1 Abstract

2 Lactobacilli contain different cell envelope proteinases (CEPs) responsible for the hydrolysis of caseins and the release of various bioactive peptides. In this work, we explored the 3 4 CEP activity of Lactobacillus casei PRA205 and Lactobacillus rhamnosus PRA331 whole cells 5 towards β -, α S1-, κ - and α S2-case ins in bovine milk. Mass spectrometry analysis of fermented milk hydrolysates identified a total of 331 peptides, which were mainly derived from β -caseins (59.0 and 6 7 60.1% for PRA205 and PRA331, respectively). The analysis of αS1-casein (f1-23) cleavage site specificity congruently supports that Lb. casei PRA205 and Lb. rhamnosus PRA331 exhibited a 8 mixed-type CEP_{1/III} activity. PRA205 and PRA331 CEPs also showed cleavage site specificity 9 toward β -case in, preferentially. These CEPs cleaved the peptide bond preferentially when 10 hydrophobic or negatively charged amino acids were present. 13.5% and 13.7% of peptides released 11 12 by Lb. casei PRA205 and Lb. rhamnosus PRA331 CEPs were found to have 100% homology with 13 previously identified bioactive peptides.

14 1. Introduction

Food intake with the goal of improving human health is an ongoing focus for research. 15 Recommendations for the consumption of certain nutritious fermented foods date back to the 16 Hippocratic Corpus of Ancient Greece. The idea that lactic acid bacteria (LAB) fermenting milk are 17 responsible for enhancing health and delaying the human aging was first proposed by the Russian 18 scientist Elie Metchnikoff more than a century ago (Mackowiak, 2013). In the past years, research 19 has documented a wide range of health benefits exerted by dairy LAB, especially immune and 20 metabolic ones, and it is now focusing to decipher the microbial mechanisms underpinning these 21 health-promoting effects (Reid, 2015). 22

Some beneficial effects exerted by LAB are due to the generation of secondary metabolites 23 with health-promoting properties. The most important biogenic compounds in fermented milk are 24 25 the bioactive peptides released from caseins via the LAB proteolytic system. Biological activities 26 associated with such peptides include immunomodulatory, antibacterial, anti-hypertensive, antioxidant, mineral binding, and opioid-like properties (Brown et al., 2017). In addition, dairy 27 28 LAB are auxotrophic for many amino acids and efficient casein breakdown is crucial to make LAB 29 competitive as dairy starters (S-LAB), as well as suitable to survive in ripened cheeses as nonstarter LAB (NS-LAB) (Kunji, Mierau, Hagting, Poolman, & Konings, 1996). The amino acid 30 release also contributes to the aroma compound formation during cheese ripening and impacts 31 sensorial properties and consumer's acceptance of dairy foods (McSweeney & Sousa, 2000). 32

Cell envelope proteinases (CEPs) are large multi-domain proteins anchored to the cell wall that catalyse the first step of hydrolysis of milk caseins into peptides. Different transport systems then internalize these peptides into the cell, where they are further hydrolysed by numerous intracellular peptidases (Savijoki, Ingmer, & Varmanen, 2006). Six different types of CEPs have been described in several LAB species: PrtB from *Lactobacillus delbrueckii* subsp. *bulgaricus* (Laloi, Atlan, Blanc, Gilbert, & Portalier, 1991); PrtH from *Lactobacillus helveticus* (Genay, Sadat, Gagnaire & Lortal, 2009); PrtL from *Lactobacillus delbrueckii* subsp. *lactis* (Villegas, Brown,

3

40	Savoy de Giori, & Hebert, 2015); PrtP from Lactococcus lactis (Kok, Leenhouts, Haandrikman,
41	Ledeboer, & Venema, 1988), Lactobacillus paracasei (Holck & Naes, 1992), Lactobacillus casei
42	(Fernández de Palencia, Peláez, Romero, & Martín-Hernández, 1997; Kojic, Fira, Banina, &
43	Topisirovic, 1991), Lactobacillus rhamnosus (Guo et al., 2016) and Lactobacillus plantarum
44	(Strahinic, Kojic, Tolinacki, Fira, & Topisirovic 2010); PrtR from Lactobacillus rhamnosus (Pastar
45	et al., 2003); and PrtS from Streptococcus thermophilus (Siezen, 1999). These proteinases vary in
46	substrate specificity, domain composition and cell wall anchoring, but all of them belong to the so-
47	called subtilase family as they contain the catalytic serine protease domain showing sequence
48	homology to the active site of subtilases (Savijoki et al., 2006; Sadat-Mekmene, Genay, Atlan,
49	Lortal, & Gagnaire, 2011a). Most frequently, LAB possess only one CEP, but the presence of two
50	CEPs has been described in lactobacilli (Sadat-Mekmene et al., 2011b).
51	Much of the current knowledge on LAB proteolytic system comes from studies on S-LAB
52	species, such as Lc. lactis, Lb. delbrueckii subsp. bulgaricus and Lb. helveticus and only few works
53	has been done to elucidate the role of NS-LAB. Recently, the NS-LAB species Lb. paracasei, Lb.
54	casei and Lb. rhamnosus were proven to generate bioactive casein-derived peptides during milk
55	fermentation (Guo et al., 2016; Solieri, Rutella, & Tagliazucchi, 2015). Lb. casei/Lb. paracasei
56	PrtP-encoded CEP was also demonstrated to degrade pro-inflammatory chemokines associated to
57	inflammatory bowel diseases (Hormannsperger, von Schillde, & Haller, 2013). Consequently, there
58	is an increasing interest to study NS-LAB proteases responsible for the release of bioactive peptides
59	(Lozo et al., 2011).
60	In our previous work, we demonstrated that two mesophilic NS-LAB strains isolated from
61	Parmigiano Reggiano ripened cheese, namely Lb. casei PRA205 and Lb. rhamnosus PRA331,

62 exhibit safety and technological performance compatible with probiotic properties (Solieri, Bianchi,

63 Mottolese, Lemmetti, & Giudici, 2014). They also release the angiotensin-I-converting enzyme

64 (ACE)-inhibiting peptides Valine-Proline-Proline (VPP) and Isoleucine-Proline-Proline (IPP) from

65 caseins at doses that may exert antihypertensive effects *in vivo* (Solieri et al., 2015). Despite these

multiple interesting properties, the activity and specificity of CEPs from strains PRA205 and
PRA331 remain unknown, as well as their potential to release additional milk-derived peptides
other than VPP and IPP. The aim of this work was to fill this gap and to evaluate the pattern of
casein breakdown by PRA205 and PRA331 whole cells CEP activities through a peptidomic
approach.

71 **2.** Materials and Methods

72 2.1 Microorganisms, media and growth conditions

Lactobacillus casei PRA205 and *Lb. rhamnosus* PRA331 were isolated from ripened
 Parmigiano Reggiano cheese (Solieri, Bianchi, & Giudici, 2012) and deposited in Unimore
 Microbial Culture Collection (www.umcc.unimore.it) for long-term preservation. The cultures were
 activated from their frozen forms (stored in MRS medium supplemented with 25% (v/v) glycerol at
 -80°C) by transferring them in MRS broth and incubating at 37°C for 24h under anaerobic
 conditions. After two rounds of growth on the same medium, strains were routinely maintained on
 MRS medium supplemented with 7% (w/v) agar at 4°C for the duration of the experiments.

80 2.2 Inoculum preparation and milk fermentation

Milk fermentation trials were carried out in triplicate as follows. Single-colony cultures were 81 inoculated in MRS broth for 24h at 37°C. Cells were washed twice with 50 mmol L⁻¹ Tris-HCl 82 buffer (pH 6.5), re-suspended in 10% (w/w) skimmed milk and used as pre-cultures (2% v/v) to 83 inoculate milk batches prepared with 50 mL of ultra-high temperature-treated (UHT) skimmed 84 85 bovine milk. Fermentation was carried out for 72h at 37°C at 10 rpm. pH values were determined over time as previously reported (Solieri et al., 2015). At the end of the fermentation (pH values \leq 86 87 4.0 for at least two consecutive measurements), samples were taken to estimate milk protein hydrolysis, ACE-inhibitory and radical scavenging activities as reported in section 2.4. 88

89 2.3 Cell viability assay

90	PRA205 and PRA331 cells were harvested by centrifugation after 24, 48 and 72h of milk
91	fermentation, twice washed with physiological solution (9 g L ⁻¹ NaCl) and re-suspended at the final
92	concentration of 10^7 CFU mL ⁻¹ , according to the correlation curves between OD _{600nm} and CFU
93	values previously established for every strain (Rutella, Tagliazucchi, & Solieri, 2016). Bacterial
94	suspensions were stained with LIVE/DEAD BacLight Bacterial Viability Kit (Invitrogen) and
95	live/dead cell ratio was measured according to manufacture instructions. Fluorescence intensity was
96	measured with a Jasco FP-6200 spectrofluorometer (Jasco, Orlando FL, U.S.A.).
97	2.4 Determination of milk protein hydrolysis, radical scavenging and angiotensin I-converting
98	enzyme (ACE)-inhibitory activities
99	Milk protein hydrolysis and radical scavenging activity were determined on the TCA-
100	soluble supernatants (peptidic fractions) obtained by treating fermented milk with 1% (w/v) TCA
101	followed by a centrifugation at 10,000g for 20 min (4°C). In particular, milk protein hydrolysis was
102	determined by measuring the amounts of released amino groups using the 2,4,6-
103	trinitrobenzenesulfonic acid (TNBS) assay (Adler-Nissen, 1979). Briefly, 50 µL of appropriately
104	diluted peptidic fractions were mixed with 400 μ L of sodium phosphate buffer (0.1 mmol L ⁻¹ ; pH

105-8.2) and $400\,\mu L$ of 0.1% TNBS solution (prepared in the same sodium phosphate buffer). After 60

106 min of incubation at 50°C, the reactions were stopped by adding 800 μ L of HCl 0.1 mmol L⁻¹. The

absorbance values at 340 nm were read using a Jasco V-550 UV/Vis spectrophotometer (Jasco,

108 Orlando, FL, USA.). A calibration curve was prepared using leucine as standard (range 0.1-2.0

109 mmol L^{-1}) and the results were expressed as mmol L-1 of leucine equivalents.

The antioxidant activity of the peptidic fractions was measured as radical scavenging
activity using the ABTS radical cation decolourization assay (Re et al., 1999) and expressed as mg
L⁻¹ of Trolox.

6

- ACE-inhibitory (ACEi) activity was determined according to Ronca-Testoni (1983) on the
 ultra-filtrated fraction obtained from fermented milk as previously reported (Solieri et al., 2015).
 The tripeptide 2-furanacryloyl–phenylalanylglycylglycine (FAPGG) was used as substrate assay
- and the ACEi activity was calculated as percent of inhibition (ACEi%).
- 117 Three analytical replicates were run for each sample collected at the end of each
- 118 fermentation trial (carried out in triplicate) in all the assays.

119 2.5 Determination of peptides with nanoflow LC-ESI-QTOF MS analysis

Peptidomic analysis was performed by injecting the TCA-soluble supernatant of fermented 120 milk on a 1200 Series Liquid Chromatographic two-dimensional system coupled to a 6520 121 Accurate-Mass QTOF LC/MS via a Chip Cube Interface (Agilent Technologies, Santa Clara, CA, 122 123 USA) as described in Tagliazucchi, Helal, Verzelloni, Bellesia, & Conte (2016). Chromatographic separation was performed on a ProtID-Chip-43(II) including a 4 mm 40 nL enrichment column and 124 a 43 mm \times 75 µm analytical column, both packed with a Zorbax 300SB 5 µm C18 phase (Agilent 125 126 Technologies). The mobile phase consisted of (A) $H_2O/acetonitrile/formic acid (96.9:3:0.1, v/v/v)$ and (B) acetonitrile/H₂O/formic acid (94.9:5:0.1, v/v/v). The sample (2 μ L) was loaded onto the 127 Chip enrichment column at a flow rate of 4 μ L min⁻¹ with a mobile phase consisting of 100% A 128 using a G1376A capillary pump. A flush volume of 2 μ L and a flush-out factor of 5 were used. 129 After valve switching, a gradient elution was performed throughout the enrichment and analytical 130 columns at 500 nL min⁻¹ using a G2226A nano pump. The gradient started at 0% B for 1 min, and 131 then linearly ramped up to 90% B in 70 min. The mobile phase composition was maintained at 90% 132 B for 15 min in order to wash both enrichment and analytical columns. The mass spectrometer was 133 134 tuned and calibrated according to the manufacturer's instructions in extended dynamic range (2 GHz) mode as reported by Dei Più et al. (2014). 135

For peptide identification, MS/MS spectra were converted to .mgf files and were then
searched against the Swiss-Prot database using Protein Prospector (<u>http://prospector.ucsf.edu</u>) and

MASCOT (Matrix Science, Boston, MA, USA) protein identification softwares. The following 138 parameters were considered: enzyme, none; peptide mass tolerance, ± 40 ppm; fragment mass 139 tolerance, ± 0.12 Da; variable modification, oxidation (M) and phosphorylation (ST); maximal 140 number of post-translational modifications permitted in a single peptide, 4. We considered only 141 peptides with a best expected value lower than 0.05 that corresponded to P < 0.01. The assignment 142 process was complemented and validated by the manual inspection of MS/MS spectra. Three 143 replicates for each fermentation trial was injected in the mass spectrometer and only the peptides 144 present in at least two replicates were considered significant and included in the analysis. 145

146 2.6 Identification of bioactive peptides

The identified peptides in milk samples were investigated for literature-identified bioactive peptides 147 using the BIOPEP database and the Milk Bioactive Peptide Database (MBPDB) (Minkiewicz, 148 Dziuba, Iwaniak, Dziuba, & Darewicz, 2008; Nielsen, Beverly, Qu, & Dallas, 2017). Only peptides 149 with 100% homology to known functional peptides were considered as bioactive peptides. 150 151 The relative amount of the bioactive peptides was estimated by integrating the area under the peak (AUP). AUP was measured from the extracted ion chromatograms (EIC) obtained for each peptide 152 and normalized to the peptide content of milk hydrolysates. The peptide content was determined at 153 the end of the fermentation trials by using the TNBS method as described in section 2.4 and 154

expressing the results as mg of leucine equivalent mL^{-1}

156

157 2.7 Calculation of the cleavage specificity

.

158 The cleavage probability and positive or negative influence on the cleavage of an amino acid159 in the P1 and P1' subsites were calculated according to Keyl (1992).

160 The subsite nomenclature was according to Schechter & Berger (1967) where the amino 161 acid residues are designated as P1 in the N-terminal direction (on left of the sequence) and Pl' in the 162 C-terminal direction (on right of the sequence) from the cleaved bond. The subsite P1 interacts with the subsite S1 in the enzyme active site, whereas the subsite P1' interact with the subsite S1' in the enzyme active site. Therefore, the peptidic bond cleaved by the protease was defined as the P1-P1' bond. We quantitatively analysed the influence of specific amino acid residues in position P1 or P1'on the CEP cleavage probability.

167 If the amino acid residue *A* is in the position *n* (P1 or P1' subsite), the cleavage probability168 of the P1–P1' bond will be:

169

172
$$\%Pn = \frac{\text{total amino acid A cleaved in position } n}{\text{total amino acid A in proteins}} \times 100$$

170

and in consequence the mean cleavage probability:

174
$$\%\overline{Pn} = \sum_{\#=1}^{20} \frac{\%Pn}{20}$$

173

The coefficient *Kn* was used to quantify the positive or negative influence of an amino acidresidue *A* in the P1 and P1' subsites:

$$Kn = \frac{\% Pn}{\% \overline{Pn}} - 1$$

178 Kn values >0 indicated a positive influence of the amino acid A in the specific subsite on the 179 cleavage of the P1-P1' bond, whereas Kn values <0 suggested a negative effect on the cleavage.

180 2.8 Statistical analysis

181 All data are presented as mean \pm standard deviation (SD) for three replicates. The Student's 182 t-test was performed using GraphPad Prism 6.0 (GraphPad Software, San Diego, CA, USA). The 183 differences were considered significant with *P* <0.05. Venn diagrams were drawn using the online 184 tool VENNY 2.1.0 (Oliveros, 2015).

185 3. Results and Discussion

186 *3.1 Characterization of fermented milk*

Analysis of CEP activities on purified caseins could tend to overestimate the true caseinolytic capability of whole cells towards casein micelles in milk (Sadat-Mekmen et al., 2011b). The use of purified CEPs instead whole-cell anchored CEPs may also modify the specificity of the proteinase towards caseins (Fernández de Palencia et al., 1997). Therefore, we decided to evaluate the CEP activities of whole cells of *Lb. casei* PRA205 and *Lb. rhamnosus* PRA331 towards the caseins in UHT milk.

Milk samples were inoculated with standardized amounts of PRA205 and PRA331 single 193 cultures without any pre-adaptation step. After 72h of incubation, pH values were 4.00 in both sets 194 195 of samples and remained stable over time. At the end of fermentation, strain PRA205 showed value of leucine equivalents of 10.93 ± 0.93 mmol L⁻¹, whereas PRA331 of 6.40 ± 0.92 mmol L⁻¹. These 196 data agree with earlier results showing that PRA205 is more proteolytic than PRA331 towards milk 197 198 caseins (Solieri et al., 2015). Lb. casei PRA205 produced milk hydrolysates with ACEi activity higher than that exhibited by milk hydrolysates with *Lb. rhamnosus* PRA331 (75.8 \pm 3.2 vs 68.5 \pm 199 2.6 ACEi%). Similarly, antioxidant activity was slightly higher in hydrolysates by strain PRA205 200 than the hydrolysates by strain PRA331 (249.12 \pm 15.10 vs 202.57 \pm 18.66 mg L⁻¹ of trolox, 201 respectively). 202

The level of bacterial lysis during milk fermentation was monitored to exclude that the peptides could be generated by intracellular peptidases released into the hydrolysates. Cell viability was estimated app. 100% for both PRA205 and PRA331 after 24 and 48h of incubation (data not showed). Interestingly, at the end of milk fermentation the percentage of viable cells was 90.49 \pm 0.74% and 94.59 \pm 5.70% for PRA205 and PRA331, respectively. These data indicated that no significant lysis occurred during milk fermentation and supported that the observed casein proteolysis was mainly due to the action of CEPs anchored on the whole cells rather thanintracellular proteinases or peptidases.

3.2. Peptidomic analysis of milk fermented with Lactobacillus casei PRA205 and Lactobacillus rhamnosus PRA331

Mass spectrometry analysis was used to identify the full set of peptides present in milk hydrolysates by the selected strains. A total of 331 milk peptides were released by the CEPs activities of PRA205 and PRA331 whole cells. In particular, 178 peptides were identified in PRA205 samples (see supplementary online **Tables S1-S4** and **Figures S1-S4**) and 153 peptides in PRA331 samples (see supplementary online **Tables S5-S8** and **Figures S1-S4**).

The analysis of the identified sequences according to their protein of origin showed that the 218 219 main identified peptides were derived from β -casein, which was the preferred substrate over α S1-, κ - and α S2-caseins. The β -casein-derived peptides were 59.0 and 60.1% of the total identified 220 peptides in PRA205 and PRA331 samples, respectively, followed by aS1-casein-derived peptides 221 222 (18.5 and 19.0% of the total identified peptides in PRA205 and PRA331 samples, respectively) and κ -case in-derived peptides (16.3 and 15.0% of the total identified peptides in PRA205 and PRA331 223 samples, respectively). PRA205 and PRA331 CEPs poorly hydrolysed aS2-casein, resulting in only 224 11 (corresponding to the 6.2% of total identified peptides) and 8 peptides (corresponding to the 225 5.9% of total identified peptides), respectively. As expected, no significant proteolysis of whey 226 227 proteins was observed for both the strains. The Venn diagram (Figure 1) showed that 24.6 and 14.0% of peptides were specific for PRA205 and PRA331 milk hydrolysates, respectively. The 228 229 majority of the identified peptides were found in both the milk hydrolysates, suggesting that 230 PRA205 and PRA331 share a similar caseinolytic pattern.

CEPs are classified on the basis on their caseinolytic specificity (Kunji et al. 1996).
Typically, two CEPs have been identified: a P_I-type, which preferentially hydrolyses β-casein, and a
P_{III}-type, which acts on αS1-, β- and κ –caseins equally well (Pritchard & Coolbear, 1993; Visser,

11

Exterkate, Slangen & de Veer 1986). A third group, termed P_I/P_{III}-type has been described to 234 235 classify intermediate proteases, capable to cleave β -case in like the P_I-type and, to a lesser extent, α and k-caseins (Exterkate, Alting, & Bruinenberg, 1993). Both Lb. casei PRA205 and Lb. rhamnosus 236 237 PRA331 exhibited a predominant CEP activity towards β -casein, and a lower proteolytic activity towards α - and κ -case ins. Cell viability data allowed us to exclude that intracellular aminopeptidase 238 released by lysed cells may significantly contribute to this pattern of casein breakdown. 239 Furthermore, no extracellular aminopeptidases have been reported for Lb. casei and Lb. rhamnosus 240 (Christensen, Dudley, Pederson, & Steele, 1999). Overall, these evidences support that the observed 241 CEP activities could be due to the mixed P_I/P_{III}-type proteases. P_I/P_{III}-type proteases have been 242 243 characterized in lactobacilli (Fernandez de Palencia et al., 1997; Sadat-Mekmene et al., 2011a Villegas et al., 2015) and lactococci (Nikolić, Tolinački, Fira, Golić, & Topisirović, 2009). In 244 particular, like PRA331, Lb. rhamnosus BGT10 has PrtR protease suitable to cleave both β- and α-245 caseins. 246

247 3.3. Analysis of the α S1-casein (f1-23) cleavage sites

CEPs are commonly classified according to their specificities toward the αS1-casein fragment 248 comprising residues from 1 to 23 (Exterkate, 1995). In strains PRA205 and PRA331, CEPs 249 250 hydrolysed the α S1-casein (f1-23) fragment at the H₈-Q₉, Q₉-G₁₀, Q₁₃-E₁₄, N₁₇-E₁₈ and L₂₁-R₂₂ 251 positions, respectively (Figure 2). In addition, PRA331 also cleaved at the L₁₆-N₁₇ position. The majority of these cleavage sites are typical of mixed P_1/P_{III} -type CEPs isolated from several 252 lactococci, S. thermophilus CNRZ 385, Lb. delbrueckii subsp. lactis CRL 581 and Lb. helveticus 253 254 L89 (Exterkate, 1995; Fernandez-Espla, Garault, Monnet, & Rul, 2000; Hebert et al., 2008; Kunji et al., 1996). Two additional cleavage sites were found at the P₂-K₃ and E₁₈-N₁₉ positions. The 255 cleavage site E₁₈-N₁₉ has been already reported for the CEP of *Lb. delbrueckii* subsp. *lactis* CRL 256 581 (Hebert et al., 2008), whereas the cleavage site P₂-K₃ has never been identified in any CEPs 257 previously described from lactobacilli. These results collectively suggested that CEPs from *Lb*. 258

12

casei PRA205 and Lb. rhamnosus PRA331 could belong to the mixed P_I/P_{III}-type. This result 259 260 disagrees with the P₁-type CEP previously characterized in *Lb. casei* HN14 (Kojic et al., 1991), while it is consistent with the mixed P_I/P_{III} type CEPs isolated from Lb. rhamnosus CGMCC11055 261 and Lb. casei subsp. casei IFLP 731 (Guo et al., 2016; Fernández de Palencia et al., 1997). Overall, 262 these evidences strongly support the high level of intra- and inter-species variability in protease 263 repertoire exhibited by lactobacilli (Liu, Bayjanov, Renckens, Nauta, & Siezen, 2010). As reported 264 above, the cell viability near to 100% measured at the end of the fermentation trials allowed us to 265 exclude that intracellular peptidase released from lysed cells may contribute to the hydrolysis of the 266 fragment aS1-casein (f1-23). Indeed, as reported by Christensen, Broadbent, & Steele (2003), the 267 268 presence of cytoplasmic peptidase should results in an almost complete breakdown of the peptide αS1-casein (f1-9). 269

270

271 3.4. Analysis of the β -case in cleavage site-specificity

The cleavage site-specificity of PRA205 and PRA331 CEPs was determined using β -casein as preferred substrate (**Figure 3**). In total, 76 and 72 different cleavage sites were detected in samples hydrolysed by PRA205 and PRA331 whole cells, respectively. They constitute 36.5 and 34.6% of all peptide bonds present in β -casein, showing that *Lb. casei* PRA205 and *Lb. rhamnosus* PRA331 CEPs have a very broad substrate specificity. These CEPs have almost the same specificity, as they shared 65% of cleavage sites.

Amino acid sequence analysis of the identified peptides revealed that the cleavage sites were not concentrated at the N- or C-terminus, but rather distributed throughout the entire β -casein sequence for both the CEPs activities (**Figure 3**). Most of the proteinases previously described in lactobacilli have been proven to preferentially hydrolyse the C-terminal of β -casein (Lozo et al.,

- 282 2011). Recently, the PrtP proteinase isolated from *Lb. rhamnosus* CGMCC11055 breakdowns sites
- 283 distributed along the whole β -case sequence, like PRA205 and PRA331 CEPs (Guo et al., 2016).

Furthermore, we calculated the cleavage probability (%Pn) of the Lb. casei PRA205 CEP at 284 285 the P1 and P1' positions (Table 1). This CEP cleaved preferentially when the P1 position was occupied by the hydrophobic amino acids M, L and F or the negatively charged amino acids Q and 286 N primarily, and by the polar un-charged amino acid E to a lesser extent. **Table 1** also shows how 287 the amino acids at the P1' position affected cleavage occurrence. PRA205 CEP exhibited cleavage 288 preference towards the residues S, N, A and H in this position, whereas had a reduced preference 289 for M, D, R and Y. Coefficients Kn were calculated to quantify the influence of different amino acid 290 291 residues on the P1-P1'cleavage probabilities (Figure 4). Amino acids N, M, Q, F and L in the P1 position and amino acids S, N, A and H in the P1' position exerted the strongest positive effects on 292 293 cleavage occurrence. The amino acids E in P1 position and V, M, D, R and Y in P1' position also exerted a positive but weaker effect on cleavage probability. By contrast, G, I, P and D in the P1 294 position and P and I in the P1' position strongly inhibited the cleavage probability. Similarly, a 295 296 negative effect was also found for the amino acids E and T at the P1' position. Previous works found that CEPs preferentially cleave negatively charged and hydrophobic amino acids (Hebert et 297 298 al., 2008; Juillard et al., 1995; Lozo et al., 2011; Monnet, Ley, & Gonzalez, 1992). For instance, Q 299 and E at the P1 position positively affect the cleavage by CEP from *Lb. delbrueckii* subsp. *lactis* CRL 581 (Hebert et al., 2008), whereas the occurrence of Q and F at the same position positively 300 affects the cleavage by CEPs from Lb. rhamnosus BGT10, Lb. helveticus BGRA43 and Lb. 301 paracasei subsp. paracasei BGHN14 (Lozo et al., 2011). In Lb. casei PRA205 CEP exhibited a 302 303 pattern of cleavage site preferences similar to P_I/P_{III}-type CEP described in *Lc. lactis* subsp. *lactis* strain NCDO763 (Monnet, Ley, & Gonzalez, 1992), but different from those described for the PI-304 305 type CEP in Lc. lactis subsp. cremoris strain Wg2 and for the P_I/P_{III}-type CEP in Lb. rhamnosus strain CGMCC11055. In strain Wg2 the residue Y at the P1 position and the residues N and T at the 306 307 P1' position were preferred (Juillard et al., 1995), whereas in strain CGMCC11055 the residue P was preferred in both P1 and P1' subsites (Guo et al., 2016). By contrast, strain NCDO763 had a 308 309 CEP activity positively affected by Q and N at the P1 position, and by S and A at the P1' position

(Monnet et al., 1992). Additionally, the residue P in both the P1 and P1' positons negatively 310 affected CEP cleavage in NCDO763 (Monnet et al., 1992). Similarly, the presence of a P residue 311 bound to one of the preferred cleaved amino acids prevented CEP from Lb. casei PRA205 to cut the 312 peptidic bond. For example, the preferentially cleaved amino acids O and L formed seven and nine 313 peptidic bonds with the amino acid P, respectively, but no one of these bonds was cleaved by 314 PRA205 CEP (Figure 3). Finally, PRA205 CEP activity displayed the following two unique 315 properties: M at the P1 position exerted a strong positive effect on cleavage occurrence, whereas I 316 in both the P1 and P1' positions exerted a strong negative effect. To the best of our knowledge, this 317 cleavage site-specificity pattern has never been described in lactobacilli. 318

As reported in **Table 1** and **Figure 4**, CEP from *Lb. rhamnosus* PRA331 had a profile of cleavage specificity similar to *Lb. casei* PRA205. The main differences were the negative effect exerted by the amino acid H at the P1 position and the lack of the positive effect exerted by A at the P1' position.

323 *3.5. Identification of bioactive peptides using functional peptides databases*

The peptides cleaved by PRA205 and PRA331 CEPs in milk hydrolysates were searched against 324 the general bioactive peptide database BIOPEP (Minkiewicz et al., 2008) and the milk bioactive 325 peptide database MBPDB (Nielsen et al., 2017), in order to find peptides which match sequences to 326 known bioactive peptides. Out of 331 identified peptides, 24 shared 100% homologies with 327 functional peptides previously reported to have various bioactivities (Table 2). These bioactive 328 peptides represented 13.5% and 13.7% of the peptides totally released by Lb. casei PRA205 and Lb. 329 rhamnosus PRA331 whole cells, respectively. Twenty-one peptides were commonly released by 330 331 both the strains, whereas three peptides were uniquely identified in samples hydrolysed by Lb. casei PRA205 (Figure 1). Nineteen bioactive peptides derived from β -casein, four from α S1-casein and 332 one from α S2-casein, whereas no bioactive peptides were found from κ -casein. (Table 2). The three 333 334 Lb. casei PRA205-specific bioactive peptides were the β-casein fragments 192-209

(LYQEPVLGPVRGPFPIIV), 58-72 (LVYPFPGPIPNSLPQ) and 8-14 (VPGEIVE). Eighteen 335 peptides were ACE-inhibitors, two had immunomodulatory activity, one showed dipeptidyl-336 peptidase IV (DPPIV) inhibitory activity and one was an antimicrobial peptide. Two peptides, 337 338 VYPFPGPIPN and YPFPGPIPN, were multi-functional bioactive peptides with ACEi, antioxidant and opioid agonist or ACEi, DPPIV-inhibitory and opioid agonist activities, respectively (Table 2). 339 Among the peptides with ACEi activity, YPFPGPIPN, KVLPVPQ, RPKHPIKHQ and LHLPLP 340 showed in vivo antihypertensive activity in spontaneously hypertensive rat (Maeno, Yamamoto, & 341 Takano, 1996; Quirós et al., 2007; Saito, Nakamura, Kitazawa, Kawai, & Itoh, 2000). For all the 342 other identified bioactive peptides, the bioactivity was previously demonstrated with in vitro assays. 343 344 The physiological effects of bioactive peptides depend on their capability to arrive at the target organs in an active form (Udenigwe, & Fogliano, 2017). This required resistance to 345 gastrointestinal proteases and brush border membrane peptidases, and absorption through the 346 intestinal epithelium. Usually, P-containing peptides are considered resistant to degradation by 347 digestive proteases. Peptides containing from one to four P residues in their sequences and with, in 348 349 many cases, P at or near to carboxylic end, were found to survive in vitro gastro-intestinal digestion 350 (Tagliazucchi et al., 2016). Among the identified bioactive peptides, seven of them were able to survive in vitro gastro-intestinal digestion (Picariello et al., 2015; Tagliazucchi et al., 2016) and 351 352 were also found in human gastro-intestinal tract (Boutrou et al., 2013), namely DKIHPF, VYPFPGPIPN, YPFPGPIPN, NIPPLTQTPV, LHLPLP, FVAPFPEVF and VAPFPEVF. The 353 intestinal brush-border membrane and the colonic cells also contain aminopeptidases e specific 354 prolyl peptidases. However, the great quantity of P-rich peptides and the presence of peptides with 355 inhibitory activities (as for example against DPP-IV and intestinal ACE) may slow down the action 356 357 of prolyl peptidases, protecting the short peptides from hydrolysis and favouring their biological actions. Short peptides (two or three amino acids) are absorbed intact across the brush border 358 359 membrane by a specific peptide transport system, whereas largest peptides via paracellular and/or

16

transcellular mechanisms (Vermeirssen, Van Camp, & Verstraete, 2004). The peptide LHLPLP 360 showed *in vivo* anti-hypertensive activity in rats, and, after incubation with Caco-2 cells, it was 361 hydrolysed by cellular peptidases to HLPLP prior to transport across the intestinal epithelium 362 (Ouirós, Dávalos, Lasunción, Ramos, & Recio, 2008). The penta-peptide HLPLP showed an 363 absolute bioavailability of 5.2% and an absorption half-life of 2.8 min in rats (Sánchez-Rivera et al., 364 2014). HLPLP was found to be hydrolysed by plasma peptidases in shorter peptides, which retained 365 the anti-hypertensive properties in rats (Quirós et al., 2008; Sánchez-Rivera et al., 2014; Sánchez-366 Rivera et al., 2016). No data on absorption or pharmacokinetics of the other identified bioactive 367 peptides are available in literature. 368

369

370 *3.6. Bioactive peptides abundance across PRA205 and PRA331 fermented milk*

Each identified bioactive peptide was relatively quantified in the samples by integrating the 371 372 area under the peak (AUP) from the extracted ion chromatogram. The ionization of specific peptides in mass spectrometry experiments is a major limitation in quantitative analysis with 373 374 electrospray ionization mass spectrometry (ESI-MS). The relative ionization of individual peptides 375 is dependent on intrinsic and extrinsic factors. The most important extrinsic factor is the so-called "matrix effect" which is caused by the co-elution of matrix components (typically salts, ions, highly 376 polar compounds and carbohydrates) that alter, either suppressing or enhancing, the ionization of 377 the target analyte (Furey, Moriarty, Bane, Kinsella, & Lehane 2013). The intrinsic factor are related 378 to the amino acid sequence of the peptides. Some amino acids, such as basic or hydrophobic amino 379 acids, are ionized more efficiently than the others and gave more intense signal in ESI-MS 380 experiments (Cech, & Enke, 2000). Here, we compared the relative amount (expressed as AUP) of 381 the same peptide in two different hydrolysates coming from the same matrix (fermented milk), thus 382 we can exclude errors related to the extrinsic effect and assume that differences in peak intensity of 383 the same analyte accurately reflects relative differences in its abundance. 384

Among the bioactive peptides detected in both milk hydrolysates, 17 exhibited mean abundances significantly different between *Lb. casei* PRA205 and *Lb. rhamnosus* PRA331 (*P*<0.05). In particular, five peptides were more abundant in *Lb. casei* PRA205 milk hydrolysates and twelve in *Lb. rhamnosus* PRA331 milk hydrolysates (**Table 2**). When peptides intensities were summed, the bioactive peptides released by *Lb. rhamnosus* PRA331 whole cells were significantly higher than those released by *Lb. casei* PRA205 (11.50x10¹⁰ ± 0.39x10¹⁰ vs. 8.63x10¹⁰ ± 0.37x10¹⁰; *P*=0.0007).

392 4. Conclusions

393 Nowadays, there is an increasing interest in developing novel dairy healthy products. Studies on strains Lb. casei PRA205 and Lb. rhamnosus PRA331 may represent a proof-of-concept 394 of the working flowchart to develop novel functional adjunct culture and the subsequent functional 395 396 delivery food. We isolated proteolytic and stress-resistant strains from a stressful food niche (no sugars available, high salt concentration, low aw), such as Parmigiano Reggiano, and identified 397 them using a rigorous polyphasic identification frame-shift (Solieri et al., 2012). We demonstrated 398 399 that all of them are safe (sensitive to all tested antibiotics) and some resistant to *in vitro* gastrointestinal conditions (Solieri et al., 2014). We positively tested their ability to release VPP and IPP 400 both in milk (Solieri et al., 2015) and in yogurt (Rutella et al., 2016), supporting the development of 401 a double functional food, i.e. yogurt enriched in potentially probiotic viable cells and in 402 antihypertensive peptides released by themselves. In this work, we characterized the CEPs that are 403 404 the first enzymatic activities responsible for these relevant proteolytic features. For this purpose, a cutting-edge peptidomic approach was implemented in order to define the pattern of caseins 405 breakdown by CEP activity from whole cells grown in milk. We demonstrated that CEPs activities 406 407 of Lb. casei PRA205 and Lb. rhamnosus PRA331showed two unique features: a new cleavage site (P_2-K_3) on the α S1-case in fragment 1-23 and a novel pattern of β -case in cleavage site-specificity. 408 Through a BIOPEP and MBPDB databases analysis, we also demonstrated that several identified 409

peptides matched the sequences of previously reported bioactive peptides. This information could 410 be relevant, mainly considering the wide heterogeneity in distribution of different proteinase-411 encoding genes among and within Lactobacillus species. Comparative genome analysis showed that 412 lactobacilli strongly differ in the components of their proteolytic systems at strain level (Liu et al., 413 2010). This strain-specificity accounts for the high phenotypic diversity in caseinolytic activity and 414 in of the resulting released bioactive peptides, as well as makes necessary to deeply characterize 415 each strain selected for functional food applications. However, it is important to note that protein 416 hydrolysis catalysed by proteases is a dynamic process and that, in the present work, bioactive 417 peptides were identified in fermented milk samples at one single time. We cannot exclude that 418 shorter or longer incubation of milk with Lb. casei PRA205 and Lb. rhamnosus PRA331 whole 419 cells may result in a different bioactive peptide profile of the samples. In addition, future 420 biochemical assays with the synthesized peptides are needed to complement the *in silico* evidences 421 422 collected here.

Overall, the results provided in the present work will increase the knowledge about the proteolytic system of two important NS-LAB species, such as *Lb. casei* and *Lb. rhamnosus*, which are poorly studied compared to the best-described lactococci and thermophilic lactobacilli. Finally, since strains PRA205 and PRA331 released several potential bioactive peptides, they could be promising functional starters or adjunct cultures for formulating dairy products with health properties.

Figure Captions

Figure 1. Venn diagram showing differences between *Lactobacillus casei* PRA205 and *Lactobacillus rhamnosus* PRA331 CEPs in patterns of peptides and bioactive peptides cleaved from milk caseins. The complete pattern of peptides identified at the end of the fermentation trials by mass spectrometry can be found in Supplementary on line Tables S1-S8. In the preparation of the Venn diagram related to bioactive peptides, only peptides found from the literature to have 100% homology to known functional peptides were reported in the Figure. Peptides present in at least two of a triplicate's samples were considered present.

Figure 2. Specificity of CEPs from strains *Lactobacillus casei* PRA205 and *Lactobacillus rhamnosus* PRA331 toward aS1-casein fragment 1-23. The cleavage sites are indicated by arrows.

Figure 3. Distribution of the cleavage sites identified in the primary sequences of β-casein by CEPs from *Lactobacillus casei* PRA205 and *Lactobacillus rhamnosus* PRA331. The cleavage sites are indicated by arrows.

Figure 4. Cleavage preference of *Lactobacillus casei* PRA205 and *Lactobacillus rhamnosus* PRA331 CEPs towards eighteen amino acids at the P1 and P1' subsites. (A) Influence of the different amino acids in the P1 subsite by CEP from *Lb. casei* PRA205. (B) Influence of the different amino acids in the P1' subsite by CEP from *Lb. casei* PRA205. (C) Influence of the different amino acids in the P1 subsite by CEP from *Lb. rhamnosus* PRA331. (D) Influence of the different amino acids in the P1' subsite by CEP from *Lb. rhamnosus* PRA331. (D) Influence of the different amino acids in the P1' subsite by CEP from *Lb. rhamnosus* PRA331. See materials and methods section for the calculation of the coefficient *Kn*. Positive and negative values indicate a positive or negative influence exerted by each residue on the cleavage of the P1-P1' bond, respectively. Please note that the amino acid C is not present in the sequence of β -casein, whereas W was omitted from the analysis since it occurs once in the β -casein sequence.

Table 3. Peptides with previously demonstrated bioactivity identified in the milkhydrolysates by whole cells of Lactobacillus casei PRA205 or Lactobacillus rhamnosusPRA331.

Abbreviations are: ACEi, angiotensin converting enzyme-inhibitory; DPPIV, dipeptidyl peptidase IV. ^aAmounts were calculated by measuring the area under the peak (AUP) from the extracted ion chromatograms (EIC) obtained for each peptide and AUP values were normalized to the total peptide content of the milk hydrolysates. Values are means \pm standard deviation. Statistically significant differences between PRA205 and PRA331 samples were calculated by Student's t-test (*P*<0.05).

Abbreviations are: ACEi, angiotensin converting enzyme-inhibitory; DPPIV, dipeptidyl peptidase IV. Only peptides found from the literature to have 100% homology to known functional peptides were reported in the **Table**. The complete list of identified peptides can be found in Supplementary on line **Tables S1-S8**. ^aAmounts were calculated by measuring the area under the peak (AUP) from the extracted ion chromatograms (EIC) obtained for each peptide and AUP values were normalized to the total peptide content of the milk hydrolysates as described in section 2.6. Values are means \pm standard deviation. Statistically significant differences between PRA205 and PRA331 samples were calculated by Student's t-test (*P*<0.05). **Figure S1**. β-casein derived peptides identified in the TCA-soluble supernatant obtained from milk fermented with *Lactobacillus casei* PRA205 and *Lactobacillus rhamnosus* PRA331. The peptides are reported as bars below the corresponding amino acid sequences. Red bars correspond to peptides with angiotensin-converting enzyme (ACE) inhibitory activity. Yellow bars correspond to peptides with dipeptidyl peptidase IV (DPP-IV) inhibitory activity. Green bars correspond to peptides with antioxidant activity. Light blue bars correspond to peptides with anti-microbial activity. Blue bars correspond to peptides with opioid agonist activity. Purple bars correspond to peptides with immunomodulation activity. Peptides with more than one activity are presented with multi-colour bars.

Figure S2. αS1-casein derived peptides identified in the TCA-soluble supernatant obtained from milk fermented with *Lactobacillus casei* PRA205 and *Lactobacillus rhamnosus* PRA331. The peptides are reported as bars below the corresponding amino acid sequences. Red bars correspond to peptides with angiotensin-converting enzyme (ACE) inhibitory activity. Yellow bars correspond to peptides with dipeptidyl peptidase IV (DPP-IV) inhibitory activity. Green bars correspond to peptides with antioxidant activity. Light blue bars correspond to peptides with anti-microbial activity. Blue bars correspond to peptides with opioid agonist activity. Purple bars correspond to peptides with immunomodulation activity. Peptides with more than one activity are presented with multi-colour bars.

Figure S3. αS2-casein derived peptides identified in the TCA-soluble supernatant obtained from milk fermented with *Lactobacillus casei* PRA205 and *Lactobacillus rhamnosus* PRA331. The peptides are reported as bars below the corresponding amino acid sequences. Red bars correspond to peptides with angiotensin-converting enzyme (ACE) inhibitory activity. Yellow bars correspond to peptides with dipeptidyl peptidase IV (DPP-IV) inhibitory activity. Green bars correspond to peptides with antioxidant activity. Light blue bars correspond to peptides with anti-microbial activity. Blue bars correspond to peptides with opioid agonist activity. Purple bars correspond to

peptides with immunomodulation activity. Peptides with more than one activity are presented with multi-colour bars.

Figure S4. κ-casein derived peptides identified in the TCA-soluble supernatant obtained from milk fermented with *Lactobacillus casei* PRA205 and *Lactobacillus rhamnosus* PRA331. The peptides are reported as bars below the corresponding amino acid sequences. Red bars correspond to peptides with angiotensin-converting enzyme (ACE) inhibitory activity. Yellow bars correspond to peptides with dipeptidyl peptidase IV (DPP-IV) inhibitory activity. Green bars correspond to peptides with antioxidant activity. Light blue bars correspond to peptides with anti-microbial activity. Blue bars correspond to peptides with opioid agonist activity. Purple bars correspond to peptides with immunomodulation activity. Peptides with more than one activity are presented with multi-colour bars.
