#### Abstract

3 Previous research has shown that women eating small portions of food (vs. eating big 4 portions) are perceived as more feminine, whereas men eating large portions are perceived as more 5 masculine. The specific type of food items have also been shown to carry connotations for gender 6 stereotyping. In addition, matching the co-eater's food quantity is also a means to ingratiate him or 7 her. Thus, a potential motivational conflict between gender identity expression and ingratiation 8 arises when people eat in opposite-sex dyads. Scholars have, thus far, focused their attention on 9 one of these two dimensions at a time, and rarely in relation to the co-eaters' sex. The present study investigated, through a restaurant scenario, the way in which women and men, when asked to 10 11 imagine having lunch in dyads, combine food choice and quantity regulation as a function of the co-12 eater's sex. Results showed that participants use the quantity dimension to communicate gender identity, and the food type dimension to ingratiate the co-eater's preferences by matching her/his 13 14 presumed choice, following gender-based stereotypes about food. In opposite-sex dyads, dishes that incorporate the two dimensions were chosen above the expected frequency. 15

3 4

5 Mary is sitting at a restaurant table with her friend John. Mary feels she should eat lightly, 6 but at the same time she worries about appearing too picky in front of John. John loves the big 7 burgers with fries that he often eats with his friends, but he is concerned not to appear too uncouth in Mary's eyes. This scenario exemplifies the dilemma people may face when eating in social 8 9 situations. Indeed, many studies have documented that food choice in social situations fulfils a function of impression management (Herman, Roth, & Polivy, 2003, Vartanian, 2015). In 10 11 particular, this literature shows that both the quantity of food eaten and the type of food chosen are useful tools in signaling gender identity and creating a good impression in co-eaters' eyes (for a 12 review, see Vartanian, Herman, & Polivy, 2007). This is because there are cultural shared 13 14 expectations regarding how much and what kind of food a feminine woman or a "real man" should eat: For example, women are expected to prefer vegetables, white meat, fish or dairy food in small 15 16 quantities, whereas men are expected to prefer large portions of red meat (e.g. Rozin, Hormes, Faith, & Wansink, 2012; Stein & Nemeroff, 1995). Thus, when people conform to those 17 expectations they successfully appear as particularly feminine or masculine (for a recent review, see 18 19 Higgs & Thomas, 2016).

However, another line of research examining impression management revealed that adapting one's behaviour to that of a co-eater is also a means by which to gain social approval (for a recent meta-analysis, see Vartanian, Spanos, Herman, & Polivy, 2015). Indeed, individuals eating in pairs tend to adapt their food intake to that of their companion in order to enhance social acceptance (e.g. Hermans, et al, 2012; Robinson, Tobias, Shaw, Freeman, & Higgs, 2011). Therefore, in same-sex dyads, eating the amount and the type of food stereotypically associated with one's gender would be the best choice, as this allows to express one's own gender identity while at the same time matching

### Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 4 ACCEPTED MANUSCRIPT

the other's presumed preferences (on the basis of gender stereotypes). But in opposite-sex dyads,
 the motivation to express one's own gender identity while also ingratiating the co-eater via
 imitation could diverge and pose a problem of choice.

4 To date, scholars interested in expressive and communicative functions of food have mostly 5 studied the quantity and quality dimensions of food choice regulation separately (e.g. Dibb-Smith, & Brindal, 2015: Hermans, et al., 2012: Kaisari, & Higgs, 2015). A recent exception is a study in 6 7 which both portion size and food type (masculine vs feminine) were manipulated and crossed. It 8 showed that they both influenced the perceived food-gender association and that this association 9 mediated the intention of women and men to eat their gender-congruent food, irrespective of the 10 situation in which the dish will be consumed (Cavazza, Butera, & Guidetti, 2015a). However, in 11 this study participants evaluated their intention to eat the proposed foods without reference to a 12 concrete interpersonal context. Thus, only the function of gender identity expression has been 13 considered, while neglecting the ingratiating motivation.

We present a study in which we investigated whether people eating in dyads, and in
conditions in which they decide both the amount and the type of food to be eaten, ascribe a specific
function to quantity and quality dimensions in order to manage both their gender identity expression
and the presumed preferences of the co-eater, based on self- and other-stereotypes, respectively.

18

#### **Food Amount**

In the epic 20th century movie *Gone with the wind*, the iconic female lead Scarlett is advised by Mammy to eat like a bird when it comes to having dinner with Mr Wilkes, as befits a lady. That food amount suppression could be a matter of femininity display is a piece of folk wisdom that received empirical support in scientific literature. Indeed, different studies documented that eating little elicits a feminine impression (Chaiken & Pliner, 1987; Pliner & Chaiken, 1990). The association between eating lightly, or dieting, and femininity is widespread and shared (Bourdieu, 1984; Fagerli & Wandel, 1999; McPhail, Beagan, & Chapman, 2012; Sobal, 2005). Moreover,

### Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 5 ACCEPTED MANUSCRIPT

1 limiting the food amount seems to be a deliberate behaviour for women, who were shown to 2 regulate food consumption as a strategy of gender identity reaffirmation (Mori, Chaiken, & Pliner 3 1987; Robinson et al., 2011). In line with this, Young, Mizzau, Mai, Sirisegaram, and Wilson 4 (2009) observed male and female university students eating together in the naturalistic setting of a 5 cafeteria in Canada. They confirmed the main effect of eater's sex, such that women tended to eat less than men. However, interestingly, they also highlighted that, in same-sex dyads, men and 6 7 women ate a similar amount of calories, whereas in opposite sex-dyads, women particularly tended 8 to choose food with fewer calories than men. In sum, if eating lightly is a behaviour particularly 9 manifested by women, they further minimize their intake when motivated to affirm their own 10 gender identity (e.g., in opposite-sex dyads). Another line of research highlighted that food quantity may also be regulated in order to 11 12 match the co-eater's intake, because similarity among co-eaters facilitates the creation of a good 13 impression. Robinson and colleagues (2011) found that female participants converged with a confederate who ate a large quantity of popcorn after priming need of social acceptance, whereas 14 15 this convergence did not emerge in a neutral condition. 16 The two research projects illustrated above exemplify how food amount regulation may 17 fulfil both a function of gender identity expression and of ingratiation, particularly for women. However, in opposite-sex dyads, a woman should eat little in order to appear feminine, but also eat 18 19 like a man (i.e., a lot) in order to match her co-eater. How does she overcome this dilemma? 20 Fortunately, in real situations we have the opportunity to vary another useful symbolic dimension of food: food type. 21

22

#### **Food Type**

Food type also conveys femininity or masculinity (Sobal, 2005). A great deal of research
has examined the so-called gender-stereotyped foods present in every culture (e.g., Counihan &
Kaplan, 2004). This line of study showed that red meat is widely perceived as the prototypical food

### Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 6 ACCEPTED MANUSCRIPT

for men, whereas vegetables, dairy products, fish, fruit and sweets are generally considered
feminine foods (O'Doherty Jensen & Holm, 1999). As other gender role expectations, men and
women learn in the course of experience what is a gender-appropriate food choice (Rolls, Fedoroff,
& Guthrie, 1991). The consequence is that co-eaters perceive masculinity or femininity of targets
based on the foods they eat (e.g., Stein & Nemeroff, 1995). Observers rate both men and women
eating "feminine" foods as more feminine than those eating "masculine" foods (Chaiken & Pliner,
1987; Mori et al., 1987; Mooney & Lorenz, 1997; Stein & Nemeroff, 1995).

8 Likewise, White and Dahl (2006) found that food choices are influenced by the desire of the 9 eaters to dissociate themselves from a devaluated reference group (e.g., men preferred not to eat a 10 steak that was defined in the menu as a "lady's cut"). Gal and Wilkie (2010) proposed a similar manipulation of the dish label, naming the same courses in a menu either in a feminine (e.g., Filet 11 Paulette) or in a masculine way (e.g., Rutherford Ribeye). Participants had to order a meal in 12 13 conditions of high vs low cognitive resource availability. Results showed that women tended to choose a greater number of feminine than masculine items, irrespective of resource availability, 14 whereas men tended to order gender congruent dishes particularly in a condition of high resource 15 16 availability.

17 However, these studies did not consider the co-eaters' sex. Actually, research examining gender-stereotypical food consumption has almost exclusively limited the attention to food's 18 19 expressive function of identity, whereas evidence regarding the influence of a co-eater's 20 characteristics is very scant. Taking the co-eaters' sex into consideration, a recent study (Cavazza, 21 Guidetti, & Butera, 2015b) showed that participants tended to prefer their co-eaters' gendercongruent foods over and above their own gender-congruent foods. In this case participants had to 22 express the likelihood to eat either a Caprese salad (i.e., a feminine dish) or a hamburger (i.e., a 23 24 masculine dish) during a dinner with a men or a women. Male and female participants were more likely to prefer the feminine food when eating with women and the less feminine food when eating 25

### Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 7 ACCEPTED MANUSCRIPT

with men, even though this orientation to adapt their choice to the co-eaters was particularly true for
men. This pattern did not change when the co-eater was a dating partner. However, participants
only had the opportunity to vary their choice of food type, but not the amount, as a function of their
co-eaters' sex.

5

### **The Present Research**

Examining the literature on the psychological functions covered by food regulation and food 6 7 choice in terms of gender identity expression and ingratiation, a motivational conflict appears as a 8 potential outcome of eating in opposite-sex dyads. Indeed, when a person eats with an opposite-sex 9 partner, the motivation to model the presumed other's choice is at odds with the motivation to 10 express one's own gender identity (i.e. making gender-congruent choices). The question of whether 11 individuals reconcile the two motivations, ascribing a specific and prevalent function to quantity 12 regulation and food choice, is still open, because the experimental paradigms used in the studies 13 reviewed above did not give participants the opportunity to vary both food type and amount in 14 relation to the co-eater's sex. This is why we devised the present study, in which we asked male 15 and female participants to imagine having lunch with a (female vs. male) friend and asked them to 16 choose one dish from a fictitious menu including a list of male- and female-stereotyped dishes, 17 either in medium or big portions.

On the basis of the literature reviewed above, we could infer that the regulation of food amount and the choice of food type may be strategically used in order to, respectively, behave in a gender-congruent way and model the partner at the same time. This would allow the eater to satisfy two different expressive functions of food – that is, conveying one's own gender identity while ingratiating the co-eater.

23 More specifically, we formulate the following hypotheses:

Hypothesis 1: On the basis of the findings by Young and colleagues (2011), we expected the quantity dimension to be used for the gender identity expressive function. In operational terms, we

### Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 8 ACCEPTED MANUSCRIPT

expected to find more frequent gender-congruent than -incongruent choices on the quantitative
 dimension (i.e. medium portions, and dishes estimated as less caloric, for women, vs. big portions,
 and dishes estimated as more caloric, for men).

Hypothesis 2: In line with the findings by Cavazza et al. (2015b), we expected the food
choice dimension to be used for the ingratiating function. In operational terms, we expected to
observe more frequent partner's gender-congruent than -incongruent choices on the food type (i.e.
feminine dishes for people lunching with women and masculine dishes for people lunching with
men).

9 Hypothesis 3: Accordingly, as a way to satisfy both the motivation of gender identity 10 expression and co-eater ingratiation, we expected to find a combination of the choices of food 11 amount and food type as a function of the dyad composition. In particular, we should find over-12 representation of medium-portion masculine dishes among women in dyads with men, and of big 13 portions of feminine dishes among men in dyads with women. In contrast, we should observe an 14 over-representation of medium portions of feminine dishes among women in dyads with other 15 women, and big portions of masculine dishes among men in dyads with other men.

16

### Method

17 The purpose of the present study was to explore the combination of quantity and type of 18 food in the choice of men and women as a function of the co-eater's sex. In order to test the 19 hypotheses, the experiment design was a 2 (respondents' sex) x 2 (co-eater's sex) between-20 participants, and the menu list was set in order to offer two categories of dish type (masculine and 21 feminine), each in two portion sizes (medium or big).

22 **Participants** 

One hundred and eighty-eight participants (59% women) aged 18–65 (M = 28.55, SD =9.96) were recruited through a university student mailing list, Facebook contacts and snowball sampling. They gave their informed consent to participate on a voluntary basis in the study and were asked to complete an online questionnaire about food habits implemented on the LimeSurvey
 platform.

### **3 Design and Procedure**

4 The questionnaire presented a restaurant scenario in which participants were invited to 5 imagine having lunch with a female or male friend. Participants were randomly distributed to the 6 male/female co-eater condition. In order to make salient the manipulation of the partner's sex, we 7 asked participants to think of an actual friend and write down his/her first name. In case of 8 incongruence between the assigned condition and the name written by participants (n = 39), we 9 assigned the participants to the condition that corresponded to the name they wrote. They were then 10 invited to read the menu and choose only one dish - the one they would like to eat in that situation along with the portion size. The menu prepared for experimental purposes included 12 options, 11 each of them available in a medium or a big portion. It should be noted that we offered medium and 12 13 big portions, instead of small and big, because we limited the choice to one item, and choosing just a small portion of a single dish would not be enough in size to constitute a lunch to the participants. 14 15 The selection of the dishes was made on the basis of a pilot study in which 30 participants had to categorize a list of 26 prepared dishes according to how much they associated these dishes 16 17 with men, women, or neither. We included in the experimental menu the six dishes associated with men and the six associated with women by at least 70% of the pilot respondents. All dishes 18 19 associated with men included pork or red meat (e.g., pork knuckles in spicy sauce), whereas the 20 dishes associated with women included chicken, vegetables and/or cheese (e.g., caprese salad). The 21 scenario did not include a decision about wine or other beverages to drink with food. No actual foods were presented to participants. The gendered stereotypicality of the dish (feminine vs. 22 masculine) and the portion size (medium vs big) were our critical dependent variables. 23 24 Before reading the menu, the participants were asked to report how hungry they felt on a 10-

25 point scale (from 1 = not at all, to 10 = very much).

# Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 10 ACCEPTED MANUSCRIPT

1	After having stated their choices, participants were invited to estimate the calories of the				
2	chosen dish. Then, the questionnaire included some personality scales that were not used for the				
3	present purposes. <sup>1</sup> Finally, participants were invited to report some socio-demographic information.				
4	The goal of the study was then explained, and respondents were thanked for their participation.				
5	Results				
6	In the present study, we expected to find systematic variations of food type choice and				
7	quantity regulation as a function of the dyad composition (same- vs opposite sex), as evidence of				
8	the need to combine both the motivation to express one's gender identity and to ingratiate the co-				
9	eater.				
10	Globally, 39% of the participants chose a medium portion of a masculine dish, 26.7% a				
11	medium portion of a feminine dish, 23.5% a big portion of a masculine dish, and 10.7% a big				
12	portion of a feminine dish. In order to test Hypotheses 1 and 2, logistic regression analyses with				
13	backward stepwise elimination were performed. This analysis begins with the test of the full model,				
14	as in ordinary linear regressions, and sequentially removes terms. At each stage, it removes the least				
15	damaging term for the model (e.g., that with the largest <i>p</i> -value). The process stops when any				
16	further deletion significantly decreases the model fit (Agresti & Kateri, 2011).				
17	We considered a first logistic regression model, where portion size and sex of the				
18	respondent, sex of the co-eater, the interaction term, and hunger evaluation (control variable) were				
19	the predictors, as the starting point of the stepwise backward elimination model selection procedure.				
20	In line with Hypothesis 1, the final model, $\chi^2(1) = 7.29$ , $p = .007$ , $-2LL = 233.01$ , Cox and Snell $R^2$				
21	= .04, Nagelkerke $R^2$ = .05, included the significant effect of the respondents' sex, $b =84$ , $ES =$				
22	.31, $Exp(b) = .43$ , $p = .007$ . Women chose a medium portion and men chose a big portion more				
23	than the expected value (Adj. Res. = $\pm 2.7$ ), irrespective of the co-eater's sex (Table 1).				
24	In addition, an analysis of variance on the calorie estimate of the dish chosen as a function				
25	of sex of the respondent and sex of the co-eater confirmed that women reported a lower estimate of				

1 calories for the dish chosen (M = 349.01, SD = 160.65) than men (M = 424.50, SD = 204.11), F(1, 155) = 6.90, p = .009,  $\eta^2 = .04$ , irrespective of the co-eater's sex and after controlling for the hunger 3 effect.

4 A second identical logistic regression model was considered with gendered stereotypicality of the dish as the dependent variable (0 = masculine, 1 = feminine dish). The final model,  $\gamma^2$  (2) = 5 9.16, p = .03, -2LL = 240.09. Cox and Snell  $R^2 = .05$ . Nagelkerke  $R^2 = .06$ , included the significant 6 7 effect of the co-eater's sex, b = -.74, ES = .33, Exp(b) = .48, p = .024, after controlling for hunger 8 effect, b = -.12, ES = .06, Exp(b) = .89, p = .046. When imagining having lunch with a female 9 friend, the choice of a feminine dish was significantly more frequent than expected, whereas 10 masculine dishes were chosen more than expected when participants imagined having lunch with a male friend (Adj. Res. =  $\pm 2.2$ ), irrespective of a participant's sex (Table 2). 11

In order to capture the combined use of food-amount and food-type dimensions as a 12 13 strategic way of satisfying the two motivations of gender identity expression and co-eater 14 ingratiation (H3), we analyzed the distribution of the chosen dish category (masculine/big portion, masculine/medium portion, feminine/big portion, feminine/medium portion) as a function of dyad 15 composition (same sex, opposite sex). The chi-squared analyses confirmed that the dish choice was 16 17 influenced by the dyad composition. For the same-sex dyads, the relationship was only marginally significant,  $\chi^2(3) = 6.34$ , p = .096; however, male respondents in same-sex dyads tended to choose 18 19 big portions of masculine dishes more than expected, and conversely, female respondents tended to 20 avoid this same kind of choice (Adj. Res. =  $\pm 2.4$ ; Table 3). For opposite-sex dyads, in line with our hypothesis, men chose a big portion of a feminine dish more than expected (Adj. Res. = 2.2), and 21 women chose a medium portion of a masculine dish more than expected (Adj. Res. = 2.6),  $\gamma^2(3)$ = 22 10.02, p = .018 (Table 3). 23

### Discussion

### Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 12 ACCEPTED MANUSCRIPT

Our findings confirmed that the sex composition of a dyad at a table actually differentially affects the choice of food type and the regulation of food amount. With the present study we intended to bridge two usually separated literatures: that concerning the psychological functions of food amount regulation and that concerning food type choice. Previous research has shown that both food choice and amount regulation can be tools with which the eaters convey their gender identity and manage impressions given to others. However, scholars, thus far, have focused their attention on one of these two dimensions at a time, and rarely in relation to the co-eaters' sex.

8 Our findings clearly showed that, when the opportunity to decide what and how much to eat 9 is available, as generally happens in real dining situations, our participants signaled their gender 10 identity mainly through food amount regulation (women by choosing medium, less caloric portions, and men by choosing big, more caloric portions), which is in line with Hypothesis 1. At the same 11 time, participants also considered the specific other-stereotype: they ingratiated the co-eater mainly 12 13 by taking advantage of the gendered stereotypicality of food and matching the presumed partner's 14 preference (masculine dishes were preferred with men and feminine dishes with women), which is in line with Hypothesis 2. Importantly, this functional specificity of food amount and food type 15 16 allowed prospective eaters to reconcile the motivational conflict potentially arising in opposite-sex 17 dyads. Indeed, as expected (H3), a tendency to converge on dishes that incorporate the two dimensions emerged in this condition, which resulted in the choice of the dishes that synthesize the 18 19 possibility of both ingratiating the co-eater, thanks to the gender stereotypicality of the food, and 20 communicating their own gender identity with the portion size.

Because impression management concerns are served by fulfilling social expectations
(Leary & Kowalski, 1990), and in line with studies showing that social expectations are more
binding for women than for men, particularly in the food domain (Chaiken & Pliner, 1987; Pliner &
Chaiken, 1990; Graziani, Cavazza, & Guidetti, submitted), we observed that the medium portion of
feminine dishes was the most chosen category among our female participants (23 out of 42),

### Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 13 ACCEPTED MANUSCRIPT

whereas men choosing a big portion of a feminine dish when in feminine company, although higher
than the expected frequency, remained a minority (5 out of 47). About one-third of men imagining
having lunch with a woman preferred to make a totally gender-congruent choice (i.e. a big portion
of masculine food).

5 The functional specificity of quantity regulation and food choice was also confirmed by the over-representation of the choice of totally gender-congruent dishes in same-sex dyads. In such a 6 7 condition, male participants were particularly prone to make a "real men" choice (i.e. big portion of 8 meat-based dishes). This is in line with previous findings highlighting the avoidance of feminine 9 foods by men as a means by which to dissociate from the outgroup (White & Dahl, 2006; Gal & 10 Wilkie, 2010); however, the present results go one step further in showing that this is more likely in a gender-homogeneous context. In a gender-mixed context, a need to converge with the lunch 11 12 companion pushes some men towards more feminine (and light) foods. This suggests that the 13 functional specificity attributed to food-amount regulation and choice we observed may have a 14 secondary benefit in promoting food variety. We consider this an avenue worth exploring.

15 Of course, we recognize that the proposed fictitious scenario only partially represents what 16 happens in real situations where the dish has to be actually eaten after the choice. First of all, our 17 participants did not have to worry about the dinner cost, whereas in real situation this could be part of the selection criteria set. Participants' BMI, physical activity and socio-economic status may also 18 19 influence their choice of a meal dimension and energy content (e.g. Liebman, et al. 2003; Sato, 20 Gittelsohn, Unsain, Roble, & Scagliusi, 2016), and we did not control for these variables in the 21 current study. Thus, the applicability of these results may need additional investigation because they 22 were derived from choices of hypothetical dishes under artificial and simplified conditions. Future 23 studies might overcome this limitation through the observation of actual choices in restaurants. 24 Furthermore, we did not take into account the nature of the relationship between the coeaters, and thus we cannot conclude at this time as to whether contexts of simple acquaintance, 25

### Running head: SPECIFIC FUNCTIONS OF AMOUNT REGULATION AND FOOD CHOICE 14 ACCEPTED MANUSCRIPT

friendship or romantic relationship induce variations in the combination of food-amount and foodtype dimensions due to the variation in the urge to manifest one's own gender appropriateness and impression management concerns. However, since people are particularly motivated to impress others when they are strangers than when they are friends, we might even expect that results would have been much stronger had we evoked a simple acquaintance or a potential romantic partner rather than a friend as (hypothetical) co-eater. Investigating the exact role for the nature of the interpersonal relationship is left to future research.

8 Another challenge in this context is the question of whether the strategy of choosing a dish 9 according to the co-eater's sex and regulating the portion size according to one's own gender 10 expectations is actually successful in both communicating gender identity and making a good impression on others. We speculate that the attribution of specific functions to food type and food 11 amount is due to the fact that individuals have learned from experience that it works. However, 12 13 future research could manipulate the combination of food amount and food type chosen by a fictitious (male or female) target in order to compare impressions given to men and women 14 15 potentially eating with him/her, and also deepen our understanding of whether people are aware of 16 these functioning.

17

### Conclusion

Notwithstanding these limitations, the present research is the first (to the best of our knowledge) to show that, when eating with a partner, people regulate both the food type and the food amount with a view to expressing their gender identity and their impression management needs, respectively. In other words, individuals appear to use the quantity dimension to communicate gender identity, and the food type dimension in order to ingratiate the co-eater by matching her/his presumed choice, in line with the gender-based stereotypes about foods. In this respect, this study contributes to the understanding of the processes by which individuals deal with
