ABSTRACT

1
2 Planktonic forms of Gastrotricha have been known since the 1850s, despite the fact
3 that they are rather uncommon and difficult to collect. They are characterized by a
4 round sack-shaped body, an absence of furcal adhesive tubes, and a different
5 distribution of the locomotory ciliation compared to epibenthic and periphytic
6 gastrotrichs. Today, planktonic gastrotrichs are classified into the three taxa –
7 Dasydytidae, Neogosseidae, and *Undula* – but their origin and whether they share a
8 recent common ancestor remains largely unknown. A long held view is that
9 planktonic taxa derive from benthic ancestors related to *Chaetonotus (Zonochaeta)*,
10 but the hypothesis has never been properly tested. Here, in order to elucidate the
11 phylogeny and origin of planktonic Gastrotricha, we provide the first molecular data
12 on the very rare genera *Kijanebalola* and *Neogosseia*, both members of the family
13 Neogosseidae. We use Bayesian and maximum likelihood phylogenetics to analyze
14 sequences of 18S rDNA, 28S rDNA and COI mtDNA spanning 71 taxa in total. We
15 find high support for a common origin of planktonic gastrotrichs, with monophyly of
16 both Dasydytidae and Neogosseidae. Planktonic forms have evolved from epibenthic
17 or periphytic ancestors, and the closest extant clade comprises members of
18 *Chaetonotus (Zonochaeta)* + *Chaetonotus heteracanthus* Remane, 1927. These results
19 further imply that the motile spines and underlying muscle patterns that control them
20 in species of Dasydytidae are adaptations to the planktonic environment that evolved
21 independently of those in other species of Gastrotricha.

INTRODUCTION

Gastrotricha is a small phylum of aquatic acoelomate animals with approximately 850 species (see Balsamo et al. 2009; 2014; Hummon and Todaro 2010; Kieneke and Schmidt-Rhaesa 2014; Todaro et al. 2014; and references therein). The group is a common component of the meiofauna and is hypothesized to act as an important link between the microbial loop and larger invertebrate predators (Balsamo and Todaro 2002). The phylum is divided into the two orders Chaetonotida and Macrodasysida. Chaetonotida, present in both freshwater and marine habitats, are generally tenpin-shaped with adhesive tubes confined to the posterior end, and with the cuticle generally sculptured into various arrangements of scales and spines. Macrodasysida, with few exceptions are entirely marine and vermiform, with adhesive tubes not confined to the posterior end, and with a smooth or sculptured cuticle.

Freshwater gastrotrichs within Chaetonotida are very small, ranging from 60 μm to 770 μm in total body length. Most species are epibenthic, periphytic or interstitial, but some also have a planktonic life-style. The first records of planktonic gastrotrichs were those of *Dasydytes goniathrix* Gosse, 1851 and *Dasydytes antenniger* Gosse, 1851 (now *Neogosseia antennigera*). In the years leading up to the 20th century several findings of new planktonic gastrotrichs were published, e.g. *Chitonodytes longisetosus* (Metschnikoff, 1865), *Haltidytes saltitans* (Stokes, 1887), *Stylochaeta fusiformis* (Spencer, 1890) and *Setopus bisetosus* (Thompson, 1891). Zelinka (1889) separated *N. antennigera* (Gosse, 1851) from the rest of the planktonic gastrotrichs based on the cephalic tentacles. Daday (1905) erected the families Dasydytidae and Gosseidae (now Neogosseidae) and gave diagnostic characters for each group. The very rare *Kijanebalola* was described from an Ugandan lake by Beauchamp (1932), and regarded as a close relative to *Neogosseia*. A leap in the knowledge of planktonic forms was made during the 1980s by Kisielewski (1991), who found several new and very interesting semi-planktonic gastrotrichs from an evolutionary point of view, among them *Undula*, *Ornamentula* and *Kijanebalola*. Common features of the planktonic species are the absence of the furcal adhesive tubes and a rearrangement of the locomotory ciliation. In planktonic taxa the ciliation includes discrete tufts along the trunk region and at least a band of long strong propelling cilia, which more or less completely encircles the head. Today planktonic gastrotrichs are classified into three taxa: (i) the monotypic *Undula*, forming the subfamily Undulinae, which is provisionally considered a sister group of the

1 subfamily Chaetonotinae (Kisielewski 1991); (ii) Dasydytidae, which is characterized
2 by long and movable spines (Kisielewski 1991; Kieneke and Ostmann 2012); and (iii)
3 Neogosseidae, characterized by long posterior spines, either distributed in an unpaired
4 median group (*Kijanebalola*) or in a paired lateral group (*Neogossea*), and a pair of
5 club-shaped cephalic tentacles (Todaro et al. 2013).
6
7

8
9 The origin and evolution of planktonic gastrotrichs remain largely unknown
10 (Hochberg and Litvaitis 2000; Kieneke et al. 2008a). However, the long-held
11 hypothesis that at least some planktonic forms may have been derived from benthic
12 ancestors (e.g. related to *Chaetonotus* (*Zonochaeta*) Remane, 1927a; see Kisielewski
13 1991) has gained support in a recent phylogenetic study based on molecular data
14 (Kånneby et al. 2013). In the latter study the authors showed that the planktonic
15 Dasydytidae is nested within a non-monophyletic Chaetonotidae. However, the non-
16 monophyly of Chaetonotidae had been known for quite some time prior to that study,
17 based on morphological data (e.g. Hochberg and Litvaitis 2000; Kieneke et al.
18 2008a). It should be emphasized that the systematics of the entire order Chaetonotida,
19 and especially within the largest group Chaetonotidae, is unstable. This is mainly due
20 to the classification's heavy reliance on cuticular structures and ornamentation,
21 characters that are extremely variable and thereby inconsistent on higher levels of
22 classification (e.g. genus, family etc.) (see Kånneby et al. 2013). A phylogenetic
23 approach based on molecular data may prove to be helpful in the process of re-
24 systematization of chaetonotidan taxa, similar to what is happening in the
25 systematization of the Macrotrichida (Todaro et al. 2012; 2014) However, several
26 groups of chaetonotidans have not yet been sampled for molecular data; this includes
27 Dichaeturidae, Neogosseidae and Proichthyidiidae, mainly because of lack of material.
28 It should be emphasized that members of these groups are very uncommon, with
29 some species only reported from their respective, often remote, type localities; as a
30 consequence, information on these animals is generally very poor and their origin and
31 phylogenetic alliances remain obscure.

51 In this study, in order to shed some light on the hypothesized relationship
52 between Dasydytidae and Neogosseidae suggested by previous authors, we have
53 obtained specimens and sequences of 18S rDNA, 28S rDNA and COI mtDNA for the
54 uncommon planktonic genera *Kijanebalola* and *Neogossea*, comprising Neogosseidae
55 (Table 1). We also hope, if possible, to shed light on the origin of planktonic
56

1 Gastrotricha. Although efforts were made to find *Undula paraënsis* Kisielowski,
2 1991, at its type localities in Brazil, these attempts were fruitless.
3
4

5 MATERIALS AND METHODS 6

7 *Collection and documentation* 8

9 *Kijanebalola devestiva* Todaro et al. 2013 (Fig. 1A) and *Neogosseia acanthocolla*
10 Kisielowski, 1991 (Fig. 1B) were collected in February 2013 from a freshwater pond
11 in the iSimangaliso wetland park (Kwazulu-Natal, South Africa); for details on
12 specimen sampling, recording and storage prior to DNA processing refer to Todaro et
13 al. (2013). Individuals of *Neogosseia antennigera* (Fig. 1C, D) were collected with a
14 plankton net with a mesh size of 25 µm at Bryan Country Club Lake, Bryan, Texas,
15 USA (30°38'32.18"N; 96°21'44.05"W) on two occasions, May 23, 2012 and June 26,
16 2012. Collected samples contained *Ceratophyllum* spp. and *Lemna* spp. It is also
17 noteworthy that the water of the lake as well as ambient sediment contain arsenic
18 levels that exceed the human health criterion and are not optimal for aquatic life
19 (Clark et al. 1998). Subsamples were treated with a 1% MgCl₂-solution and
20 subsequently studied under an Olympus LMS225R dissecting microscope.
21 Gastrotrichs were picked out with a micropipette, mounted on a slide and documented
22 alive with an Olympus BH-2 microscope equipped with DIC optics and a Canon EOS
23 Rebel T1i digital camera or a Nikon Eclipse 80i DIC microscope equipped with a
24 Nikon Digital Sight DS-Fi1 digital camera. For molecular studies, specimens were
25 recovered from the slide and put in 95-100% EtOH and stored at -18 to -20°C until
26 further treatment. The specimens of Neogosseidae used in the phylogeny have been
27 photographed and the photos have been deposited as collection 855412 in Morphbank
28 (<http://www.morphbank.net/855412>) (Table 1). Also refer to collection 799280 in
29 Morphbank (<http://www.morphbank.net/799280>) for photographs of the other
30 specimens used in our analysis (Table 1).

51 *Phylogenetic analyses* 52

53 DNA extraction, amplification and sequencing of 18S rDNA, 28S rDNA and COI
54 mtDNA follow the protocol presented in Kånneby et al. (2012). The new sequences
55 were analyzed together with most of the sequences obtained by Kånneby et al. (2013).
56 However, to keep the dataset more manageable, only a single sequence per
57 morphological species per gene was included, with the exception of Neogosseidae
58
59
60
61
62

64
65

1 where in some instances two sequences from the same morphological species were
2 used (Table 1).

3
4 The nuclear genes were aligned with Muscle (Edgar 2004) implemented in
5 Geneious v. 7.1.8 (Kearse et al. 2012) using the default settings. COI was aligned in
6 the same way as the nuclear genes using the translation align option, ensuring that
7 gaps in the alignment correspond to the translated amino acid sequences. The
8 concatenated dataset (18S rDNA, 28S rDNA and COI mtDNA) was analyzed with
9 MrBayes v.3.2.3 (Ronquist *et al.* 2012) on the CIPRES Science Gateway v. 3.3
10 (Miller et al. 2010) under the mixed model setting with gamma distributed rate
11 variation across sites and an estimated proportion of invariable sites. The gamma
12 shape parameter, the substitution rates for the GTR-model, the proportion of
13 invariable sites and the character state frequencies were all unlinked. The dataset was
14 partitioned according to each nuclear gene and by codon position for COI. To ensure
15 sufficient mixing and a reliable sample from the posterior distribution the dataset was
16 analyzed with 8 MCMC chains for each run and a heating parameter of 0.1. The
17 analysis started from a random starting tree and was run for 40 million generations.
18 Convergence of the two runs was ascertained by checking the log likelihood graphs,
19 the average standard deviation of split frequencies and the potential scale reduction
20 factor (PSRF+) (Gelman & Rubin 1992). After a burn-in of 5 million generations,
21 chains were sampled every 1000th generation. *Musellifer delamarei* (Renaud-
22 Mornant, 1968) within Muselliferidae, a group hypothesized to be the sister group of
23 all other Paucitubulatina (e.g. Hochberg and Litvaitis 2000; Todaro et al. 2006; Leasi
24 and Todaro 2008; K anneby et al. 2014), was used as outgroup. The alignments of the
25 concatenated dataset and the resulting consensus trees from the Bayesian and the
26 maximum likelihood analyses has been deposited in TreeBASE at
27 <http://purl.org/phylo/treebase/phyloids/study/TB2:S17533>

RESULTS

The final alignment of the concatenated dataset yielded 7109 positions, with 1830, 4612 and 667 positions for 18S rDNA, 28S rDNA and COI mtDNA, respectively.

1 In general the concatenated phylogenies based on both the Bayesian and the
2 maximum likelihood alignments follow the results obtained by K anneby et al. (2013).
3 Given the included data, none of the currently recognized subgenera appear
4 monophyletic except for *Chaetonotus (Zonochaeta)*. *Lepidochaetus*, considered a
5 subgenus within *Chaetonotus* by Balsamo et al. (2009), is also monophyletic. The
6 hypothesized reinvasion of certain Chaetonotidae (*Halichaetonotus* and marine
7 *Heterolepidoderma* in a sister group relation to the freshwater taxon *Chaetonotus*
8 *schultzei* Metschnikoff, 1865) from a limnic environment to a marine environment by
9 K anneby et al. (2013) also gains high support in this study (pp=0.98) (Fig. 2).

16 For individual gene trees there are no major conflicts when taking into account
17 bootstrap support values above 70. Deeper nodes within the Chaetonotidae +
18 Dasydytidae + Neogosseidae clade generally have very low bootstrap support (results
19 not shown).

23 With regard to the main aims of the current study, the Bayesian analysis gives
24 high support for monophyly of the planktonic gastrotrichs
25 (Dasydytidae+Neogosseidae) in our study (pp=1). Within this clade both Dasydytidae
26 (pp=0.99) and Neogosseidae (pp=1) are monophyletic (Fig. 2). For Neogosseidae,
27 both *Kijanebalola (K. devestiva, n=2)* and *Neogosseia (N. acanthocolla, n=1 + N.*
28 *antennigera, n=2)* are monophyletic with high bootstrap support (pp=1). *N.*
29 *acanthocolla* and *N. antennigera* are sister taxa. Within Dasydytidae two major clades
30 can be discerned: *Haltidytes squamosus + Ornamentula para ensis* and *Dasydytes +*
31 *Stylochaeta* (Fig. 2). Within the latter clade *Stylochaeta fusiformis* and *Stylochaeta*
32 *scirtetica* are in a sister group relation to *Dasydytes (Prodasydytes) elongatus*
33 Kisielewski, 1991 and *Dasydytes (P.) papaveroi* Kisielewski, 1991 (pp=1). The
34 subgenus *Dasydytes (Prodasydytes)* is non-monophyletic, because of the sister group
35 relationship of *Dasydytes (P.) carvalhoae* Kisielewski, 1991 to *D. (P.) elongatus + D.*
36 *(P.) papaveroi* and *Stylochaeta* (pp=1).

49 The sister group of the planktonic gastrotrichs (Dasydytidae + Neogosseidae)
50 appears as *Chaetonotus (Zonochaeta) spp. + Chaetonotus heteracanthus* Remane,
51 1927 (pp=0.99). *Polymerurus* is the sister group of the latter clade and the planktonic
52 gastrotrichs (Fig. 2).

56 The maximum likelihood analysis of the concatenated dataset supports
57 monophyly of planktonic Gastrotricha (bs=90). However, Dasydytidae appear non-
58 monophyletic, although with very low support (bs=55), since *Stylochaeta+Dasydytes*

1 is in a sister group relationship to Neogosseidae. *Haltidytes squamosus* Kisielewski,
2 1991 and *Ornamentula paraënsis* Kisielewski, 1991 form the sister group of
3 *Stylochaeta*+*Dasydytes*. Further, the support for *Chaetonotus* (*Zonochaeta*) as the
4 sister clade of planktonic gastrotrichs is also very low (bs=45). The deeper nodes of
5 the maximum likelihood phylogeny generally have very low support.
6
7
8
9

10 DISCUSSION

11 Inside the primarily benthic phylum Gastrotricha, the occurrence of planktonic taxa is
12 in many respects of particular interest. For instance, within an evolutionary
13 framework these animals may prove to be excellent for studies dealing with the origin
14 and evolution of adaptations to the planktonic environment. Knowledge of the co-
15 location of pelagic dwellers along the gastrotrich evolutionary tree would benefit
16 studies dealing with, for example, ancestral character patterns and evolution of traits
17 such as movable spines and muscle systems arrangement (Kieneke and Ostmann
18 2012).
19
20
21
22
23
24
25
26

27 Unfortunately, the origin and phylogenetic alliances of planktonic Gastrotricha
28 has not been studied to any great extent. Kisielewski (1991) considered Dasydytidae
29 and Neogosseidae as two separate lineages, and discussed their possible origin from a
30 benthic ancestor within Chaetonotidae. This hypothesized ancestor would have
31 developed a sack-shaped body, by reduction of the caudal lobes and adhesive tubes.
32 The ventral ciliation would also have been modified into tufts and bands encircling
33 the head. However, whether the two groups arose from a common ancestor or not was
34 left open.
35
36
37
38
39
40
41

42 Based on morphological observations, both Remane (1927a) and Kisielewski
43 (1991) agree on a close relationship between *Chaetonotus* (*Zonochaeta*) and
44 Dasydytidae (and possibly Neogosseidae). In fact, members of *Chaetonotus*
45 (*Zonochaeta*) and Dasydytidae both possess movable spines of similar structure and
46 function, e.g. strongly cuticularised, scaleless spines with a notched apex, used for
47 locomotion and/or defence (Schwank 1990; Kisielewski 1991; Kieneke and Ostmann
48 2012). In his 1991 authoritative paper on Brazilian freshwater Gastrotricha,
49 Kisielewski described the subgenus *Dasydytes* (*Prodasydytes*), whose members he
50 considered to have retained the plesiomorphic character states among the planktonic
51 Gastrotricha. Comparing morphology it is evident that *Dasydytes* (*P.*) *carvalhoae*,
52 *Dasydytes* (*P.*) *elongatus* and *Dasydytes* (*P.*) *papaveroi* exhibit several similarities

65

1 with members of the putative Dasydytidae sister taxon, *Chaetonotus (Zonochaeta)*.
2 These traits are: (i) long and specialized spines with denticles and bifurcated tips; (ii)
3 similar shape of scales; and (iii) long parafurcal spines. In addition, dasydytids
4 possess long ventrolateral and/or dorsolateral motile spines. To be more specific,
5 dasydytids, by virtue of a peculiar complex system made up of serially arranged
6 oblique muscles and segmental longitudinal muscles, can quickly raise their spines,
7 which causes the animal to leap through the water, e.g. in response to a predator or
8 other threat (Kieneke et al. 2008a; Kieneke and Ostmann 2012). On the other hand,
9 species of *Chaetonotus (Zonochaeta)* are further characterized by a peculiar
10 transverse row of spines, commonly known as the girdle, across the trunk. These
11 spines can also be raised by muscle action. Consequently, the combination of
12 movable spines and the associated musculature can be seen as potentially homologous
13 characters shared by the dasydytids and species of *Chaetonotus (Zonochaeta)* (e.g.
14 Kisielewski 1991).

15
16 The first cladistic analysis of Gastrotricha, based on 81 morphological
17 characters, showed a sister group relationship between Dasydytidae and Neogosseidae
18 in close alliance to Proichthyridae and Dichaeturidae (Hochberg and Litvaitis 2000).
19 A subsequent, more inclusive analysis based on 135 morphological characters found a
20 monophyletic Neogosseidae nested within Dasydytidae, although with low statistical
21 support at nodes (Kieneke et al. 2008b). In the latter work, planktonic Gastrotricha
22 appeared as a subset of Chaetonotidae, with low statistical support at nodes, although
23 not in a close relationship with *Chaetonotus (Zonochaeta)*. In the recent phylogenetic
24 analysis, based on three molecular markers, K anneby et al. (2013) found a sister
25 group relation between Dasydytidae (*Dasydytes*, *Haltidytes*, *Ornamentula* and
26 *Stylochaeta*) and a clade containing *Chaetonotus (Zonochaeta)*, and thereby
27 somewhat confirming the early hypothesis by Remane (1927a) and Kisielewski
28 (1991).

29
30 The current study supports the general phylogenetic scenario obtained by
31 K anneby et al. (2013) and provides further evidence, on a molecular basis, for a
32 common origin of Dasydytidae and Neogosseidae. The major findings of our study
33 are: (i) Dasydytidae and Neogosseidae both appear as monophyletic groups; (ii)
34 Dasydytidae and Neogosseidae are in a sister group relation; and (iii) the planktonic
35 lineage evolved from a benthic or periphytic ancestor within Chaetonotidae. Strong
36 nodal support and congruence with previous phylogenies (e.g. K anneby et al. (2013)

1 for the general scenario and Hochberg and Litvaitis (2000) for the sister group
2 relationship between Dasydytidae and Neogosseidae) make our findings very likely.

3 Neogosseidae is monophyletic and the clade has high support in our analyses.
4 Neogosseidae can be separated from Dasydytidae morphologically by the presence of
5 a pair of club-shaped cephalic tentacles in neogosseids. Within Neogosseidae,
6 *Kijanebalola* and *Neogosseia* (Fig. 1) are sister groups in our phylogeny, and can be
7 separated morphologically from each other based on distinct autapomorphic traits of
8 the posterior end, which appears truncate and provided with a pair of tufts in
9 *Neogosseia*, and rounded with a median group of spines in *Kijanebalola* (Todaro et al.
10 2013).

11 Dasydytidae also appears monophyletic in our analysis (Fig. 2).
12 Morphologically, the presence of groups of motile spines along the trunk, that aid
13 ciliary swimming can be considered an autapomorphy for the family (e.g. Kieneke
14 and Ostmann 2012). Likewise, the peculiar system of somatic oblique and segmented
15 lateral muscles associated with the cuticular movable spines, may at least
16 provisionally be considered an additional autapomorphy of Dasydytidae (Kieneke and
17 Ostmann 2012). Within Dasydytidae two major clades can be distinguished (Fig. 2).
18 The first contains two species, *Haltidytes squamosus* and *Ornamentula paraënsis*.
19 The second contains five species, *D. (P.) elongatus*, *D. (P.) carvalhoae*, *D. (P.)*
20 *papaveroi*, *Stylochaeta fusformis* and *Stylochaeta scirtetica*. The grouping of
21 *Haltidytes* + *Ornamentula* in one clade and *Dasydytes* in another provides support to
22 the in-group evolutionary scenario envisioned by Kisielewski (1991) on the basis of
23 the structure and organization of the cuticular apparatus (scales and spines), but is in
24 contrast to the phylogenetic hypothesis put forward by Kieneke and Ostmann (2012;
25 see position of *Ornamentula* and *Stylochaeta* in Fig. 10) based mainly on characters
26 of the muscular system. All the sampled species in our phylogeny belong to the
27 subgenus *Dasydytes* (*Prodasydytes*), which is, according to the results, non-
28 monophyletic due to the early divergence of *D. (P.) carvalhoae* along the *Dasydytes* +
29 *Stylochaeta* branch. By virtue of the highly uniform anatomy of species of *Dasydytes*,
30 and the strong difference compared to species of *Stylochaeta*, we consider this result
31 quite unlikely and perhaps an artifact due to contamination.

32 Our phylogeny supports the existence of a monophyletic planktonic clade, as
33 shown by Hochberg and Litvaitis (2000) and Kieneke et al. (2008b). However, in
34

64
65

1 contrast to the latter study, Neogosseidae appear to be the sister taxon of Dasydytidae
2 and not nested within it.

3
4 In the present study the planktonic clade appears as an offshoot of the
5 Chaetonotidae as repeatedly indicated in the literature, for example, by Kisielewski
6 (1991). Due to lack of material we did not include specimens of Dichaeturidae nor
7 Proichthydidae, and because of this, the hypothesis by Hochberg & Litvaitis (2000),
8 where the planktonic taxa are most closely related to these groups, cannot be properly
9 tested. It should be emphasized that Dichaeturidae and Proichthydidae are very rare,
10 that the original descriptions are poor, and that both these conditions could make the
11 very existence of these taxa as independent evolutionary lines open to doubt. For
12 instance, the recent and most accurate description of a third species of Dichaeturidae
13 (Suzuki et al. 2013), reports characteristics that could well fit for a taxon belonging to
14 the current Chaetonotidae. However, a taxonomic revision of Dichaeturidae and
15 Proichthydidae lies beyond the scope of the present paper; yet in agreement with
16 Kisielewski (1991), we consider our finding very likely. According to our results the
17 evolution of the genuine planktonic life-style in Chaetonotida occurred only once
18 (Dasydytidae+Neogosseidae) and probably from a benthic/periphytic ancestor.
19
20
21
22
23
24
25
26
27
28
29
30

31 From a morphological point of view, a lineage originally affiliated with the
32 Chaetonotidae and evolving to the split between Dasydytidae and Neogosseidae,
33 would have undergone several morphological adaptations to cope with the change
34 from a benthic or periphytic life-style to a permanent planktonic life-style. Both
35 Dasydytidae and Neogosseidae lack a furca and adhesive tubes, and have a rounded
36 posterior end. There are also reductions and rearrangements of the locomotory
37 ciliature: while benthic chaetonotids commonly have ventral longitudinal bands of
38 cilia, planktonic taxa possess transverse bands or tufts of cilia along the trunk and
39 around the head, which may increase speed and maneuverability when swimming.
40
41
42
43
44
45
46

47 These dramatic changes would also have involved the ancestors that the
48 Dasydytidae + Neogosseidae clade share with the sister group revealed by the
49 Bayesian analysis in our study, e.g. *Chaetonotus (Zonochaeta)* spp. + *Chaetonotus*
50 *heteracanthus*. The maximum likelihood analysis does not show high support for this
51 sister group relation, suggesting *Polymerurus* as a possible alternative sister group.
52 However, we note that the most relevant autapomorphic trait of *Polymerurus* is the
53 extraordinarily long furca, which makes it hard to unite taxa lacking a furca
54 (planktonic gastrotrichs) with taxa possessing a particularly long furca. On the other
55
56
57
58
59
60
61
62
63
64
65

1 hand the presence of strong scaleless spines could testify in favor for a close
2 relationship between Dasydytidae + Neogosseidae and *Chaetonotus (Zonochaeta)*
3 spp. + *C. heteracanthus*. In this scenario we acknowledge the possible independent
4 origin of the musculature, associated with the movable spines, in dasydytids and
5 *Chaetonotus (Zonochaeta)*, respectively. Future morpho-functional studies on the
6 musculature of species of *Chaetonotus (Zonochaeta)* could support or disprove this
7 hypothesis.
8
9

10
11
12 To summarize, the phylogenetic hypothesis generated by this study gives
13 strong support for a common origin of Dasydytidae and Neogosseidae, and also a
14 hypothesized common origin of planktonic Gastrotricha. It also appears very plausible
15 that the planktonic clade has evolved from a benthic or periphytic ancestor, by
16 morphological adaptations to a life in the water column. Morphology and molecular
17 data prefers *Chaetonotus (Zonochaeta)* spp. (and *C. heteracanthus*) as the sister group
18 of planktonic Gastrotricha. The close relationship of these groups to *Polymerurus* is
19 somewhat confusing and should be evaluated in future studies.

29 ACKNOWLEDGEMENTS

30 The authors wish to thank Dr. Mary K. Wicksten, Department of Biology, Texas A &
31 M University for collecting some of the samples. Dr. Ronald Griffin, Department of
32 Agricultural Economics, Texas A & M University is greatly acknowledged for
33 providing necessary equipment and chemicals. We are also thankful to Mr. James J.
34 Kirk for improving the language and grammar of an early version of this paper. The
35 final text benefited from the comments of two anonymous reviewers. This study was
36 financially supported by a grant from Lennanders Stiftelse (to TK). The Swedish
37 Taxonomy Initiative is also acknowledged.
