#### Abstract

The $B^{0}-\bar{B}^{0}$ oscillation frequency $\Delta m_{d}$ is measured by the LHCb experiment using a dataset corresponding to an integrated luminosity of $1.0 \mathrm{fb}^{-1}$ of proton-proton collisions at $\sqrt{s}=7 \mathrm{TeV}$, and is found to be $\Delta m_{d}=0.5156 \pm 0.0051$ (stat.) $\pm 0.0033$ (syst.) $\mathrm{ps}^{-1}$. The measurement is based on results from analyses of the decays $B^{0} \rightarrow D^{-} \pi^{+}\left(D^{-} \rightarrow K^{+} \pi^{-} \pi^{-}\right)$and $B^{0} \rightarrow J / \psi K^{* 0}\left(J / \psi \rightarrow \mu^{+} \mu^{-}, K^{* 0} \rightarrow K^{+} \pi^{-}\right)$and their charge conjugated modes. © 2013 CERN. ## 1. Introduction

The frequency $\Delta m_{d}$ of oscillations between $B^{0}$ mesons and $\bar{B}^{0}$ mesons also describes the mass difference $\Delta m_{d}$ between the physical eigenstates in the $B^{0}-\bar{B}^{0}$ system, and has been measured at LEP [1], the Tevatron [2,3], and the $B$ factories [4,5]. The current world average is $\Delta m_{d}=0.507 \pm 0.004 \mathrm{ps}^{-1}$ [6], whilst the best single measurement prior to this Letter is by the Belle experiment, $\Delta m_{d}=0.511 \pm 0.005$ (stat.) $\pm 0.006$ (syst.) $\mathrm{ps}^{-1}$ [5]. In this document the convention $\hbar=c=1$ is used for all units.

With increasing accuracy of the measurement of $\Delta m_{s}$, the counterpart of $\Delta m_{d}$ in the $B_{s}^{0}-\bar{B}_{s}^{0}$ system [7], a more precise knowledge of $\Delta m_{d}$ becomes important, as the ratio $\Delta m_{d} / \Delta m_{s}$ together with input from lattice QCD calculations [8,9] constrains the apex of the CKM unitarity triangle [10,11]. Therefore, the measurement of $\Delta m_{d}$ provides an important test of the Standard Model [12,13]. Furthermore, $\Delta m_{d}$ is an input parameter in the determination of $\sin 2 \beta$ at LHCb [14].

This Letter presents a measurement of $\Delta m_{d}$, using a dataset corresponding to $1.0 \mathrm{fb}^{-1}$ of $p p$ collisions at $\sqrt{s}=7 \mathrm{TeV}$, using the decay channels $B^{0} \rightarrow D^{-} \pi^{+}\left(D^{-} \rightarrow K^{+} \pi^{-} \pi^{-}\right)$and $B^{0} \rightarrow$ $J / \psi K^{* 0}\left(J / \psi \rightarrow \mu^{+} \mu^{-}, K^{* 0} \rightarrow K^{+} \pi^{-}\right)$and their charge conjugated modes.

For a measurement of $\Delta m_{d}$, the flavour of the $B^{0}$ meson at production and decay must be known. The flavour at decay is determined in both decay channels from the charge of the final state kaon; contributions from suppressed $B^{0} \rightarrow D^{+} \pi^{-}$amplitudes are negligible. The determination of the flavour at production is achieved by the flavour tagging algorithms which are described in more detail in Section 4.

The $B^{0}$ meson is defined as unmixed (mixed) if the production flavour is equal (not equal) to the flavour at decay. With this
knowledge, the oscillation frequency $\Delta m_{d}$ of the $B^{0}$ meson can be determined using the time dependent mixing asymmetry
$\mathcal{A}_{\text {mix }}^{\text {signal }}(t)=\frac{N_{\text {unmixed }}(t)-N_{\text {mixed }}(t)}{N_{\text {unmixed }}(t)+N_{\text {mixed }}(t)}=\cos \left(\Delta m_{d} t\right)$,
where $t$ is the $B^{0}$ decay time and $N_{(\text {un }) \text { mixed }}$ is the number of (un)mixed events.

## 2. Experimental setup and datasets

The LHCb detector [15] is a single-arm forward spectrometer covering the pseudorapidity range $2<\eta<5$, designed for the study of particles containing $b$ or $c$ quarks. The detector includes a high precision tracking system consisting of a silicon-strip vertex detector surrounding the $p p$ interaction region, a large-area silicon-strip detector located upstream of a dipole magnet with a bending power of about 4 Tm , and three stations of silicon-strip detectors and straw drift-tubes placed downstream. The combined tracking system has a momentum resolution $\Delta p / p$ that varies from $0.4 \%$ at 5 GeV to $0.6 \%$ at 100 GeV , and an impact parameter (IP) resolution of $20 \mu \mathrm{~m}$ for tracks with high transverse momentum. Charged hadrons are identified using two ring-imaging Cherenkov detectors. Photon, electron and hadron candidates are identified by a calorimeter system consisting of scintillating-pad and pre-shower detectors, an electromagnetic calorimeter and a hadronic calorimeter. Muons are identified by a system composed of alternating layers of iron and multiwire proportional chambers. The trigger consists of a hardware stage, based on information from the calorimeter and muon systems, followed by a software stage which applies a full event reconstruction.

Events including $B^{0} \rightarrow D^{-} \pi^{+}$decays are required to have tracks with high transverse momentum $p_{T}$ to pass the hardware trigger. The software trigger requires a two-, three- or four-track secondary vertex with a large sum of the $p_{T}$ of the tracks, significant displacement from the associated primary vertex (PV), and at

Fig. 1. Distribution of the $B^{0}$ candidate mass (black points). (Left) $B^{0} \rightarrow D^{-} \pi^{+}$candidates with the invariant mass PDF as described in Section 6 and two additional components for the physics background taken from MC simulated events. The blue dashed line shows the fit projection of the signal, the dotted orange line corresponds to the combinatorial background, the filled areas represent the physics background, and the black solid line corresponds to the fit projection. (Right) $B^{0} \rightarrow J / \psi K^{* 0}$ candidates, with the results of the fits described in Section 6 superimposed. The blue dashed line shows the fit projection of the signal, the dotted orange line corresponds to the combinatorial background with long lifetime and the dash dotted red line shows the combinatorial background with short lifetime. The black solid line corresponds to the fit projection.
least one track with $p_{T}>1.7 \mathrm{GeV}$ and a large impact parameter with respect to that PV, and a good track fit. A multivariate algorithm is used for the identification of the secondary vertices [16].

Events in the decay $B^{0} \rightarrow J / \psi K^{* 0}$ are first required to pass a hardware trigger which selects a single muon with $p_{T}>1.48 \mathrm{GeV}$. In the subsequent software trigger [16], at least one of the final state particles is required to have $p_{T}>0.8 \mathrm{GeV}$ and a large IP with respect to all PVs in the event. Finally, the tracks of two or more of the final state particles are required to form a vertex which is significantly displaced from the PVs in the event.

For the simulation studies, $p p$ collisions are generated using PyTHIA 6.4 [17] with a specific LHCb configuration [18]. Decays of hadronic particles are described by EvtGen [19] in which final state radiation is generated using Рнотоs [20]. The interaction of the generated particles with the detector and its response are implemented using the Geant4 toolkit [21,22] as described in Ref. [23].

## 3. Selection

The decay time $t$ of a $B^{0}$ candidate is evaluated from the measured momenta and from a vertex fit that constrains the $B^{0}$ candidate to originate from the associated PV [24], and using $t=\ell \cdot m\left(B^{0}\right) / p$, with the flight distance $\ell$. The associated PV is the primary vertex that is closest to the decaying $B^{0}$ meson. No mass constraints on the intermediate resonances are applied. For the calculation of the invariant mass $m$, no mass constraints are used in the $B^{0} \rightarrow D^{-} \pi^{+}$channel, while the $J / \psi$ mass is constrained to the world average [6] in the analysis of the decay $B^{0} \rightarrow J / \psi K^{* 0}$.

All kaons, pions and muons are required to have large $p_{T}$ and well reconstructed tracks and vertices. In addition to this, particle identification is used to distinguish between pion, kaon and proton tracks.

The $B^{0} \rightarrow D^{-} \pi^{+}$selection requires that the $D^{-}$reconstructed mass be in a range of $\pm 100 \mathrm{MeV}$ around the world average [6]. Furthermore, the $D^{-}$decay vertex is required to be downstream of the PV associated to the $B^{0}$ candidate.

The sum of the $D^{-}$and $\pi^{+} p_{T}$ must be larger than 5 GeV . The $B^{0}$ candidate invariant mass must be in the interval $5000 \leqslant$ $m\left(K^{+} \pi^{-} \pi^{-} \pi^{+}\right)<5700 \mathrm{MeV}$. Additionally, the cosine of the pointing angle between the $B^{0}$ momentum vector and the line segment between PV and secondary vertex is required to be larger than 0.999.

Candidates are classified by a boosted decision tree (BDT) [25, 26] with the AdaBoost algorithm [27]. The BDT is trained with $B_{s}^{0} \rightarrow D_{s}^{-} \pi^{+}$candidates with no particle ID criteria applied to the
daughter pions and kaons. The cut on the BDT classifier is optimised in order to maximise the significance of the $B^{0} \rightarrow D^{-} \pi^{+}$ signal. Several input variables are used: the IP significance, the flight distance perpendicular to the beam axis, the vertex quality of the $B^{0}$ and the $D^{-}$candidate, the angle between the $B^{0}$ momentum and the line segment between PV and $B^{0}$ decay vertex, the angle between the $D^{-}$momentum and the line segment between PV and the $D^{-}$decay vertex, the angle between the $D^{-}$momentum and the line segment between the $B^{0}$ decay vertex and $D^{-}$ decay vertex, the IP and $p_{T}$ of the $\pi^{+}$track, and the angle between the $\pi^{+}$momentum and the line segment between PV and $B^{0}$ decay vertex. Only $B^{0}$ candidates with a decay time $t>0.3 \mathrm{ps}$ are accepted.

To suppress potential background from misidentified kaons in $D_{s}^{-} \rightarrow K^{-} K^{+} \pi^{-}$decays, all $D^{-}$candidates are removed if they have a daughter pion candidate that might pass a loose kaon selection and are within a $\pm 25 \mathrm{MeV}$ mass window (the $D^{-}$mass resolution is smaller than 10 MeV ) around the $D_{s}^{-}$mass when that pion is reconstructed under the kaon mass hypothesis.

Remaining background comes from $B^{0} \rightarrow D^{-} \rho^{+}$and $B^{0} \rightarrow$ $D^{*-} \pi^{+}$decays. In both cases the final state is similar to the signal, except for an additional neutral pion that is not reconstructed. This leads to two additional peaking components with invariant masses lower than those of the signal candidates. Therefore, for the measurement of $\Delta m_{d}$ only candidates with an invariant mass in the range $5200 \leqslant m<5450 \mathrm{MeV}$ are used.

The $B^{0} \rightarrow J / \psi K^{* 0}$ selection requires that the $K^{* 0}$ candidate has a $p_{T}>2 \mathrm{GeV}$ and $826 \leqslant m\left(K^{+} \pi^{-}\right)<966 \mathrm{MeV}$.

The unconstrained $\mu^{+} \mu^{-}$invariant mass must be within $\pm 80 \mathrm{MeV}$ of the $J / \psi$ mass [6]. $B^{0}$ candidates are required to have a large IP with respect to other PVs in the event and the $B^{0}$ decay vertex must be significantly separated from the PV. Additionally, $B^{0}$ candidates are required to have a reconstructed decay time $t>0.3 \mathrm{ps}$ and an invariant mass in the range $5230 \leqslant m\left(J / \psi K^{+} \pi^{-}\right)<5330 \mathrm{MeV}$. To suppress potential background from misidentified $B_{s}^{0} \rightarrow J / \psi \phi$ decays, all candidates are removed for which the $K^{+} \pi^{-}$mass is within a $\pm 10 \mathrm{MeV}$ window around the nominal $\phi$ (1020) mass when computed under the kaon mass hypothesis for the pion. The resulting mass distributions for the two decay channels are shown in Fig. 1.

## 4. Flavour tagging

This analysis makes use of a combination of opposite side taggers and the same side pion tagger to determine the flavour of the $B^{0}$ meson at production. The opposite side taggers, which use
decay products of the $b$ quark not belonging to the signal decay, are described in detail in Ref. [28].

The same side pion tagger uses the charge of a pion that originates from the fragmentation process of the $B^{0}$ meson or from decays of charged excited $B$ mesons. Pion tagging candidates are required to fulfil criteria on $p_{T}$ and particle identification, as well as their IP significance and the difference between the $B^{0}$ candidate mass and the combined mass of the $B^{0}$ candidate and the pion [29].

Depending on the tagging decision, a mixing state $q$ is assigned to each candidate, to distinguish the unmixed ( $q=+1$ ) from the mixed $(q=-1)$. Untagged events ( $q=0$ ) are not used in this analysis. The tag and its predicted wrong tag probability $\eta_{c}$ are evaluated for each event using a neural network calibrated and optimised on $B^{+} \rightarrow J / \psi K^{+}, B^{0} \rightarrow J / \psi K^{* 0}$ and $B^{0} \rightarrow D^{*-} \mu^{+} \nu_{\mu}$ events.

To take into account a possible difference in the overall tagging performance between the calibration channels and the decay channels used in this analysis, the corrected wrong tag probability $\omega$ assigned to each event is parametrised as a linear function of $\eta_{c}$ (the method is described and tested in Ref. [28])
$\omega\left(\eta_{c} \mid p_{0}, p_{1}\right)=p_{0}+p_{1}\left(\eta_{c}-\left\langle\eta_{c}\right\rangle\right)$,
where $p_{0}$ and $p_{1}$ are free parameters in the fit for $\Delta m_{d}$ described in Section 6. In this way, uncertainties due to the overall calibration of the tagging performance are absorbed in the statistical uncertainty on $\Delta m_{d}$ returned by the fit.

## 5. Decay time resolution and acceptance

The decay time resolution of the detector is around 0.05 ps [30]. This is small compared to the $B^{0}$ oscillation period of about 12 ps and does not have significant impact on the measurement of $\Delta m_{d}$. The resolution is accounted for by convolving a Gaussian function $G\left(t ; \sigma_{t}\right)$, using a fixed width $\sigma_{t}=0.05 \mathrm{ps}$, with the signal probability density function (PDF) from Eq. (5). Possible systematic uncertainties introduced by the resolution are discussed in Section 7.

Trigger, reconstruction and selection criteria introduce efficiency effects that depend on the decay time. While these effects cancel in the asymmetry of Eq. (1) for signal events, they can be important for event samples that include background. As will be shown in Section 6, the only relevant background in the $B^{0}$ signal region is combinatorial in nature. For this background the asymmetry $N_{q=1}^{\mathrm{bkg}}(t)-N_{q=-1}^{\mathrm{bkg}}(t)$ is expected to cancel to first order as $q$ has no physical meaning. Therefore,

$$
\begin{align*}
\mathcal{A}_{\text {mix }}(t) & \propto \frac{\left(N_{q=1}^{\mathrm{sig}}(t)+N_{q=1}^{\mathrm{bkg}}(t)\right)-\left(N_{q=-1}^{\mathrm{sig}}(t)+N_{q=-1}^{\mathrm{bkg}}(t)\right)}{\left(N_{q=1}^{\mathrm{sig}}(t)+N_{q=1}^{\mathrm{bkg}}(t)\right)+\left(N_{q=-1}^{\mathrm{sig}}(t)+N_{q=-1}^{\mathrm{bkg}}(t)\right)}  \tag{3}\\
& \propto \frac{S(t)}{S(t)+B(t)} \cos \left(\Delta m_{d} t\right),
\end{align*}
$$

where $N_{q= \pm 1}^{\text {sig, bkg }}(t)$ denotes the number of unmixed or mixed signal (sig) and background (bkg) events. $S(t)$ and $B(t)$ denote the number of signal and background events as a function of the decay time. Thus, the shapes of $S(t)$ and $B(t)$ have to be known to account for the time dependent amplitude of the asymmetry function.

In the analysis of decays $B^{0} \rightarrow J / \psi K^{* 0}$, the decay time acceptance is determined from data, using a control sample of $B^{0} \rightarrow$ $J / \psi K^{* 0}$ events that is collected without applying any of the decay time biasing selection criteria. The decay time acceptance is evaluated in bins of $t$ and is implemented in the fit described in Section 6.

In the decay $B^{0} \rightarrow D^{-} \pi^{+}$there is no control dataset that can be used to measure the decay time acceptance. From an analysis of simulated events, it is determined that the decay time acceptance can be described by the empirical function
$\epsilon_{\mathrm{acc}}\left(t \mid a_{1}, a_{2}\right)=\arctan \left(a_{1} \exp \left(a_{2} t\right)\right)$,
where the parameters $a_{1}$ and $a_{2}$ are both free in the maximum likelihood fit for $\Delta m_{d}$ described in Section 6.

## 6. Measurement of $\Delta \boldsymbol{m}_{\boldsymbol{d}}$

The value of $\Delta m_{d}$ is measured using a multi-dimensional extended maximum likelihood fit. The $B^{0} \rightarrow D^{-} \pi^{+}$data are described by a two component PDF in which one component describes the signal and the other describes the combinatorial background. The signal component consists of the sum of a Gaussian function and a Crystal Ball function [31] with a common mean for the mass distribution, multiplied by a function $\mathcal{P}_{\text {sig }}^{t}$ to describe the decay time distribution,

$$
\begin{align*}
& \mathcal{P}_{\text {sig }}^{t}\left(t, q ; \tau, \Delta m_{d}, \omega, \sigma_{t}, a_{1}, a_{2}\right) \\
& \propto \propto\left[\Theta(t-0.3 \mathrm{ps}) \cdot \mathrm{e}^{-\frac{t}{\tau}}\left(1+q\left(1-2 \omega\left(\eta_{c} \mid p_{0}, p_{1}\right)\right) \cos \left(\Delta m_{d} t\right)\right)\right. \\
& \left.\quad \otimes G\left(t ; \sigma_{t}\right)\right] \cdot \epsilon_{\mathrm{acc}}\left(t \mid a_{1}, a_{2}\right) \tag{5}
\end{align*}
$$

Here, $\Theta(t)$ is the step function, while the $B^{0}$ lifetime $\tau$ is a free fit parameter and the average decay time resolution $\sigma_{t}$ is fixed. Other fit parameters are $a_{1}$ and $a_{2}$ from the decay time acceptance function $\epsilon_{\text {acc }}\left(t \mid a_{1}, a_{2}\right)$ described in Section 5 , as well as the parameters $p_{0}$ and $p_{1}$ from the tagging calibration function $\omega\left(\eta_{c} \mid p_{0}, p_{1}\right)$ described in Section 4. Any $B^{0} / \bar{B}^{0}$ production asymmetry cancels in the mixing asymmetry function, and is neglected in this analysis.

The combinatorial background component consists of an exponential PDF describing the mass distribution and the decay time PDF

$$
\begin{align*}
& \mathcal{P}_{\mathrm{bkg}}^{t}\left(t, q ; \tau_{\mathrm{bkg}}, \omega_{\mathrm{bkg}}, \sigma_{t}\right) \\
& \quad \propto\left[\Theta(t-0.3 \mathrm{ps}) \cdot \mathrm{e}^{-\frac{t}{\tau_{\mathrm{bkg}}}}\left(1+q\left(1-2 \omega_{\mathrm{bkg}}\right)\right) \otimes G\left(t ; \sigma_{t}\right)\right] \tag{6}
\end{align*}
$$

The PDF is similar to the signal decay time PDF with $\Delta m_{d}$ fixed to zero. The parameter $\omega_{\mathrm{bkg}}$ allows the PDF to reflect a possible asymmetry in the number of events tagged with $q= \pm 1$ in the background. The effective lifetime $\tau_{\text {bkg }}$ of the long-lived background component is allowed to vary independently in the fit.

Possible backgrounds from misidentified or partially reconstructed decays are studied using mass templates determined from simulation. These are found to be negligible in the mass window $5200 \leqslant m\left(K^{+} \pi^{-} \pi^{-} \pi^{+}\right)<5450 \mathrm{MeV}$ that is used in the fit (cf. Fig. 1).

In the $B^{0} \rightarrow J / \psi K^{* 0}$ analysis, the signal mass distribution is modelled by a double Gaussian function with a common mean and the decay time PDF is the same as described in Eq. (5), except for the decay time acceptance $\epsilon_{\text {acc }}\left(t \mid a_{1}, a_{2}\right)$ that is replaced by the acceptance histogram described in Section 5 and has no free parameters. The mass distribution of the combinatorial background in $B^{0} \rightarrow J / \psi K^{* 0}$ decays is also described by an exponential function. However, the decay time distribution includes a second component of shorter lifetime to account for prompt $J / \psi$ candidates passing the selection. The long-lived component is described by the same function as the combinatorial background in $B^{0} \rightarrow D^{-} \pi^{+}$decays as in Eq. (6), whereas the short-lived component is described by a simple exponential function. No other significant source of background is found.

Fig. 2. Distribution of the decay time (black points) for (left) $B^{0} \rightarrow D^{-} \pi^{+}$and (right) $B^{0} \rightarrow J / \psi K^{* 0}$ candidates. The blue dashed line shows the fit projection of the signal, the dotted orange line corresponds to the combinatorial background with long lifetime and the dash dotted red line shows the combinatorial background with short lifetime (only in the $B^{0} \rightarrow J / \psi K^{* 0}$ mode). The black solid line corresponds to the projection of the combined PDF.

Fig. 3. Raw mixing asymmetry $\mathcal{A}_{\text {mix }}$ (black points) for (left) $B^{0} \rightarrow D^{-} \pi^{+}$and (right) $B^{0} \rightarrow J / \psi K^{* 0}$ candidates. The solid black line is the projection of the mixing asymmetry of the combined PDF.

The resulting values for $\Delta m_{d}$ are $0.5178 \pm 0.0061 \mathrm{ps}^{-1}$ and $0.5096 \pm 0.0114 \mathrm{ps}^{-1}$ in the $B^{0} \rightarrow D^{-} \pi^{+}$and $B^{0} \rightarrow J / \psi K^{* 0}$ decay modes respectively. The fit yields $87724 \pm 321$ signal decays for $B^{0} \rightarrow D^{-} \pi^{+}$and $39148 \pm 316$ signal decays for $B^{0} \rightarrow J / \psi K^{* 0}$. The fit projections onto the decay time distributions are displayed in Fig. 2 and the resulting asymmetries are shown in Fig. 3. No result for the $B^{0}$ lifetime is quoted, since it is affected by possible biases due to acceptance corrections. These acceptance effects do not influence the measurement of $\Delta m_{d}$.

## 7. Systematic uncertainties

As explained in Section 5, systematic effects due to the decay time resolution are expected to be small. This is tested using samples of simulated events that are generated with decay time distributions given by the result of the fit to data and convolved with the average measured decay time resolution of 0.05 ps. The event samples are then fitted with the PDF described in Section 6, with the decay time resolution parameter fixed either to zero or to $\sigma_{t}=0.10 \mathrm{ps}$. The maximum observed bias on $\Delta m_{d}$ of $0.0002 \mathrm{ps}^{-1}$ is assigned as systematic uncertainty. Systematic effects due to decay time acceptance are estimated in a similar study, generating samples of simulated events according to the nominal decay time acceptance functions described in Section 5. These samples are then fitted with the PDF described in Section 6, but neglecting the decay time acceptance function in the fit. The average observed shift of $0.0004 \mathrm{ps}^{-1}\left(0.0001 \mathrm{ps}^{-1}\right)$ in $B^{0} \rightarrow D^{-} \pi^{+}\left(B^{0} \rightarrow J / \psi K^{* 0}\right)$ decays is taken as systematic uncertainty. The influence of event-by-event variation of the decay time resolution is found to be negligible.

In order to estimate systematic effects due to the parametrisation of the decay time PDFs for signal and background, an alternative parametrisation is derived with a data-driven method, using sWeights [32] from a fit to the mass distribution. The sWeighted decay time distributions for the signal and background components are then described by Gaussian kernel PDFs, which replace the exponential terms of the decay time PDF. This leads to a description of the data which is independent of a model for the decay time and its acceptance, that can be used to fit for $\Delta m_{d}$. The resulting shifts of $0.0037 \mathrm{ps}^{-1}\left(0.0022 \mathrm{ps}^{-1}\right)$ in the decay $B^{0} \rightarrow D^{-} \pi^{+}$ $\left(B^{0} \rightarrow J / \psi K^{* 0}\right)$ are taken as the systematic uncertainty due to the fit model.

Uncertainties in the geometric description of the detector lead to uncertainties in the measurement of flight distances and the momenta of final state particles. From alignment measurements on the vertex detector, the relative uncertainty on the length scale is known to be smaller than $0.1 \%$. This uncertainty translates directly into a relative systematic uncertainty on $\Delta m_{d}$, yielding an absolute uncertainty of $0.0005 \mathrm{ps}^{-1}$.

From measurements of biases in the reconstructed $J / \psi$ mass in several run periods, the relative uncertainty on the uncalibrated momentum scale is measured to be smaller than $0.15 \%$. This uncertainty, however, cancels to a large extent in the calculation of the $B^{0}$ decay time, as it affects both the reconstructed $B^{0}$ momentum and its reconstructed mass, which is dominated by the measured momenta of the final state particles. The remaining systematic uncertainty on the decay time is found to be an order of magnitude smaller than that due to the length scale and is neglected.

A summary of the systematic uncertainties can be found in Table 1 . The systematic uncertainty on the combined $\Delta m_{d}$ result is calculated using a weighted average of the combined uncorrelated

Table 1
Systematic uncertainties on $\Delta m_{d}$ in $\mathrm{ps}^{-1}$.

|  | $B^{0} \rightarrow J / \psi K^{* 0}$ | $B^{0} \rightarrow D^{-} \pi^{+}$ |
| :--- | :--- | :--- |
| Acceptance | 0.0001 | 0.0004 |
| Decay time resolution | 0.0002 | 0.0002 |
| Fit model | 0.0022 | 0.0037 |
| Total uncorrelated | 0.0022 | 0.0037 |
| Length scale | 0.0005 | 0.0005 |
| Total including correlated | 0.0023 | 0.0037 |

uncertainties in both channels. The uncertainty on the length scale is fully correlated across the channels and therefore added after the combination.

## 8. Conclusion

The $B^{0}-\bar{B}^{0}$ oscillation frequency $\Delta m_{d}$ has been measured using samples of $B^{0} \rightarrow D^{-} \pi^{+}$and $B^{0} \rightarrow J / \psi K^{* 0}$ events collected in $1.0 \mathrm{fb}^{-1}$ of $p p$ collisions at $\sqrt{s}=7 \mathrm{TeV}$ and is found to be

$$
\begin{aligned}
\Delta m_{d}\left(B^{0} \rightarrow D^{-} \pi^{+}\right)= & 0.5178 \pm 0.0061 \text { (stat.) } \\
& \pm 0.0037 \text { (syst.) } \mathrm{ps}^{-1} \text { and } \\
\Delta m_{d}\left(B^{0} \rightarrow J / \psi K^{* 0}\right)= & 0.5096 \pm 0.0114 \text { (stat.) } \\
& \pm 0.0022 \text { (syst.) } \mathrm{ps}^{-1} .
\end{aligned}
$$

The combined value for $\Delta m_{d}$ is calculated as the weighted average of the individual results taking correlated systematic uncertainties into account
$\Delta m_{d}=0.5156 \pm 0.0051$ (stat.) $\pm 0.0033$ (syst.) $\mathrm{ps}^{-1}$.
It is currently the most precise measurement of this parameter. The relative uncertainty on $\Delta m_{d}$ is $1.2 \%$, where it is around $0.6 \%$ for $\Delta m_{s}$ [7]. Thus, the uncertainty on the ratio $\Delta m_{d} / \Delta m_{s}$ is dominated by $\Delta m_{d}$. As the systematic uncertainties in the $\Delta m_{d}$ and $\Delta m_{s}$ measurements are small, the error on the ratio can be further improved with more data.

## Acknowledgements

We express our gratitude to our colleagues in the CERN accelerator departments for the excellent performance of the LHC. We thank the technical and administrative staff at the LHCb institutes. We acknowledge support from CERN and from the national agencies: CAPES, CNPq, FAPERJ and FINEP (Brazil); NSFC (China); CNRS/IN2P3 and Region Auvergne (France); BMBF, DFG, HGF and MPG (Germany); SFI (Ireland); INFN (Italy); FOM and NWO (The Netherlands); SCSR (Poland); ANCS/IFA (Romania); MinES, Rosatom, RFBR and NRC "Kurchatov Institute" (Russia); MinECo, XuntaGal and GENCAT (Spain); SNSF and SER (Switzerland); NAS Ukraine (Ukraine); STFC (United Kingdom); NSF (USA). We also acknowledge the support received from the ERC under FP7. The Tier1 computing centres are supported by IN2P3 (France), KIT and BMBF (Germany), INFN (Italy), NWO and SURF (The Netherlands), PIC (Spain), GridPP (United Kingdom). We are thankful for the computing resources put at our disposal by Yandex LLC (Russia), as well as to the communities behind the multiple open source software packages that we depend on.
