), 5.41–5.53 (m, 1H, CHH), 7.23–7.38 (m, 3H, Ar), 7.40–7.50 (m, 2H, Ar), 7.63–7.73
(m, 2H, Ar), 7.74–7.85 (m, 2H, Ar). Other spectroscopic data were in agreement with those reported in the literature [53,54]. Anal. Calcld for C_{16}H_{13}NO_{3} %: C, 71.90; H 4.90; N 5.24. Found: C, 72.24; H 4.99; N 5.40.

(S)-2-(2-Hydroxy-1-phenylethyl)-1H-isouindole-1,3(2H)-dione (S)-33. Prepared as reported above for compound 64 starting from (S)-phenylglycinol and phthalic anhydride. Yield: 85 %; slightly yellowish crystals: [α]^{20}_{D} = –32 (c 2, CHCl_{3}). Other spectroscopic data were in agreement with those reported in the literature for the R-enantiomer [53,54].

(R)-2-[1-(4-amino-2,6-dimethylphenoxy)propan-2-yl]-1H-isouindole-1,3(2H)-dione hydrochloride (R)-43. Catalytic hydrogenation of (R)-7 (0.35 g, 1.0 mmol) in 10 mL of absolute EtOH was conducted at room temperature for 12 h in the presence of 10% palladium on carbon at 10 bar. The catalyst was filtered off and the solvent was removed under reduced pressure to give 0.23 g (70 %) of the free amine (R)-43 as a yellow oil which was converted into its hydrochloride salt by dissolving the free base in a small amount of aqueous 1N HCl and azeotropically removing water. The crude solid obtained was recrystallized from EtOH/Et_{2}O: mp 256–258 °C; [α]^{20}_{D} = –42 (c 2, MeOH). Spectroscopic and spectrometric data were in agreement with those found in the literature for the racemate [26]. Anal. Calcld for C_{19}H_{20}N_{2}O_{3}HCl0.33H_{2}O %: C, 62.21; H 5.95; N 7.64. Found: C, 62.16; H 6.06; N 7.24.

2-[3-(Naphthalen-1-yloxy)propyl]-1H-isouindole-1,3(2H)-dione 52. Prepared as reported above for (RS)-8 starting from (R)-64 and 1-naphthol using diethyl azodicarboxylate (DEAD) instead of DIAD. Yield: 36 %; mp 150–151 °C (EtOAc/hexane), lit [55] 154–154.5 °C; IR (KBr): 1765, 1713 (C=O) cm^{-1}; ^{1}H NMR (CDCl_{3}): δ 2.34(quintet, J = 6.9 Hz, 2H,
(4,5,6,7-Tetrachloro-2-(3-phenoxypropyl)-1H-isoindole-1,3(2H)-dione 53. Prepared as reported above for (RS)-8 starting from 65 and phenol using diethyl azodicarboxylate (DEAD) instead of DIAD. Yield: 30%; mp 211–212 °C (EtOAc/hexane); IR (KBr): 1777, 1712 (C=O) cm⁻¹; GC/MS (70 eV) m/z (%) 419 (M⁺, 6), 326 (100). Anal. calcd for C₁₇H₁₁Cl₄NO₃.05H₂O %: C, 47.70; H 2.83; N 3.27. Found: C, 47.62; H 2.65; N 3.41.

(4,5,6,7-Tetrachloro-2-[3-(phenylsulfanyl)propyl]-1H-isoindole-1,3(2H)-dione 54. Prepared as reported above for (RS)-8 starting from 67 and tetrachlorophthalimide, using diethylazodicarboxylate (DEAD) instead of DIAD. Yield: 20%; mp 140–141 °C (THF/petroleum ether); IR (KBr): 1775, 1713 (C=O) cm⁻¹; ¹H NMR (CDCl₃): δ 1.97–2.04 (m, 2H, CH₂CH₂CH₂), 2.93 (t, J = 7.1 Hz, 2H, CH₂S), 3.83 (t, J = 7.0 Hz, 2H, CH₂N), 7.15–7.35 (m, 5H, Ar); ¹³C NMR (CDCl₃): δ 27.9 (1C), 31.7 (1C), 38.1 (1C), 126.7 (2C), 127.8 (1C), 129.2 (2C), 129.8 (2C), 130.3 (2C), 135.7 (2C), 140.3 (1C), 163.7 (2C); GC/MS (70 eV) m/z (%) 433 (M⁺, 54), 149 (100).

(4,5,6,7-Tetrachloro-2-(4-phenylbutyl)-1H-isoindole-1,3(2H)-dione 55. A mixture of 4-phenylbutan-1-amine (2.0 g, 13.4 mmol), tetrachlorophthalic anhydride (3.83 g, 13.4 mmol), triethylamine (0.13 g, 1.34 mmol) in toluene (20 mL) was heated under reflux in a flask fitted
with a Dean–Stark tube for 7 h. During this period, the temperature of the oil bath is maintained at about 130 °C and water separates. All volatile matter were then evaporated under vacuum and the solid residue was taken up with EtOAc and washed with 2 N HCl, NaHCO$_3$, and H$_2$O. The organic phase was dried (Na$_2$SO$_4$) and concentrated under vacuum to give a white solid which was recrystallized from EtOAc/hexane to give 3.90 g (70%) of white crystals: mp 119–120 °C. Other spectroscopic data were in agreement with the literature [52]. Anal. calc'd for C$_{18}$H$_{13}$ClNO$_2$: C, 51.83; H 3.14; N 3.36. Found: C, 51.71; H 3.13; N 3.44.

(RS)-Ethyl 2-(2,6-dimethylphenoxy)propanoate (RS)-59. Sodium (0.38 g, 16.5 mmol) was added in small pieces to absolute EtOH (30 mL) and the mixture was heated at 70 °C. After completion of sodium dissolution, a solution of 2,6-dimethylphenol (2.0 g, 16.5 mmol) in absolute EtOH (15 mL) was added dropwise. After 30 min, a solution of (RS)-ethyl 2-bromopropanoate [(RS)-57] (2.98 g, 16.5 mmol) in absolute EtOH (15 mL) was added dropwise and the mixture was heated at reflux for 5 h. The solid residue was filtered off, the solvent was evaporated in vacuum and the residue was taken up with diethyl ether, washed with 2 N NaOH and dried (Na$_2$SO$_4$). Removal of the solvent under vacuum gave 3.11 g (85%) of (RS)-59 as a yellow oil: IR (neat): 1737 (C=O) cm$^{-1}$, $^1$H NMR (CDCl$_3$): $\delta$ 1.28 (t, 3H, $J$ = 7.1 Hz, $CH_3CH_2$), 1.53 (d, 3H, $J$ = 6.6 Hz, $CH_3$(CH)), 2.28 (s, 6H, $CH_3$Ar), 4.23 (q, 2H, $J$ = 7.1 Hz, $CH_2$), 4.49 (q, 1H, $J$ = 6.6 Hz, $CH$), 6.86–6.94 (m, 1H, Ar), 6.95–7.03 (m, 2H, Ar); $^{13}$C NMR (CDCl$_3$): $\delta$ 14.4 (1C), 17.2 (2C), 18.7 (1C), 61.3 (1C), 77.1 (1C), 124.2 (1C), 129.3 (2C), 131.1 (2C), 154.8 (1C), 172.3 (1C); GC/MS (70 eV) m/z (%) 222 (M$^+$, 91), 149 (100).

(R)-Methyl 2-(2,6-dimethylphenoxy)propanoate (R)-60. Prepared as reported above for (RS)-8 starting from 2,6-dimethylphenol and ethyl (S)-(–)-lactate [(S)-58]. Yield: 72%; slightly
yellowish oil: $[\alpha]^{20}_D = +40$ (c 2.1, CHCl$_3$). Spectroscopic data were in agreement with the (S)-isomer.

(S)-Methyl 2-(2,6-dimethylphenoxy)propanoate (S)-60. Prepared as reported above for (RS)-8 starting from 2,6-dimethylphenol and methyl (R)-(+)-lactate [(R)-58]. Yield: 37%; slightly yellowish oil: $[\alpha]^{20}_D = –39$ (c 2.1, CHCl$_3$); IR (neat): 1759 (C=O) cm$^{-1}$; $^1$H NMR (CDCl$_3$): $\delta$ 1.53 (d, $J = 6.9$ Hz, 3H, $CH_3CH$), 2.27 (s, 6H, $CH_3Ar$), 3.78 (s, 3H, $CH_3O$), 4.51 (q, $J = 6.9$ Hz, 1H, $CH$), 6.88–7.04 (m, 3H, Ar); $^{13}$C NMR (CDCl$_3$): $\delta$ 17.2 (2C), 18.7 (1C), 52.3 (1C), 77.0 (1C), 124.2 (1C), 129.3 (2C), 131.1 (2C), 154.7 (1C), 172.7 (1C); GC-MS (70 eV) m/z (%) 208 (M$^+$, 1), 122 (100).

(RS)-2-(2,6-Dimethylphenoxy)propan-1-ol (RS)-61. To a suspension of LiAlH$_4$ (1.28 g, 33.7 mmol) in dry THF (60 mL), a solution of (RS)-59 (3.74 g, 16.9 mmol) in dry THF (60 mL) under N$_2$ atmosphere was added. The mixture was stirred under moderate reflux for 1 h and then at room temperature for 24 h. The reaction was quenched by the careful addition of cold water until the end of gas evolution. The residue was removed by filtration and the filtrate shaken with H$_2$O. The aqueous phase was extracted several times with Et$_2$O. The combined extracts were dried over Na$_2$SO$_4$ and the filtrate was concentrated under vacuum. Purification by flash chromatography (EtOAc/petroleum ether 1:9) gave 1.85 g (61%) of (RS)-61 as a colorless oil: IR (neat): 3416 (OH) cm$^{-1}$; $^1$H NMR (CDCl$_3$): $\delta$ 1.17 (d, $J = 6.3$ Hz, 3H, $CH_3CH$), 2.28 (s, 7H, $CH_3Ar + OH$), 3.68–3.84 (m, 2H, $CH_2$), 4.18–4.30 (m, 1H, CH), 6.87–6.95 (m, 1H, Ar), 7.01 (d, $J = 3.8$ Hz, 2H, Ar); $^{13}$C NMR (CDCl$_3$): $\delta$ 16.4 (1C), 17.4 (2C), 67.1 (1C), 78.1 (1C), 123.8 (1C), 129.3 (2C), 131.4 (2C), 154.0 (1C); GC/MS (70 eV) m/z (%) 180 (M$^+$, 37), 122 (100).
(S)-2-(2,6-Dimethylphenoxy)propan-1-ol (S)-61. Prepared as reported above for (RS)-61 starting from (S)-60. Yield: 66%; colorless oil: $[\alpha]_{D}^{20} = +9.0$ (c 2.1, CHCl$_3$); IR (neat): 3401 (OH) cm$^{-1}$; $^1$H NMR (CDCl$_3$): $\delta$ 1.17 (d, $J$ = 6.3 Hz, 3H, CH$_3$CH), 2.21 (br s overlapping s at 2.28 ppm, exch. D$_2$O, 1H, OH), 2.28 (s overlapping br s at 2.21 ppm, 6H, CH$_3$Ar), 3.68–3.84 (m, 2H, CH$_2$), 4.18–4.29 (m, 1H, CH), 6.88–6.96 (m, 1H, Ar), 6.97–7.05 (m, 2H, Ar); $^{13}$C NMR (CDCl$_3$): $\delta$ 16.4 (2C), 17.4 (1C), 67.1 (1C), 78.0 (1C), 123.8 (1C), 129.3 (2C), 131.4 (2C), 154.0 (1C); GC/MS (70 eV) m/z (%) 180 (M$^+$, 26), 122 (100).

(R)-2-(2,6-Dimethylphenoxy)propan-1-ol (R)-61. Prepared as reported above for (RS)-61 starting from (R)-60. Yield: 62%; colorless oil: $[\alpha]_{D}^{20} = –9.1$ (c 2.1, CHCl$_3$). Spectroscopic data were in agreement with the (S)-isomer.

2-[[2'-(1-Trimethylstannyl)-1H-tetrazol-5-yl)biphenyl-4-yl]methyl]-1H-isoindole-1,3(2H)-dione 62. A solution of compound 18 (1.50 g, 4.44 mmol) in dry toluene (75 mL) and azidotrimethyltin (1.0 g, 4.89 mmol) was kept at 11 0 °C under nitrogen atmosphere for 24 h. The precipitate was filtered off and washed with hot toluene to give compound 62 as a white solid (0.90 mg, 37%): mp > 250 °C; IR (KBr): 1763, 1709 (C=O), 550 (Sn –N) cm$^{-1}$; $^1$H NMR (DMSO-$_d_6$): $\delta$ 0.32 (br s, 9H, (CH$_3$)$_3$Sn), 4.71 (s, 2H, CH$_2$), 6.98 (d, $J$ = 8.2 Hz, 2H, Ar), 7.16 (d, $J$ = 9.3 Hz, 2H, Ar), 7.35–7.55 (m, 4H, Ar), 7.75–7.95 (m, 4H, Ar); LC-MS m/z (%) 568 [M$^+$ + 23].

4,5,6,7-Tetrachloro-2-(3-hydroxypropyl)-1H-isoindole-1,3(2H)-dione 65. Prepared as reported above for (R)-33, starting from 3-aminopropanol and tetrachlorophthalic anhydride. Yield: 32%; mp 193–194 °C (EtOAc/hexane); IR (KBr): 3319 (OH), 1774, 1707 (C=O) cm$^{-1}$; $^1$H NMR (CDCl$_3$): $\delta$ 1.85–1.92 (m, 2H, CH$_2$CH$_2$CH$_2$), 1.98 (br s, 1H, OH), 3.64 (t, $J$ = 5.8 Hz, 2H,
$\text{CH}_2\text{N}$, 3.86 (t, $J = 6.3$ Hz, 2H, $\text{CH}_2\text{O}$); $^{13}\text{C}$ NMR (CDCl$_3$): $\delta$ 31.1 (1C), 35.7 (1C), 59.5 (1C), 127.7 (2C), 129.9 (2C), 140.4 (2C); 164.2 (2C); GC/MS (70 eV) $m/z$ (%) 343 (M$^+$, 24), 298 (100). Anal. calcd for C$_{11}$H$_{17}$Cl$_4$NO$_3$.H$_2$O %: C, 36.60; H 2.51; N 3.88. Found: C, 36.53; H 2.11; N 3.86.

3-(Phenylsulfanyl)propan-1-ol 67. K$_2$CO$_3$ (0.32 g, 2.32 mmol) was added to a solution of 3-bromopropanol (0.29 g, 2.11 mmol) in dry DMF (30 mL) under N$_2$ atmosphere. The reaction mixture was heated at 130 °C and then a solution of thiophenol (0.26 g, 2.32 mmol) in 20 mL of dry DMF was added dropwise during a period of 3 h. The mixture was stirred at this temperature for 24 h. After evaporation of the solvent, the residue was taken up with EtOAc, washed with 2 N NaOH, and then with brine. The organic phase was dried (Na$_2$SO$_4$) and concentrated under vacuum. The residue was purified by column chromatography on silica gel (EtOAc/petroleum ether 2:8) to give 0.36 g (69 %) of a yellow oil; IR (neat): 3356 (OH) cm$^{-1}$; $^1$H NMR (CDCl$_3$): $\delta$ 1.83–1.92 (m, 3H, $\text{CH}_2\text{C}_\text{H}_2\text{CH}_2$ + O); 3.03 (t, $J = 7.15$ Hz, 2H, $\text{CH}_2\text{SAr}$), 3.75 (t, $J = 6.1$ Hz, 2H, $\text{CH}_2\text{OH}$), 7.14–7.36 (m, 5H, ArS); $^{13}\text{C}$ NMR (CDCl$_3$): $\delta$ 30.5 (1C), 31.9 (1C), 61.6 (1C), 126.2 (1C), 129.1 (2C), 129.4 (2C), 136.5 (1C); GC/MS (70 eV) $m/z$ (%) 168 (M$^+$, 10), 110 (100).

4.2. Enzymology. The compounds were screened for their activity and their species-specificity against EcTS, EfTS, and hTS. EcTS, and EfTS were purified as described [8]. EfTS [14] was purified following the procedure used for EcTS. Enzyme kinetics experiments were conducted by chromogenic assay under standard conditions [8, 14]. The $K_m$ values, by curve-fitting to hyperbolic curves, of EcTS, EfTS, and hTS for MTHF were, respectively, 5.8 $\mu$M, 13.6 $\mu$M, and 6.9 $\mu$M. These data represent the mean of triplicate measurements; in a typical study, the
standard deviation of the data fell within ± 20% of the mean. The apparent inhibition constant ($K_{i,\text{app}}$, simply defined as $K_i$ within the text) values were obtained from the linear least-squares fit of the residual activity as a function of inhibitor concentration, assuming a competitive inhibition [8]. In the inhibition assays, the reaction mixture was the same as in the TS standard assay. Stock solutions of each inhibitor were freshly prepared in dimethyl sulfoxide (DMSO) and stored at −80 °C. In the reaction mixture, the concentration of DMSO never exceeded 5%. Each experiment was repeated at least three times and an individual measurement did not differ more than 20% from the mean.

4.3. Crystallization. Crystallization trials for $E/TS$ were performed using the vapor diffusion sitting drop method [56] at 297 K. Crystal Screen, Crystal Screen II and Greed Screen Ammonium Sulfate from Hampton Research were used for screening crystallization conditions. Drops consisting of 2 µL precipitant and 1 µL $E/TS$ solution (7.8 mg/mL in 25 mM KH$_2$PO$_4$/K$_2$HPO$_4$, pH 6.8, 40 mM dUMP, 1 mM EDTA) were equilibrated against 100 µL reservoir solution. After one month crystals were observed into a drop containing 3.2 M ammonium sulfate and 0.1 M HEPES buffer, pH 7.0 as precipitant solution. These crystals were ill-formed and provided a poor diffraction pattern when exposed to X-ray radiation, therefore we tried to improve the crystal ordering/quality by applying seeding techniques [56]. The crystals obtained were crushed and seeding solutions were prepared by dilution with the successful precipitant solution (3.2 M ammonium sulfate and 0.1 M HEPES buffer, pH 7.0). 4 µL drops of a 2.5 mg/mL $E/TS$ solution (buffer 25 mM KH$_2$PO$_4$/K$_2$HPO$_4$, pH 6.8, 40 mM dUMP, 1 mM EDTA) were mixed with 2 µL of a precipitant solution containing 2.7 M ammonium sulfate and 0.1 M HEPES buffer, pH 7.0. Streak-seeding has been performed at different dilution of the seeding solution. Drops were allowed to equilibrate at room temperature over 0.6 mL precipitant.
solution in the well. Crystals suitable for diffraction appeared in 2-3 weeks into the drops in which a seeding solution diluted 1:100 was applied. Co-crystallization trials were performed also for the complexes Ef/TS- inhibitor using the same precipitant solution identified in the previous screen for the enzyme (3.2 M ammonium sulfate and 0.1 M HEPES buffer, pH 7.0). Trials of co-crystallization were performed at 297 K using both the microbatch-under-oil crystallization technique [57,58] with a 1:1 mixture of paraffin and silicon oil (Hampton Research) as well as the sitting-drop vapor-diffusion method. Because of the low solubility in water, concentrated solutions of each inhibitor were prepared in DMSO. A 4 mM solution of each inhibitor in DMSO has been added in a 1:10 volume ratio to a 6.5mg/mL Ef/TS solution (buffer 25 mM KH₂PO₄/K₂HPO₄ pH 6.8, 40mM dUMP, 1 mM EDTA). Drops have been prepared by mixing 2 µL of the Ef/TS-inhibitor solution with 1 µL of a precipitant solution containing 3.2 M ammonium sulfate and 0.1 M HEPES buffer, pH 7.0. Crystals of Ef/TS complexes with the library molecules have been finally obtained using the microbatch-under-oil crystallization technique. As it can be appreciated from the above description, the crystallization screen has been extremely difficult and was a cumbersome process, rich of failures. Under the microscope, all the crystals obtained presented defects like cracks and lines indicating internal disorder. Before data collection, crystals were transferred to a cryoprotectant solution containing 20% ethylene glycol and 80% precipitant solution (2.7 M ammonium sulfate and 0.1 M HEPES pH 7.0) and then flash frozen in liquid nitrogen.

4.4. Structure solution and refinement. About 70 crystals were screened for diffraction at the ESRF (European Synchrotron Radiation Facilities) beamline ID29-1. The data collection demonstrated that all crystals were characterized by severe splitting and suffered from radiation damage, with the diffraction pattern decaying after about 100 seconds of exposure to X-rays
(0.5° oscillation images). Finally, we were able to obtain usable datasets referring to \((R)-2\), \((S)-12\), 14 and MTX complexes. However, all of them were complete to a maximum of about 75-80 %, but the missing data were randomly distributed in reciprocal space without jeopardizing the quality of the electron density maps [46]. Intensities were integrated using the program Mosflm [59] and scaled with the program Scala [60] or Aimless from the CCP4 Suite [61]. Data collection statistics are reported in Table S2 (see Supplementary Material). All \(E/TS\) crystals belong to space group \(P2_1\) with four \(E/TS\) subunits in the asymmetric unit. The structures were solved by molecular replacement technique as implemented in the software MolRep [62] from the CCP4 Suite [61] using the crystal structure of \textit{Lactobacillus casei} TS as model (PDB: 2TDM; 73 % sequence homology). Because of the structural flexibility that characterize some domains of TS enzymes the \textit{Lc}TS loop 82-144 was removed from the model. Molrep provided the correct solution that consists of a couple of \(E/TS\) homodimers in the crystal asymmetric unit (A-B and C-D). The \(E/TS\) molecule was manually rebuilt in the electron density maps. The whole polypeptide chain could be completely reconstructed in only in the subunits were the inhibitor was bound. The unbound subunits presented disorder in the regions corresponding to residues 81-132 that were not clearly visible in the electron density maps and could be only partially built. The Fourier difference maps showed electron density interpretable with the presence of the inhibitor only for \(E/TS\)-(S)-12, and \(E/TS\)-MTX complexes. The final models were refined using the program Refmac5 [63] from the CCP4 Suite. Water molecules have been added using the program ArpWARP [64] and checked manually. The diffraction pattern of the crystals presented split reflections due to the lattice disordering as described above. This resulted in medium quality indicators of the refinement as shown in Table S2 (see Supplementary Material). Nevertheless, the electron density maps were quite well defined and...
could be confidently interpreted, as can be judged from the reported figures. The stereochemical quality of the final model was checked using the programs PROCHECK [65] and COOT [66]. The program COOT was also used for molecular modeling and to superimpose structures. Structural models were rendered using CCP4MG [67]. Atomic coordinates and structure factors for $E/TS-(S)-12$, and $E/TS$-MTX complexes have been deposited in the Protein Data Bank (PDB), www.rcsb.org, under the accession codes 4O7U and 5J7W, respectively.
Figure Legends

Figure 1. Chemical structure of TS inhibitors and the prodrug 5FU.

Figure 2. Inhibitory activity of compounds 1-56 against *Ef*TS, hTS and *Ec*TS. The compound activity is given as % of inhibition at 100 µM. Color code: dark green (values between 100 and 35), light green (values between 34 and 10), yellow (values lower than 10), red (no detectable inhibition at 100 µM) and light blue (not tested). MTX is the reference compound. \( K_{i,EfTS} = 13 \) µM.

Figure 3. *Ef*TS x-ray crystallographic structure. (A) The *Ef*TS crystal asymmetric unit content. The two subunits of each heterodimer differ in the conformation of the small domain due to the presence of a ligand bound to the active site cavities. The subunit having a ligand bound are in closed conformation, while the unbound subunits are on open conformation. (B) comparison of closed and open conformations by superimposing subunit A (open; light blue ribbon) and B (closed; gold ribbon) of 4O7U. The 5-HMHF molecule is represented to show the position of the active site cavity.

Figure 4. Detailed view of the binding ligands. (A) Stick representation of the (S)-12 inhibitor (yellow) bound to *Ef*TS with superimposed the 2Fo-Fc electron density map at 1.3 σ (blue wire), computed with refined phases and the omit map (green wire) contoured at 3.0 σ. Cys197 is also shown as sticks together with other relevant residues in the active site cavity. (B) Stick representation of 5-HMHF (yellow) bound to *Ef*TS with superimposed the 2Fo-Fc electron density map at 1.3 σ (blue wire), computed with refined phases and the omit map (green wire) contoured at 3.0 σ. Cys197 is also shown as sticks together with other relevant residues in the active site cavity.
density map at 1.3 $\sigma$ (blue wire), computed with refined phases and the omit map (green wire) contoured at 3.0 $\sigma$. Cys197 is also shown as sticks together with other relevant residues in the active site cavity. Notice the different extent of the omit map in the PABA moiety of 5-HMHF with respect to the same region in Figure 4A.

**Figure 5.** The binding of MTX to $\text{EfTS}$. (A) Stick representation of the MTX inhibitor (yellow) bound to $\text{EfTS}$ with superimposed the 2Fo-Fc electron density map at 1.3 $\sigma$ (blue wire), computed with refined phases and the omit map (green wire) contoured at 3.0 $\sigma$. Cys197 is also shown as sticks together with other relevant residues in the active site cavity. (B) Least-squares superimposition of MTX (green sticks) and (S)-12 (yellow sticks) bound to $\text{EfTS}$. Notice the similarity of the pose.
